CONCLUSIONS: Black men are more likely to have an abnormal SA based on the WHO 2010 criteria. Black men seeking infertility treatment should be educated on the incidence of abnormal SA and actively seek male infertility evaluation. Future studies should be conducted to discover if there are potential ethnic based normative values for interpretation of SA.

INFERTILITY AMONG VETERANS: VARIATION IN DEFINITIONS AND SOCIODEMOGRAPHIC CHARACTERISTICS. Marie E. Thoma, PhD, MHS,[1] Michelle A. Mengeling, MS, PhD,[2] Anne Sadler, PhD, MS,[2] Amy M. J. O'Shea, PhD,[2] James C. Torner, PhD, MS,[3] Judy E. Stern, PhD,[4] Bradley J. Van Voorhis, MD,[3] Alicia Y. Christy, MD,[5] Ginny L. Ryan, MD, MA.[6] [1]University of Maryland, College Park, MD; [2]Iowa City VA Health Care System, Iowa City, IA; [3]University of Iowa, Iowa City, IA; [4]Dartmouth-Hitchcock, Lebanon, NH; [5]Veterans Administration, Kensington, MD; [6]University of Iowa Hospitals and Clinics, Iowa City, IA.

OBJECTIVE: Veterans face unique exposures that may influence fertility, yet our current understanding is limited by inconsistencies in how infertility measures are defined and operationalized. The objective of this study was to compare measures of lifetime infertility and infertility care among military Veterans.

DESIGN: A national sample of U.S. military Veterans aged 20-45 years, consisting of 1406 women and 1599 men with functional reproductive anatomy at birth.

MATERIALS AND METHODS: Consistent with the standard definition of infertility, lifetime infertility was defined as a time-to-pregnancy (TTP) $>$ 12 months. However, TTP was ascertained in two ways: 1) all consecutive months of unprotected intercourse (TTP_UI) or 2) only months reported trying to conceive (TTP_TC). Receipt of infertility care was ascertained as ever diagnosed or treated for infertility. Data were collected using computer-assisted telephone interviews. Infertility prevalence, odds ratios (OR), and corresponding 95% confidence intervals (CI) associated with key sociodemographic characteristics (parity, age, marital status, education, race/ethnicity, income per $10,000) were assessed by sex. Associations were estimated by multivariable logistic regression.

RESULTS: Using all periods of unprotected intercourse (TTP_UI) resulted in a higher prevalence of lifetime infertility in women (45.5%) and men (42.1%) compared with definitions that included only reported months of trying (TTP_TC: 22.4% and 16.9%, respectively). Not having had a prior child and older age (40+) were associated with increased odds of infertility for both women (OR=2.19, 95% CI: 1.48-3.23; OR=1.90, 95% CI: 1.24-2.93, respectively) and men (OR=2.99, 95% CI: 1.92-4.65; OR=1.57, 95% CI: 1.04-2.38, respectively) for TTP_TC, but not TTP_UI. Compared to lifetime infertility study measures, women and men reported lower prevalence of infertility diagnosis (13.7% and 10.7%) and treatment (8.4% and 5.6%), respectively. Sociodemographic characteristics associated with infertility care included higher income (Diagnosis: OR=1.03, 95% CI: 1.01-1.06; Treatment: OR=1.05, 95% CI: 1.02-1.08) among women and higher education (bachelor's degree or higher) (Diagnosis: OR=2.56, 95% CI: 1.32-5.00; Treatment: OR=3.23, 95% CI: 1.25-8.33) among men. We found no difference in infertility or infertility care measures between non-Hispanic black, Hispanic, and non-Hispanic white Veterans.

CONCLUSIONS: The prevalence of lifetime infertility was high among Veterans compared with their limited receipt of infertility care. The prevalence and associated sociodemographic characteristics also varied depending on whether TTP accounted for fertility intentions. Regardless of the type of infertility measure applied, we found few differences by race/ethnicity, contrasting with other U.S. studies. Overall, these findings have broader implications for identifying infertility that may be under-recognized (for couples without clear fertility intentions), gaps in access to infertility care services, and the differential effect of infertility on female and male Veterans.

P-338 4:30 PM Sunday, October 18, 2020

DOES RACE IMPACT EMBRYO MORPHOKINETICS? Luce A. Kassi, MD,[1] Dana B. McQueen, M.D., M.A.S.,[2] Rafael Confino, BS,[3] John Zhang, PhD,[4] Mary Ellen Pavone, MD, MSCI,[4] Dana Kimelman, MD.[4] [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern Feinberg School of Medicine, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology. Division of Reproductive Endocrinology and Infertility, Chicago, IL.

OBJECTIVE: To assess the relationship between race and embryo morphokinetics on time lapse microscopy (TLM).

DESIGN: Retrospective Cohort Study.

MATERIALS AND METHODS: Institutional Review Board approval was obtained. All IVF cycles between June 2015 and April 2017 were included. Racial groups included Black, Hispanic, Asian, White and other/unknown. Embryo morphokinetic parameters were assessed with TLM and included time to syngamy (TPNf), time to 2 cells, time to 3 cells, time to 4 cells and time to 8 cells. A generalized linear mixed model was used to control for potential confounders and multiple embryos resulting from a single IVF cycle.

RESULTS: 589 IVF cycles were included in the analysis. There were no significant differences in the median maternal age, anti-Mullerian hormone (AMH), days of stimulation, total gonadotropin, number of oocytes retrieved, number of mature oocytes or number fertilized oocytes between groups (Table). There were significant differences in body mass index (BMI) between groups and this was adjusted for in the final model. There was a total of 2,185 embryos assessed by TLM: 100 from Black women, 90 from Hispanic women, 281 from Asian women, 1460 from White women and 254 from women of unknown race. After adjusting for BMI, there was no significant difference in time to time to syngamy, time to 2 cells, time to 3 cells, time to 4 cells or time to 8 cells between racial groups.

CONCLUSIONS: There was no significant association between embryo morphokinetics by TLM and race. Despite the racial disparities observed

	Black (N=25)	Hispanic (N= 28)	Asian (N= 67)	White (N= 404)	Other/Unknown (N=65)	p-value
Age (yr)	36.4 (33.5, 38.4)	36.0 (34.6, 40.4)	35.1 (33.1, 38.5)	35.0 (32.7, 38.4)	36.0 (32.8, 40.2)	0.61
BMI	27.2 (23.7, 30.7)	28.4 (26.3, 35.6)	23.2 (21.5, 25.1)	23.4 (21.2, 27.6)	25.0 (21.9, 27.8)	$<.0001$
AMH (ng/ml)	3.2 (1.5, 3.8)	2.5 (1.4, 4.2)	2.8 (1.4, 3.9)	2.3 (1.1, 4.2)	2.5 (1.1, 4.7)	0.90
Days Stimulation	10.5 (9.5, 11.5)	10.0 (9.0, 11.0)	10.0 (9.0, 11.0)	10.0 (9.0, 11.0)	10.0 (9.0, 11.0)	0.82
Total IU Gonadotropin	2887.5 (2325.0, 4500.0)	3000.0 (2700.0, 4537.5)	2700.0 (2025.0, 3750.0)	3300.0 (2400.0, 4500.0)	3000.0 (2437.5, 4087.5)	0.22
Oocytes	12.0 (9.0, 21.0)	12.0 (7.0, 17.5)	14.0 (10.0, 22.0)	14.0 (10.0, 20.0)	14.0 (10.0, 19.0)	0.64
Mature Oocytes	9.0 (7.0, 16.0)	9.0 (6.0, 17.0)	12.0 (8.0, 16.0)	11.0 (7.0, 16.0)	10.0 (7.0, 13.0)	0.72
Fertilized Oocytes	7.0 (5.0, 14.0)	8.0 (5.0, 13.0)	9.0 (6.0, 13.0)	8.0 (6.0, 12.0)	7.5 (5.5, 11.0)	0.96
% ICSI	24 (96.0)	26 (92.86)	66 (98.51)	384 (96.73)	63 (98.44)	0.36

Data presented as Median(Q1-Q3) or %(N).

in IVF, this study demonstrates that race does not impact embryo development as observed on TLM.

P-339 4:30 PM Sunday, October 18, 2020

SINGLE PARENT BY CHOICE CONTENT ON FERTILITY CLINIC WEBSITES IN THE WESTERN REGION. Kajal Verma, MD,[1] Christopher de Haydu, MD,[2] Melody A. Rasouli, MD, MBA,[1] Angela H. Liu, MD,[1] Janelle M. Jackman, MBBS,[3] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD.[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]New Hope Fertility Center, New York, NY; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Information on fertility clinic websites is a primary and critical component of the shared decision-making process between patients and physicians. Single men and women comprise a growing subgroup of patients seeking fertility care to help build their families, via use of donor sperm, donor eggs, or donor embryos. The goal of this study is to assess the association of regional demographic factors of fertility centers, with the online information provided by these centers' websites, to patients seeking information on single parenting by choice (SPC) in the Western Region of the United States (WRUS).

DESIGN: Cross-sectional analysis.

MATERIALS AND METHODS: A survey was developed and two independent investigators assessed clinic websites from WRUS clinics included in the 2017 Society for Assisted Reproductive Technology (SART) database. Websites were assessed for content related to single parents seeking fertility services and SPC. The responses were ordered by county level data obtained from the US Census (2010 and 2014-2018) for demographic information including race, income/poverty, and insurance status. Descriptive statistical analyses performed included Chi-square and t-tests.

RESULTS: 100 SART-reporting fertility clinics are located in WRUS and 31% of those clinic websites had discussed SPC for single men and/or women seeking fertility services. 18% of these websites featured standalone pages describing SPC. Compared to the lower three quartiles, there was a positive association between the detail of SPC information provided and the highest quartile of median household income (MHI) ($p = 0.02$), highest quartile of income per capita (IpC) ($p = 0.005$), and the lowest quartile of persons without insurance ($p = 0.01$). This trend was significant and the same for the question regarding websites having a standalone page for SPC ($p<0.05$ for MHI, IpC, and persons without insurance). Regarding race, the quartile of counties with the largest percentage of white persons ($p = 0.01$) or the quartile with the largest percentage of Asian persons ($p = 0.002$) had significantly more information on SPC or standalone SPC pages ($p=0.042$) in relation to the counties with the quartiles with the smallest percentage of those populations (respectively).

CONCLUSIONS: 31% of SART fertility clinics in the WRUS include SPC content on their websites with 18% of them having standalone pages dedicated to this important issue. Using the fertility center's county as a geographic proxy to estimate population demographic variables, there is an association with MHI, IpC, and increased insurance level with the center's websites containing SPC information or standalone pages. Having SPC information is also positively associated with increasing percentages of white or Asian populations; raising questions regarding associations between socioeconomic or racial factors behind this uneven access to SPC information on clinic websites. Overall, this data shows that more clinics need to include SPC information on their websites. Further study to expand this analysis across all US demographic regions is ongoing.

P-340 4:30 PM Sunday, October 18, 2020

BASIC FERTILITY INVESTIGATION IN A LOW RESOURCE SETTING IS VALUABLE AS A MARKER FOR OVERALL HEALTH. Ramya Sethuram, MD,[1] Lina Fouad, BS,[1] Alexandra E. Flessel, BS,[1] Ahmad Arabi, MD,[1] Kazuhiko Shinki, Ph.D,[2] Sana Salih, MD.[1] [1]Wayne State University School of Medicine, Detroit, MI; [2]Wayne State University, Detroit, MI.

OBJECTIVE: Infertility is considered a harbinger of overall health and future morbidity and cardiovascular mortality. However, the vast majority of couples in low resource settings do not seek infertility treatment in a timely fashion due to lack of insurance coverage. While the Medicaid plan does not cover for infertility treatment in Michigan, it does cover the initial infertility workup for few visits.

DESIGN: Retrospective, cohort study at a university hospital infertility clinic comparing the results of the infertility workup in low resource settings on Medicaid vs private insurance groups.

MATERIALS AND METHODS: We performed a retrospective chart review of patients after IRB approval. New patients who visited a university health clinic at from 07/2019 –02/2020 were studied. A total of 117 patients were studied (Medicaid = 79; Private =38). All patients had infertility workup inclusive of preconception labs (TSH, Rubella immunity), hormonal profile (AMH, day 2 E2, FSH, and for PCOS, if indicated), day 2-4 TVUS and follicle count and day 4-12 SIS. We collected data on new non-infertility diagnosis that resulted from the workup. The new non-infertility diagnosis studied included ones with long term health implications: hypertension, diabetes, pre-diabetes, thyroid disease, endometrial hyperplasia and cancer, hydrosalpinx, PCOS, and Vitamin D deficiency. Statistical analysis was performed with SPSS V24.0.

RESULTS: The demographics of the patients in Medicaid vs Private groups were not significantly different. The mean age in years was 33(±6.2) ; mean BMI was 32.8 (±8.5). The results of the new non-infertility diagnosis in the two groups is represented in Table 1.

Table 1

New non-infertility diagnosis	Medicaid (n =79)	Private (n =38)	P-value
Diabetes/ Pre -diabetes	25.3% (n=20)	23.6% (n=9)	1
PCOS	24.0% (n=19)	13.1% (n=5)	0.26
Premature ovarian failure	1.2% (n=1)	0.02% (n=1)	1
Hydrosalpinx	5% (n=4)	0%	0.52
Endometrial hyperplasia ± cancer	2.5% (n=2)	0%	0.81
Vitamin D Deficiency	65.8% (n=52)	47.3% (n=18)	0.08

There was no significant difference in the newly diagnosed morbidities between the groups. The findings are still important in that 93.1% of all patients received a non-infertility diagnosis. Among them, 55% had at least two such diagnoses which carried a future health implication. This analysis did not take into account the diagnoses of obesity/ smoker and the weight loss and smoking cessation counseling that are a part of our infertility work up.

CONCLUSIONS: Infertility is not a unique disease of the reproductive axis but is often linked with metabolic diseases. Hence, a basic infertility workup should be undertaken in all patients with infertility, irrespective of their ability to afford fertility treatment post work-up.

SUPPORT: n/a

P-341 4:30 PM Sunday, October 18, 2020

SOCIOECONOMIC STATUS IS NOT ASSOCIATED WITH DONOR OOCYTE RECIPIENT SUCCESS: A PAIRED ANALYSIS UTILIZING SIBLING OOCYTES. Kelly McCarter, MD,[1] Robert Setton, MD,[2] Alice Chung, BA,[2] Zev Rosenwaks, M.D,[2] Steven Spandorfer, MD.[2] [1]Weill Cornell Medicine, New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: Lower socioeconomic status has been associated with worse perinatal outcomes; however, the literature is limited, especially in cases of IVF. These studies have also been unable to control for factors that can affect oocyte quality, including psychological stress and environmental exposures that are often associated with lower socioeconomic status. ART using sibling-oocyte recipients (oocytes from the same donor stimulation transferred to two different recipients) offers a unique model that allows a more precise assessment of the endometrial aspect of implantation, as it controls to the greatest degree possible for oocyte quality. We sought to determine if socioeconomic status affects endometrial receptivity by analyzing outcomes in sibling-oocyte recipients.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients who underwent donor egg recipient (DER) cycles who received oocytes from a donor whose oocytes from a single controlled ovarian hyperstimulation cycle were split between two recipients were included. The recipients were categorized into four quartiles based on mean income by zip code. Only paired recipients who were in discrepant quartiles were included. Patients with uterine and severe male factor infertility were excluded. The primary outcome was implantation rate. Secondary outcomes included positive pregnancy and delivery rates. Statistical analysis included paired t-test, and $p<0.05$ was deemed statistically significant.

RESULTS: A total of 1,013 patients who underwent DER cycles between January 2010 and December 2016 were screened for inclusion, of which 408 patients had received oocytes from a split donor oocyte cycle. There were 32 pairs (64 recipients) who had discrepant income quartiles that were analyzed. The two income groups compared were the lowest income quartile (mean income less than $80,025) and the highest (mean income greater than $126,107). Quartile cutoffs were determined from the patient cohort. Mean income of the entire cohort was $107,795. The groups were similar for recipient age, gravity, parity, body mass index, peak endometrial stripe thickness, and number of embryos transferred. The implantation rates (57.8% ± 7.8 vs. 53.6% vs. 7.4, p=0.72), pregnancy rates (75% ± 7.7 vs. 84.3% ± 6.5, p=0.37) and live birth rates (53.1% ± 8.9 vs. 68.75% ± 8.3, p=0.26) were found to be similar amongst the lowest and highest income quartiles. In subsequent analysis, the implantation, pregnancy, and live birth rates were also found to be similar when other income quartiles were compared, such as the lower two quartiles to the highest quartile and the lower three quartiles to the highest quartile. Additionally, no significant difference was found when quartile cutoffs were determined based on the national census data.

CONCLUSIONS: In this idealized model that controls to the greatest degree possible for oocyte quality, by using paired recipients from the same donor from the same stimulation cycle, we found that differing socioeconomic status based on mean income did not affect implantation, positive pregnancy, or delivery rates.

P-342 4:30 PM Sunday, October 18, 2020

CLINICAL BARRIERS AND FACILITATORS THAT INFLUENCE AFRICAN AMERICAN WOMEN TO INITIATE TREATMENT FOR INFERTILITY: A MIXED METHODS STUDY. Morine Cebert, Ph.D., RN,[1] Rosa Gonzalez-guarda, PhD, RN,[2] Susan G. Silva, PhD,[2] Peggy A. Shannon-Baker, PhD,[3] Renee E. Hart, MS,[4] Samad Jahandideh, PhD,[4] Eleanor Stevenson, PhD, RN.[5] [1]University of Pennsylvania & Philadelphia VA Medical Center, Philadelphia, PA; [2]Duke University School of Nursing, Durhan, NC; [3]Georgia Southern University, Statesboro, GA; [4]Shady Grove Fertility Center, Rockville, MD; [5]Duke University School of Nursing, Durham, NC.

OBJECTIVE: African American women in the United States have a high prevalence of infertility; yet are least likely to initiate treatment for infertility. This study sought to explore clinical facilitators and barriers to initiating treatment for infertility among African American women who completed an a reproductive endocrinology evaluation.

DESIGN: We conducted a convergent parallel mixed methods study that combined quantitative data from a retrospective chart review and semi-structured interviews discussing clinical perspectives associated with treatment initiation of African American women seeking treatment at a large infertility clinic in northeastern United States between January 2015 and September 2019.

MATERIALS AND METHODS: We analyzed retrospective chart review data using bivariate and logistic regression analyses on a random sample of electronic medical records of African American women to examine the association of clinical factors to treatment initiation. A sample of African American women completed a one-time interview and interview transcripts were transcribed verbatim and a thematic analysis was performed. Joint data displays were used for integration analyses of clinical influences on treatment initiation.

RESULTS: The analysis sample included 391 records of African American women patients. Of the 391, clinical workups revealed half the sample had abnormal female imaging 52% and 36.7% had one of more abnormal hormonal level. The majority (77.2%) experienced primary infertility and 45.6% female factor only. The most common treatment plan presented was IVF (77.0%), followed by IUI (21.5%). Of the total treatment seeking sample, 72.5% initiated treatment. Clinical workup, fertility type, and final treatment plan were not statistically significantly associated with initiating treatment (p>0.05). Among the 13 women who completed interviews, 6 (46.1%) initiated treatment for infertility. Four themes emerged relating to clinical influences: 3 barriers and 1 facilitator. Barriers included concerns for treatment plan complexity and applicability, desire for empathetic staff and holistic assessments, and fears of racial discrimination. The facilitator to treatment initiation was having good understanding of the treatment plan and procedures. The quantitative and qualitative findings diverged. Although clinical factors were not significantly associated with initiation, women discussed several salient clinical barriers to treatment.

CONCLUSIONS: A high proportion of the African American women initiated treatment; however, African American women reported several clinical barriers when considering whether or not to initiate proposed treatment plans. The complexity and invasiveness of the treatment plan along with interactions with staff seem to influence initiation. A staff that provides clarity in the treatment plan with holistic delivery options may further enhance treatment uptake. Nurses play a critical role in communicating treatment plans to patients and along with assessing other treatment needs and concerns.

WOMEN ≥40 YEARS OLD UNDERGOING IVF WITH FRESH EMBRYO TRANSFER HAVE DIFFERENTIAL CYCLE OUTCOMES BASED ON THEIR RACE. Stephanie Willson, MD, Pietro Bortoletto, MD, Phillip A. Romanski, MD, Owen Davis, M.D., Zev Rosenwaks, M.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine if women ≥40 years old undergoing IVF with fresh embryo transfer have differential cycle outcomes based on their race.

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: Women ≥40 years old undergoing their first IVF cycle at our center with fresh embryo transfer were stratified by race: 1) minorities (black, Asian, white [Hispanic]) and 2) white (non-Hispanic). Pregnancy and live birth rates per transfer were the primary outcomes. Multivariable logistic regression analysis was performed to examine the association between racial group and cycle outcomes while controlling for confounders identified through the construction of directed acyclic graphs A multivariate logistic regression was created controlling for age, BMI, parity, infertility diagnosis, AMH, number of mature oocytes, and embryos transferred. Odds ratios (OR) with 95% confidence intervals (CI) for cycle outcomes were estimated.

RESULTS: A total of 2,007 cycles in women ≥40 years old were analyzed, of which 576 were racial minorities and 1,431 where white (non-Hispanic) women. The mean (SD) age, 41.7 (1.6) years, was the same for both groups.Women of racial minorities had higher AMH levels than those in the white (non-Hispanic) group (1.57 vs. 1.27 ng/ml; p=0.001). The minority group also had a larger proportion of tubal and uterine factor infertility compared to white (non-Hispanic) women (6.4% vs. 4.1% and 2.6% vs. 1.3%, respectively; p=0.022). The pregnancy rate was 35.2% versus 44.1% (p=<0.001) for women in the minority group and white (non-Hispanic) group, respectively. Age >41 years old (OR 0.48, CI 0.36-0.63), having <4 mature oocytes retrieved (OR 0.63, CI 0.42-0.93), and being a racial minority (OR 0.58, CI 0.43-0.78) were all associated with reduced odds of clinical pregnancy. An AMH >0.87 ng/mL (OR 1.62, CI 1.20-2.20), retrieval of >9 mature oocytes (OR 1.45, CI 1.04-2.03), and the transfer of >3 embryos (OR 1.33, CI 0.98-1.81) were associated with increased odds of clinical pregnancy. Once pregnancy was achieved, there were no differences in live birth rates when comparing patients in the racial minority group versus white (non-Hispanic) women (17.9% vs. 18.9%, p=0.379).

CONCLUSIONS: Women ≥40 years old undergoing IVF with fresh embryo transfer have differential cycle outcomes based on their race. Women from racial minorities, even after controlling for potential confounders, are about 40% less likely to achieve a clinical pregnancy. However, once they are pregnant, their live birth rates do not differ compared to white (non-Hispanic) women. We hypothesize that the increased incidence of tubal and uterine factor infertility in racial minority patients may explain the lower pregnancy rate observed in these patients.

P-344 4:30 PM Sunday, October 18, 2020

SALINE ULTRASOUND VERSUS OFFICE HYSTEROSCOPY FOR UTERINE CAVITY EVALUATION PRIOR TO IVF: A RANDOMIZED CONTROLLED TRIAL. Sarah M. Moustafa, MD, Gina Silverstein, MD, Steven L. Young, M.D., Ph.D., Linnea R. Goodman, MD. University of North Carolina, Raleigh, NC.

OBJECTIVE: Saline infusion sonography (SIS) and hysteroscopy are commonly employed methods for uterine cavity evaluation prior to fertility treatment. We aim to compare SIS and office hysteroscopy with respect to patient and provider satisfaction, and to evaluate the capability of office hysteroscopy to manage intra-uterine pathology at the time of diagnosis to reduce delays and supernumerary procedures.

DESIGN: Prospective randomized controlled trial.

MATERIALS AND METHODS: Sixty women undergoing routine cavity evaluation prior to in vitro fertilization (IVF) were randomized to either SIS or office hysteroscopy without use of anesthetic. The LiNAscope disposable 4.2mm hysteroscope with operative port was used, with employment of hysteroscopic graspers as indicated. Abnormalities on SIS were subsequently managed by hysteroscopy. Management of abnormalities on hysteroscopy was attempted within the same screening procedure. Patients and providers completed surveys with findings and Likert rating scales for satisfaction and pain scores, respectively. The sample size was based on a power analysis to detect in the primary outcome of patient satisfaction scores. Statistical comparisons were performed with t-test or Mantel-Haenszel chi-square as applicable.

RESULTS: The study groups did not differ in age, race, body mass index, indication for IVF, or history of uterine pathology. Pain scores (10 point scale) did not differ between SIS and hysteroscopy (respectively, 2.70 $\pm$1.84 vs. 3.32 $\pm$1.89; $p = 0.20$). Time to complete the procedure, patient and provider satisfaction scores, and incidence of pathology did not differ between groups (Table 1). Of the 11 patients with abnormalities in the hysteroscopy group, 10 underwent immediate attempt at operative management (one with unicornuate uterus diagnosed), with 9/10 experiencing complete resolution of pathology.

CONCLUSIONS: Office hysteroscopy and SIS were similar with respect to patient satisfaction, tolerability, and time to complete. Both can be considered well-tolerated screening tools. However, office hysteroscopy often allowed for immediate management of abnormalities detected during uterine cavity evaluation, reducing the need for additional procedures.

Table 1. Comparison of results and management between SIS and office hysteroscopy

	SIS (n = 30)	Hysteroscopy (n = 30)	P-Value
Time to complete (min)	3.69 ($\pm$1.49)	4.22 ($\pm$2.12)	0.27
Patient satisfaction (1-5)	4.83 ($\pm$0.59)	4.77 ($\pm$0.68)	0.69
Provider satisfaction (1-5)			
Uterine cavity evaluation	4.73 ($\pm$0.52)	4.80 ($\pm$ 0.76)	0.69
Perception of pain	4.76 ($\pm$0.63)	4.70 ($\pm$ 0.60)	0.67
Overall satisfaction	4.6 ($\pm$0.77)	4.73 ($\pm$ 0.83)	0.52
Pathology found	6 (20%)	11 (36.7%)	0.15
Second procedure needed	6 (20%)	1 (0.03%)	0.04

ADENOMYOSIS IN MAGNETIC RESONANCE AND POOR REPRODUCTIVE OUTCOME. Alejandra Aguilar Crespo, doctor, Enrique Tormo Crespo, licensed in medicine, Juana Crespo Simó, MD. Equipo Juana Crespo, Valencia, Spain.

OBJECTIVE: Non-invasive diagnostic methods for adenomyosis have emerged such as the Magnetic Resonance imaging (MRI). Nevertheless, there are no universal criteria for diagnosing adenomyosis on MRI and radiologists have difficulty describing lesions and often interpret it as a trivial finding.

Adenomyosis cause implantation failure and a decrease in clinical pregnancy rate. The treatment must be individualized according to age, gestational desire and clinical symptoms.

There is no study linking adenomyosis lesions on MRI and implantation failure so, our aim is to find out the relationship between adenomyosis lesions on MRI and poor reproductive outcome (PRO) of strictly uterine origin.

The primary objective is to determine adenomyosis lesions on MRI that could be associated with a PRO. With this, we might be able to know in front of which lesions an embryo transfer would not be recommended before a treatment. The second objective is to determine what treatment (surgical, medical or both) improves the prognosis. The third aims to describe which endometrial preparation presents a higher gestational rate.

DESIGN: Descriptive and retrospective study on a single-center, non-homogeneous and unmasked. The study population consists of 389 patients who attended our center after previous embryo failures from egg donation in other centers, between 2015 and 2019 to receive an egg donation treatment.

MATERIALS AND METHODS: Inclusion criteria were applied to select patients with implantation failure or abortion of exclusively uterine cause. We included patients with 6 o more embryos failed from egg donation. After applying those criteria, 58 patients were selected.

The MRI of all of them were analyzed according to the five Bazot criteria, together with the fibrosis criterion proposed by Khaund. In total 9 variables were described and analyzed on each MRI.

RESULTS: All study patients met at least 1 criterion of adenomyosis on the MRI.

A junctional zone more than 12mm followed by uterine fibrosis were the findings that had the worst pregnancy rate (60%). 80% of patients underwent an hysteroscopy and 14% an hysteroscopy with laparoscopy. 62% of women received a treatment based on GnRh agonists.

Regarding the MRI adenomyosis criteria, those who fulfilled only one criteria had a gestational rate of 77%, while those who met all was 7%. 77% of women conceived and 52% of them did it after our first embryo transfer. 91 embryo transfers were performed, 23 following a natural cycle and 68 a substituted one. The pregnancy rate was 52.2% and 39.7 respectively.

CONCLUSIONS: All the patients in this study met at least one criterion suggestive of adenomyosis.

The more criteria are met, the worse is the gestational rate although no specific lesion could be found involving a poor outcome.

There is not a gold-standard treatment and it has not been possible to analyze the differences between medical, surgical or combined treatment, so, it must be individualized according to the patient characteristics to enhance the chances of pregnancy. The trend is towards natural cycles as it has shown a higher pregnancy rate than the substituted ones.

DOES STANDING ULTRASOUND IMPROVE THE DETECTION OF CLINICALLY IMPORTANT VARICOCELES. Nahid Punjani, MD MPH,[1] Gal Wald, BA,[1] Omar Al Hussein Alawamlh, MD,[1] Vanessa L. Dudley, MSHS,[2] Marc Goldstein, M.D.[2] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To assess the role of a standing vs supine assessment in scrotal ultrasound (SUS) during varicocele assessment by evaluating differences in clinical outcomes.

Figure 1. Clinical Outcomes of Men with Discordant Ultrasound Assessments

	Right				Left

DESIGN: Retrospective data collection.

MATERIALS AND METHODS: Men from 2008-2020 diagnosed with varicocele were reviewed. We included men with documented SUS with both supine and standing assessments including measurements with and without Valsalva. Clinical outcomes, including sperm concentration (excluding azoospermia) (SC), TUNEL and testosterone (T) levels were compared among men who had varicoceles diagnosed based on ultrasound characteristics (vein size >2.5mm, vein size >3.0mm and reversal of flow) to those that would have been missed on supine ultrasound who underwent microsurgical varicocelectomy.

RESULTS: 761 men were included. Median age was 38 (IQR 32-44). On orchidometer assessment, median testis size was 18cc (IQR 15-22) on the right and 15cc (IQR 12-18) on the left. Of these men, 396 (52.0%) underwent varicocelectomy (right: 8 (2.0%); left: 136 (34.4%); bilateral: 252 (63.6%)). Agreement between supine and standing SUS for a 2.5mm cut-off were: 79.5% on the right and 88.1% on the left; for a 3.0mm cut-off: 76.3% on the right and 79.8% on the left; for flow reversal: 81.5% on the right and 75.3% on the left. Disagreement between those with abnormal standing vs normal supine for vein size >2.5mm was: 63 men (15.9%) on the right and 34 men (8.6%) on the left, for vein size >3.0mm was: 75 men (18.9%) on the right, and 62 men (15.6%) on the left, and for flow reversal was: 35 (12.2%) on the right and 44 (15.1%) on the left. In Table 1, with a 2.5mm cut-off, only T had significant improvement on the left ($p<0.01$). With a 3.0mm cut-off significant differences were seen for SC on the left ($p=0.04$) and T on the left and right ($p<0.01$). For flow reversal, significant differences were seen for SC on the right ($p<0.01$) and T on the left ($p=0.01$).

CONCLUSIONS: Our results suggest that standing SUS identifies a greater number of men who would have been missed using supine ultrasound only.

P-347 4:30 PM Sunday, October 18, 2020

ULTRASONOGRAPHY HAS BETTER PERFORMANCE THAN MAGNETIC RESONANCE IMAGING IN DIAGNOSING DEEP ENDOMETRIOSIS RECURRENCE. Simone Ferrero, MD PhD,[1] Carolina Scala, MD,[2] Ennio Biscaldi, MD,[3] Fabio Barra, MD.[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Istituto G. Gaslini, Genova, Italy; [3]Department of Radiology, Galliera Hospital, Genova, Italy.

OBJECTIVE: Transvaginal ultrasonography (TVS) and magnetic resonance imaging (MRI) have similar performance in diagnosing deep endometriosis (DE). The diagnosis of DE recurrence may be more challenging because of the presence of postoperative fibrosis and adhesions (such as those causing obliteration of the pouch of Douglas). The objective of this study was to compare the performance of TVS and MRI in diagnosing DE recurrence.

DESIGN: Prospective study.

MATERIALS AND METHODS: This prospective study enrolled women who underwent a second surgery after surgical excision of deep endometriosis because of suspicion of DE recurrence. TVS was performed by an experienced ultrasonographer. MRI was performed within two months from TVS by a radiologist blinded to the results of TVS. Laparoscopy was performed within four months from MRI; all DE lesions were excised. The findings of TVS and MRI were compared with histological results.

RESULTS: The study included 164 women. The median interval between the first and second surgery was 7 years (range, 2-24 years). 103 patients (62.8%; 95% CI 54.9%-70.2%) had a histological diagnosis of DE after the second surgery. 69 women underwent a hysterectomy, 41 excisions of ovarian endometriomas, 23 unilateral adnexectomies, and 8 bilateral adnexectomies (some patients underwent come than one surgical procedure). The McNemar's test demonstrated that TVS has higher performance than MRI in diagnosis recurrence of DE ($p = 0.007$). The performance of MRI was: accuracy 80.5% (95%CI, 73.6-86.3), sensitivity 83.5% (74.9-90.1), specificity 75.4% (62.7-85.5), positive predictive value (PPV) 85.2% (78.6-90.0), negative predictive value (NPV), 73.0% (63.1-81.0), positive likelihood ratio (LR+) 3.40 (2.17-5.31), negative likelihood ratio (LR-) 0.22 (0.14-0.35). The performance of TVS was: accuracy 88.4% (82.5-92.9), sensitivity 86.4% (78.3-92.4), specificity 91.8 (81.9-97.3), PPV 94.7% (88.5-97.6), NPV 80.0 (71.0- 86.8), LR+ 10.54 (4.54-24.50), and LR- 0.15 (0.09-0.24).

CONCLUSIONS: TVS is superior to MRI in diagnosing postoperative recurrence of DE. MRI has poor specificity in diagnosing DE recurrence, possibly because of postoperative fibrosis.

P-348 4:30 PM Sunday, October 18, 2020

CORRELATION BETWEEN CT VIRTUAL HYSTEROSALPINGOGRAPHY FINDINGS WITH THOSE OF HISTEROSCOPY AND LAPAROSCOPY, IN PATIENTS WITH PREGNANT DESIRE. Débora Cristina Siqueira, MD,[1] Natália Fontoura Vasconcelos, Ms,[2] Andrey Cechin Boeno, MD, Msc,[2] Gabriela Buchner, MD,[2] Rayane Felippe Nazário, MD,[2] Angela Figueiredo Pinto Agostini, MD,[2] Marta Ribeiro Hentschke, MD, PhD.[2] [1]Pontifical Catholic University of Rio Grande do Sul, Porto Alegre, Brazil; [2]■■■.

OBJECTIVE: Correlate CT Virtual Hysterosalpingography findings with those of histeroscopy and laparoscopy in patients with pregnant desire.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study included patients who were submitted to CT-HSG from january/2019 to february/2019, in a university hospital in Brazil, and subsequently were submitted to laparoscopy and hysteroscopy according to medical indication. The data collection was based on the hospital's electronic medical records. The study analyzed clinical characteristics of patients, imaging and surgeries findings, regarding uterine tubes,

TABLE 1. Clinical pregnancy rate by percentage of compaction

Compaction cutoff, %	Compacted n/N (%)	Not Compacted n/N (%)	P-value	Sensitivity %	Specificity %	Positive predictive value %	Negative predictive value %
5	88/116 (75.9%)	167/290 (57.6%)	0.0006	34.5	81.5	75.9	42.4
10	53/71 (74.6%)	202/335 (60.3%)	0.023	20.8	88.1	74.6	39.7
15	34/46 (73.9%)	221/360 (61.4%)	0.098	13.3	92.1	73.9	38.6
20	13/16 (81.3%)	242/390 (62.1%)	0.12	5.1	98	81.3	37.9

uterine cavity and ovaries. The study was approved by the University Research Ethics Committee. The CT-HSG was indicated for infertility investigation, and for the evaluation of tubal stump in patients who were planning the tubal reversal surgery. The image exam followed the protocol established by the hospital gynecology and radiology service. Data were analyzed using SPSS version 22.0, and presented as mean± SD and percentage. Pearson's correlation test was applied considering p< 0.05.

RESULTS: The CT-HSG examination was performed on 204 women in reproductive age, seeking for pregnancy. Women and partners mean age was 32.7±3.4 and 33.2±6.4 years old, respectively, and women mean BMI was 26.0± 3.4. From those who underwent CT-HSG, 12 were submitted to hysteroscopy and 11 to laparoscopy (9 due to infertility investigation and 3 due to reverse tubal desire). The mean time between CT-HSG and the surgery was 6.4±2.6 months. The findings related to the uterus presented 75% of compatibility (r=0.556; p=0.061). Regarding tubal findings between CT-HSG and surgical findings, including 11 patients, a statistically positive direct correlation was seen (r=0.498; p=0.018), which was mainly due to the the right tube (90% of compatibility). In all exams the data regarding the ovaries were in agreement (r=1.00; p<0.0001).

CONCLUSIONS: The present study showed a positive correlation between CT-HSG and laparoscopy/hysteroscopy findings for tubes and ovaries. For the uterus, although no statistical significance was observed, seems to have a clinical correspondence. Hence, CT-HSG seems to be an option for evaluation, not only the tubes, but also the uterine cavity and ovaries. The 3D image can be created, as well as the virtual navigation for better clinical evaluation. The discordant findings are open to discussion considering the time between the exam and the surgery, and the possible false positives and negatives in both situations, which shows the importance of the study follow-up.

P-349 4:30 PM Sunday, October 18, 2020

ULTRASOUND IMAGING PREDICTS ENDOMETRIAL RECEPTIVITY – A DECREASE IN ENDOMETRIAL THICKNESS (COMPACTION) PRIOR TO EMBRYO TRANSFER IS ASSOCIATED WITH AN INCREASE IN CLINICAL PREGNANCY RATE IN SYNTHETIC FROZEN EUPLOID IVF CYCLES.

Pavan Gill, MD,[1] Julia G. Kim, MD, MPH,[2] Paul A. Bergh, MD,[2] Richard Thomas Scott, Jr., MD.[2] [1]University of Toronto, Toronto, ON, Canada; [2]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Two recently published studies demonstrated that pregnancy rates were higher among patients whose endometrium compacted (became thinner) during secretory transformation in both frozen euploid and non-PGT-A embryo transfer cycles (1, 2). An important limitation of these studies was that transabdominal ultrasound images were utilized. This study seeks to assess whether endometrial compaction (a decrease in endometrial thickness) after progesterone treatment as measured by transvaginal ultrasound (TVUS) in synthetic cryopreserved euploid IVF cycles prognosticates clinical pregnancy rates.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All patients completing a synthetic euploid cryopreserved embryo transfer during 2018 and 2019 were reviewed. Patients who had a TVUS completed within two days prior to starting PIO injections and had a second TVUS on day five of progesterone exposure prior to embryo transfer were selected. Ultrasound images were reviewed while blinded to the pregnancy outcomes and the change in endometrial thickness calculated. The primary outcome was clinical pregnancy rate. Comparison of continuous variables between the two groups was conducted using the Student's t test. Chi-square was used for comparison of categorical variables. Logistic regression was used for multivariate analysis. P < .05 was considered statistically significant.

RESULTS: Images from 406 cycles met inclusion criteria. A 10% or greater decrease of endometrial thickness (compaction) resulted in an ongoing clinical pregnancy rate of 74.6% versus 60.3% if there was no compaction (p = 0.023). The sensitivity and specificity of using a 10% cut off were 20.8% and 88.1%, respectively (Table 1). There was no significant difference in age, BMI or embryo quality when comparing those that compacted by at least 10% versus those that did not. Logistic regression controlling for age and BMI found that endometrial compaction of 10% or greater significantly increased the rate of ongoing clinical pregnancy (OR 1.99, 95% CI, 1.05- 3.36, p =0.032).

CONCLUSIONS: A decrease in endometrial thickness after initiating progesterone resulted in a higher ongoing pregnancy rate in our study. Our findings support the recent studies on endometrial compaction as a potential non-invasive marker of endometrial receptivity.

UTILITY OF THREE-DIMENSIONAL ULTRASOUND (3D-US) IN WOMEN WITH ARCUATE UTERI SCHEDULED FOR INVITRO-FERTILIZATION (IVF): A SCENARIO ECONOMIC ANALYSIS.

Reda S. Hussein, MD,[1] Ahmed M. Abdelmagied, MD,[2] Mohamed F. Aboelnasr, MD,[3] Nada M. Elnugomi, MD,[4] Amal Y. Zaman, MD,[4] Fawzia Ahmed Habib, MD,[4] Tameem Mazen AL jayousi, MD,[4] Ahmed M. Abbas, MD.[2] [1]Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN; [2]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [3]Departement of Obstetrics and Gynecology, Faculty of Medicine, Menoufiya University, Shebin Elkom, Egypt; [4]Department of Obstetrics and Gynecology, Faculty of Medicine, Taibah University, Saudi Arabia.

OBJECTIVE: Subtle septae have been reported in women with hysterosalpingography (HSG) diagnosis of arcuate uterus who had prior failed IVF. The optimal diagnostic tool and definition for arcuate uterus diagnosis, that behaves benignly from implantation perspective, is an area of debate. This study is a scenario economic analysis to determine whether implementation of 3D-US after HSG to screen for subtle septae in women with arcuate uterus anomaly prior to IVF treatment could be cost-effective.

DESIGN: A decision-analytic-model

MATERIALS AND METHODS: A decision-analytic-model was developed to compare 2 screening strategies utilized in daily practice. Modeled women were 100 infertile women, indicated for IVF with HSG diagnosis of arcuate uterus. The first strategy (3D strategy) offers 3D-US screening of subtle septum in IVF women with arcuate uterus diagnosis based on initial HSG. The second strategy (NO-3D strategy) is the reference standard that

adopts proceeding to IVF without 3D-US screening in similar cohort; widely practiced in low resource settings. ASRM-2016 defining criteria for uterine septum were followed to categorize modeled women. Model endpoints were cumulative costs and live birth (LB) after 3 successive IVF cycles. The incremental cost-effectiveness ratio (ICER) was calculated. Baseline input probability data were obtained utilizing the best available evidence concerning the effect of uterine septum incision before IVF therapy and the prevalence of missed septum in a population of arcuate uterus. Medicare 2019 National Fee Estimates were considered for costs assumptions. Costs were reported in US dollars. USA population based LB for year 2017 was also used. For modeling and analysis, we used TreeAge Pro Healthcare 2020 software. Sensitivity analysis was conducted.

RESULTS: Base-case analysis revealed that 3D-US screening strategy prior to IVF was more cost effective than NO-3D strategy. After 3 IVF cycles, 3D-US screening resulted in cumulative LB of 73.2% with $ 2,203,250 total costs compared to 58.9 % cumulative LB and $ 2,255,000 total costs in NO-3D strategy. 3D-US implementation would cause initial costs of $142,250 for diagnosis of missed septae and their accompanying metroplasty procedure; however, this would yield cost saving of $ 3620 per live birth gained after 3 IVF cycles. Even in the worst-case-scenario of sensitivity analysis, when low probability of missed septate was evaluated, 3D strategy was still cost effective with extra-costs and more benefits (ICER: $1160 per LB) utilizing $50,000/QALY willingness-to-pay threshold. The higher the probability of missed septum detection in arcuate IVF population and the higher the increase in LB after septum resection, the more would be the cost effectiveness of 3D-startegy. Sensitivity analyses were robust.

CONCLUSIONS: Adoption of 3D-US prior to IVF, to reevaluate arcuate uteri initially diagnosed by HSG, could minimize the financial burden due to failed cycle caused by missed septum. This strategy may be helpful, since randomized controlled trials in IVF women with uterine septum face recruitment challenges.

SONOGRAPHIC OBSERVATION OF ENDOMETRIAL COMPACTION AS A POTENTIAL PREDICTOR OF ENDOMETRIAL RECEPTIVITY.

Leah A. Kaye, MD,[1] Melody A. Rasouli, MD, MBA,[2] Angela H. Liu, MD,[2] Ankita Raman, MD,[3] Carrie E. Bedient, MD,[1] Forest C. Garner, MS,[1] Bruce S. Shapiro, M.D., Ph.D., H.C.L.D.[4] [1]Fertility Center of Las Vegas, Las Vegas, NV; [2]University of Nevada, Las Vegas, Las Vegas, NV; [3]University of Nevada, Las Vegas, School of Medicine, Las Vegas, NV; [4]Fertility Center of Las Vegas, Las Vagas, Nevada, NV.

OBJECTIVE: Two recent reports of a correlation between changes in endometrial thickness after progesterone (P4) exposure and outcome after thawed embryo transfer suggest a potential relationship with endometrial receptivity. However, these studies had opposite findings, with one associating endometrial compaction with improved outcome, while the other associated endometrial expansion with improved outcome. This study investigates any correlation between the percent change in endometrial thickness and outcome after transfer of single vitrified-warmed blastocysts.

DESIGN: IRB-approved retrospective cohort study of single vitrified-warmed blastocyst transfers at a private fertility center.

MATERIALS AND METHODS: There were 232 autologous vitrified-warmed single-blastocyst transfers following transvaginal ultrasonographic (TVU) measurement of endometrial thickness on the day of P4 start and 5 days later, on the day of transfer. Vitrified-warmed blastocysts were transferred on the 6th day of P4 injection (100 mg/day) in cycles of artificial endometrial preparation with exogenous estradiol. Outcomes were pregnancy (+hCG in serum) and ongoing pregnancy (fetal heart tone at 10 weeks gestation). Logistic regression was used to determine if the percent change in endometrial thickness from the day of P4 start until 5 days later correlated with pregnancy (+hCG in serum) and ongoing pregnancy (fetal heart tone at 10 weeks gestation). Also included in the model were blastocyst morphology (diameter, inner cell mass size, trophectoderm cell count), patient age at egg collection, and the use of PGT-A (yes/no). $P<0.05$ was considered significant. Ranges of endometrial thickness change were then used to show the magnitude of the effect across these ranges.

RESULTS: Of the available variables, significant predictors of pregnancy (+hCG) were the percent change in endometrial thickness (P=0.0031) and blastocyst diameter (P=0.0060). Lesser percent change in endometrial thickness (including compacting endometria) and larger blastocyst diameter were associated with increased chance of pregnancy. Significant predictors of ongoing pregnancy were percent change in endometrial thickness (P=0.0202), age at retrieval (P=0.0243), and the use of PGT-A (P=0.0039). Lesser percent change in endometrial thickness, younger age at retrieval, and the use of PGT-A were associated with increased chance of ongoing pregnancy. To convey the magnitude of this effect, pregnancy rates were 89.5% when endometria compacted by more than 10%, 83.2% when there was between 10% compaction and 10% expansion, and 73.7% when there was $\geq$10% expansion. Ongoing pregnancy rates were 63.2%, 64.2%, and 54.2% in these respective groups.

CONCLUSIONS: Pregnancy and ongoing pregnancy had negative associations with TVU-observed endometrial expansion after progesterone exposure, and a positive association with endometrial compaction. This association suggests an optimal endometrial response to exogenous P4, and perhaps optimal endometrial receptivity, might be sonographically identifiable in artificial cycles of thawed blastocyst transfer.

THREE-DIMENSIONAL ULTRASOUND GUIDANCE: THE NEW FRONTIER OF EMBRYO TRANSFER?

Yusuf Beebeejaun, MRCOG MHDL MBBS BSc(Hons),[1] Sesh Sunkara, MRCOG,[1] Ippokratis Sarris, MRCOG DM,[2] James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons)[3] [1]King's College London, London, United Kingdom; [2]King's Fertility, London, United Kingdom; [3]Institute for Women's Health, University College London, Greater London, United Kingdom.

OBJECTIVE: A systematic review and meta-analysis to assess the value of using transabdominal, transvaginal or 3D ultrasound guidance during embryo transfer.

DESIGN: Systematic review and meta-analysis of randomized controlled trials evaluating the effectiveness of transabdominal, transvaginal or 3D ultrasound guided embryo transfer.

MATERIALS AND METHODS: Cochrane Collaboration methods were used. Summary estimates and 95% confidence intervals were calculated using random-effects methods.

RESULTS: Twenty-eight randomised trials involving 9,907 women were included. Compared to transfer performed without simultaneous ultrasound (clinical touch method), transabdominal ultrasound guided transfers were associated with a significantly higher live birth rate (OR 1.74, 95% CI 1.04-2.89), pregnancy rate (OR 1.46, 95% CI 1.25-1.70), and biochemical pregnancy rate (OR1.20, 95%CI 00.86-1.68). Transvaginal ultrasound guided transfers were associated with significantly higher live birth rate when compared with transabdominal ultrasound guided transfers (OR 2.56, 95% CI 1.02-6.56). There was no significant difference in pregnancy rate when comparing transabdominal 3D ultrasound with 2D ultrasound guided transfer (OR 0.98, 95% CI 0.75-1.21). Live birth outcomes were poorly reported for this comparison.

CONCLUSIONS: Ultrasound should be routinely used during embryo transfer as it improves clinical outcomes. Other ultrasound modalities, including transvaginal and 3D ultrasound, appear to improve live birth and pregnancy rates respectively. Transvaginal ultrasound should be offered to women during embryo transfer. Further research is required to evaluate the effectiveness of transvaginal and 3D ultrasound. Clinicians and professional societies should champion the routine use of ultrasound during embryo transfer.

SUPPORT: No financial support.

P-353 4:30 PM Sunday, October 18, 2020

AUTOMATED 3D (SONOAVC) VERSUS 2D ULTRASONOGRAPHY IN OVARIAN FOLLICLES COUNT IN PATIENTS WITH LARGE OVARIAN ENDOMETRIOMA UNDERGOING IN VITRO FERTILIZATION. Simone Ferrero, MD PhD,[1] Carolina Scala, MD,[2] Giulio Evangelisti, MD,[1] Michele Altieri, MD,[1] Fabio Barra, MD.[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Istituto G. Gaslini, Genova, Italy.

OBJECTIVE: To compare the performance of bidimensional ultrasonography (2D-TVS) and three-dimensional automated volume calculation (SonoAVC) in calculating ovarian follicle count in patients with large endometriomas undergoing in vitro fertilization (IVF) cycles.

DESIGN: Prospective single centre study.

MATERIALS AND METHODS: This study included patients with ovarian endometrioma with largest diameter $\geq$ 5 cm undergoing IVF. Exclusion criteria for the study were: previous unilateral ovariectomy, premature ovarian failure, non-endometriotic ovarian cysts. The exams were performed by using a Voluson E10 machine. The number and mean diameter of follicles were measured manually using 2D ultrasound. 3D data were then acquired and analyzed using Sono-AVC. Only ovaries with endometriomas with largest diameter $\geq$ 5 cm were considered in the analysis.

RESULTS: This study included 173 patients and 176 ovaries. 170 women had unilateral endometrioma with diameter $\geq$ 5 cm; three patients had bilaterale endometriomas with diameter $\geq$ 5 cm. The mean diameter of the large endometrioma was 7.0 ($\pm$1.4) cm. 33 patients had other endometriomas with diameter $<$ 5 cm, which were located in the ovary with the large endometrioma in 13 cases, in the contralateral ovary in 18 cases and in both the ovaries in 2 cases. The mean follicular count per ovary was significantly lower when measured manually than with SonoAVC ($p<0.001$). There was no significant difference in the number of follicles with mean diameters $\geq$ 17 mm measured by 2D-TVS and SonoAVC. SonoAVC identified significant more follicles with mean diameters $\geq$ 9 mm ($p=0.003$) and $\geq$ 13 mm ($p=0.036$) than 2D-TVS. There was no significant difference in the diameter of the leading follicle measured manually or by SonoAVC ($p=0.804$). There was a good correlation between the number of oocytes retrieved and the number of follicles detected by 2D-TVS (Pearson correlation coefficient, 0.836) or by SonoAVC (0.906).

CONCLUSIONS: This large prospective study demonstrates that, when large ovarian endometriomas are present, SonoAVC may improve the detection of follicles with diameter $<$ 17 mm.

P-354 4:30 PM Sunday, October 18, 2020

TO REMOVE OR NOT TO REMOVE? THAT IS THE QUESTION - THE DILEMMA OF DILATED TUBES. Stephanie R. Brownridge, M.D., Arielle Yeshua, MD, Randi H. Goldman, M.D., Susan Maxwell, MD, Gerald Scholl, MD, Nicole Noyes, MD. Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Hysterosalpingograms (HSGs) are integral to fertility care. We looked to determine whether surgical removal of dilated fallopian tubes improves pregnancy outcome.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: All HSGs performed at our academic center by a single practitioner from 1/2015-12/2019 were assessed. Reports were reviewed for the following terms: “tubal dilation” (TD) & “hydrosalpinx” (HS). A discussion took place regarding surgery at the time of diagnosis. Pregnancy rates of the TD/HS subset were compared between patients who had surgery (salpingectomy/proximal occlusion, $\pm$ adhesiolysis) vs. those who did not. A sub-analysis was done for patients with patent (PAT) vs. occluded (OCC) tubes. Statistical analysis: Fisher’s exact tests with $p<0.05$ as significant.

RESULTS: TD or HS was diagnosed in 72/1,398 (5%) HSGs. Of these, 6 patients were excluded: 3 - insufficient data, 2 - high FSH, 1 - planned egg freeze, leaving 66 (Table). 35/66 (53%) achieved a pregnancy. 20/66 (30%) patients had surgery and 46 (70%) did not. Of those that had surgery, 18/20 (90%) had a salpingectomy, 1 had laparoscopic proximal occlusion due to disease severity & 1 had adhesiolysis. Of surgical patients who underwent salpingectomy, all had pathologic confirmation of tubal disease. Notably, pregnancy rates were similar in patients with TD/HS whether they had surgery (11/20, 55%) or not (24/46, 52%). Within the Surgery group, 10/11 (91%) conceived with IVF vs. 9/24 (34%) in the No-Surgery group. 0% of Surgery & 4% of No-Surgery patients had ectopic pregnancies. On subgroup analysis comparing TD/HS-PAT vs. TD/HS-OCC, there was a significantly higher likelihood of pregnancy after tubal removal in the OCC group.

Table Pregnancy rates relative to tubal patency & whether surgery was performed.

	Pregnancy (n, %)	Pregnancy (n, %)	
	Surgery (n=20)	No Surgery (n=46)	p-value
Patients with TD or HS (n=66)	11/20 (55%)	24/46 (52%)	NS
PAT (n=30)	25%	65%	NS
OCC (n=36)	75%	35%	0.02
Pregnancy Outcome			
Delivery (n=22)	73%	58%	NS
Ongoing (n=6)	18%	17%	NS
Biochemical/Spontaneous ab (n=2)	9%	4%	NS
Ectopic (n=1)	0%	4%	NS
Unknown (n=4)	0%	17%	NS

CONCLUSIONS: Surgical intervention for TD/HS has been recommended since the 90s when trials suggested a HS negatively impacted ART outcomes. This is from an era of cleavage-stage embryo transfer, and less accurate venereal disease testing. Our data demonstrates pregnancy & live birth can be achieved with a TD in vivo, especially if PAT. Thus, patients should be counseled regarding the option of conservative management for TD. Surgery should still be encouraged in the case of TD/HS-OCC. Our HSG data was obtained from a single provider, decreasing variations in diagnostic criteria. This study was limited by its small sample size and retrospective design.

P-355 4:30 PM Sunday, October 18, 2020

IMPACT OF ULTRASOUND DIAGNOSIS OF ADENOMYOSIS ON PREGNANCY RATE AND OUTCOME IN IVF CYCLES WITH DONATED OOCYTES: A PROSPECTIVE STUDY. Caterina Exacoustos, MD, PhD,[1] Martina Cosentino, MD,[1] Luisa Loiudice, MD,[2] Francesco Giuseppe Martire, MD,[1] Daniela Galliano, MD, PhD,[3] Antonio Pellicer, M.D., Ph.D.[3] [1]University of Rome ’Tor Vergata’, Italy; [2]IVI Istituto Valenciano de Infertilidad in Roma and Valencia, University of Valencia affiliated Infertility clinic, Roma, Italy; [3]IVI Istituto Valenciano de Infertilidad in Roma and Valencia, University of Valencia affiliated Infertility clinic, Italy.

OBJECTIVE: The aim of this prospective study was to evaluate in patients who underwent embryo transfer (ET) in an oocyte donation cycle, the impact of adenomyosis, diagnosed by transvaginal sonographic (TVS), on the implantation rate. Also type and degree of adenomyosis scored by TVS were correlated to the implantation rate and pregnancy outcome.

DESIGN: All the patients undergoing their first IVF with oocyte donation were evaluated before ET by TVS to assess presence or absence of adenomyosis. Type and grade of the disease was correlated to pregnancy rate and outcome.

MATERIALS AND METHODS: All the patients aged $\leq$ 45 years old undergoing, for several personal problems, their first oocyte donation at IVI center Rome from June 2019 were included in this study. All had as usual an accurate workup which included history, pelvic exam and 2/3D TVS scan which was saved as images, videoclips and volumes and stored. The off line evaluation of the stored TVS was performed blind to IVF indication and outcomes by expert sonographer of the University of Rome Tor Vergata, who assessed the presence or absence of TVS signs of adenomyosis. Patients were divided into 2 groups according to findings on a baseline pre-treatment TVS: patients with and without adenomyosis. Any medical treatment was given for adenomyosis. In the patients with adenomyosis, the disease was further classified according to type (diffuse,focal), localization (inner and

outer myometrium) and extension inside the uterus (mild, moderate, severe) and correlated to pregnancy rate and outcome

RESULTS: A total of 51 patients were included in this study: 24 with adenomyosis and 27 without adenomyosis. Those with TVS signs of adenomyosis showed a lower pregnancy rate (62.5%) compared to those in the control group (74.1%). Women with adenomyosis that infiltrated only the external myometrium showed a lower pregnancy rate (50%) compared to those who had the involvement of only the inner myometrium (71%). The presence of ultrasound findings of focal disease was associated with a lower pregnancy rate (66%) compared to the diffuse disease (70%); We observed a slightly higher miscarriage rate in the first trimester in patients with adenomyosis in particular in the diffuse type

CONCLUSIONS: The presence, type and degree of adenomyosis showed an important correlation to embryo implantation rate and early miscarriage. Results of this study may be used to evaluate the impact of different medical or surgical treatment in women with adenomyosis undergoing IVF.

P-356 4:30 PM Sunday, October 18, 2020

IMAGE GUIDED TRANSVAGINAL & TRANSABDOMINAL DRAIN PLACEMENT FOR SURGICAL NAVIGATION IN A PATIENT WITH TUBO-OVARIAN ABSCESS AND OBSTRUCTED HEMIVAGINA WITH UTERUS DIDELPHYS. Pamela B. Parker, M.D., M.P.H.,[1] Jared Ray Edwards, MD,[2] Teodora Bochnakova, MD,[1] David Lee, MD.[1] [1]Oregon Health & Science University, Portland, OR; [2]Naval Medical Center San Diego, San Diego, CA.

OBJECTIVE: To highlight a minimally invasive, image-guided technique to treat obstructed hemivagina in ipsilateral renal anomaly (OHVIRA) syndrome complicated by tubo-ovarian abscess (TOA)

DESIGN: Case Report

MATERIALS AND METHODS: A case of a 15-year-old female with history of uterine didelphys and longitudinal vaginal septum deviated to the left with concomitant left-sided renal agenesis presented with TOA. MRI of the abdomen and pelvis demonstrated a 13 centimeter loculated, fluid-filled, pelvic mass as well as a complex, fluid-filled structure near the obstructed left hemivagina. She underwent hysteroscopy, cystoscopy, and attempted excision of the vaginal septum and neosalpingostomy. Excision of the vaginal septum was unsuccessful because prior spontaneous drainage from the left vagina to the right through a tract, perhaps partially involving the bladder, left all of the vaginal septal tissue infected and unable to optimally hold suture. Similarly, after extensive robotic lysis of abdominal and pelvic adhesions, surgical planes remained ill-defined given the extensive purulent tissue. Ultimately interventional radiology (IR) was consulted intraoperatively for placement of a transabdominal drain under direct visual guidance through a laparoscopic port. The patient subsequently underwent transperineal ultrasound-guided placement of a transvaginal drain into the hemivaginal collection and CT-guided transabdominal drain placement in the IR suite 8 days following initial surgery. After a cool-down period receiving broad spectrum IV antibiotics, she underwent cystoscopy, vaginoscopy, successful excision of the vaginal septum, drainage and excision of left TOA, removal of drains, and creation of left neosalpingostomy. Placement of the transvaginal drain allowed for subsequent intraoperative identification of the correct anatomy to safely resect the transvaginal septum of the previously obstructed hemivagina. Additionally, placement of the transabdominal drains allowed for successful identification of the abscesses. She was discharged home the following day.

RESULTS: At her 1-week and 3-month follow-up visits, the patient was symptom-free without evidence of vaginal stenosis nor evidence of recurrent infection.

CONCLUSIONS: Patients with OHVIRA syndrome, with and without TOA, can be managed with minimally invasive techniques. In this case, a joint approach allowing for successful placement of a TOA drain placed laparoscopically and a transvaginal catheter placed under image-guidance allowed for the correct incision site into the vaginal septum. Given the anatomic complexity, preoperative measures that aid in intraoperative anatomic navigation are critical in ensuring successful treatment. Collaboration with interventional radiology and pediatric gynecology is particularly helpful for treatment of complicated mullerian and vaginal variants.

SUPPORT: none

P-357 4:30 PM Sunday, October 18, 2020

FOLLICULAR TRACKING WITH ULTRASOUND DOES NOT IMPROVE PREGNANCY RATE IN LETROZOLE-INTRAUTERINE INSEMINATION (IUI) CYCLES. Kristy Cho, MD, FRCSC,[1] Jason K. M. Au, MSc,[2] Rachel N. J. Sen-Laurenz, BA,[3] Arianne Y. K. Albert, PhD,[4] Jon C. Havelock, MD, FRCSC, DABOG,[2] Caitlin Dunne, MD, FRCSC.[5] [1]Division of Reproductive Endocrinology and Infertility, University of British Columbia, Vancouver, BC, Canada; [2]Pacific Centre for Reproductive Medicine, Burnaby, BC, Canada; [3]University of British Columbia, Vancouver, BC, Canada; [4]Women's Health Research Institute, Vancouver, BC, Canada; [5]Division of Reproductive Endocrinology and Infertility, University of British Columbia, Burnaby, BC, Canada.

OBJECTIVE: The use of letrozole for ovarian stimulation in intrauterine insemination (IUI) has increased in popularity in recent years due to its efficacy for patients with PCOS and the current shortage of the alternate medication, clomiphene. However, much of the evidence guiding cycle management has been based on clomiphene IUI cycles. This study aimed to determine if the probability of pregnancy was associated with ultrasound monitoring or human chorionic gonadotrophin (HCG) trigger in letrozole IUI cycles.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: This study included letrozole IUI cycles performed at two Canadian university-affiliated fertility centers from 2016 to 2019. Exclusion criteria included anovulatory cycles, tubal factor infertility, or total motile sperm < 1 million. The patients were divided into 2 groups: ultrasound-monitored and unmonitored. The associations between pregnancy rate and ultrasound use, lead follicle size at last ultrasound, or HCG use were determined using regression analysis, Fisher's exact test, or Wilcoxon rank-sum test.

Letrozole 2.5-7.5 mg was administered from cycle day 3-7 or day 1-9. In the unmonitored group, patients used ovulation predictor kits (OPK) daily starting on cycle day 10. In the ultrasound-monitored group, patients presented for an ultrasound at baseline, on day 10-12, and as needed until ovulation. HCG 10,000 IU was given for ovulation trigger when clinically indicated. The IUI was performed on the same day as a positive OPK or the day after the HCG trigger.

RESULTS: Out of the 2678 cycles undertaken by 1,397 patients, 351 cycles (13%) were monitored with ultrasound. Overall, the pregnancy rate was 12% per cycle. In this cohort, the cumulative pregnancy rate, up to 6 cycles of IUI, was 53% (95% CI 34% to 66%). Compared to patients who did not conceive, a higher proportion of the patients who achieved pregnancy utilized letrozole $\geq$5mg on cycle day 3-7. The use of letrozole on cycle day 1-9 was associated with a lower rate of pregnancy compared to cycle day 3-7 (9.4% vs 12.6%, $P< 0.05$). Ultrasound monitoring was not associated with an increased pregnancy rate in letrozole IUI treatments ($p= 0.09$).

Adjusting for age and body mass index, there was no relationship between lead follicle size and the odds of pregnancy (OR 0.95, 95% CI 0.85 to 1.05, $p= 0.35$). Multi-follicular response was also not associated with a significantly increased pregnancy rate; the presence of 2 or more lead follicles $\geq$18mm had 1.27 adjusted odds of pregnancy ($p= 0.5$). For those who underwent ultrasound monitoring, 12% required HCG to trigger ovulation. There were no statistically significant differences in pregnancy rates between those who utilized HCG trigger and those who did not ($p= 0.14$).

CONCLUSIONS: The use of ultrasound monitoring was not associated with an improved pregnancy rate in letrozole IUI cycles.

No financial support.

POSTER SESSION: INFERTILITY AND CANCER

P-358 4:30 PM Sunday, October 18, 2020

EFFECT OF DISTAL CANCER ON THE TELOMERIC LENGTH OF OVARIAN CORTEX CELLS. Lucía Chico-Sordo, MSc,[1] Inmaculada Soler, MD,[2] Jose M. Mateu-Pascual, MSc,[1] Isabel Córdova-Oriz, MSc,[1] Alba M. Polonio, MSc,[1] Marta Medrano, Lab Technician,[3] María J. Soriano, MSc,[1] Juan A. Garcia-Velasco, MD, PhD,[3] Elisa Varela, PhD[3] [1]IVI Foundation, IIS La Fe, Valencia,

Spain; [2]Gynecology, Hospital de Xativa Lluis Alcanyis, Valencia, Spain; [3]IVI-RMA Madrid, Rey Juan Carlos University, Madrid, Spain.

OBJECTIVE: Telomeres are tandem repeats of hexanucleotides which, together with the shelterin protein complex, protect the ends of chromosomes, to preserve genomic integrity. However, over organismal lifetime telomeres shorten on each cell division. Harsh erosion of telomeres compromises chromosome structure with consequences for aging and cancer. In the cancer context, unprotected telomeres promote cell transformation by a process called telomere crisis that leads to numerous genomic alterations including chromosome rearrangements, areas susceptible of mutations and tetraploidization. The aim of the study is to determine whether breast cancer can exert telomere damage in a distal organ as the ovary reducing women's fertility, even before they have undergone any cancer therapy.

DESIGN: Analytic and prospective cohort study.

MATERIALS AND METHODS: Women who participated in this study were recruited between April 2013 and May 2014 from Hospital La Fe (Valencia). Ovarian biopsies from 46 individuals, serum from 44 women and leukocytes from 49 participants were collected. Samples of ovarian tissue and blood from healthy women and cancer patients, prior to cancer treatment, were collected and analyzed. Blood samples were collected before the surgical procedure. Serum and leukocytes were obtained by centrifugation using a Ficoll gradient. Samples of ovarian tissue were obtained at the time of surgery to preserve patients' fertility, and during tubal ligation surgery in controls. Telomere length was measured by Quantitative Fluorescent In Situ Hybridization (Q-FISH) followed by image acquisition using high resolution confocal microscopy.

RESULTS: A total of 57 women have participated, 29 cancer patients (mean 27.92 $\pm$ 7.54 years) and 28 controls (mean 36.78 $\pm$ 4.32 years). From controls, 11.1% were smokers, and 21.7% of cancer patients. The mean AMH values were 1.50 $\pm$ 1.43 and 2.60 $\pm$ 3.08 ng/mL (controls and cancer patients, respectively). Telomere length (TL) was similar between cancer patients and healthy controls, when all cell types of the ovary were analyzed (21.85$\pm$ 0.079 and 22.45 $\pm$ 0.123 a.u., respectively). Granulosa cells of cancer-diagnosed women bore shorter telomeres (TL = 22.34 $\pm$ 8.86 a.u.) compared to control group (TL = 26.37 $\pm$ 9.85 a.u.). In oocytes, a lower mean telomeric length was observed in cancer patients (21.03 $\pm$ 8.64 a.u.) compared to control women (24.54 $\pm$ 12.73 a.u.).

CONCLUSIONS: The telomere length of ovarian cortex cells is altered in cancer patients, indicating a systemic effect of breast cancer on the ovaries, which are known to be very sensitive to toxic insults. The systemic effect of distal cancers has effected mainly to granulosa cells and oocytes, suggesting that these cell types are more susceptible than ovarian stroma cells. All these alterations in telomere biology have been observed before women had undertaken cancer therapy. Collectively, these results remark the urgency of ovarian cortex cryopreservation once the cancer has been diagnosed, in women who wish to became pregnant.

P-359 4:30 PM Sunday, October 18, 2020

FERTILITY PRESERVATION IN BREAST CANCER PATIENTS: A LONGITUDINAL STUDY OF RETRIEVAL AND OOCYTE/EMBRYO UTILIZATION. Sydney Chang, MD,[1] Susan Finch, MD,[1] Joseph A. Lee, BA,[2] Alan B. Copperman, MD,[1] Christina Weltz, MD[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Breast cancer is the most commonly diagnosed malignancy for women living in the United States and more than 26,000 newly diagnosed patients per year are under the age of 45.[1] Given that most chemotherapeutic agents and hormonal therapies used for adjuvant treatment of breast cancer are gonadotoxic and/or teratogenic, fertility preservation is critical prior to initiating treatment. Increased awareness of the need to preserve fertility, timely referral to infertility specialists, and development of ovarian stimulation protocols that are safe in breast cancer patients have increased rates of fertility consultation and treatment among women diagnosed with breast cancer. The objective of this study is to describe the frequency with which breast cancer patients who consulted with fertility experts underwent retrieval procedures and also the rate of utilizing cryopreserved oocyte/embryos.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Patients with breast cancer who were identified within the center's electronic medical between 2002-2019 were included in the study. Demographic information, cycle characteristics, use of preserved oocyte and embryos, pregnancy outcomes and length of follow-up were collected.

RESULTS: A total of 215 patients with a breast cancer diagnosis (196 invasive, 19 in situ) presented for consultation. The majority of the study population (78.6% [169/215]) saw a REI specialist prior to chemotherapy and/or radiation. Of patients who presented for a consultation, 44.2% (95/215) decided to proceed with an oocyte or embryo freezing cycle, and 2.8% (6/215) pursued oocyte donation. The average age of patients undergoing cryopreservation was 35.9 $\pm$ 5.6 (22-47). 50.5% (48/95) of patients underwent retrieval to freeze oocytes; 47.3% (45/95) underwent retrieval to freeze embryos; 2.1% (2/95) were cancelled prior to retrieval. 33.7% (32/95) of patients had their retrieval within 4 weeks of their initial consultation.

Of patients who underwent cryopreservation, 25.3% (24/95) returned to utilize their oocytes/embryos either at our center (n=12) or at an alternative center (n=12). Of patients undergoing a transfer at our center, 58.3% (7/12) achieved a pregnancy and 50% (6/12) achieved a live birth. From this cohort, there were 3 singleton and 3 twin deliveries. 12.5% (3/24) created embryos for future transfer into a gestational carrier. Mean follow up time was 4.8$\pm$3.3 years, median was 4.5 years. Many patients (43.7% [31/71]) who have yet to return and use their oocytes/embryos underwent cryopreservation $<$3 years ago.

CONCLUSIONS: With 5-year breast cancer survival rate at 90%1, fertility preservation in patients of reproductive age is of paramount importance. Of 215 breast cancer patients who presented for discussion of fertility preservation, 95 underwent retrieval procedures and 24 have returned to utilize their oocytes/embryos. Further research will seek to identify individual patient's decision making relevant to fertility preservation and treatment with the goal of optimizing breast cancer patients' chances of achieving live birth.

HEREDITARY BREAST CANCER AND FERTILITY PRESERVATION OUTCOMES. Suha Arab, MD, MS,[1] William Buckett, M.D.[2] [1]Doctor, Montreal, QC, Canada; [2]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Centre, Montreal, QC, Canada.

OBJECTIVE: BRCA mutations are the most common genes linked to hereditary breast cancer, but other inherited genes are also associated with breast cancer. While several studies have evaluated the impact of BRCA gene mutations on response to ovarian stimulation, albeit with conflicting results, few have assessed the impact of other related genes. The objective of this study was to determine the prevalence of hereditary breast cancer associated with different mutated genes as well as the respective fertility preservation outcomes in young patients with active breast cancer presenting for fertility preservation.

DESIGN: A retrospective cohort study of breast cancer patients with known genetic testing results who underwent fertility preservation at a university teaching hospital ART center from 2005-2019.

MATERIALS AND METHODS: All breast cancer patients $<$ 40 years old who had a genetic testing result and underwent fertility preservation before starting gonadotoxic therapy. The total number of oocytes retrieved, number of MII oocytes, number of embryos (where appropriate), and the number of cryopreserved oocytes and/or embryos from genetically positive and negative were compared. Age, stage of cancer, parity, BMI and ovarian reserve were also compared.

RESULTS: Of 244 breast cancer patients, 40 patients tested genetically positive (16%). 31 (77.5%) patients had a BRCA mutation, 3(7.5%) had ATM, 2 (5%) had CHK2 and one (2.5%) for each of the following genes: PALP2, NF, MUTYH.c.536A ,and TP53. A total of 127 patients were $<$ 40 years old: 87 patients were genetically negative; 40 patients were genetically positive. Patients in the hereditary breast cancer group were significantly younger than patients in the non-hereditary group (30.7+/-4.3 vs 32.4+/-3.9) (P=0.034). Both groups were similar regarding ovarian reserve, BMI, parity, and stage of cancer. Proportion undergoing IVF or IVM were similar and IVM outcomes were similar in the two groups. Total gonadotrophin dose and days of stimulation were also comparable. In terms of reproductive outcome, there was no significant difference between the groups in the total number of eggs retrieved overall, the number of MII oocytes

collected, and the number of cryopreserved oocytes. Interestingly the number of fertilized oocytes (5.15+/-6.6 vs 2.90+/-4.2)(P=0.054), and the number of cryopreserved embryos (3.35+/-3.7 vs 1.9+/-2.8)(P=0.046) were borderline significantly higher in hereditary than the non-hereditary group. Sub-analysis showed no difference between the different genes. Outcomes following IVF and IVM were similar.

CONCLUSIONS: 16% of all breast cancer patients and 31% of those under 40 years old were genetically positive to 7 different mutated genes. More than 77% of positive mutated genes were BRCA. Patients with hereditary breast cancer, including BRCA, have similar fertility preservation outcomes to those with non-hereditary breast cancer and should be encouraged to consider fertility preservation.

SUPPORT: No financial support.

P-361 4:30 PM Sunday, October 18, 2020

HAVE ONCOFERTILITY INFORMATION FOR PATIENTS IMPROVED? OBJECTIVE ASSESSMENT OF INTERNET BASED FERTILITY PRESERVATION RESOURCES AT NCI CANCER CENTERS FROM 2015-2020.

Melody A. Rasouli, MD, MBA,[1] Christopher de Haydu, MD,[2] Angela H. Liu, MD,[1] Janelle M. Jackman, MBBS,[3] Kajal Verma, MD,[1] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]The Camran Nezhat Institute, Palo Alto, CA; [4]University of California Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Fertility preservation is a critical patient counseling component following cancer diagnosis. The aim of this study was to compare change and quality of fertility preservation information available to patients on the websites of National Cancer Institute (NCI) designated cancer centers over five years (2015 to 2020) for both women and men.

DESIGN: Longitudinal observational study.

MATERIALS AND METHODS: All NCI designated cancer center (and the Cleveland Clinic) websites were queried in a systematic fashion for information on oncofertility in 2020 publicly available to patients. The methodology and rubric were previously employed by this group, in 2015, to establish minimum content quality standards for the validation process. Two investigators collected the data from NCI cancer center (NCICC) websites and a third member from a separate institution reviewed the data for discrepancies. Specific questions included: 1) Does the web site discuss the effects of cancer and cancer treatment on fertility? 2) Are options for fertility preservation discussed? 3) Is there a standalone page dedicated to educating patients on fertility preservation? 4) Was parenting-related cancer survivorship addressed. 5) Does the web site discuss the effects of cancer and cancer treatment on fertility, particularly male fertility? Descriptive statistical analysis and chi-squared testing were performed. Data was then compared with the same data points from 2015 to see the effect of time on availability of oncofertility information.

RESULTS: All 65 websites of NCICC (and the Cleveland Clinic) were evaluated; 92% were affiliated with academic institutions. The risk of cancer treatment on fertility was mentioned by 86% of centers and 83% discussed fertility preservation, which were not significantly different from 2015. Among NCICC, significantly more centers have a standalone page for fertility preservation in 2020 compared with 2015 ($p = 0.004$). Survivorship information on family building significantly increased from 32% in 2015 to 82% in 2020 ($p= 0.0077$). Among all cancer centers, there was a significant increase in information on fertility preservation specifically directed toward men, such as sperm cryopreservation; an increase from only 60% in 2015 to 70% in 2020 ($p= 0.0140$). In counties in the United States with an above average number of people living in poverty, there were significantly fewer NCI centers that discussed the effect of cancer treatment on male fertility ($p=0.012$).

CONCLUSIONS: There was a significant increase in standalone pages for fertility preservation, survivorship information and information on fertility preservation specifically directed toward men on NCI CC websites over the past five years. Sixteen percent of centers still do not discuss any options for male fertility preservation, and these centers are disproportionately located in lower socioeconomic counties. Given the increasing recognition of the importance of oncofertility in cancer survivorship, more education should be available about options for fertility preservation, particularly among men in lower socioeconomic areas.

P-362 4:30 PM Sunday, October 18, 2020

LIKELIHOOD OF WOMEN ACHIEVING MORE THAN ONE LIVE BIRTH AFTER VARIOUS TYPES OF CANCERS.

Deepika Garg, MD,[1] Huong Dieu Meeks, PhD,[1] Erica Johnstone, MD,[1] Sarah L. Berga, MD,[1] Ken R. Smith, PhD,[1] James Hotaling, MD,[2] Joseph M. Letourneau, MD[1] [1]University of Utah, Salt Lake City, UT; [2]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT.

OBJECTIVE: Future family building is an important concern for many cancer survivors and many may hope for more than one child after cancer treatment. Much of the focus in cancer survivorship research has been on whether a single pregnancy can be achieved, rather than on how many children might be born. Limited data is available about the impact of various cancer types and their treatment on the fertility and reproductive window of cancer survivors.

DESIGN: Population-based cohort study

MATERIALS AND METHODS: The Utah Population Data Base (UPDB) was used to identify female cancer survivors at age 18-45 years in Utah state with first time cancer diagnosed between 1952 to 2014. We identified first and last live births of cancer survivors (n= 6,317) in various cancer types and reported these relative to the timing of their cancer diagnosis. Descriptive statistics and chi-square testing were used where appropriate. Poisson regression models for the number of live births after cancer diagnosis were estimated which adjusted for number of live births prior to cancer diagnosis.

RESULTS: The most common cancer types among the cohort were breast cancer in 23%, neurological cancers 4%, lymphomas in 4%, leukemia in 2% and soft tissue cancers less than 1%. Based on the cancer staging, 43% of women had localized disease, 25% had carcinoma In-situ, 11% had involvement of regional lymph nodes, and 8% had distant metastases. When compared with general population, women with breast cancer were least likely to have more than one child after cancer treatment and those Hodgkin's lymphoma appeared most likely to do so, as reflected in the table below.

CONCLUSIONS: Live births after cancer treatment vary by cancer treatment type. This is likely a reflection of treatment type and average age of diagnosis associated with each cancer type. With the exception of survivors of Hodgkin's lymphoma, fewer than 25% of female cancer survivors had two or more children after their cancer diagnosis. This type of information can be used to assist patients in understanding their chances of achieving a desired family size after cancer treatment, and this may impact decisions on fertility preservation treatments.

SUPPORT: None

Table: Estimated effect of being diagnosed with cancer on parity

Number of live births after cancer treatment	Breast (N=4145)	GI (N=129)	Leukemia (N=322)	CNS (N=763)	Non- Hodgkin's lymphoma (N=393)	Soft tissue (N=166)	Hodgkin's lymphoma (N=399)
0	3950 (95%)	122 (94%)	291 (90%)	646 (85%)	331 (84%)	137 (82%)	270 (68%)

FERTILITY PRESERVATION (FP) IN BREAST CANCER PATIENTS: PREDICTORS AND OUTCOMES.

Molly B. Moravek, MD, MPH,[1] Rafael Confino, BS,[2] Angela K. Lawson, Ph.D.,[3] Kristin Smith, B.S.,[3] Susan Klock, PhD,[4] Mary Ellen Pavone, MD, MSCI[3] [1]University of Michigan, Ann Arbor, MI; [2]Northwestern Feinberg School of Medicine, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [4]Northwestern University, Chicago, IL.

OBJECTIVE: In breast cancer patients, there is often concern regarding the safety of the increased estradiol (E2) levels and potential delays in treatment associated with ovarian stimulation for FP. The primary objective of this study was to compare recurrence and survival in breast cancer patients who pursued FP to those who did not (no-FP). Secondary outcomes were predictors for utilizing FP, utilization of cryopreserved specimens, and pregnancy outcomes. We hypothesized there would be no difference in cancer outcomes between the 2 groups, regardless of receptor status.

DESIGN: Retrospective Cohort Study

MATERIALS AND METHODS: We reviewed charts of women with breast cancer who contacted the FP patient navigator (PN) at a single institution from 01/2005-01/2018. Cancer stage, estrogen receptor (ER) status, date of initial contact with the PN, subsequent cancer treatment dates, relapse, and mortality data were collected. Ovarian stimulation and pregnancy outcome data were also examined. Data were analyzed by chi-square test or regression, as appropriate. Kaplan-Meier curves were used to examine cancer recurrence and survival. Power analysis indicated 140 patients were required per group to detect 10% difference in disease-free survival with 80% power. Statistical analyses were performed with SPSS IBM Statistics 26.0 for Windows.

RESULTS: 332 patients were included, of which 157 (47.3%) underwent ovarian stimulation for FP. Median age (years) was 33.1 for FP patients and 37.29 for no-FP (NS). Median follow up time (years) was 4.22 for the FP group and 6.19 for no-FP (NS). Median days to cancer treatment after consulting the PN was 35 in the FP group and 21 in no-FP ($P<0.05$). Cancer recurrence was noted in 10 (6.4%) FP and 15 (8.6%) no-FP patients (NS), and mortality in 5 (3.2%) FP patients and 7 (4.0%) no-FP patients (NS). Within the FP group, no significant differences were found in recurrence or mortality based on ER status, age, BMI, peak E2 level or total gonadotropin dose. We modeled decision to pursue FP based on age, race, and parity and found the log odds of choosing FP was related to lower age (OR=1.13, 95%CI=1.08, 1.19) and parity (OR=1.76, 95%CI=1.25, 2.47). Cancer stage did not affect likelihood of pursuing FP. Of FP patients who underwent oocyte retrieval (8 cycles were cancelled), median peak E2 was 1460 pg/ml, median days of stimulation was 10, and median number mature oocytes was 8. To date, 22 (14.0%) have used cryopreserved specimens, and 13 (59.1%) had a live birth. 13% used a gestational carrier. Median time from FP to return was 831 days. There were no differences in age or AMH between patients who returned and those who have not. To date, 5.7% FP and 5.1% no-FP patients had a live birth from spontaneous pregnancy.

CONCLUSIONS: FP is safe and effective in breast cancer patients, regardless of receptor status; E2 elevations and the 2-week delay in treatment start are unlikely to be clinically significant. The findings are unique in that our institution does not use letrozole during stimulation to minimize E2 elevations in breast cancer patients. FP choice was primarily a function of age and parity, and was not affected by cancer stage.

ONCOFERTILITY AND THIRD PARTY REPRODUCTION: ANALYSIS OF PATIENT DIRECTED INFORMATION AND REGIONAL BARRIERS.

Melody A. Rasouli, MD, MBA,[1] Christopher de Haydu, MD,[2] Angela H. Liu, MD,[1] Janelle M. Jackman, MBBS,[3] Kajal Verma, MD,[1] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]The Camran Nezhat Institute, Palo Alto, CA; [4]University of California Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Third party reproduction is often overlooked in patient counseling following cancer diagnosis, when discussing future fertility. However, for some patients, this may be the only option due to the extent of their disease. The aim of this study was to investigate the availability and quality of patient directed information, on third party reproduction, on the web sites of National Cancer Institute (NCI) designated cancer centers.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: All NCI designated cancer center web sites were queried in a systematic fashion for patient directed information on oncofertility. A rubric was employed to establish minimum content quality standards for the validation process. Descriptive statistical analysis and chi-square tests were performed. Specific questions included: 1) Are options for fertility preservation discussed? 2) Are options for future fertility with donor oocytes and sperm discussed? 3) Is the option of gestational surrogacy discussed? Data were then evaluated based on each cancer center's state income to test whether there was a demographic effect on oncofertility information. State surrogacy laws were reviewed, and each state was categorized in two groups, states where surrogacy is permitted for all parents and states where there are any restrictions on surrogacy.

RESULTS: All NCI designated cancer center (and the Cleveland Clinic) websites were evaluated; 94% were affiliated with academic institutions. Among NCI cancer centers (NCICC's), 86% discuss the risk of cancer treatment on future fertility. Of all NCICC's fertility preservation websites, 60% do not mention the option of donor oocytes or sperm for future fertility and 69% do not discuss the option of gestational surrogacy for future pregnancy. Only 24% of all NCI designated cancer centers discuss both donor gametes and gestational surrogacy. NCICC's in states with the top 50% of medium income were significantly more likely to discuss future fertility with donor gametes ($p=0.01$) and gestational surrogacy ($p=0.003$). Discussion of gestational surrogacy was found to be significantly more likely on NCI cancer centers in states where surrogacy is permitted for all parents ($p=0.002$). There were no differences observed when similar adjustments & analyses were performed by race or percentage of population insured.

CONCLUSIONS: Fifty percent of NCI designated cancer center web sites do not discuss options for any third party reproduction and only 24% discuss both donor gametes and gestational surrogacy. Third party reproduction is less likely to be discussed in states with lower medium income and in states with any regulation on gestational surrogacy. Given the increasing recognition of the importance of oncofertility in cancer survivorship, more education should be available about options for fertility preservation, particularly through third party reproduction.

P-365 4:30 PM Sunday, October 18, 2020

THE IMPACT OF LETROZOLE ON OVARIAN STIMULATION RESPONSE IN CANCER PATIENTS WITHOUT BREAST CANCER UNDERGOING FERTILITY PRESERVATION.

Suha Arab, MD, MS,[1] William Buckett, M.D.[2] [1]Doctor, Montreal, QC, Canada; [2]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Centre, Montreal, QC, Canada.

OBJECTIVE: Letrozole had been introduced initially to reduce estrogen level exposure in women with estrogen-sensitive cancer undergoing ovarian stimulation (OS) for fertility preservation. The impact of letrozole on ovarian stimulation response in non-breast cancer oncofertility cases has been inadequately investigated. Some studies suggested that adding letrozole to the gonadotropins yield more mature oocytes at lower estradiol levels compared to gonadotropins alone, some studies found patients who had OS with letrozole would reduce the oocyte maturation, and some studies found no significant differences between OS with and without letrozole. Most of these studies compared the impact of OS with letrozole in breast cancer to OS without letrozole in non-breast cancer patients. The purpose of our study is to investigate whether using letrozole has an influence on the ovarian stimulation response for fertility preservation (FP) within non-breast cancer patients and evaluate if it will modify the risk of ovarian hyperstimulation syndrome (OHSS).

DESIGN: A retrospective cohort study on 209 cancer patients who underwent fertility preservation with and without letrozole supplementation during OS at a university teaching hospital ART center between 2009 -2019.

MATERIALS AND METHODS: Our study included all non-breast cancer patients who presented for FP with an antagonist protocol, no previous chemotherapy, at or $<$ 40 years old, no other ovarian disease, and both ovaries were present at the time of treatment. Of the total of 209 patients, the first group underwent OS with letrozole supplementation (n=18) and the second group underwent OS without letrozole (n=191). Primary outcomes were the total number of oocytes retrieved, number of MII oocytes, and the number of oocytes and/or embryos (where appropriate)

cryopreserved between both groups. Secondary outcomes were the number of cases of mild, moderate,and severe OHSS.

RESULTS: Age, BMI, and AFC were similar between both groups. Compared to OS without letrozole, OS with letrozole had higher numbers of oocytes retrieved (18.9 vs 12.8, p=0.006), MII oocytes (12.7 vs 8.2, p=0.02) and a lower level of serum estradiol (1695.2 vs 4675.8 IU/L, p<0.001). In multivariate regression, AFC, rather than the addition of letrozole supplementation, was associated with a higher number of MII oocytes (OR=1.1, CI 95% (1.053-1.155), p<0.001) vs OR 0.371, CI 95% (0.112-1.234), p=0.106). A total of 12 out of the 209 patients developed OHSS 5.7%, 11 cases were mild and only one was severe OHSS. In a multivariate logistic analysis, the odds to develop OHSS was slightly lower in OS with letrozole supplementation (OR=0.210, CI 95% (0.034-1.311), p=0.095). As expected, AFC was the strongest predictor of OHSS (OR 1.087, CI(1.006-1.173), p=0.035).

CONCLUSIONS: Letrozole supplementation to OS in fertility preservation in non-breast cancer patients does not seem to have an important effect on OS response, although there was an insignificant tendency to decrease the odds of OHSS. This deserves further investigation. Larger prospective studies would be able to determine whether there is any real benefit.

SUPPORT: No financial support.

OUTCOMES OF FERTILITY PRESERVATION AMONG CANCER PATIENTS UNDERGOING OOCYTE AND EMBRYO CRYOPRESERVATION.

Alex Robles, MD,[1] Brittany Noel Robles, MD, MPH,[2] Laura C. Gemmell, MD,[1] Paula C. Brady, MD[1] [1]Columbia University Medical Center, New York, NY; [2]Wyckoff Heights Medical Center, Brooklyn, NY.

OBJECTIVE: To compare the outcomes of ovarian stimulation in oncology patients undergoing fertility preservation to outcomes of age and AMH-matched controls.

DESIGN: A matched retrospective cohort study

MATERIALS AND METHODS: All oncology patients who underwent embryo or oocyte cryopreservation at our institution 1/2019 through 2/2020 were included (n=42). We identified a comparison group matched by age (within 1 year), AMH (within 0.5 ng/mL), and cycle type (oocyte cryopreservation or IVF/ICSI). Primary outcomes were number of oocytes retrieved, maturity and fertilization rates, and blastocysts frozen. Patients with estrogen-receptor positive tumors (n=23) received letrozole (5 mg/day) during stimulation. Univariate comparisons between cases and controls were performed using the Fisher's exact or Wilcoxon rank sum test as indicated; a p-value of $\leq .05$ was considered statistically significant. Analyses were performed using online calculators available at http://astatsa.com.

RESULTS: Among both cases and controls, the mean age was 31 years (range 16-42, Table) and mean AMH was 3.0 ng/mL (range 0.1-11.8). The distribution of oncologic diagnoses was breast (n=19, 45%), hematologic (n=9, 21%), ovary (n=6, 14%), colorectal (n=2, 5%), and 1 of each of the following: Bone, brain, cervical, renal, uterine and vulvar. Thirty three oncology patients (79%) had random start stimulations, and all cycles utilized an antagonist protocol. In both groups, final oocyte maturation was achieved using hCG (71%), a GnRH-agonist (17%), and a combination (12%). While total oocyte yield was similar between cases and controls (14.6 vs 15.7, respectively, p>0.05), mean oocyte maturity rate was significantly lower (65% vs 77%, respectively, p=0.01). In stratified analysis according to letrozole use, mean oocyte maturity remained lower among cases (62% with, 70% without, p>0.05). Among patients who underwent embryo cryopreservation (n=12), fertilization rates and numbers of blastocysts frozen were similar (p>0.05).

CONCLUSIONS: Studies debate whether oncology patients have worse outcomes than the general population in oocyte and embryo cryopreservation, including lower egg yield and/or maturity.[1,2] In the present study, when compared to healthy age and AMH matched controls, oncology patients had similar numbers of oocytes retrieved, but a lower proportion were mature. Fertilization rate and blastocyst number were similar, though numbers were small. The effect of letrozole use on final oocyte maturity warrants further investigation in future studies.

POST CHEMOTHERAPY AMH DOES NOT PREDICT MENSTRUAL CYCLE RESUMPTION IN CANCER SURVIVORS.

Ebubechukwu Okeke, B.S.,[1] Terri L. Woodard, M.D.,[2] Bryan Fellman, M.S.,[2] Laurie J. McKenzie, M.D.[2] [1]University of Texas School of Public Health, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.

OBJECTIVE: To assess post chemotherapy AMH as a predictor of menstrual cycle resumption in cancer survivors

DESIGN: Retrospective chart review and phone survey at a tertiary care enter

MATERIALS AND METHODS: A retrospective chart review was performed of women registered in our institution's Oncofertility Database from May 2013 to July of 2016. Inclusion criteria was women of reproductive age (18-45 years) that underwent gonadotoxic chemotherapy for cancer and had a pre and/or post chemotherapy AMH assessment. Exclusion criteria was menopausal status prior to chemotherapy, hysterectomy or bilateral oophorectomy as part of their cancer treatment and deceased status at time of phone interview. Patients that met inclusion criteria were contacted by phone to review menstrual and reproductive history. Demographic and clinical variables of interest were compared to menstrual cycle resumption status using t-test, Mann-Whitney test, chi-squared, or Fisher's exact test depending on the underlying distribution of the data. Logistic regression models were conducted to estimate the odds of menstrual cycle resumption status. This is considered an exploratory analysis and statistical significance was defined at the 0.05 level.

RESULTS: Of 281 records evaluated, 56 patients (mean age 29.3, SD 6.5) met inclusion criteria and menstrual cycle interview data was obtained on 44 of the 56 (76%). Fifty-five patients had baseline AMH values (98%), 28 patients had post chemotherapy AMH values (50%), and 27 had both (48%). The median post chemotherapy AMH was 0.1 (range 0.03-6.40), and average time of AMH collection post chemotherapy was 21 months. Menses resumed following chemotherapy in 75% (95% CI: 60 – 87) of women, and 45% of those with resumed menses reported having regular menses. There was insufficient evidence that either post chemotherapy AMH or the change in post chemotherapy AMH from baseline was associated with resumption of menses.

CONCLUSIONS: The American Society for Clinical Oncology recommends that "health care providers should address the possibility of infertility with patients treated during their reproductive years and be prepared to discuss fertility preservation options" (1). Despite these recommendations however, the data regarding predictors of future fertility is limited. Predicting fertility function post treatment is critical as it impacts fertility treatment options and likelihood for success. AMH testing after chemotherapy however does not accurately predict resumption of menses, nor does the change in AMH from baseline.

THE EFFICACY OF ONCO-TESTICULAR SPERM EXTRACTION (ONCO-TESE): A SINGLE-CENTER ANALYSIS.

Shinnosuke Kuroda, M.D., Kimitsugu Usui, M.D., Teppei Takeshima, M.D., Ph.D., Mitsuru Komeya, M.D., Ph.D., Tomonari Hayama, M.D., Ph.D., Hiroji Uemura, MD.Ph.D, Yasushi Yumura, M.D., Ph.D. Yokohama City University Medical Center, Yokohama, Japan.

OBJECTIVE: Although sperm cryopreservation is recommended before cancer therapy to preserve fertility in adolescent and young adult patients with malignancy, it is not always achieved owing to various causes such as azoospermia or ejaculatory dysfunction. Onco-testicular sperm extraction (Onco-TESE) is an efficient salvage option for such patients; however, only few studies have investigated its efficacy. The aim of this study was to analyze the efficacy of Onco-TESE.

DESIGN: A retrospective study in a single center

MATERIALS AND METHODS: Between June 2012 and May 2020, 373 patients visited our reproductive health center for sperm preservation. Of these patients, 57 (15.3%) could not achieve preservation mainly because of azoospermia at the time of introduction. Among these 57 patients, we retrospectively

evaluated those who underwent Onco-TESE and analyzed their data on background disease, operation time, and sperm retrieval rate (SRR).

RESULTS: Among the 57 patients, 12 (mean age: 26.8 years) underwent Onco-TESE (21.1%). The background diseases were hematological malignancy in 6 patients; testicular cancer in 3; and colon cancer, bladder cancer, and spinal cord tumor in 1 each. Overall, 10 patients showed azoospermia; 2 showed necrospermia, and 2 showed ejaculatory dysfunction. All 6 patients with hematology malignancy were introduced after the initiation of chemotherapy. In patients with testicular cancer, TESE was performed ex vivo simultaneously with orchiectomy. The mean operation time was 71.5±30.7 min. Sperm retrieval was successful in 8 patients (SRR: 66.7%). No postoperative complications occurred.

CONCLUSIONS: Onco-TESE can be considered an efficient and safe option for preserving fertility in cancer patients with azoospermia and ejaculatory dysfunction.

P-369 4:30 PM Sunday, October 18, 2020

DOSE DENSE CHEMOTHERAPY PROTOCOLS RESULT IN HIGH RATES OF POI (PREMATURE OVARIAN INSUFFICIENCY) IN YOUNG WOMEN WITH BREAST CANCER. Alexandra Gannon, M.D.,[1] Terri L. Woodard, M.D.,[2] Laurie J. McKenzie, M.D.[2] [1]Baylor College of Medicine, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.

OBJECTIVE: To assess the reproductive impact of dose dense chemotherapy protocols in breast cancer survivors

DESIGN: Retrospective chart review

MATERIALS AND METHODS: 142 reproductive aged (18-45 years) women were identified at our institution that underwent treatment for a new diagnosis of breast cancer from May 2013 to May 2016. Thirty women received a dose dense schedule of chemotherapy administration and had follow up menstrual data. Dose dense chemotherapy was defined by chemotherapy administration every two weeks as opposed to every three weeks (1). Premature ovarian insufficiency was defined by the absence of spontaneous menses for at least twelve months following completion of chemotherapy. Exclusion criteria was age >40 years, irregular menses or diminished ovarian reserve prior to chemotherapy, zoladex use, premature ovarian insufficiency at onset of chemotherapy, and lack of ovarian reserve testing prior to treatment.

RESULTS: Twenty-one patients met inclusion criteria. Average age of the patients that received the dose dense protocol was 32 (range ages 25-40). All patients received an alkylating agent treatment protocol with a dose-dense administration schedule. All 23 patients received treatment with cyclophosphamide, doxorubicin and a taxane. Five patients also utilized a monoclonal antibody (trastuzumb, atezolizumab, or pertuzumab) and two utilized talazoparib. All patients demonstrated normal ovarian reserve testing prior to the administration of chemotherapy. Average baseline AMH was 4.02 ng/mL (range 1-13 ng/mL) and normal menstrual cycles (range 21-35 days). Premature ovarian insufficiency was reported in 7 of 21 patients (33%) that received dose dense scheduling as defined by absence of spontaneous menses for 12 months or greater.

CONCLUSIONS: Dose dense chemotherapy regimens have recently demonstrated increased disease-free survival in women with high-risk breast cancer compared to conventional dosing schedules (2). However, it is uncertain if this more aggressive regimen of chemotherapy administration would further decrease future fertility in breast cancer survivors. Our findings indicate that dose dense chemotherapy regimens exhibit a high rate of premature ovarian insufficiency in reproductive aged women even in this exceedingly young cohort of women. These findings are important to communicate during fertility counseling of future patients.

TYPE OF CANCER AND OVARIAN STIMULATION PARAMETERS IN ONCOFERTILITY PATIENTS. Reda S. Hussein, MD, Zaraq Khan, MD, Yulian Zhao, Ph.D. Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN.

OBJECTIVE: To evaluate the influence of type of cancer and cancer itself on the ovarian response during controlled ovarian stimulation (COS) for fertility preservation (FP).

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: This was a retrospective cohort study performed at a single academic tertiary-care infertility center. Women diagnosed with cancer who underwent COS with GnRH antagonist protocol between January 2009 and December 2018 were included in this study. Patients were categorized into three groups; breast/gynecologic, hematologic, and other cancers. We secondarily compared the COS parameters and ovarian reserve markers in oncofertility cases against non-cancer patients who pursued FP for deferred reproduction. The primary outcome was number of mature oocytes. Secondary outcomes included oocyte yield (number of retrieved oocytes/number of follicles aspirated at time of retrieval) and oocyte-maturity index, defined as number of mature oocytes/total oocytes retrieved.

RESULTS: A total of 96 cancer patients were referred for FP counseling before starting their anti-cancer therapy. Clinical characteristics and ovarian response parameters were comparable between the three groups. Type of cancer was not a predictor for number of mature oocytes (p=0.33), oocyte-maturity index (p=0.630), or oocyte yield, (p=0.087) after adjustment to cycle covariates. Moreover, cancer did not have impact on the number of mature oocytes (p=0.699), oocyte-maturity index (p=0.251) and oocyte yield (p=0.094).

CONCLUSIONS: There is no difference observed in outcomes of ovarian stimulation based on primary cancer diagnosis in oncofertility patients undergoing FP. Interestingly, no significant impact for cancer itself was observed on ovarian reserve or response to gonadotrophins stimulation.

P-371 4:30 PM Sunday, October 18, 2020

CHANGES IN SPERM CONCENTRATION AND TOTAL MOTILITY, BEFORE AND AFTER THAWING IN CANCER PATIENTS COMPARED TO SPERM DONORS. Irving Olaf Morales, M.D.,[1] Roberto Santos, M.D.,[2] Jose I. Obeso Montoya, PhD,[2] Jesus A. Roiz Castro, MD,[3] Karla Alejandra Cantú, M. Sc.[2] [1]IECH-Biología de la Reproducción Humana, Monterrey, NL, Mexico; [2]IECH, Monterrey, NL, Mexico; [3]IECH, Mexico, Monterry, NL, Mexico.

OBJECTIVE: To determine the changes in sperm concentration and total motility, before and after thawing in post-pubertal patients diagnosed with cancer (PDC) compared to a group of semen donors (DS).

DESIGN: Retrospective, comparative, cross-sectional study

MATERIALS AND METHODS: A total of 153 semen samples (DS=85 and PDC=68) from men attending Fertility Center (IECH), Monterrey, Mexico fertility preservation from 2000 to 2018, were evaluated. Sperm analysis was performed according to the World Health Organization (WHO) criteria. Post-thaw differences in concentrations and total motile sperm were determined and the Student's t-test was used for statistical analysis, considering the p value <0.05 to be significant.

RESULTS: Significant differences were recorded in the sperm concentration after thawing: 18.43% vs 9.67%, p <0.05 (from 27.46 to 22.24 million / mL and from 90.54 to 81.78 million / mL, in the PDC versus DS, respectively) and in total motility: 49.30% vs. 36.17%, p <0.05 (from 67.35% to 34.14% and from 94% to 60.75% in PDC versus DS, respectively).

CONCLUSIONS: Patients diagnosed with cancer have a greater reduction in sperm concentration and total motility after thawing compared to the group of semen donors. This finding is important for counseling patients planning sperm cryopreservation.

P-372 4:30 PM Sunday, October 18, 2020

ALTERNATIONS OF SPERM PROTEIN PROFILES TO ELUCIDATE THE MECHANISM OF IMPAIRED SPERMATOGENESIS BY CANCER CHEMOTHERAPY. Teppei Takeshima, M.D., Ph.D., Shinnosuke Kuroda, M.D., Yasushi Yumura, M.D., Ph.D. Yokohama City University Medical Center, Yokohama, Japan.

OBJECTIVE: This study aims to analyze alterations in proteomic profiles and validate selected protein biomarkers of spermatozoa in men with history of undergoing cancer chemotherapy.

DESIGN: This research is a cross-sectional research of control versus treatment. A group of patients with a history of anticancer drug

administration in cancer diagnosis was assigned as "cancer group"(n=3), and a fertile donor group was assigned as "control group"(n=3). Written informed consent was obtained from all patients and this study design was approved by institutional review board of Yokohama City University Medical Center.

MATERIALS AND METHODS: The original diseases of cancer group were non-Hodgkin malignant lymphoma(n=2) and malignant soft tissue tumor(n=1). Measuring the total sperm count by CASA, they were adjusted to 6 million in all specimens, and protein concentration was adjusted by BCA assay. After trypsin digestion and desalting, the expressed proteins in spermatozoa were analyzed by LQ-MS/MS and database searching was performed in two groups. Validation was performed for the proteins with different expression levels by Western-blotting.

RESULTS: A total of 1,152 proteins and 5,268 peptides were identified by global proteomics in both groups. Sorted by max fold change of expressions (>5 folds) and ANOVA ($p<0.01$), 29 proteins were identified. Of these identified proteins, we focused on a few proteins, one is cancer-associated protein highly expressed in digestive tract and urinary tract. In sperm of patients with cancer, this protein was overexpressed 54.8-folds more than that of fertile donor. This protein co-works with other protein of T-cell proliferation factor. Regimens of cancer chemotherapy patients in cancer group received were ABVD and IFM, ADM, and VCM therapy, respectively. It was speculated that T cell proliferation was induced by protein interaction after induction of cancer chemotherapy. By the Western-blotting, expression of this protein was validated. Moreover, oxidative stress-associated proteins with different expression levels compared to control were identified, which supported our previous study.

CONCLUSIONS: It was speculated that T cell proliferation was induced by interaction between these proteins after induction of cancer chemotherapy. Moreover, cancer chemotherapy could induce oxidative stress apoptosis in spermatozoa. Functional analysis of these proteins would provide clue to the mechanisms of impaired spermatogenesis after cancer chemotherapy.

FERTILITY-SPARING SURGERY FOR CERVICAL CANCER IN REPRODUCTIVE-AGED WOMEN.

Viviana Beatriz Ventura, MD,[1] Rodolfo Martin Riege, MD,[2] Jeronimo Costa, MD,[3] Valeria Paz, embriologist,[4] Martina Salvai, MD,[3] Maria Victoria Vivas, MD[5] [1]Chief of Reproductive Medicine Center Grupo Gamma, rosario, Argentina; [2]Chief of Gynecology Department Grupo Gamma, ROSARIO, Argentina; [3]Gynecologist, Rosario, Argentina; [4]Chief of Embriology Reproductive Center Grupo Gamma, rosario, Argentina; [5]Fellow of Gynecological Oncology, Rosario, Argentina.

OBJECTIVE: Historically, radical abdominal hysterectomy with pelvic lymphadenectomy has been the surgical mainstay in nulliparous women of childbearing age with early stage cervical cancer. A number of surgical approaches, have been proposed to allow fertility preservation while still ensuring adequate oncological outcomes. Based on this, our objective is to evaluate if conservative treatment could be an option for patients with cervical cancer who wish to preserve their fertility.

DESIGN: retrospective observational study

MATERIALS AND METHODS: Patients with a histopathological diagnosis of cervical cancer, FIGO stages IA with lymphovascular space invasion through IB3, were included. All patients received conservative surgical treatment between January 2010 and March 2018 with reproductive counseling prior to surgery. Patients with stage Ib3 treated with neoadyuvant chemotherapy needed a reduction in tumor size, demonstrable by magnetic resonance imaging, to less than 2cm in order to be included. A follow-up period of at least 12 months was required. Clinical and oncological leave for pregnancy was only given after one year of disease-free survival.

RESULTS: Nineteen patients were included. Disease-free survival and overall survival during a 5-year period were 94.4% and 100% respectively, with a median follow-up of 45 months. Eleven patients attempted pregnancy after conservative surgery. Pregnancy rate was 63.6%; of these, four (36.3%) were spontaneous pregnancies and three (27.3%) were achieved through in-vitro fertilization, one of which was preformed with cryopreserved ovocytes.

CONCLUSIONS: The results suggest that is possible to offer fertility-sparing surgery in selected patients with cervical cancer. Pregnancy after treatment achieved either spontaneously or through assisted fertilization. Conservative surgery associated with reproductive counseling is an acceptable treatment course for patients wishing to preserve their fertility.

FERTILITY PRESERVATION WITH IN VIVO OOCYTE RETRIEVAL AMONG YOUNG WOMEN WITH OVARIAN CANCER: A CASE SERIES.

Alex Robles, MD,[1] Brittany Noel Robles, MD, MPH,[2] Laura C. Gemmell, MD,[1] Paula C. Brady, MD[3] [1]Columbia University Medical Center, New York, NY; [2]Wyckoff Heights Medical Center, Brooklyn, NY; [3]Columbia University Fertility Center, New York, NY.

OBJECTIVE: To examine outcomes of controlled ovarian hyperstimulation (COH) with in vivo transvaginal oocyte retrieval (TVOR) for fertility preservation among young women with ovarian cancer.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Six patients (mean age 26.3, range 23-31 years) diagnosed with ovarian cancer (endometrioid carcinoma, mucinous epithelial carcinoma, yolk sac tumor, immature teratoma, mixed germ cell tumor (MGCT), and recurrent serous borderline ovarian cancer, n=1 of each) underwent fertility preservation with COH and TVOR at our academic center from 2018-2020. Four patients had stage I disease, and two had stage III germ cell tumors. Five patients had prior unilateral salpingo-oophorectomy, and one (stage I MGCT) underwent prior chemotherapy (4 cycles of cisplatin/bleomycin, vincristine [1 cycle] and etoposide [3 cycles]). Patient and cycle demographics were collected and descriptive statistics were reported.

RESULTS: Five patients underwent oocyte cryopreservation and one elected to freeze embryos. The mean AMH was 2.5 ng/mL (range 0.4-6.4, Table). All cycles used antagonist protocols with hCG trigger; half were random start stimulations. A mean of 11 oocytes were retrieved (range 1-19), with mean 76% maturity. There were no complications or delays in oncology treatment.

CONCLUSIONS: Nearly 12% of ovarian cancers are diagnosed in women <45 years, and ovarian cancers are increasingly managed with fertility preserving surgery when possible.[1,2] This is the first series reporting in vivo TVOR in women with ovarian cancer, whereas prior reports have focused on ex-vivo retrieval or borderline tumors only.[3,4]. Clinicians may discourage in vivo TVOR in ovarian cancer due to risk of tumor spread. In this series, patients either had stage I tumors post-oophorectomy with no residual tumor (n=3), or had known tumor spread (due to cystectomy, or confirmed metastases, n=3); in each case, gynecologic oncologists agreed that TVOR did not confer significant risk of recurrence or upstaging disease. Patients responded well despite prior oophorectomy (mean 13 oocytes, range 4-19). COH with in vivo TVOR can be considered for young women with ovarian cancer following fertility sparing surgery, specifically those for whom TVOR is deemed unlikely to impact their overall cancer prognosis

FERTILITY PRESERVATION COUNSELING IN REPRODUCTIVE AGED WOMEN WITH LOCALIZED GYN CANCERS AT AN URBAN SAFETY NET HOSPITAL: A PILOT STUDY.

Cyra M. Cottrell, MD,[1] Gail Ohaegbulam, MD,[1] Giuseppe del Priore, MD, MPH[2] [1]Morehouse School of Medicine, Atlanta, GA; [2]80 Jesse Hill Dr, Atlanta, GA.

OBJECTIVE: To determine whether women diagnosed with GYN cancers at an urban safety net hospital, which represents a predominantly African American population, were made aware of the potential impact treating their cancer may have on their future fertility. Specifically, we sought to determine if they were counseled for fertility preservation.

DESIGN: Investigator administered questionnaire via telephone survey.

MATERIALS AND METHODS: Data from The Tumor Registry for Grady Memorial Hospital in Atlanta, GA was sorted by patient age, cancer

type, and tumor staging. Women included were between 18-40 years old with cervical, endometrial, ovarian, and uterine cancer with date of first contact in 2016-2018. We also chose to limit our study population to those with stage 0 or 1 as these patients are more likely to benefit from fertility sparing interventions. All women with prior permanent sterilization were excluded. Currently, there is no formally validated survey on patient satisfaction of fertility counseling in gynecologic cancer patients. As a result, a 6-question survey was created using the American Society of Clinical Oncology and the American Society for Reproductive Medicine counseling guidelines for physicians and was administered to patients.

RESULTS: After review of Grady Memorial Hospital's Tumor Registry, 53 patients met all inclusion criteria. Of these patients, 8 were unable to be reached due to incorrect or disconnected telephone services. An attempt of 2 times was made to contact patients before we deemed them lost to follow up. Of the remaining 45 patients who were able to be contacted, 8 declined to participate in the study. Ultimately, we were able to obtain responses from 9 patients; 6 received some form of counseling informing them of potential effects on their reproductive ability; 3 of 9 were offered resources for fertility preservation; 2 out of 9 were formally referred to a reproductive endocrinologist.

CONCLUSIONS: Unfortunately, our study had a poor response rate and there may be an overestimation of the results applicability to our population. The results of our pilot study showed that a majority of patients receive counseling on the effects of cancer treatment on their future reproductive capabilities. However, although patients may receive adequate counseling, efforts to provide appropriate resources and referrals to patients appear insufficient. Nevertheless, we believe this initial study showed our hospital may be lacking in our efforts to refer patients for appropriate fertility intervention. As a hospital without REI services and a patient population with an income predominately at or below poverty level, there is substantial difficulty in providing for their reproductive potential. This study may highlight the need for more efforts and partnerships with REI offices and safety-net hospitals. The next steps are to sample prior years to better investigate and interpret patient fertility counseling. Also, we aim to evaluate GYN/ONC physicians on the priority of fertility in their decision-making and self-reported average of referrals as compared to GYN/ONC providers in non-urban settings.

HOSPITALIZATIONS IN THE 8 YEARS FOLLOWING DELIVERY IN ART-TREATED AND SUBFERTILE WOMEN.

Leslie V. Farland, Sc.D.,[1] Chia-Ling Liu, RN, MPH, ScD,[2] Howard J. Cabral, PhD, MPH,[3] Stacey A. Missmer, ScD,[4] Charles C. Coddington, MD,[5] Sunah S. Hwang, MD MPH,[6] Judy E. Stern, PhD.[7] [1]University of Arizona, Tucson, AZ; [2]MPDH, Boston, MA; [3]Boston University, Boston, MA; [4]College of Human Medicine, Michigan State University, Grand Rapids, MI; [5]University of North Carolina, Charlotte, NC; [6]University of Colorado School of Medicine, Aurora, CO; [7]Dartmouth-Hitchcock, Lebanon, NH.

OBJECTIVE: To investigate hospitalizations up to 8 years after livebirth among women who utilized ART or non-ART medically assisted reproduction (MAR) or who were subfertile with no fertility treatment, compared to women who conceived naturally.

DESIGN: Retrospective cohort

MATERIALS AND METHODS: Massachusetts deliveries among privately-insured women ≥18 years old between 2004-2017 from state vital records were linked to the Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SART CORS), and hospital observational/inpatient stays. We compared ART, MAR, and unassisted subfertile (USF) delivery to fertile delivery. Post-delivery hospitalization information was derived from most prevalent ICD codes for discharges and were combined by type. The relative risks (RR) and 95% confidence intervals (CI) of hospitalization for the first 8 years post-delivery were modeled using generalized estimating equations with a log link and a Poisson distribution with person-months as the offset term. Models were adjusted *a priori* for maternal age, parity, year of delivery, and plurality.

RESULTS: Among 492,515 deliveries, 5.6% used ART, 1.6% used MAR, 1.8% were USF, and 91% were fertile.Compared to fertile women, ART, MAR and USF women were more likely to have inpatient or observational hospitalizations for a variety of conditions including conditions of delivery, the cardiovascular system, overweight/obesity, the reproductive tract, the

Indication for hospitalization up to 8 years after livebirth	Fertile	ART	MAR	USF
		RR(95% CI)	RR(95% CI)	RR(95% CI)

PUBLIC REPORTING OF CLINICAL OUTCOMES IN ASSISTED REPRODUCTIVE TECHNOLOGY IN THE US FOR 2014-2017: REPORTING TO CDC ONLY IS ASSOCIATED WITH FEWER CANCELLATIONS AND LOWER SUCCESS RATES.

Thanh Ha Luu, MD,[1] Liesl Nel-Themaat, PhD, HCLD,[1] Tracy Truong, MS,[2] Alex J. Polotsky, M.D., M.S.[1] [1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Department of Biostatistics & Bioinformatics, Duke University Medical Center, Durham, NC.

OBJECTIVE: Reporting of IVF outcomes in the US is mandated by law to the Center for Disease Control (CDC). The Society for Assisted Reproductive Technology (SART) provides a voluntary reporting platform for additional cycle-specific public information. SART submits reported data to the CDC for its members to minimize duplication. Guidelines for both SART and CDC were changed in 2015 and 2016, respectively. We sought to compare outcomes between the reporting platforms prior to and following guideline changes.

DESIGN: Retrospective.

MATERIALS AND METHODS: Publicly available IVF outcomes published by the CDC for autologous oocytes in 2014-17 were compared between mandatory ("CDC only") vs. voluntary clinics ("SART member clinics") using Wilcoxon rank sum tests.

RESULTS: Cancellation was reported more frequently for voluntary reporting clinics (SART members) for both fresh and frozen embryo cycles (Table). Among all fresh cycles, pregnancy rates were lower among SART members vs CDC only clinics for 2014-2016. In contrast, among all frozen embryo cycles, pregnancy rates were higher among SART members vs CDC only clinics for 2014-2016. Similarly, live birth rates were lower for SART member clinics among fresh cycles but higher than CDC only clinics among frozen cycles for 2015-2016. In 2017, fresh and frozen embryo outcomes were combined and SART member clinics had higher success rates.

CONCLUSIONS: Among CDC only clinics, cancellation was less frequent and success rates appeared higher among all fresh cycles. However, success rates were higher for SART member clinics when fresh and frozen cycles were considered together, potentially due to the varying differences in cancellation reported between the two platforms. Increasing transparency in public ART reporting should be encouraged to ensure accurate reporting of all initiated cycles.

P-378 4:30 PM Sunday, October 18, 2020

A LONG-TERM FOLLOW-UP STUDY OF HEALTH OUTCOMES OF FAST TRACK AND STANDARD TREATMENT TRIAL (FASTT) PARTICIPANTS COMPARED TO U.S. WOMEN.

Katherine G. Koniares, MD,[1] Marlene B. Goldman, ScD,[2] June L. Fung, PhD,[2] Carleigh B. Nesbit, DO,[3] Denis A. Vaughan, MD,[4] Thomas L. Toth, MD,[5] Richard H. Reindollar, MD.[2] [1]Tufts Medical Center, Boston, MA; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Dartmouth Hitchcock Medical Center, Lebanon, NH; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Boston IVF, Waltham, MA.

OBJECTIVE: To compare the long-term health of women with unexplained infertility who participated in FASTT to those of U.S. women as reported in NHANES.

DESIGN: Long-term follow-up of randomized controlled trial (RCT) participants.

MATERIALS AND METHODS: In FASTT, from 2001-2006, 503 couples with women aged 21-39 years and unexplained infertility were randomized to 3 cycles of clomiphene citrate (CC)/IUI, 3 cycles of gonadotropin/IUI, then IVF or 3 cycles of CC/IUI prior to IVF. Between March 2019-February 2020 a 22-question telephone survey with branching logic was administered to couples who were enrolled in FASTT. National Health and Nutrition Examination Survey (NHANES, 2017-2018) data for women aged 40-56 years were used to compare data from the current study to the U.S. general population. With regard to mental illness, the NHANES questionnaire asked whether participants had seen a mental health professional in the past year. Analysis was performed using SAS v9.2. Categorical variables were analyzed using chi-square and Fisher's exact tests while continuous variables were analyzed with two-sample t-tests with $P<0.05$ considered significant.

RESULTS: Of the 503 women enrolled in FASTT, 311 (61.8%) were contacted during the current study and 286 (56.9%) consented to participate with an average age of 49.5 ±3.4 years. 120 (42.0%) women reported being diagnosed with a medical condition since FASTT: 45 (15.7%) thyroid disease, 10 (3.5%) diabetes, 5 (1.8%) joint problems, 21 (7.3%) heart disease, 1 (0.4%) stroke, 11 (3.9%) cancer, and 52 (18.2%) mental illness including 40 (14.0%) with anxiety and/or depression. There were no statistically significant differences in development of long-term medical conditions in patients who did or did not have a live birth during FASTT, those who ever conceived a live birth and those who did not, and those who underwent IVF and/or gonadotropin cycles and those who did not. Patients in FASTT were statistically less likely than women in the general U.S. population to report diabetes ($P=0.0001$), joint problems ($P<0.0001$), stroke ($P=0.002$), and cancer ($P=0.005$), and reported a significantly higher incidence of mental illness ($P=0.02$) and heart disease ($P<0.0001$). Women who underwent IVF and/or gonadotropin cycles were less likely than women in the general U.S. population to report a cancer diagnosis (3.3% vs. 8.9%, $P=0.006$).

CONCLUSIONS: The long-term follow-up of women from FASTT demonstrated that patients with unexplained infertility reported more heart disease and consultations with mental health professionals but less diabetes and cancer compared to women in the general U.S. population.

INTRA CAVITY FLUID WITH PREVIOUS CAESAREAN SECTION COMPROMISED CLINICAL PREGNANCY AFTER IVF/ICSI TREATMENT. Xing Yang, Ph.D.,[1] Mei-hong Cai Master.[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Guangzhou First People's Hospital, School of Medicine, South China University of Technology, Guangzhou, China.

OBJECTIVE: Caesarean section (CS) rates are rising worldwide, the scar is considered to have impact on the subsequent pregnancy. Researchers reported a lower pregnancy rate in patients with a previous CS compared to a previous vaginal delivery, but the potential causes are still to be determined. Lawrenz et al. reported the relationship between intra cavitary fluid (ICF) with uncompromised clinical outcomes on frozen embryo transfer (FET) cycles[1]. The goal of this study was to explore whether the presence of ICF influence the pregnant outcome of patients with CS in fresh embryo transfer cycles.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A total of 1643 women with at least one previous delivery undergoing the first in vitro fertilization / intracytoplasmic sperm injection (IVF/ICSI) cycle and had their fresh embryo transferred during January 2015 to August 2019 in a university-based hospital were enrolled for analysis. According to the previous delivery method and the ultrasound monitoring results——ICF detected on day of embryo transfer, women were separated into three subgroups, cesarean group with intra cavity fluid (CS-ICF, n=114), cesarean group without intra cavity fluid (CS-noICF, n=572) and another 957 patients without ICF were included in vaginal delivered group (VD, n=957). Main outcome was clinical pregnancy rate. Baseline characteristics data, controlled ovarian hyperstimulation procedures and pregnancy outcomes were extracted from medical databases and were compared among three groups. Potential confounders were adjusted by multivariate logistic regression analyses, including age, previous delivery times, body mass index (BMI), failed attempts of IVF, endometrium thickness, embryo quality and stage of development.

RESULTS: Baseline characteristics and the quality of embryos transferred in the three groups were comparable. Less number of embryos were transferred in CS groups than VD group influenced by clinicians' preference($P<0.05$). There was significantly lower clinical pregnancy rate (33.3% vs 45.2%, P=0.015) and twin pregnancy rate (7.9% vs 24.5%) in CS-ICF group compared with VD group, while the rates were comparable between CS-noICF group and VD group. There is a tendency that the live birth rate in VD group is higher than that in CS-ICF group. After adjusted for all the confounding factors listed above, the presence of ICF was an independent factor associated with lower clinical pregnancy rate (OR 0.586, 95%CI 0.375-0.914, P=0.018). Age and ratio of good quality embryos were also associated with clinical pregnancy rate.

CONCLUSIONS: It is the presence of ICF but not the isthmocele per se that significantly compromised the clinical pregnancy rate in patients with CS. CS interferes with the integrity of uterine, ICF may accompany with inflammatory cytokines and potentially pathogenic bacteria, which further disrupt the endometrial receptivity. Large prospective cohort study is required to better understand the potential mechanism and explore effective therapeutic scheme.

P-380 4:30 PM Sunday, October 18, 2020

DEVELOPING A MINIMUM DATA SET FOR INFERTILITY RESEARCH. James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Cindy Farquhar, FRANZCOG FRCOG MD MPH.,[2] COMMIT: Core Outcomes and Outcome Measure for Infertility Trials[1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop a minimum data set, known as a core outcome set, for infertility research.

DESIGN: Consensus development study.

MATERIALS AND METHODS: ***Identifying potential core outcomes:*** Potential core outcomes were identified by extracting outcomes previously reported in infertility trials.

Determining core outcomes: Potential core outcomes were entered into a three-round eDelphi survey. Professionals, researchers and people with infertility were asked to score the importance of each outcome. Based on their feedback, potential core outcomes were prioritised, and subsequently discussed during a consensus development meeting. Using the modified Nominal Group Technique, a minimum data set for infertility was agreed.

Determining how core outcomes should be defined: A long list of potential definitions was developed by identifying definitions which had been reported by formal definition development initiatives, clinical practice guidelines and Cochrane systematic reviews. Potential definitions were discussed in a consensus development meeting. Using a formal consensus development method consensus definitions were developed.

RESULTS: ***Identifying potential core outcomes:*** A long list of 101 potential core outcomes was developed by extracting outcomes reported in infertility trials.

Determining core outcomes: When considering the Delphi survey, 372 participants, from 41 countries, responded. Twenty-eight consensus outcomes were identified and discussed during the consensus development meeting. Thirty participants, from 27 countries, engaged in the consensus development meeting. A minimum data set for infertility research was agreed (Table 1).

Figure 1 A core outcome set for infertility research.

Viable intrauterine pregnancy confirmed by ultrasound accounting for singleton pregnancy, twin pregnancy, and higher multiple pregnancy
Pregnancy loss accounting for ectopic pregnancy, miscarriage, stillbirth, and termination of pregnancy
Live birth
Gestational age at delivery
Birth weight
Neonatal mortality
Major congenital anonmly
When applicable: time to pregnancy leading to live birth

Determining how core outcomes should be defined: Forty-four potential definitions were identified. Twenty-seven participants, from 11 countries, took part in the consensus development meeting and agreed consensus definitions for individual core outcomes.

CONCLUSIONS: Embedding the core outcome set within future infertility research should ensure the comprehensive selection, collection, and reporting of core outcomes, including live birth. Research funders, the SPIRIT statement, and over 80 speciality journals, including *Fertility and Sterility,* have committed to implementing this core outcome set.

LONG TERM FOLLOW UP OF REPRODUCTIVE OUTCOMES IN FASTT PARTICIPANTS. Denis A. Vaughan, MD,[1] Marlene B. Goldman, ScD,[2] June L. Fung, PhD,[2] Katherine G. Koniares, MD,[3] Carleigh B. Nesbit, DO,[4] Thomas L. Toth, MD,[5] Richard H. Reindollar, MD.[2] [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Tufts Medical Center, Boston, MA; [4]Dartmouth Hitchcock Medical Center, Lebanon, NH; [5]Boston IVF, Waltham, MA.

OBJECTIVE: To evaluate reproductive outcomes in couples who were enrolled in a large randomized controlled trial (RCT, FASTT[1]) that studied optimal treatment for unexplained infertility.

DESIGN: Long term follow up of RCT participants.

MATERIALS AND METHODS: Between March 2019 and February 2020, a telephone survey was administered to women who had been enrolled in FASTT, an RCT conducted from 2001-2006 that evaluated optimal treatment for unexplained infertility in women ages 21-39 years (3 cycles of Clomiphene/IUI and 3 cycles of gonadotropin/IUI prior to proceeding to IVF) versus a fast track (3 cycles of Clomiphene/IUI before proceeding to IVF). All women enrolled in FASTT had a basal FSH <15 mIU/ml. Statistical analyses were performed using SAS v 9.2. Categorical variables were compared between groups using chi-square and Fisher's exact tests and continuous variables with two-sample t-tests and analysis of variance with P<0.05 as significant.

RESULTS: Of the 503 women originally enrolled in FASTT, 311 (61.8%) were contacted of whom 286 (56.9%) consented to participate in the survey. Mean age and mean FSH at enrollment in FASTT was 33.1 ± 3.2 years and 6.8 ± 2.2 mIU/ml respectively, for those who participated in the follow up survey. Mean age at follow-up was 49.5 ± 3.4 years. 194 (67.8%) women delivered a live birth during the trial and 225 (78.7%) continued to try to conceive after FASTT. There were a total of 360 clinical pregnancies, by all methods, with 251 (69.7%) live births. Of those who tried to spontaneously conceive (157), 101 (64.3%) had a successful live birth while a further 12 (5.3%) delivered a live birth via IUI and 82 (36.4%) via autologous oocyte IVF. Overall 182 women (80.9%) achieved a live birth following FASTT with a mean time to conception of 1.4 years (95% CI 1.2-1.6) following the trial. 113 women (77.4%) who had a live birth during FASTT had another live birth after, compared to 69 (87.3%) of those who hadn't had a live birth during FASTT (P=0.08). A higher proportion of those who had a history of smoking did not achieve a live birth in FASTT compared to those who did not have a history of smoking (24/92, 26.1% vs 31/194, 16.0%, (P=0.05), however there was no difference between those who had a history of smoking and those who did not in terms of ever delivering a live birth (4/18, 22.2% vs 50/267, 18.7%, P=0.75. Controlling for age at enrollment to FASTT, a higher basal FSH was noted in those women who never had a live birth (7.9 ± 1.5 vs 6.6 ± 2.2, P=0.05). The time to conception after the trial for those who hadn't had a live birth during the trial was 0.8 (95% CI 0.5-1.2) years compared to 1.6 years (95% CI 1.4-1.9) for those who had a live birth during the trial (P=0.01).

CONCLUSIONS: The majority of couples in FASTT were able to achieve a live birth following the trial with a large proportion of those achieved spontaneously. Independent of age, those women who never had a live birth had a higher FSH at enrollment to FASTT.

Neither the delivery of a baby during FASTT nor the method by which a live birth was achieved determined the couples' ability to achieve a live birth following the trial.

LONGITUDINAL FAMILY BUILDING SATISFACTION IN COUPLES ENROLLED IN THE FAST TRACK AND STANDARD TREATMENT TRIAL (FASTT). Carleigh B. Nesbit, DO,[1] Marlene B. Goldman, ScD,[2] June L. Fung, PhD,[2] Katherine G. Koniares, MD,[3] Denis A. Vaughan, MD,[4] Thomas L. Toth, MD,[5] Richard H. Reindollar, MD.[2] [1]Dartmouth Hitchcock Medical Center, Lebanon, NH; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Tufts Medical Center, Boston, MA; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Boston IVF, Waltham, MA.

OBJECTIVE: To investigate factors contributing to long term family building satisfaction in couples enrolled in FASTT from 2001-2006.

DESIGN: Long term follow-up of randomized controlled trial (RCT) participants.

MATERIALS AND METHODS: From March 2019 to February 2020, a telephone survey was administered to couples who had been enrolled in FASTT, an RCT which investigated time to conception and cost effectiveness of conventional treatment for unexplained infertility vs a fast track approach in women ages 21-39 years. The survey contained questions pertaining to long term health and fertility outcomes and was administered by one of three physicians. Statistical analyses were performed using SAS v 9.2. Categorical variables were compared between groups using chi-square and Fisher's exact tests and continuous variables with two-sample t-tests with $P < 0.05$ as significant.

RESULTS: Of the 503 couples enrolled in FASTT, 311 (61.8%) were able to be contacted of whom 286 (56.9%) consented to participate in the telephone survey. The mean age of female participants at enrollment in FASTT was 33.1 ± 3.2 years and mean age at follow-up was 49.5 ± 3.4 years. The majority of couples surveyed reported satisfaction with their current family size (62.1%). Three couples (1.1%) reported continued attempts to expand their family. Couples who reported family building satisfaction were more likely than those who did not to have two (55.7% vs 41.9%), three (27.6% vs 10.5%), four (5.2% vs 0.0%), or five children (0.6% vs 0%) ($P < 0.0001$). Couples who were not satisfied were more likely than those who were satisfied to have one child (40.0% vs 10.9%) or no children (7.6% vs 0%) (P<0.0001). Time to conception was not significantly different between these two groups ($P = 0.28$). Seven couples (2.4%) achieved a live birth using donor oocytes and 14 (4.9%) adopted children. There were no statistically significant differences between couples who were satisfied with their family size and those who were not in terms of number who conceived using donor oocytes (55.6 vs 44.4%, $P = 0.73$) or adopted children (57.1% vs 42.9%, P= 0.95). Family building satisfaction, ultimate family size, and time to conception did not differ between couples enrolled in the conventional or fast track arm. Couples who achieved a live birth through FASTT reported a higher incidence of family building satisfaction than those who did not (66.7% vs 52.8%, P=0.02) and were more likely than those who did not to have two (53.1 % vs 42.9%), three (25.3% vs 11.0%), or four children (4.1% vs 1.1%). Couples who did not achieve a live birth during FASTT were more likely than those who achieved a live birth to have one child (34.0% vs 17.5%) or no children (9.9% vs 0%) (P<0.0001).

CONCLUSIONS: In this long term follow up of 286 couples enrolled in FASTT between 2001 and 2006, the majority reported current satisfaction with their family size. Predictive factors were the achievement of a live birth during FASTT and having $\geq$ 2 children regardless of how families were built.

P-383 4:30 PM Sunday, October 18, 2020

LIVE BIRTHS AFTER UTERUS TRANSPLANTATION: REPORT OF THE FIRST SIX DELIVERIES AT A SINGLE CENTER—DUETS (DALLAS UTERUS TRANSPLANT STUDY). Liza Johannesson, MD, PhD,[1] J. Michael Putman, MD,[2] Lilly Zhang, PhD,[2] E. Colin Koon, MD, PhD,[1] Zachary S. Rubeo, MD,[3] Greg McKenna, MD,[1] Johanna Bayer, MD,[1] Jackie York, MD,[1] Giuliano Testa, MD,[1] Anthony Gregg, MD.[1] [1]Baylor University Medical Center, Dallas, TX; [2]Fertility Center Dallas, Dallas, TX; [3]Obstetrix Medical Group of Texas, Fort Worth, TX.

OBJECTIVE: Uterus transplantation is the only treatment that allows women with absolute uterine-factor infertility to experience gestation and childbirth. This is the first detailed report of a series of live births after uterus transplantation from a single center. We describe aggregated pregnancy outcomes including maternal factors and fetal/newborn factors after uterus transplantation.

DESIGN: Retrospective review.

MATERIALS AND METHODS: Twenty women received a uterus transplant at Baylor University Medical Center in Dallas (a tertiary referral center) from 2016 to 2019 (NCT02656550). Data were reviewed retrospectively for pregnancy outcomes, maternal factors, and fetal/newborn factors for the first six patients who reached 20 weeks' gestation.

RESULTS: Among the first six patients who carried pregnancies past 20 weeks' gestation, all uteri were from nondirected living donors. In this

cohort, all recipients underwent uterus transplantation due to congenital agenesis of the uterus (Mayer Rokitansky Kuster Hauser syndrome).

In vitro fertilization was performed before transplantation, and the first attempt at embryo transfer was successful in five of these six recipients (83%) at 15 to 31 weeks postsurgery. The immunosuppression protocol was modified to reduce fetal exposure to medications and allow a shorter transplant-to-embryo-transfer time. No organ rejection was detected during pregnancy. Fetal growth was not impaired, and the median birthweight was 2890 g (range 1770-3140 g [>25th percentile]). Maternal weight gain was higher than Institute of Medicine recommendations. Maternal medical complications were observed in two recipients (elevated creatinine and gestational diabetes). In two recipients, complications led to early delivery (33w1d, elevated creatinine; 30w6d, preterm labor). The median gestational age at delivery was 36w3d (range 30w6d–37w2d). All infants born were healthy, with Apgar scores ≥7 at 1 and 5 min.

CONCLUSIONS: Pregnancy outcomes after uterus transplantation once pregnancy reaches 20 weeks' gestation appear to be favorable. Pregnancy complications that lead to early delivery can occur. Fetal growth and development are expected to be normal, and low birthweight does not appear to a concern in uterus transplantation as in other solid organ transplantations. Uterus transplantation should only be performed at centers with the capability of assembling a multidisciplinary team that can identify and respond to unforeseen complications during pregnancy.

P-384 4:30 PM Sunday, October 18, 2020

INTRAVAGINAL EMBRYO CULTURE AFTER LETROZOLE (LTZ) / GONADOTROPIN MILD STIMULATION AND IMMEDIATE ICSI: SINGLE-CENTER OUTCOMES OF 339 AUTOLOGOUS CYCLES IN 252 COUPLES. Karen R. Hammond, DNP, CRNP,[1] Lisa J. Ray, MS, HCLD,[2] Nicholas A. Cataldo, MD, MPH,[1] Cecil A. Long, MD.[1] [1]America Institute for Reproductive Medicine, Birmingham, AL; [2]ART Labs Unlimited, Streamwood, IL.

OBJECTIVE: To describe outcomes in our practice of a novel ART protocol combining mild ovarian stimulation with immediate ICSI and 5-day intravaginal embryo culture.

DESIGN: Practice cohort of all 252 women with 339 cycle starts on this protocol from 6/2018 to 12/2019 planning fresh transfer, who comprised nearly all our ART cycles.

MATERIALS AND METHODS: Couples desiring lower-cost ART, mostly self-referred to our practice. LTZ x5 days, started 4 days after oral contraceptives were stopped, was overlapped on the 5th day with customized dose gonadotropins. No GnRH analogs were used. Cycle monitoring was repeated if necessary before hCG trigger; retrieval was 35 h later under mild sedation in a hospital office. Metaphase (M) oocytes were immediately treated by ICSI and placed with media into an INVOcell (INVO Biosciences, Sarasota, FL), which was secured in the upper vagina by a diaphragm. The device was typically removed after 5 days, and if found, 1-2 blastocysts (blasts) were transferred; otherwise, cleavage-stage embryos were transferred. We calculated descriptive statistics from prospective data including 87 repeat cycles. Ongoing pregnancy includes reaching 24+ weeks' gestation or live birth as of 5/15/2020.

RESULTS: Mean female age was 34.3 (±4.5) yr; 25% had AMH <1.0 ng/mL, 68% were nulliparous, and 43% had prior pregnancy loss(es). Stimulations used 2.5–10 mg/day LTZ (5 mg in 62%) plus 1100 ± 591 units FSH total over a median of 4 days (range 1-10). Only one follicle scan was needed in 78% of cycles. Cancellation rate was 15%. Successful retrievals, defined as obtaining M-stage oocyte(s), were 94% of attempts (M-2 oocytes in 77% of attempts), with a mean of 1.8 M-2 and 1.4 M-1 oocytes. Transfer [of blast(s)] followed 78% [58%] of 272 successful retrievals, with 97% of transfers done on Day 5.

Of 94 pregnancies [pregnancy rate (PR) 32.8% of attempted retrievals], 14 were biochemical, 2 ectopic, and 14 miscarried, with 64 ongoing pregnancies. In women aged 41+ yr, there were 9 retrievals but 0 pregnancies. In women aged less than 41 yr (319 cycles), PR [and ongoing pregnancy rate (OPR)] were 29.5% [20.1%] per cycle start, 35.7% [24.3%] per successful retrieval, and 43.5% [29.6%] per transfer. At least 1 blast was found in 59% of retrieved INVOcell devices. When exactly 1 blast was transferred, sometimes along with an earlier-stage embryo, PR [OPR]/transfer was 49.4% [35.3%] (85 cycles); after 2-blast transfer, PR [OPR] was 61.4% [41.4%] (70 cycles). When only cleavage-stage embryos were found after 5-day culture (N=49), PR [OPR] was 10% [4%]. Twins were 12% of ongoing pregnancies; there were no higher-order multiple pregnancies and there was no ovarian hyperstimulation syndrome. The cost to patients was about 1/3 of typical US ART cycles.

CONCLUSIONS: Our low-cost ART protocol, which includes a LTZ-based mild ovarian stimulation, few monitoring visits, and intravaginal embryo culture, is a promising regimen that also limits excess embryo production and cryostorage needs. These aspects give our protocol the potential to bring about increased access to IVF care.

P-385 4:30 PM Sunday, October 18, 2020

IMPACT OF PRE-IVF TSH LEVELS ON PREGNANCY OUTCOMES. Maria Bustillo, M.D,[1] Ineabelle Collazo, BS,[2] Katherine L. Palmerola, MD,[1] Sabrina A. Gerkowicz, MD,[2] Juergen Eisermann, M.D,[1] Nicholas Hendon, BS,[2] Himanshu Arora, PhD.[3] [1]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [3]University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: Serum thyroid-stimulating hormone (TSH) levels are routinely screened in women with infertility given the negative impact of thyroid disease on ovarian function. Women with clinical hypothyroidism (TSH levels > 4.2 uIU/mL) are treated with thyroid replacement. However, it is unclear whether subclinical hypothyroidism, defined as TSH levels > 2.5 uIU/mL (and </= 4.2 uIU/mL), affects pregnancy outcome. In the present study, we evaluated the IVF treatment/pregnancy outcomes in euthyroid women and in those with subclinical hypothyroidism (both untreated and treated with low dose thyroid replacement) in the years 2016-2017.

DESIGN: A retrospective cohort study

MATERIALS AND METHODS: Patients were categorized into three groups. Group 1, euthyroid, consisted of women who had pre-IVF TSH levels < 2.5 uIU/mL. Individual practitioners decided whether or not to give low dose thyroid supplementation (treatment) to women with TSH levels > than 2.5 but ≤4.2 uUI /mL (subclinical hypothyroidism, SCl hypoT). For that reason, group 2 included women with SCl hypoT who were **not treated,** and Group 3 included women who were **treated**. All women underwent standard IVF protocols following usual individualized practice in our IVF clinic. The relative pattern of IVF outcomes was compared between the three groups. GraphPad Prism (GraphPad Software) was used for statistical analysis. Chi-square test was used to evaluate the differences between the patient cohorts.

RESULTS: A total of 1,160 patients were categorized into Group 1, euthyroid, with 919 women who had pre-IVF TSH levels < 2.5 uIU/mL, Group 2 included 74 women with SCl hypoT who were **not treated,** and Group 3 included 167 women who were **treated**. The overall pregnancy rate was significantly lower in women with SClhypoT without treatment (compared to Euthyroid (p=0.015). However treated women with SClhypoT, group 3 showed no significant differences compared to Euthyroid, group 1 (p=0.237).

* p= 0.015, # p=0.237

CONCLUSIONS: Our findings suggest that subclinical hypothyroidism may impact IVF success and pregnancy outcomes. Low dose thyroid supplementation may be beneficial in patients with sub-clinical hypothryoidism. Further in-depth studies are ongoing considering parameters such as the presence of TPO antibodies, BMI and other specific treatment strategies which may have an additional effect on successful IVF outcomes..

P-386 4:30 PM Sunday, October 18, 2020

DAY 7 EMBRYO CULTURE INCREASES BLASTOCYST YIELD FOR DIFFERENT AGED FEMALE PATIENTS. Nancy L. Bossert, PhD,[1] Rebecca L. Krisher, PhD,[2] William B. Schoolcraft, MD,[2] Hannah Van Der Geest, BS,[1] Jason E. Swain, PhD, HCLD.[3] [1]CCRM Minneapolis, Edina, MN; [2]CCRM Colorado, Lone Tree, CO; [3]CCRM IVF Network, Lone Tree, CO.

OBJECTIVE: Traditional embryo culture systems grow embryos for up to 6 days to reach the blastocyst stage. The assumption is that after this point, the potential for good quality blastocyst (GQB) development is minimal. However, studies have recently shown that blastocysts with the ability to support live birth can develop in vitro on Day 7. The objective of this study was to determine whether an extra day of embryo culture may be a source of additional GQBs and if this varied by female age.

DESIGN: Retrospective data analysis.

Female Age	# Patients	Day 5 Total Bast Rate	Day 5 GQB	Day 5/6 Total Blast Rate	Day 5/6 GQB	Day 5/6/7 Total Blast rate	Day 5/6/7 GQB	% Increase in GQB from D7
<30 yrs	22	63.7%[a]	29.5%[ac]	72.2%[ab]	51.6%[ab]	76.2%[a]	52.7%[ab]	1.1%[ab]
30-34	166	61.1%[a]	28.5%[a]	69.7%[a]	50.4%[a]	74.5%[a]	51.1%[a]	0.7%[a]
35-37	152	51.0%[b]	23.5%[bc]	63.4%[bc]	42.7%[bc]	73.0%[ab]	45.2%[bc]	2.5%[b]
38-40	149	47.8%[bd]	19.4%[be]	59.8%[cd]	39.6%[cd]	71.9%[ab]	41.1%[cd]	1.5%[ab]
41-42	61	42.8%[bd]	11.6%[d]	54.4%[df]	31.1%[df]	68.9%[ab]	32.9%[df]	1.8%[ab]
>42	40	36.9%[cd]	12.3%[de]	45.0%[ef]	22.7%[ef]	63.9%[b]	25.6%[ef]	2.88%[ab]

Different superscripts within a column indicicate significant, differences between age groups p<0.01.

MATERIALS AND METHODS: All embryos were cultured in the same fashion, utilizing a sequential culture media system with 10% SPS protein under ~6% CO2, 5% O2. GQBs of grade 3BB or better were cryopreserved on D5 and D6. In an effort to balance desire for additional embryos with laboratory logistics and impact on incubator capacity, any patient with remaining morulae or early stage blastocysts on D6 were kept in culture for one more day to determine if additional blastocysts were available. Blastocyst conversion was compared between various female age groups using one way ANOVA and Bonferroni multiple comparison test.

RESULTS: The number of GQBs decreased as female age increased. In general, each age group was significantly different from all others except for the age group immediately younger in regard to GQB produced on days 5 and 6, as well as days 5, 6 and 7. One extra day of culture increased GQB in all age groups (1.1% <30yrs, 0.7% 30-34yrs, 2.5% 35-37yrs, 1.5% 38-40yrs, 1.8% 40-42yrs, 2.8% >42yrs), although not significantly (p=0.12 overall). However, the increase in GQB obtained from day 7 culture was higher in women 35-37 yrs than 30-34 yrs.

CONCLUSIONS: Female patients in any age group may obtain extra useable blastocysts from a seventh day of embryo culture**.** While this does not mean that every individual patient may result in more blastocysts after culture to day 7, use of an extra day of culture may help obtain extra embryos. The practice of culturing embryos to day 7 may be useful for any patient who has no or lower than expected blastocysts by day 6, to further increase their reproductive potential following IVF.

INCIDENCE OF MULTIPLE BIRTHS IN RELATION TO CURRENT REGULATIONS IN TURKEY REGARDING EMBRYO TRANSFER. Semra Kahraman, MD, Prof., Ipek Nur Balin Duzguner, MD, Soner Duzguner, MD, Yucel Sahin, MD. Istanbul Memorial Hospital, Istanbul, Turkey.

OBJECTIVE: The aim of our study is to evaluate the 2010 regulations in Turkey regarding the number of embryos which can be transferred.

DESIGN: This retrospective single center study evaluated single versus multiple births before and after the introduction of 2010 Turkish regulations.

MATERIALS AND METHODS: The study is based on data from Istanbul Memorial Hospital, ART and Genetics Center used to evaluate the 2010 regulations, which restricts the number of embryos to be transferred. According to the regulation; double embryo transfer (DET) is allowable after two unsuccessful attempts in cases up to maternal age of 35 and in any one cycle in cases ≥35.

For the period from March 2003 to June 2019, a total of 31,459 cycles were analyzed to evaluate the overall effect of 2010 regulations.

For the period from January 2014 to July 2019, a total of 4450 cycles were evaluated according to two different ages groups, patients <35 and patients from 35-42 years of age with single or double blastocyst transfer performed in compliance with current regulations.

First the overall effect of the introduction of the regulations on multiple births was evaluated regardless of previous ART attempts and maternal age. Secondly, the clinical results of fresh and frozen-thawed single or double blastocyst transfer in patients <35 years with a history of 2 or 3 previous unsuccessful ART attempts and in patients ≥ 35 (35-42) years with a history of either no previous attempts or 1,2 or 3 attempts were evaluated.

RESULTS: In the first study groups (March 2003 to July 2019), the parameter most significantly affected by the introduction of the regulations was the number of the embryos transferred. The percentage of single embryo transfer (SET) cycle increased dramatically from 14% to 56.6%. However, despite a fall from 32.4%, the incidence of twin births remained high at 15.5%. In the second study groups from January 2014 to July 2019, in young patients <35 years with 2 or 3 previous cycles, the twin birth rate was very high at 47.26 % in the double blastocyst group whereas it was only 1.75% when a single blastocyst was transferred (p=0.0001). In patients ≥ 35 years (35-42) with zero,1,2 and 3 previous cycles, in the double blastocyst transfer group, the twin birth rate was again high at 28.4% whereas in the single blastocyst transfer group it was only 1.8% (p=0.0001). Importantly, there was no statistically significant difference in clinical pregnancy rates between these two groups (67.4% vs 67.5% in the <35 group, and 59.1% vs 54.1% in the ≥ 35 year group) (p=0.846 and p=0.055). Thus, in DET, there was a high risk of twin births and no advantage in terms of pregnancy rates.

CONCLUSIONS: As a result of the wording of the current regulations, there has been a high demand for DET in both young and older patients. Our study strongly suggests that, especially in the light of the success of blastocyst transfer, the Turkish regulations should be amended to limit the use of DET and encourage the use of SET apart from in exceptional cases and particularly in women under 35 years old.

P-389 4:30 PM Sunday, October 18, 2020

CESAREAN SECTION: RISK FOR ECTOPIC IN SUBSEQUENT PREGNANCY. Alixandra Domney, M.D., M.P.H.,[1] Stephanie R. Brownridge, M.D.,[2] Christine Mullin, M.D.[2] [1]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: To determine whether history of cesarean section increases the risk of ectopic pregnancy in assisted-reproductive technology (ART) cycles.

DESIGN: Retrospective, case-control study.

MATERIALS AND METHODS: We reviewed all ART cycles at a single academic institution from 2008-2020. Of the 12,000 cycles reviewed, 105 ectopic pregnancies (cases) and 316 intrauterine pregnancies (controls) were identified. Controls were selected by timing of diagnosis of intrauterine gestation in relation to timing of diagnosis of ectopic pregnancies (cases) to ensure laboratory and clinic practice were similar for that time period. Patient characteristics, cycle type, and previous mode of delivery were compared between the two groups using the Student's unpaired t-test and Fisher's exact test as appropriate, with statistical significance set at a p value of <0.05.

RESULTS: No differences amongst the case and control groups were seen in regard to age, FSH, average number of embryos transferred (ET), history of tubal disease, or smoking. As our primary outcome, history of cesarean section bared no significant difference when comparing cases (21%) to controls (21%). Fresh transfers were more likely to result in an ectopic pregnancy when compared to those undergoing a frozen ET (65% vs. 35%, p= 0.0002). An increase in ectopic pregnancy rate was not seen in patients who had a prior cesarean section regardless of embryo transfer type.

Table 1. Comparison of patient and cycle characteristics in Ectopic vs. Intrauterine Pregnancies

	ECTOPIC (N=105)	INTRAUTERINE (N=316)	P-VALUE
AGE (YEARS)	35.0	35.0	NS
MAX FSH (IU/mL)	7.0	8.0	NS
AVERAGE #ET	2.0	2.0	NS
%TUBAL DISEASE	10.0	8.0	NS
%SMOKER	22.0	24.0	NS
%FRESH ET	65.0	43.0	0.0002
%FROZEN ET	35.0	57.0	0.0002
%PRIOR C/S	21.0	21.0	NS
%PRIOR C/S + FRESH ET	10.5	6.0	NS
%PRIOR C/S + FROZEN ET	10.5	15.0	NS

CONCLUSIONS: A history of prior cesarean section does not appear to be a risk factor for subsequent ectopic pregnancy. Moreover, there was not a higher percentage of patients with a history of tubal disease or smoking in women with an ectopic versus an intrauterine pregnancy. However, patients undergoing a fresh ET had a significantly increased chance of an ectopic pregnancy as compared to those undergoing a frozen transfer. Frozen embryo transfers are a potential treatment strategy to lower the risk of ectopic pregnancy in women undergoing ART.

P-390 4:30 PM Sunday, October 18, 2020

DOES JUNCTIONAL ZONE (JZ) THICKNESS EFFECT IMPLANTATION AND IN VITRO FERTILIZATION (IVF) SUCCESS RATES IN UNEXPLAINED INFERTIL PATIENTS? Temel Ceyhan, M.D., Professor,[1] Murat Ozekinci, M.D., Associate Prof,[2] Cem Korkmaz, M.D., Professor,[1] Mehmet Sakinci, M.D., Associate Prof,[3] Baris Baykal, M.D.[1] [1]University of Health Sciences, Ankara, Turkey; [2]Memorial Antalya Hospital, Antalya, Turkey; [3]Akdeniz University Hospital, Antalya, Turkey.

OBJECTIVE: To assess the sonographic changes in JZ anatomy during IVF cycles in unexplained infertility and to observe whether sonographic findings are prognostic for IVF outcomes.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: In this prospective study, patients with unexplained infertility were prospectively recruited between January 2012 and December 2012. Exclusion criteria were presence of known cause of infertility including tubal factor, endometriosis, male factor, and decreased ovarian reserve; history of irregular menses, pelvic or uterine surgery, myoma utery or adenomyosis.

JZ anatomy was evaluated with serial transvaginal ultarsonographic meausurements.Transvaginal ultrasound scans of endometrium and JZ were performed on the day of initiation of ovulation induction(day 2), day 7 of ovulation induction, the day of HCG injection, and the day of oocyte retrieval. Measurements of the JZ were done as anterior,posterior and fundal dimensions in sagittal plane. At the end of the treatment, patients who conceived and who did not were compared for junctional zonal changes.

RESULTS: A total of 56 subjects were included in the study. Twenty three pregnant women (mean age: 32,1 $\pm$ 4.1, range 25 to 38) and 33 non-pregnant women (mean age: 30, 1 $\pm$5.0, range 24 to 38) were analysed in the final comparisons. Basic characteristics of the groups in terms of age, duration of ovulation, total dosages of gonodotropines used, number of oocytes retrieved, quality of embryo and number of embryos transferred were similar.

Anterior, posterior, fundal, maximum and mean JZ diameters were meausured. Mean anterior diameter measured on the initiation day among pregnant women was significantly lower compared to non-pregnant women (3.88 $\pm$ 0.77 vs. 4.47 $\pm$ 0.96, p=0.024), JZ thickness on the initiation day was markedly lower and consistently increased during the cycle among women who achieved pregnancy. However, non-pregnant women had higher initial JZ thickness which remained almost similar thereafter. Posterior, fundal, maximum and the mean of all four JZ diameters were similar on the initiation day, Day 7, day of HCG injection and day of oocyte retrieval measurements of these for diameters were all similar in pregnant and non-pregnant women.

CONCLUSIONS: Anterior JZ thickness at the initiation of ovulation induction has some influences on ivf outcomes in unexplained infertile patients. Randomised controlled trials including more patients are required to elucidate the complexity of the 'enigmatic JZ' and its potential effects on reproduction

EFFECT OF AN ISTHMOCELE ON IVF OUTCOME IN INFERTILE PATIENTS UNDERGOING STIMULATED IVF TREATMENT. Chung-Hoon Kim, M.D., Ph.D., Jei-Won Moon, M.D., Shin Yong Moon, M.D., Ph.D. M Fertility Center, Seoul, Korea, Republic of (South).

OBJECTIVE: This study was performed to investigate the effect of an isthmocele after previous cesarean section delivery on IVF outcome in infertile women undergoing IVF in stimulated cycles.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A total of 104 infertile patinets who underwent IVF in controlled ovarian stimulation (COS) cycles between May 2018 and April 2020 was included in this study. Of 104, sixty-one patients had no isthmocele, a cesarean scar (group 1) but forty-three had an existing isthmocele. Twenty-three patients of 43 had a small isthmocele with residual myometrial thickness (RMT) of 3mm or more (group 2) and 20 had a large isthmocele with RMT less than 3mm (group 3). COS results and IVF outcome were compared among the three groups. Analysis of variance (ANOVA) was used to compare the mean values among three groups. Chi-square test and Fisher's exact test were used for the comparisons of fraction. Statistical significance was defined as $P<.05$.

RESULTS: The demographic characteristics of subjects were comparable among the three groups. There were also no differences in the three groups with respect to the number of oocytes retrieved, mature oocytes retrieved, fertilized oocytes and grade 1 or 2 embryos. However, intracavitary fluid (ICF) in the day of oocyte retrieval was more frequently developed in group 3 (large isthmocele group), compared with group 1 or 2 ($P = .005$ vs group 2, and $P < .001$ vs group 1). Clinical pregnancy rate (CPR) in group 3 was significantly lower than in group 1 ($P = .028$) and also lower than in group 2 with a borderline significance ($P = .080$). Miscarriage rate was similar in three groups. CPR was significantly lower in IVF treatment group with developing ICF than in group without development of ICF ($P < .001$).

CONCLUSIONS: Large isthmocele was associated with developing ICF and had an adverse effect on the IVF outcome in infertile patients undergoing IVF in COS cycles.

DOES A HISTORY OF UNEXPLAINED INFERTILITY INCREASE THE RISK OF COMPLICATIONS IN SUBSEQUENT PREGNANCIES? A FOLLOW-UP STUDY OF FAST TRACK AND STANDARD TREATMENT TRIAL (FASTT) PARTICIPANTS. Katherine G. Koniares, MD,[1] Marlene B. Goldman, ScD,[2] June L. Fung, PhD,[2] Carleigh B. Nesbit, DO,[3] Denis A. Vaughan, MD,[4] Thomas L. Toth, MD,[4] Richard H. Reindollar, MD.[2] [1]Tufts Medical Center, Boston, MA; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Dartmouth Hitchcock Medical Center, Lebanon, NH; [4]Boston IVF, Waltham, MA.

OBJECTIVE: To compare pregnancy complications and birth outcomes of live births conceived by couples with a history of unexplained infertility.

DESIGN: Long-term follow-up of randomized controlled trial (RCT) participants.

MATERIALS AND METHODS: In FASTT, from 2001-2006, 503 couples with women aged 21-39 years and unexplained infertility were randomized to 3 cycles of clomiphene citrate (CC)/IUI, 3 cycles of gonadotropin/IUI, then IVF or 3 cycles of CC/IUI prior to IVF. Between March 2019-February 2020 a 22-question telephone survey with branching logic was administered to couples who were enrolled in FASTT. Analysis was performed using SAS v9.2. Categorical variables were analyzed using chi-square and Fisher's exact tests while continuous variables were analyzed with two-sample t-tests with $P<0.05$ considered significant.

RESULTS: Of the 503 women enrolled in FASTT, 311 (61.8%) were contacted during the current study and 286 (56.9%) consented to participate with an average age of 49.5 ±3.4 years. Participants reported a total of 251 live births conceived after participation in FASTT. Of the 251 live births, 129 (51.4%) were conceived spontaneously, 8 (3.2%) via COH without IUI, 13 (5.2%) via COH with IUI, 90 (35.9%) via IVF with fresh or frozen embryos, and 11 (4.4%) via IVF with donor eggs. Among these methods of conception, there were no statistically significant differences in incidence of preterm delivery, low birth weight, gestational hypertension, preeclampsia, gestational diabetes, placental abruption, abnormal placentation, fetal growth restriction, or postpartum hemorrhage. Pregnancies conceived via IVF with fresh or frozen embryos were more likely to result in twins (22.2%) compared with spontaneous conception (2.3%), COH without IUI (0%), COH with IUI (15.4%), and IVF with donor eggs (9.1%), overall $P<0.0001$. However, the number of embryos transferred in pregnancies conceived via IVF is unknown. Survey respondents reported that 27/251 (10.8%) live births conceived after FASTT resulted in a child that is not alive and well today. 18/27 respondents provided diagnoses and although the numbers are small, the most common abnormalities included asthma (n=6), allergies (n=5), autism (n=3), ADHD (n=3), and trisomy 21 (n=2).

CONCLUSIONS: Women with a history of infertility treated with ovarian stimulation with or without IVF are not at increased risk of developing gestational hypertension, preeclampsia, gestational diabetes, abnormal placentation, fetal growth restriction, postpartum hemorrhage, or having a preterm delivery in subsequent pregnancies.

P-393 4:30 PM Sunday, October 18, 2020

THE CHANGE IN ANTRAL FOLLICLE COUNT EFFECT ON PREGNANCY RATE IN CONSECUTIVE CONTROLLED OVARIAN STIMULATION AND INTRAUTERINE INSEMINATION CYCLES. Melissa A. Mathes, MD, Elizabeth A. Kastrick, MD, Stephanie Gustin, MD. The University of Nebraska Medical Center, Omaha, NE.

OBJECTIVE: Various methods of measuring ovarian reserve exist, including antral follicle count (AFC). Ovarian reserve tests, as they relate to pregnancy rates, have mostly been studied in IVF populations (1-3). In the few articles available, an AFC minimum of 5 to 7.5 are cited to improve pregnancy outcomes in IUI cycles (4, 5). In addition, there is limited knowledge regarding the change in ovarian reserve tests, specifically AFC, with consecutive cycles of ovarian stimulation for IUI cycles. The aim of this study was to determine if there was a change in AFC in consecutive cycles of patients undergoing controlled ovarian stimulation with IUI and how this impacts pregnancy rate.

DESIGN: A retrospective cohort study of all IUI cycles at a private practice infertility center from June 2014 to May 2018.

MATERIALS AND METHODS: We obtained female characteristics including age, gravida, parity, BMI, AMH, AFC, tubal patency, stimulation medication, number of dominant follicles, endometrial thickness, post-wash semen parameters, and clinical pregnancy rate. Clinical pregnancy was defined by fetal cardiac activity on ultrasound. Our primary outcome of interest was to determine the change in AFC in consecutive cycles and the impact this had on the pregnancy rate. Consecutive cycles were defined as two IUIs <35 days apart. A secondary outcome was the pregnancy rate correlation with AFC. Cycles with no ovarian stimulation medication were excluded when evaluating the effect of consecutive cycles. Cycles greater than 90 days apart were removed from the analysis of consecutive cycles as to decrease the impact of declined ovarian reserve with time. A mixed effects model including AFC change and days between cycles was used.

RESULTS: A total of 999 women with a total of 2169 IUI cycles were included. Over 92% of IUIs were less than 180 days apart. Although not significant, there was a trend of improved pregnancy rate with cycles beginning with AFC >5. Clinical pregnancy OR for AFC 0-5, 6-10, 11-15, and 16-20 were 0.41, 0.79, 0.75 and 0.88 respectively with p-value 0.003, 0.159, 0.068 and 0.443 respectively. Overall, the AFC decreases overtime, approximately 0.006 per day. The AFC change between cycles <35 days apart was -0.6 and in cycles 35-90 days apart was -0.7 with p-value 0.851. The consecutive cycles that did have a decline in AFC had improved pregnancy rates. Clinical pregnancy OR for AFC change -1 to -5, -6 to -10, and -11 to -15 were 1.43, 1.12 and 1.04 respectively with p-value 0.269, 0.756, 0.940 respectively.

CONCLUSIONS: In this study, we sought to determine if there was an effect of AFC change on pregnancy outcomes in consecutive cycles of controlled ovarian stimulation and IUI. We did find an improved pregnancy rate with AFC >5. The small decrease in AFC of 0.006 per day is likely an impact of a decline in fertility with age. There does not appear to be a significant change in AFC when comparing consecutive stimulated cycles to cycles that have greater time between them. Although insignificant, there was a trend in improved pregnancy rates with a decrease in AFC in consecutive cycles. A prospective analysis is needed to further characterize this trend.

EFFICACY ANALYSIS OF LETROZOLE AS CO-TREATMENT AGENT IN PROGESTIN-PRIMED OVARIAN STIMULATION PROTOCOL ON PREDICTED NORM/HIGH RESPONDERS. Xiaolan Li, M.D.,[1] Jiawei Cai, M.D.[2] [1]The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [2]■ ■ ■.

OBJECTIVE: We aimed to evaluate efficacy of Letrozole co-treatment with PPOS in predicted norm/high responders undergoing in vitro fertilization/intracytoplasmic sperm injection (IVF/ICSI).

DESIGN: A retrospective cohort analysis.

MATERIALS AND METHODS: Patients adopting PPOS with 5-day Letrozole in our unit between January 2018 and December 2019 in were included in this retrospective study. Inclusion criteria were as follows: ①basal FSH<10IU/L ; ②basal AFC>7 ; ③ basal AMH≥1.1ng/ml ; age <40 years old. For comparison, we enrolled patients using PPOS only as control group. All patients administered Gn () and medroxyprogesterone acetate (MPA) (10mg/d; Shanghai Xinyi Pharmaceutical Co., Shanghai, China) or Utrogestan () from cycle day 3 onward. In study group, 2.5-5mg Letrozole for 5 days were administered daily beginning on cycle day 3. The final stage of oocyte maturation was triggered was triggered with a GnRH agonist or co-triggered by GnRH agonist and hCG, when at least two follicles with ≥18

mm in diameter was observed. ICSI was performed if the concentration of motile sperm was $<1\times10^6$/mL, otherwise a conventional IVF was used. The cycle outcomes were compared between groups. All statistical analysis were conducted using SPSS 25.0. A $P<0.05$ was considered statistical significance.

RESULTS: In total, 267 patients were recruited in study group and 352 in control groups. There were no significant differences in demographic characteristics between groups, such as age, etiologies of infertility, BMI, antimullerian hormone and antral follicles counts ect.. We found similar Gn dose, Gn stimulation day and number of oocyte retrieval (10(9) vs. 10(9), P = 0.178) between two groups. Although estrogen level on trigger day was significantly lower in study group (947.5(910.4)) vs. 604(2712.5) , P<0.001), patents in two groups had comparable incidence of moderate to severe OHSS (2.25% vs. 1.14% for study group and control group respectively ,P =0.341). The percentage of women with profound pituitary suppression (LH level on trigger day < 1 IU/L) was significantly lower in the study group than in the control group ((1.50% vs 7.67%, P < 0.001). In addition, the LH level on trigger day was higher in study group than in the control group (P<0.001), but comparable percentage patients in two groups exhibited a premature LH surge (4.49% vs. 3.13%, P= 0.372). As for laboratory outcomes, 2pn rate was significantly lower in study group (52.90% vs.58.24%, P<0.001)). But no statistical significance were observed in viable embryo rate (P=0.08), rate of top-quality embryo(P=0.358) and blastulation rate (0= .613) between groups.

CONCLUSIONS: For predicted norm/high responders, Adding 2.5-5 mg of Letrozole for 5 days to PPOS protocol could not increase ovarian response and reduce incidence of moderate to severe OHSS. Although Letrozole supplementation in the PPOS protocol effectively alleviated profound pituitary suppression from progesterone administration without interfering with its LH surge blockade effect, it might compromise fertilization of oocyte.

P-395 4:30 PM Sunday, October 18, 2020

COST ANALYSIS OF ESTROGEN PRIMING VS MICRODOSE LEUPROLIDE FLARE PROTOCOLS FOR WOMEN WITH DIMINISHED OVARIAN RESERVE UNDERGOING IVF. Nicole D. Ulrich, MD,[1] Nicholas S. Raja, MD,[2] Charley Jiang, MS,[3] Molly B. Moravek, MD, MPH.[2] [1]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]MD/MSCR candidate, Ann Arbor, MI.

OBJECTIVE: Previous studies comparing E2 priming and leuprolide flare IVF protocols report that E2 priming protocols result in longer cycles and higher total gonadotropin dose with similar oocyte yield, fertilization, and pregnancy rates; though, one report suggests a trend toward higher quality embryos in E2 priming cycles. We aimed to compare cost effectiveness between these two cycle types in women with DOR and hypothesized that a leuprolide flare protocol would be more cost effective.

DESIGN: Retrospective cost effectiveness analysis.

MATERIALS AND METHODS: We reviewed all IVF cycles in women diagnosed with DOR with E2 priming protocol or microdose leuprolide flare protocol in an academic fertility clinic by retrospective chart review from January 2016 through February 2020. We included only the first cycle of either type and excluded any cycles cancelled before retrieval. Variables assessed included patient age at retrieval, markers of ovarian reserve, total dose of gonadotropins, cycle length, number of mature oocytes (M2) retrieved, and number of 2 pronuclear embryos (2PN). We calculated total cost based on charge data from number of monitoring visits, estimated medication cost, and relevant procedure codes. The effectiveness was calculated as total M2 per cycle and total 2PN per cycle. We performed a separate cost effectiveness analysis for each measure, M2 and 2PN. Descriptive statistics, cost effectiveness, and t-test analysis were conducted using SAS 9.4. P values <0.05 were considered statistically significant.

RESULTS: We evaluated a total of 182 cycles (149 E2 priming, 33 leuprolide flare). Mean age was 36.8 years in the E2 priming group, and 37.97 years in the leuprolide flare group. There was an average of 6.95 monitoring visits in the E2 priming groups and 6.18 visits in the leuprolide flare group. The cycle length was shorter (p value=0.013) and the total dose of gonadotropins was lower (p value=0.0026) in the leuprolide flare group (11.0 days, 4536.3 IU) vs E2 priming (12.3 days, 5301.7 IU). The mean number M2 per cycle was higher in the E2 priming group (7.06) vs leuprolide flare (5.0) (p value=0.035). The mean number of 2PN per cycle was also higher in the E2 priming group (5.46) vs leuprolide flare (3.48) (p value=0.002). The total cost per cycle was $24,156 in the E2 priming groups and $22,112 in the leuprolide flare group. The cost per both M2 and 2PN was lower in the E2 priming group ($3,209 and $4,424, respectively) than the leuprolide flare group ($4,134 and $6,345, respectively).

CONCLUSIONS: Despite a longer cycle, higher total gonadotropin dose, and higher overall cost per cycle, patients treated with E2 priming protocol in our cohort had a greater mean number of M2 and 2PN, resulting in significantly lower cost per M2 and 2PN. Based on these data, E2 priming appears to be more cost effective than leuprolide flare in women with DOR. Cost effectiveness of medical care is becoming increasingly important in health systems, and application of this type of analysis in the field of reproductive medicine can help increase treatment success, improve allocation of resources, and ultimately increase access to infertility care.

P-396 4:30 PM Sunday, October 18, 2020

THE CORRELATION BETWEEN SALINE INFUSION SONOGRAM FINDINGS AND HISTOPATHOLOGY IN THE MANAGEMENT OF INTRAUTERINE FILLING DEFECTS IN INFERTILE PATIENTS. Ramya Sethuram, MD,[1] Alexandra E. Flessel, BS,[1] Lina Fouad, BS,[1] Damla C. Gonullu, MD,[1] Abhijit Mandal, PH.D,[2] Sana Salih, MD.[1] [1]Wayne State University School of Medicine, Detroit, MI; [2]Wayne State University, Detroit, MI.

OBJECTIVE: In infertile patients, the natural course of endometrial polyps remains unclear and the current evidence on their management is mixed. Surgical resection of endometrial polyps is recommended prior to infertility treatment in order to increase natural conception or assisted reproductive pregnancy rates. Hysteroscopic polypectomy remains the gold standard for surgical treatment. However, there is scarcity of literature examining the correlation between ultrasound findings of small polyps or intrauterine filling defects and histology in patients treated for infertility. Our objective is to study the correlation between polyps identified on saline infusion sonogram (SIS) + 3-dimensional transvaginal ultrasound (3D TVUS) with hysteroscopy and histology.

DESIGN: Retrospective study at a university hospital infertility center.

MATERIALS AND METHODS: We performed a retrospective chart review after IRB approval. All patients who underwent surgery at a university health infertility center from July 2019 to Feb 2020 were included. These patients had a diagnosis of filling defect on SIS + 3D TVUS during their infertility work-up. Patients who had prior hysteroscopic intrauterine surgeries were excluded. A total of 33 patients were studied. We compared the results of the SIS + 3D TVUS with the intra operative and histopathology results in patients who underwent hysteroscopic surgery. All the polyps were resected with Truclear device. Statistical analysis was performed with SPSS V24.0

RESULTS: The mean age of the study group was 34 years (±6.2). The mean BMI was 31.8 (±6.3). Of the total of 33 patients studied, 30 patients had an ultrasound diagnosis of polyp based on appearance and vascularity. Of these, 25 (83%) patients we determined to have a polyp < 1cm, rest (n=5, 17%) had a polyp > 1 cm but $\leq$ 2 cm on ultrasound. On hysteroscopy, findings included: intrauterine polyp in 24 (80%) patients; uterine synechiae in 2 (6%); partial uterine septum in 1 patient (3%); (PPV=80% for polyps). Of the 30 patients, 21 (70%) patients had a positive histological correlation for polyp/ fibroid (PPV =70%). Larger polyp sizes did not correlate better with intra operative and histological correlation of findings a polyp (p = 1 for polyps $\leq$ 1 cm diameter and p = 0.9 for polyps > 1 cm but < 2 cms diameter).

CONCLUSIONS: The diagnosis of a polyp using a combination of SIS and 3D TVUS is a good predictor for finding a polyp intraoperatively and in histology. Most of the polyps studied were sub-centimeter polyps. A polyp size larger than 1 cm diameter but < 2cms, as determined by ultrasound, is not a better predictor for finding a polyp intraoperatively and in histology, when compared to sub-centimeter polyps.

P-397 4:30 PM Sunday, October 18, 2020

THE APPLICATION OF DROTAVERINE IN IVF-ET FRESH CYCLE: AN ANALYSIS OF 840 CYCLES. Tingting Li, Doctor,[1] Panyu Chen, Master,[2] Cong Fang, PHD, MD.[2] [1]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the clinical value of drotaverine in in vitro fertilization-embryo transfer (IVF-ET) for fresh embryo transfer.

DESIGN: A retrospective study.

MATERIALS AND METHODS: A retrospective study was conducted with clinic-based data in the Reproductive Medicine Research Centre of the Sixth Affiliated Hospital of Sun Yat-sen University from May 2017 to May 2018. Patients aged below 40 years old underwent their first or second IVF-ET cycle and transferred 1-2 good embryos with AMH≥1.1ng/ml are involved. A total of 840 cycles were analyzed. All the cycles were divided into 2 groups according to whether they use drotaverine 80 mg bid 1 day before embryo transfer: cycles with drotaverine (Group A, n=352) , cycles without drotaverine (Group B , n=488).

RESULTS: There were no significantly differences with regard to age, BMI, AMH, and number of transferred embryos between 2 groups. Chemical pregnancy rate (64.77% VS 60.71 %) and implantation rate (42.81% VS 36.71 %) of group A and group B was statistically significant different (P<0.05).

CONCLUSIONS: Drotaverine can significantly improve embryo implantation and pregnancy rate for D3 embryo transfer in fresh cycle.

	Group A (n=352)	Group B (n=488)	*P*
Age(y)	31.61±3.736	31.57±3.705	0.987
BMI(kg/m^2)	22.07±3.170	21.93±3.011	0.218
Basal FSH(IU/L)	6.91±1.925	6.91±2.206	0.776
Basal LH(IU/L)	6.625±4.325	5.917±4.255	0.131
Basal E_2(pg/ml)	34.584±12.905	33.941±13.390	0.504
AMH(ng/ml)	3.5±2.035	3.46±3.025	0.904
Number of oocytes retrieved	10.67±4.26	10.85±4.43	0.548
2PN fertilized oocytes	6.92±3.25	7.23±3.52	0.054
Number of transferrable embryo	5.11±2.89	5.32±2.90	0.180
Number of embryo transferred	1.95±0.221	1.95±0.235	0.760
Chemical pregnancy	64.77%(228/352)	60.71%(272/488)	**0.008***
Clinical pregnancy	62.50%(220/352)	54.10% (264/488)	**0.002***
Implantation rate	42.84% (293/684)	36.71% (348/948)	**0.012***

Chemical pregnancy rate=number of biochemical pregnant cycle/number of embryo transfer cycle; Clinical pregnancy rate=number of clinical pregnant cycle/number of embryo transfer cycle; Embryo implantation rate=number of gestational sac/number of embryo transferred; * *P* values < 0.05

P-398 4:30 PM Sunday, October 18, 2020

A PILOT STUDY INCLUDING A RETROSPECTIVE ANALYSIS OF DEMOGRAPHIC, CLINICAL, LABORATORY DATA AND PREGNANCY OUTCOMES OF PATIENTS PRESENTED TO OUR ART CLINIC TO ESTABLISH A SUITABLE NATIONALLY AVAILABLE DATABASE. Elif Ece Inceli, Medical Doctor,[1] Nafïye Yilmaz, PROFESSOR,[1] Aytekin Tokmak, Assoc. Prof.[2] [1]Health Science University Turkey, Ankara City Hospital, Ankara, Turkey; [2]Health Science University Turkey, Mersin City Hospital, Mersin, Turkey.

OBJECTIVE: The aim of this study is to present the analysis of demographic, clinical, laboratory datas and pregnancy results of the patients admitted to our hospital's ART clinic for 3 years as an example for the creation of a database in accordance with international standards.

DESIGN: Our study was planned for retrospective analysis of demographic, clinical and laboratory findings and pregnancy outcomes of 1294 cycles of oocyte pick up (OPU) treated at the ART Clinic of Zekai Tahir Burak Women's Health Education and Research Hospital between January 2015 and December 2017. Age, duration of infertility, BMI, indication of ART, basal hormone levels, basal AFC, number of previous IVF cycles, primary or secondary infertility, previous pregnancy, stimulation protocol, number of oocytes collected and studied, number of embryos obtained, transferred, embryo grade, transfer day, TESE application, total progressive motile sperm count (TPMSS), Kruger morphology, pregnancy outcome, delivery type, sex, birth week, birth weight and complication rates of the cycles were evaluated.

MATERIALS AND METHODS: Informed consent was obtained from the patients about ART treatment options, complications and results before treatment. For controlled ovarian hyperstimulation, agonist and antagonist protocols were applied. The data were separated according to age groups and indications. The number of embryos transferred, the day of embryo transfer and the quality of the embryo transferred were grouped and pregnancy outcomes were analyzed.

RESULTS: It is important to present our results in order to collect and access ART data in our country with the parameters included from the international ART data. Overall pregnancy rate per cycle was 28.6% and pregnancy rate per ET was 32.7%. The live birth rate was 20.5% per cycle and 23.4% per ET. A significant correlation was found between patient age and live birth rates, live birth rates decreased with increasing age of women (p: 0.004). When the live birth rates were examined according to the indications, live birth rates per ET were significantly higher (37.3%) in the ovulatory disfunction group compared to the other groups (p <0.001). In the male factor group, there was a statistically significant difference between the rates of live birth between cycles with TESE procedure (17.9%) and cycles without TESE procedure (27%) (p <0.001). There was a significant difference between twin live birth rates according to the number of transferred embryos, 0.2 % in single ET group and 5.2 % in double ET group (p: 0.001). Clinical pregnancy and live birth rates were similar in transfers of D4 and D5 embryos. Live birth rates were higher in D5 embryo transfer cycles (32.3%) compared to embryos at other stages (p: 0.004). The clinical pregnancy and live birth rates were significantly higher in Grade 1 group (31.2%) compared to Grade 2 group (18%). (p <0.001).

CONCLUSIONS: Pregnancy results of our clinic were observed to be highly similar to the literature. In order to establish a standardized national database in the centers that applying ART in our country, datas of the clinics should be analyzed with international standards.

SUPPORT: None.

P-399 4:30 PM Sunday, October 18, 2020

OUTCOMES AFTER ADJUNCT GROWTH HORMONE TREATMENT WITH A LOW, INTERMEDIATE, OR HIGH DOSE PROTOCOL IN IVF CYCLES WITH POOR RESPONDERS. Reeva B. Makhijani, MD,[1] Stephanie M. Hallisey, MD,[1] Prachi N. Godiwala, MD,[2] Chantal Bartels, MD,[1] Daniel R. Grow, MD,[1] Lawrence Engmann, MD,[1] John Nulsen, MD,[1] Claudio A. Benadiva, MD.[1] [1]University of Connecticut Health Center, Center for Assisted Reproductive Services, Farmington, CT; [2]University of Connecticut Health Center, Center for Advanced Reproductive Services, Farmington, CT.

OBJECTIVE: Adjunct growth hormone (GH) is used in poor responders to improve IVF cycle and pregnancy outcomes. There is no consensus on the ideal GH protocol. We compared the extended low, intermediate, and high dose GH protocols used at our center to determine if there was a difference in IVF and pregnancy outcomes.

DESIGN: Retrospective cohort study of women age 26-46 who underwent IVF with adjunct GH from 2013-19 at our center.

MATERIALS AND METHODS: Patients were divided into three groups according to GH protocol: 1) extended low (0.35 IU GH daily for ~30 days before IVF stimulation and with stimulation until day of trigger); 2) intermediate (4.7 IU GH daily for 10 days with stimulation); or 3) high (8.7 IU GH daily for 10 days with stimulation). Primary outcome was ongoing pregnancy or live birth rate (OPR/LBR) per cycle start for fresh transfer or primary frozen-thawed embryo transfer (FET) following a freeze-all cycle. Secondary outcomes were implantation rate (IR), clinical pregnancy rate (CPR), multiple pregnancy rate (MPR), and clinical loss rate (CLR). Subgroup analysis was done for primary euploid blastocyst FET cycles. One-way ANOVA and chi-square tests were used to compare continuous and categorical variables, respectively. A two-sided p-value of 0.05 was considered statistically significant.

RESULTS: 267 patients were included for analysis (low, n=71; intermediate, n=123; high, n=73). There was no significant difference in baseline or IVF cycle outcomes including age, BMI, AMH, number of previous cycles, number of oocytes retrieved, fertilization rate, number of day 3 embryos or blastocysts, use of PGT, number of freeze-all cycles, or cancellation rate between groups. There was no significant difference in OPR/LBR, IR, CPR, MPR, or CLR for fresh transfer or primary FET of euploid or non-PGT tested embryos (Table 1). Subgroup analysis of primary euploid blastocyst FET also showed no difference in OPR/LBR or proportion of cycles with euploid embryos available for transfer between groups.

Table 1. Overall Cycle and Pregnancy Outcomes

Pregnancy Outcomes	Extended low Dose	Intermediate Dose	High Dose	p-value
No. oocytes retrieved (n ± SD)	7.3 ± 2.8	7.7 ± 5.4	8.0 ± 5.5	0.81
No. day 5 blastocysts (n ± SD)	1.4 ± 1.5	1.4 ± 1.8	1.4 ± 1.8	0.97
Cancellation rate (%, n)	23.9 (17/71)	26.0 (32/123)	17.8 (13/73)	0.42
IR (%, n)	30.4 (21/69)	25.6 (31/121)	23.2 (16/69)	0.61
CPR (%, n)	26.1 (18/69)	24.0 (29/121)	20.3 (14/69)	0.72
OPR/LBR (%, n)	26.1 (18/69)	20.7 (25/121)	15.9 (11/69)	0.34
MPR (%, n)	16.7 (3/18)	17.2 (5/29)	21.4 (3/14)	0.93
CLR (%, n)	0.0 (0/18)	13.8 (4/29)	21.4 (3/14)	0.15

CONCLUSIONS: There was no significant difference in IVF cycle or pregnancy outcomes between GH protocol groups. Low dose protocols may be preferred to reduce the additional cost of adjunct GH.

CYTOMEGALOVIRUS IMMUNOPOSITIVITY DOES NOT CORRELATE WITH ABNORMAL SPERM PARAMETERS WITHIN A LARGE SPERM DONOR POPULATION.

Ariella Farzan Nikou, BS,[1] Joanne Won, BS,[2] Stephanie Pan, MS,[1] Hyewon Choi, MS,[1] Joseph A. Lee, BA,[2] Christopher Antonelli, BS,[3] Natan Bar-Chama, MD,[2] Jaime M. Shamonki, MD,[4] Alan B. Copperman, MD.[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY; [3]Generate Life Sciences, Los Angeles, CA; [4]Generate Life Sciences, Los Angeles, NY.

OBJECTIVE: Studies have shown that cytomegalovirus (CMV) can be detected in sperm samples [1-3]. CMV infected cultures of human testes have been shown to have decreased number of precursor sperm cells when compared to uninfected cultures [4]. However, there is conflicting evidence about the association between CMV infection, sperm quality, and reproductive potential [2, 5-7]. This study aimed to assess the association between CMV immunopositivity in sperm donors and sperm quality.

DESIGN: Retrospective study.

MATERIALS AND METHODS: The study included male sperm donors between November 2007 and December 2017. Group A included donors who tested CMV IgG+ within a month of first donation. Group B included donors who tested IgG- for the duration of all donations. The following sperm parameters were collected at donation: BMI, age, total sperm count (M), total motile sperm (M), average motility (% of total sperm, motile), and average concentration (M/mL). The association between IgG status and donor parameters was calculated with Student's t-tests or Wilcoxon rank-sum tests. The association between IgG status and sperm quality was evaluated using a general estimate equation (GEE) model to account for the repeated donations per donor.

RESULTS: A total of 1310 sperm donors participated in the study. CMV IgG+ donors (n=394) were compared to CMV IgG- donors (n=916). Demographic factors and sperm parameters at the initial visit are shown (Table 1). CMV IgG status did not affect sperm parameters when accounting for all of a donor's donations: total sperm count (β=-8.89, p=0.16), total motile sperm (β=-5.79, p=0.25), average motility (β=0.47, p=0.36), and average concentration (β=2.68, p=0.18). Controlling for age and BMI, the effect sizes trended upwards but did not reach statistical significance: total sperm count (β=-10.02, p=0.12), total motile sperm (β=-6.44, p=0.21), average motility (β=0.55, p=0.28), and average concentration (β=2.92, p=0.15).

CONCLUSIONS: This study of sperm donors demonstrated that immunological evidence of prior CMV infection does not significantly correlate with sub-optimal sperm parameters. Reproductive medicine practitioners can be reassured that CMV IgG+ status does not significantly impact sperm parameters when compared to CMV IgG- status.

MOTIVATIONS OF SPERM DONORS.

Ariella Farzan Nikou, BS,[1] Joanne Won, BS,[2] Hyewon Choi, MS,[1] Stephanie Pan, MS,[1] Joseph A. Lee, BA,[2] Christopher Antonelli, BS,[3] Natan Bar-Chama, MD,[2] Jaime M. Shamonki, MD,[4] Alan B. Copperman, MD.[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY; [3]Generate Life Sciences, Los Angeles, CA; [4]Generate Life Sciences, Los Angeles, NY.

Table 1. Donor Parameters at Initial Visit

Donor Parameters	Total	CMV lgG+	CMV lgG-	p-value
Age	26 (23,29)	26 (24,30)	25 (23, 29)	0.002
BMI	24.3 (22.5, 26.1)	24.3 (22.4,26.4)	24.3 (22.5, 26)	0.35
Total Sperm Count (M)	245 (171, 340.2)	232.6 (156, 335.8)	250.4 (177.4, 346.8)	0.02
Total Motile Sperm (M)	183.7 (124.3, 253.4)	173.2 (112.9, 247.5)	186.5 (129, 259.9)	0.02
Average Motility (%)	75 (69, 82)	76 (69, 81)	75 (69, 82)	0.92
Average Concentration (M/mL)	80 (62, 103)	77 (61, 99)	80 (62.5, 104)	0.18

OBJECTIVE: The limited knowledge base on sperm donors' motivations includes mostly international studies with small sample sizes [1-6]. In the decades since its inception, sperm donation has shifted from an anonymous physician-led process for infertile heterosexual couples to a holistic process led by the prospective parents, including single mothers by choice and the LGBTQ community, who often request a better understanding of a sperm donor's motivations [7]. The objective of this study was to investigate the association between sperm donor motivations and demographic factors such as age, decade of birth, and highest level of education.

DESIGN: Multi-center, retrospective cohort study.

MATERIALS AND METHODS: The motivations of U.S. sperm donors aged 18-39, from 2008-2010 and 2016-2018, were coded according to the following four categories: financial, desire to pass on genes, general altruism, and personal altruism (i.e. a personal experience inspired the donor). Primary, secondary, and tertiary motivations were included when multiple reasons were cited. Donors were excluded if their motivation did not fit within one of the four categories. Data on age, decade of birth (1970's, 1980's, and 1990's), and highest level of education (Undergraduate/Associate's, Bachelor's, Master's, Doctorate degrees) at the time of donation was also collected. Continuous and categorical measures were compared using a Kruskal-Wallis test and Fisher's exact test, respectively.

RESULTS: A total of 586 sperm donors aged 26.90 $\pm$ 4.54 participated in this study. The most commonly cited motivations were financial and general altruism. 65.02% (n= 381) of donors cited financial as their primary, secondary or tertiary reason, while 27.65% (n=162) of donors selected general or personal altruism as their primary reason with no other reason. Age was significantly associated with primary motivation with a median age of 26 for financial, general and personal altruism, while 30 was the median age for the desire to pass on genes (p=0.0002). Financial and general altruism were the most cited motivations for every decade of birth; general altruism decreased in frequency and financial increased in frequency with every decade (p=0.0026). The highest level of education was not significantly associated with the primary motivation among all ages (p=0.017).

CONCLUSIONS: This robust study of sperm donors demonstrated that financial and general altruism were the most commonly cited motivations, though financial was a prominent motivating force for approximately 2/3rd of donors (65.02%), whereas altruism was the only motivating force for less than 1/3rd (27.65%) of donors. We also noted a generational gap, wherein older generations appeared more altruistic as compared to younger generations. Additionally, donors who expressed a primary desire to pass on genes were significantly older (30.00 (26.00,34.00); p=0.0002). In conclusion, our study is part of ongoing longitudinal research into the sociology surrounding sperm donation — research that is crucial as modern families become more common and donor-conceived offspring come of age.

DOES SHIPPING IMPACT CRYO-SURVIVAL OR USABLE EMBRYO RATES DERIVED FROM VITRIFIED DONOR OOCYTES?. Jenna Friedenthal, MD,[1] Joseph A. Lee, BA,[2] Wayne Caswell, MS,[3] Melissa O. Stratton, BA,[4] Christine Briton-Jones, PhD, HCLD,[2] Alan B. Copperman, MD.[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY; [3]Donor Egg Bank, USA, Rockville, MD; [4]Donor Egg Bank, USA, Rockville, NY.

OBJECTIVE: Over the last decade, there have been significant advancements in oocyte cryopreservation (OC) and increased utilization of vitrified oocytes (VOs) within modern assisted reproduction technology (ART). While donated oocytes (DOs) have for decades been utilized to treat patients who cannot produce viable oocytes, access was limited by local availability. However, with the expansion of DO banks nationwide resulting from improvement in OC technology, women may now select DOs from across the country. The advantages of a nationwide DO bank rely upon shipping VOs between centers. Concern has been raised regarding the potential impact of temperature fluctuations in the process of shipping on VOs [1], with evidence suggesting that temperature fluctuations may be detrimental to the spindle complex and oocyte integrity[2,3]. The objective of this study was to evaluate the impact of shipment on the clinical potential of donated VOs.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study included VOs from a DO bank network from 2012-2019. Following oocyte retrieval, oocytes were vitrified and allotted into cohorts of 6 or 7 eggs (oocyte lots). VOs were categorized as Internal or External. Internal: warmed and utilized in the same laboratory. External: transported to a second location where warming, fertilization, embryo culture, embryo transfer and embryo vitrification occurred. Internal oocytes were stored in standard liquid nitrogen storage dewars at -196 ^{o}C until warming; external oocytes underwent 1-2 days of shipping, held in vapor-based dry shippers and monitored to alert if temperatures rose above -150^{o}C until they were transferred into standard liquid nitrogen dewars at recipient laboratory. Baseline demographics were obtained:donor age, number of oocytes retrieved, and number of metaphase II (MII) oocytes retrieved. The primary outcome was oocyte thaw survival rate (OTSR). Secondary outcomes were fertilization rate (FR), total number of usable embryos (UEs), and usable embryo rate (UER). UEs were defined as embryos available for transfer or cryopreservation based on developmental stage and a given fertility center's standard operating procedure. Data were analyzed using t-tests and Wilcoxon signed-rank test, with P<0.05 considered significant.

RESULTS: 248 internal oocyte lots and 5,202 external lots were thawed during the study time and were included in analysis. No significant differences were observed in donor age, number of oocytes retrieved, number of MII oocytes retrieved, or maturation rate. There was no difference in OTSR between Internal and External cohorts (91.41% vs 89.72%, P=0.12). There were also no differences in FR, the total number of UE, or UER.

CONCLUSIONS: Shipping of donated VOs does not adversely affect oocyte cryo-survival. Additionally, we found that shipping had no impact on either FR or the number of UEs. Our results indicate that vapor-based dry shippers maintain VOs in a comparable state to liquid nitrogen for the period they are in transit. Future studies should aim to investigate the impact of transport on precise molecular markers for oocyte integrity.

OCCURRENCE OF SECONDARY FINDINGS DURING UNIVERSAL CARRIER SCREENING FOR EGG DONOR CANDIDATES. Amber Gamma, MS, CGC, Mary Rausch, MD, Jeanette Tomasino, Ph.D., Marie Marella, RN, BSN, Marianne Farkas, RN, BSN. Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Describe the frequency of secondary findings, specifically risks to autosomal recessive disease carriers, during genetic screening of candidate egg donors at one academic fertility clinic.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: All fresh egg donor candidates or repeat fresh egg donors presenting for donation between August 1st, 2018 and February 1st, 2020 underwent genetic screening, including three-generation pedigree, hemoglobinopathy evaluation, karyotype and universal carrier screening. Universal carrier screening included >100 conditions and was performed at one of two commercial laboratories. Results were evaluated

Table 1. Secondary findings identified in potential fresh egg donors undergoing genetic screening

Gene	Associated Disorder	Associated Carrier Risks	# of Identified Donors
ATM	Ataxia-telangiectasia/hereditary susceptibility to breast cancer	Increased risk for female breast cancer. Possible increased risk for pancreatic, prostate and ovarian cancers.	1
LDLR	Familial hypercholesterolemia	Significantly increased cholesterol levels and risk for heart attack prior to 50	2

by the genetic counselor and communicated to the candidate by phone with follow-up documentation sent by mail. Those candidates carrying X-linked conditions or with secondary findings were excluded from donation. Appropriate medical follow-up was recommended as necessary.

RESULTS: A total of 44 fresh egg donor candidates began or completed genetic screening during the study time period. Three candidates were excluded based on family history and one candidate did not complete blood draw for genetic testing. Forty candidate donors completed universal carrier screening. 26 of 40 candidate donors (65%) were a carrier of at least one condition. 4 of 40 (10%) were excluded based on their universal carrier screening with 3 of these individuals (11.5%) having secondary findings that included increased risk for cancer(s) and increased risk for cardiovascular disease (see Table 1). Two of these three individuals reported no family history of associated disease symptoms.

CONCLUSIONS: When performing universal carrier screening for fresh egg donor candidates, secondary findings are not uncommon and may not be readily apparent from family history information. These results must be taken into account when evaluating donor screening and choosing to accept a donor. Candidate donors must also be counseled about the potential health information that could be discovered on universal carrier screening and should be informed of appropriate follow-up.

P-404 4:30 PM Sunday, October 18, 2020

EXAMINING PREDICTORS OF PREGNANCY-RELATED COMPLICATIONS AMONG GESTATIONAL CARRIERS. Erika L. Fuchs, PhD, MPH, Abbey B. Berenson, MD, PhD. University of Texas Medical Branch, Galveston, TX.

OBJECTIVE: The purpose of this study was to examine associations between demographic characteristics and pregnancy-related complications in gestational carriers.

DESIGN: A cross-sectional online survey was conducted.

MATERIALS AND METHODS: From November 2015-February 2016, women ≥18 years living in the United States who delivered at least one baby in 2009 or later as a gestational carrier (n = 204) completed an online survey. Potential predictors of labor, delivery, and postpartum complications were examined using chi-squared tests, Fisher's exact tests, t-tests, and multivariable adjusted logistic regression. Logistic regression models were adjusted for age at delivery, race, Hispanic ethnicity, relationship status, household income, type of health insurance, and whether a third-party reproduction agency was used throughout the process. Statistical analyses were conducted using Stata SE Version 16.1 with α=0.05.

RESULTS: Pregnancy-related complications were reported by 53% of participants. Over one third (36.8%) of participants delivered by cesarean section. The most common complications were preterm labor (14.7%), preterm premature rupture of membranes (9.3%), postpartum hemorrhage (7.8%), high blood pressure (7.4%), and gestational diabetes (6.4%). In bivariate analysis, there were few associations between health outcomes and demographic characteristics. In multivariable analysis, increased age was associated with self-reported gestational diabetes (odds ratio 1.14, 95% confidence interval 1.01-1.28).

CONCLUSIONS: Demographic characteristics were infrequently associated with pregnancy-related complications among gestational carriers.

SUPPORT: Dr. Fuchs is a scholar supported by a research career development award (K12HD052023: Building Interdisciplinary Research Careers in Women's Health Program –BIRCWH; Principal Investigator: Berenson) from the Office of the Director at the National Institutes of Health.

P-405 4:30 PM Sunday, October 18, 2020

CLINICAL FACTORS ASSOCIATED WITH EGG DONORS UNDERGOING ADDITIONAL OOCYTE DONATIONS AFTER THEIR FIRST DONOR CYCLE. Diane Tober, PhD,[1] Kevin S. Richter, PhD,[2] Shannon Kokjohn, MSc,[3] Natalia Villegas, BS,[4] Katarina Cook, BS,[4] Raquel Cool, BA,[5] Kezia Mostak, MS,[4] Cristina Garibaldi, MS,[4] Cris Zubizarreta, BA,[4] Said Daneshmand, MD.[3] [1]UCSF Institute for Health and Aging, San Francisco, CA; [2]Fertility Science Consulting, Silver Spring, MD; [3]San Diego Fertility Center, San Diego, CA; [4]University of California, San Francisco, San Francisco, CA; [5]We Are Egg Donors, Santa Cruz, CA.

OBJECTIVE: To examine how experiences of adverse effects related to oocyte donation affect egg donors' decisions to donate again.

DESIGN: Survey.

MATERIALS AND METHODS: Oocyte donors (n=318) in the US were surveyed regarding adverse clinical events associated with their first donation, and the subsequent probability that they undergo additional donations after their first. Donors providing eggs to a friend or relative were excluded.

RESULTS: Patient-reported severity of ovarian hyperstimulation syndrome (OHSS) experienced during egg donors' first oocyte donation cycle was significantly associated with the frequency of donors opting to undergo additional donor cycles after their first. The proportion of egg donors choosing to undergo additional donations declined with increasing severity of OHSS in their first donor cycle; 89.1% for no OHSS (n=64), 83.8% for mild OHSS (n=142), 73.2% for moderated OHSS (n=82), and 66.7% for severe OHSS (n=30) (p=0.0015, Kendall's test for significant association). Donors reporting migraine/headaches, missed work due to complications associated with their donation, insufficient anesthesia during oocyte retrieval, or surgical complications during their first donation were all significantly less likely to undergo a second donation (Table).

	Proportion of patients undergoing repeat cycle(s) according to presence or absence of adverse events during first donation		
Adverse Event	Yes	no	*P*-value (C^2)
Migraine/headaches (n=51)	62.7%	83.9%	0.00048
Missed work due to complications (n=41)	58.5%	83.8%	0.00014
Insufficient anesthesia (n=12)	50.0%	81.7%	0.0065
Surgical complications (n=14)	42.9%	82.2%	0.00028

CONCLUSIONS: Experiences of adverse effects related to oocyte donation reduce the likelihood that an egg donor will donate again. The lowest frequency of second donations was observed among egg donors who experienced surgical complications or who reported insufficient anesthesia during the oocyte retrieval, both of which were associated with a repeat donation rate of 50% or less.

SUPPORT: This study was supported by the University of California, San Francisco, Institute for Health and Aging; UCSF Individual Investigator Grant (#7501159); and funding from the National Science Foundation (#1828783).

P-406 4:30 PM Sunday, October 18, 2020

PERINATAL OUTCOMES IN RECIPROCAL VS. ANONYMOUS DONOR OOCYTE IVF CYCLES. Devora Aharon, MD,[1] Lucky Sekhon, MD,[2] Joseph A. Lee, BA,[2] Jeffrey Klein, MD,[2] Matthew A. Lederman, MD,[2] Beth McAvey, MD,[1] Alan B. Copperman, MD.[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Pregnancies in donor egg recipients are associated with a higher risk of adverse perinatal outcomes, potentially due to immunologic reactions to a foreign oocyte resulting in impaired placentation.[1-3] Reciprocal IVF in same-sex female couples involves the use of a patient's oocyte to create an embryo that is transferred to the their partner to conceive a pregnancy.[4] In reciprocal IVF (Co-IVF), the oocyte comes from a familiar source to which the recipient may have developed a level of immune tolerance. Whether Co-IVF might mitigate perinatal risks seen with donor oocyte IVF has never been studied. The objective of this study was to compare the perinatal outcomes of pregnancies conceived from Co-IVF in same-sex female couples and anonymous donor oocyte IVF.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Oocyte recipient transfer cycles from January 2011 to June 2019 were included in the study. Co-IVF recipient cycles were compared to anonymous donor (AD) oocyte recipient cycles. Demographic and cycle characteristics including recipient age, oocyte age, parity, endometrial thickness, fresh vs. frozen embryos, fresh vs. frozen oocytes, euploid transfer, and high quality embryo transfer were compared between the groups. Primary outcomes were gestational age at delivery, preterm birth, birth weight, low birth weight (<2500g), and macrosomia (>4000g). Comparative statistics and adjusted logistic and linear regression were used for analysis.

RESULTS: A total of 2620 oocyte recipient cycles were identified and included in the study, of which 108 were reciprocal IVF cycles and 2512 were anonymous donor cycles. Recipient age was significantly lower among Co-IVF compared to AD recipients, while oocyte age was significantly higher. Co-IVF recipients had significantly lower parity and thicker endometrial lining at transfer, and were less likely to use frozen oocytes and to transfer a high-quality embryo. The groups had similar rates of frozen embryo and euploid embryo transfers. Live birth rate was similar between the groups. Gestational age at delivery was significantly higher among Co-IVF recipients compared to AD recipients. No significant differences were seen in preterm birth rate, birth weight, low birth weight, or macrosomia. On multivariate logistic regression, no significant differences were seen in gestational age at delivery (β=0.217, p=0.64), preterm birth (OR 0.84, 95% CI 0.15-4.74, p=0.84), birth weight (β=120.84, p=0.72), low birth weight (OR 0.95, 95% CI 0.16-5.59, p=0.86), or macrosomia (OR 1.18, 95% CI 0.95 0.19-7.41, p=0.86) when controlling for confounders.

CONCLUSIONS: Our study demonstrates similar perinatal outcomes among Co-IVF and AD oocyte recipients. This data suggests that the non-autologous oocyte induces a similar immunologic reaction within the recipient even when derived from a familiar source. Further study should investigate the mechanism behind adverse perinatal outcomes in donor oocyte recipients. Identification of markers associated with immunological acceptance and compatibility may serve as the basis for optimizing anonymous donor selection.

P-407 4:30 PM Sunday, October 18, 2020

ATTITUDES OF OOCYTE DONORS AND NON-DONORS TOWARDS THEIR GENETIC MATERIAL. Julia Taylor Woodward, PhD,[1] Katherine E. MacDuffie, PhD.[2] [1]Duke University Health System, Durham, NC; [2]University of Washington, Seattle, WA.

OBJECTIVE: The decision to donate gametes is distinct from other donations such as blood or organs given the permanent genetic link created between the donor and any resulting offspring. As the demand for donated oocytes continues to outpace the available supply, efforts to recruit and retain donors would benefit from a more precise understanding of how women conceptualize the donation of their genetic material. The goal of the current study was to explore sociodemographic and psychological factors related to women's willingness and intention to donate oocytes.

DESIGN: A quantitative survey was developed and administered online to a group of women who applied to be oocyte donors ($n = 104$) and a demographically-matched comparison sample ($n = 104$).

MATERIALS AND METHODS: A novel 8-item measure—the Beliefs About Oocytes Scale—was developed for the purpose of measuring specific attitudes towards oocytes. Exploratory factor analysis revealed that the scale generated two distinct, anticorrelated factors: 1) conceptualizing eggs as future offspring, or 2) conceptualizing eggs as an ample or generous biological resource to be shared with others. Existing validated scales were included to measure other factors hypothesized to relate to intention to donate including religiosity, attitudes towards parenthood, belief in the importance of genetic link towards children, knowledge of family of origin, adult attachment style, self-esteem, and altruism. Stepwise logistic regression was used to predict intention to donate.

RESULTS: Intention to donate oocytes was most strongly predicted by the belief that oocytes are a generous resource. Prospective oocyte donors were also characterized by higher altruism scores, more secure attachment style, lower self-esteem, and emphasis on the importance of family and parenthood, regardless of the genetic link between parent and child.

CONCLUSIONS: These data suggest women who choose to donate oocytes value childrearing and family, regardless of genetic relatedness, and do not view their eggs as future offspring. These findings have implications for the recruitment, retention, and counseling of potential egg donors, and may be usefully extended to explore donation of gametes and embryos in other contexts and cultures.

UTILIZING A STRUCTURAL SUMMARY APPROACH IN THE PSYCHOLOGICAL INTERPRETATION OF PAI PROFILES OF EGG DONOR AND GESTATIONAL CARRIER CANDIDATES. Mary P. Riddle, Ph.D.,[1] John E. Kurtz, Ph.D.[2] [1]Penn State University, Park, PA; [2]Villanova University, Villanova, PA.

OBJECTIVE: The structural summary approach is a method of data integration that aids clinicians in psychological profile interpretation of the Personality Assessment Inventory (PAI). Study objectives were to conduct both a positive distortion analysis and a Self/Other Issue Cluster interpretation for PAI profiles of egg donor (ED) and gestational carrier (GC) candidates to determine the clinical utility of using a structural summary approach for assessment purposes.

DESIGN: This study is a combined analysis of retrospective chart data and prospectively collected test data.

MATERIALS AND METHODS: 80 de-identified PAI test protocols of gestational carrier (n = 58) and egg donor (n = 22) candidates were examined. Mean scale scores on clinical scales and validity indicators were calculated for each group and Self/Other Issue Clusters were explored. Positive distortion configural analyses were calculated and compared between groups using SPSS statistical software.

RESULTS: Self/Other Cluster analysis shows high levels of self-efficacy, average levels of self-esteem, and high stability in self-concept for both groups. Interpersonally, EDs show a warm, dominating style compared to a more warm, submissive style among GCs. Consistent with previous research, EDs had significantly higher scores than GCs on mean scale scores of Dominance ($p < .05$), Grandiosity ($p < .05$), Egocentricity ($p < .05$), and Stimulus Seeking ($p < .05$). EDs also scored significantly higher than GCs on

the subscale score of PAR-R (Resentment) ($p < .05$) which has not been previous reported. Most significantly, the Defensiveness Index (DEF) is significantly higher ($p < .05$) among EDs although additional validity scale scores (PIM; CDF) did not differ significantly. This, in turn, appears to have influenced noticeable differences in the positive distortion configural analysis with EDs having higher rates of effortful (conscious) distortion (64%) than GCs (53%).

CONCLUSIONS: The PAI is a self-report personality inventory commonly used in psychological screening of ED/GC candidates and no research has examined utilizing a structural summary analysis of either group. Interpersonally, both groups showed high levels of self-efficacy and stability in self-concept. GCs appear to have a more warm/submissive interpersonal style associated with higher levels of dependency and emphasis on maintaining attachments. This study showed significant differences in mean scale scores (Dominance, Grandiosity, Stimulus Seeking, Egocentricity, and Resentment) which contribute to significantly higher Defensiveness Index scores among EDs. Positive distortion analyses show a higher percentage of EDs engaging in "effortful" positive distortion (64%) as opposed to GCs (53%). This study shows that there are likely differences in interpersonal styles between groups that impact tendencies towards more effortful attempts by EDs to present favorably on self-report. A structural summary approach to PAI data interpretation may have clinical utility for an in-depth consideration of self-concept/self-presentation of EDs/GCs presenting for psychological evaluation.

RACIAL AND ETHNIC DISPARITIES AMONG DONOR OOCYTE BANKS IN THE UNITED STATES. Shelun Tsai, MD,[1] Esther H. Chung, MD,[1] Tracy Truong, MS,[2] Jeremy M. Weber, MS,[2] Amanda S. Farrell, BS,[1] Jenny Wu, BS,[1] Onyinye Ohamadike, BA,[1] Jennifer L. Eaton, MD, MSCI.[1] [1]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC; [2]Department of Biostatistics & Bioinformatics, Duke University Medical Center, Durham, NC.

OBJECTIVE: Donor oocyte banks offer databases of profiles for people seeking third party reproduction. Minorities face challenges in finding donors concordant with their identified race or ethnicity. Our objective was to determine whether the racial and ethnic distribution of oocyte donors contributing to United States (US) oocyte banks differs from the demographics of the US population and those of donor oocyte recipients.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: "Donor egg bank" and "donor oocyte" were used as Google search terms to identify US donor oocyte banks. Publicly available demographic data on donors was entered into a REDCap database. Only cryopreserved donor oocyte profiles were included. The proportions of women in each race/ethnicity category were compared between oocyte donors, the US population of women based on the 2018 census, and US women undergoing IVF with cryopreserved donor oocytes from 2012-2015 as reported to the Society for Assisted Reproductive Technologies Clinical Outcomes Reporting System (SART CORS). Chi-square or Fisher's exact tests were used for analyses.

RESULTS: 12 donor oocyte banks were identified, encompassing 1,574 donors (Table). Compared to the population of the US and cryopreserved donor oocyte recipients, a significantly higher proportion of donors identified as Hispanic (24.1% vs. 17.9% vs. 8.9%, $P<.001$) or as two or more races (16.1% vs. 2.2% vs. 0.5%, $P<.001$). In contrast, Black donors were significantly underrepresented compared to the US population (8.9% vs. 12.9%, $P<.001$) and recipients of cryopreserved donor oocytes (8.9% vs. 10.3%, $P=.047$). While Asian donors were overrepresented when compared to the US population (7.7% vs. 5.9%, $P=.003$), they were underrepresented when compared to the donor oocyte recipients (7.7% vs. 10.6%, $P=.001$).

CONCLUSIONS: The race/ethnicity distribution of oocyte donors differs significantly from the demographics of the US population and recipients of cryopreserved donor oocytes. These data suggest a need for targeted recruitment of Black and Asian oocyte donors.

P-410 4:30 PM Sunday, October 18, 2020

FRESH EMBRYO TRANSFER IMPROVES LIVE BIRTH RATE OVER FROZEN EMBRYO TRANSFER IN FRESHLY RETRIEVED DONOR EGG CYCLES. Iris Insogna, MD, MBE, Andrea Lanes, PhD, Malinda S. Lee, MD, MBA, Elizabeth S. Ginsburg, MD, Janis H. Fox, MD. Brigham and Women's Hospital, Boston, MA.

OBJECTIVE: To test the hypothesis that in cycles using embryos derived from freshly retrieved donor eggs, a fresh embryo transfer (fresh ET) is more likely to result in a clinical pregnancy and live birth compared to a cryopreserved-thawed embryo transfer (CET).

DESIGN: Retrospective cohort study using national data from the Society for Assisted Reproductive Technology (SART).

MATERIALS AND METHODS: Donor egg cycles in the SART database from 2014-2017 were collected. Only cycles using freshly retrieved eggs from anonymous donors were included. Cycles in which eggs were previously frozen, a known donor was used, or recipient age at time of transfer was over 55 years were excluded. All included cycles had at least one embryo available to transfer at either the cleavage or blastocyst stage. Using log binomial regression, relative risks and 95% confidence intervals were calculated for clinical pregnancy rate (CPR), live birth rate (LBR) and miscarriage rate. Crude and adjusted analyses were performed, controlling for donor age.

RESULTS: Of a total of 51,942 donor egg cycles, 15,308 (29.5%) were fresh ET cycles and 36,634 (70.5%) were CET cycles. Both groups were similar in terms of age, gravidity, parity, BMI, infertility diagnosis, and race/ethnicity. A majority of recipients had blastocyst(s) transferred (92.4% of fresh ETs and 96.5% of CETS), with a similar mean number of embryos transferred: 1.52 ± 0.52 in the fresh and 1.39 ± 0.53 in the CET groups.

Both CPR and LBR were lower after CET compared to fresh ET (CPR 54.2% vs 66.7%, aRR 0.78 [95% CI 0.76-0.79]; LBR 44.0% vs 56.6%, aRR 0.74 [95% CI 0.72-0.75]), controlled for donor age. Miscarriage rate was similar for both (9.4% following CET vs 9.3% following fresh ET, aRR 1.02 [95% CI 0.96-1.10]).

CPR and LBR following transfer of fresh non-PGT-A embryos were statistically significantly higher than following transfer of PGT-A embryos (either fresh or frozen) with no difference in miscarriage rates (Table).

Race and ethnicity distribution

	Oocyte Donors	US Population		Donor Oocyte Recipients	
Race/Ethnicity	N=1,574	N=166,038,755	P[a]	N=4,650	P[a]
White	678 (43.1%)	100,127,799 (60.3%)	<.001	3,234 (69.6%)	<.001
Black/African American	140 (8.9%)	21,342,200 (12.9%)	<.001	479 (10.3%)	.047
American Indian/Alaska Native	1 (0.1%)	1,227,668 (0.7%)	<.001	3 (0.1%)	1.000
Asian	121 (7.7%)	9,809,751 (5.9%)	.003	493 (10.6%)	.001
Hawaiian/Pacific Islander	1 (0.1%)	291,352 (0.2%)	.537	8 (0.2%)	.464
Two or more races	253 (16.1%)	3,602,424 (2.2%)	<.001	21 (0.5%)	<.001
Hispanic	380 (24.1%)	29,637,561 (17.9%)	<.001	412 (8.9%)	<.001

[a] Comparing to the oocyte donor group using Chi-square or Fisher's exact tests

	Fresh non-PGT-A N = 15044	Fresh and frozen PGT-A N = 2327	Frozen PGT-A N = 2063	RR (95% CI)	aRR (95% CI)*	RR (95% CI) ‡	aRR (95% CI) * ‡
Clinical pregnancy	10026 (66.6%)	1420 (61.0%)	1237 (60.0%)	0.92 (0.88-0.95)	0.89 (0.85-0.94)	0.90 (0.87-0.93)	0.84 (0.79-0.90)
Live birth	8505 (56.5%)	1191 (51.2%)	1031 (50.0%)	0.91 (0.87-0.94)	0.89 (0.83-0.95)	0.88 (0.84-0.93)	0.82 (0.75-0.89)
Miscarriage	1396 (9.3%)	203 (8.7%)	183 (8.9%)	0.94 (0.82-1.08)	0.94 (0.76-1.17)	0.96 (0.83-1.11)	1.01 (0.80-1.29)

* adjusted for donor age. ‡ relative risk for only frozen PGT-A compared to fresh non-PGT-A

CONCLUSIONS: Both CPR and LBR following the use of fresh donor eggs are over 10% higher after a fresh rather than frozen embryo transfer. This study suggests that recipients should be encouraged to undergo fresh donor egg embryo transfer without PGT-A.

SUPPORT: None.

THE EFFECT OF DONOR AND RECIPIENT RACE ON OUTCOMES OF ASSISTED REPRODUCTION USING DATA FROM A VITRIFIED DONOR OOCYTE BANK.

Yijun Liu, MPH,[1] Heather S. Hipp, MD,[2] Zsolt Peter Nagy, MD, PhD,[3] Sarah M. Capelouto, MD,[4] Daniel B. Shapiro, MD,[3] Jessica B. Spencer, MD, MSc,[5] Audrey J. Gaskins, ScD.[1] [1]Emory University, Rollins School of Public Health, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Reproductive Biology Associates, Atlanta, GA; [4]University of Texas Southwestern Medical Center, Dallas, TX; [5]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA.

OBJECTIVE: A growing literature suggest that minority races, particularly Black women, have a lower probability of live birth and a higher risk of perinatal complications after autologous assisted reproductive technology (ART); however, questions still remain as to whether racial disparities are associated with differences in oocyte/embryo quality, an impaired uterine environment, or a combination of the two. To investigate this question further, we evaluated how oocyte donor and recipient race is associated with ART outcomes using data from a large, racially diverse vitrified donor oocyte bank.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Our study included 327 oocyte donors and 899 oocyte recipients who underwent a total of 1601 embryo transfer cycles between 2008 and 2015 at a private fertility clinic in Georgia. All embryo transfer cycles included in this study used oocytes that were cryopreserved via vitrification for an oocyte bank and later thawed for recipients' use. Self-reported race of the donor and recipient and clinical endpoints were abstracted from medical records. We used multivariable cluster weighted generalized estimating equations to evaluate the associations between donor and recipient race and probability of live birth adjusted for donor age and BMI, recipient age and BMI, tubal and uterine factor infertility, and year of oocyte retrieval. Secondary outcomes included the percentage of oocytes that survived warm, fertilized, and developed into usable embryos.

RESULTS: The overall racial profile of our donors and recipients were similar: 73% White, 13% Black, 4% Hispanic, 8% Asian, and 2% Other. There was a high concordance of race between oocyte donors and recipients (96% for White, 73% for Black, 62% for Asian, and 32% for Hispanic recipients). The percentage of warmed oocytes that developed into usable embryos was significantly higher for Black (56.9%) and Hispanic (64.5%) donors in comparison with White donors (40.9%). Women who received oocytes from Hispanic donors had significantly higher probability of live birth (adjusted relative risk (aRR) 1.20, 95% CI 1.05, 1.36) compared with women who received oocytes from White donors. Among Hispanic recipients, however, there was no significant difference in probability of positive pregnancy test or live birth compared with White recipients. Embryo transfer cycles with oocytes from Black donors (aRR 0.86, 95% CI 0.72, 1.03) and Black recipients (aRR 0.84, 95% CI 0.71, 0.99) had a lower probability of live birth compared to White donors and recipients, respectively. There was no significant difference in the probability of live birth among Asian and Other race female donors and recipients compared with White donors and recipients.

CONCLUSIONS: Our study corroborates and extends previous literature showing that Black women have less favorable ART outcomes even when using oocytes from young healthy oocyte donors. In contrast, women who utilized Hispanic oocytes had better ART outcomes regardless of recipient race.

SUPPORT: Dr. Gaskins is supported by a career development grant, R00ES026648, from the National Institute of Environmental Health Sciences (NIEHS). REDCap support was provided by UL1 TR000424 at Emory University.

P-412 4:30 PM Sunday, October 18, 2020

OUTCOMES OF FROZEN OOCYTE DONOR IN VITRO FERTILIZATION (IVF) CYCLES USING FRESH VERSUS FROZEN SPERM.

Colleen Miller, M.D.,[1] Chandra Shenoy, M.D.,[1] Yulian Zhao, Ph.D.,[2] Stephanie Duong, M.S.,[1] Matthew Hathcock, M.S.[1] [1]Mayo Clinic, Rochester, MN; [2]Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN.

OBJECTIVE: To compare outcomes of frozen oocyte donor IVF cycles with intracytoplasmic sperm injection (ICSI) when fresh versus frozen sperm is used for insemination.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We identified patients who underwent their first IVF with ICSI cycle using frozen donor oocytes between 2013 and 2019 at Mayo Clinic Rochester. Oocytes were selected from one of two commercial egg banks and either frozen or fresh sperm was used for ICSI. The primary outcome was live birth rate (LBR). Secondary outcomes included fertilization rate (FR), blastocyst development rate (BR), and clinical pregnancy rate (CPR). Patient characteristics, sperm parameters, and outcomes were compared using chi-square tests and two-sample t-tests, as appropriate.

RESULTS: A total of 52 patients underwent an embryo transfer following a frozen donor oocyte IVF with ICSI cycle. Seven patients were excluded due to a semen total motile sperm (TMS) count of less than 20 million. Of the included 45 patients, the mean age was 40.5 (SD 6.1). Fresh sperm was used by 26 patients and frozen sperm was used by 19 patients. There were no differences noted between the groups in regards to infertility diagnosis, use of specific egg bank, mean patient age (41.5 vs. 39.7 years), mean partner age at sample collection (39.1 vs. 39.8 years), median semen TMS count (92.1 vs. 101.1 million), or average sperm morphology (9.3% vs. 7.3%). In regards to outcomes, there were no differences observed between frozen versus fresh sperm on the mean FR, mean BR, or CPR (Table 1). Additionally, the difference in the LBR was not statistically significant (52.6% vs. 61.5%, p = 0.55).

CONCLUSIONS: Although other studies have examined the effects of various male factors on IVF outcomes, this is the first study to examine the impact of using a fresh versus frozen sperm sample in frozen donor oocyte IVF with ICSI cycles. Our study did not find statistically significant differences when fresh versus frozen sperm were used. These results may reassure providers that using a frozen sample will not negatively impact cycle success. However, further study may be warranted with a larger cohort of patients to adjust for additional covariates when comparing outcomes.

Table 1. Comparison of Outcomes According to Type of Sperm Used for Insemination

	Type of sperm			
Outcome measure	Frozen (N=19)	Fresh (N=26)	Total (N=45)	$P^{\dagger}$
Primary Outcome				
LBR *(n)*	52.6% (10)	61.5% (16)	57.8% (26)	0.55
Secondary Outcomes				
FR *Mean (SD)*	77.5% (21.7)	82.2% (13.2)	80.2% (17.2)	0.37
BR *Mean (SD)*	55.3% (35.8)	49.1% (29.1)	51.7% (31.9)	0.52
CPR *(n)*	57.9% (11)	65.4% (17)	62.2% (28)	0.61

†Comparisons between groups were evaluated using the chi-square test for CPR and LBR; the two-sample t-test was used for FR and BR.

P-413 4:30 PM Sunday, October 18, 2020

WHAT PATIENT FACTORS AFFECT SUCCESS IN WOMEN UTILIZING FROZEN DONOR EGGS? A SART DATABASE ANALYSIS.

Rhea Chattopadhyay, MD,[1] Hasina Momotaz, MS,[2] James H. Liu, M.D.,[1] Rebecca Flyckt, MD,[1] Rachel S. Weinerman, MD.[1] [1]University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH; [2]Case Western Reserve University, Cleveland, OH.

OBJECTIVE: To determine patient factors that predict success in embryo transfer (ET) cycles utilizing cryopreserved donor oocytes to intended parent recipients

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The SART database was used to identify cryopreserved donor oocyte cycles that resulted in fresh ET from 2014 to 2015. An initial univariate analysis was performed to identify patient factors associated with live birth rate. These included history of prior: full term birth (FTB), preterm birth (PTB), spontaneous abortion (SAB), biochemical pregnancy; as well as fertility diagnosis, age, race, BMI, smoking status, and number of embryos transferred. Factors with a p-value <0.2 in our primary univariate analysis were included as potential predictors in the final model. The final model was performed via multiple logistic regression. A two-sided p value <0.05 was considered significant in our multiple regression model.

RESULTS: A total of N= 5001 cryopreserved donor oocyte fresh ET cycles were analyzed. Overall livebirth rate was 40.6% in this population. On average, patients were 41.6 (Standard Deviation (SD): 4.88) years old, primarily of white (36.6%) or other (46.5%) race with BMI 26 (SD: 5.56). 6.2% of patients were identified as African American, and 3.8% of the total cohort were defined as smokers. The average number of embryos transferred was 1.54 (SD 0.56). The univariate analysis demonstrated no association of live birth rate with the following factors: history of FTB, PTB, SAB, biochemical pregnancy, number of embryos transferred, or fertility diagnosis, with the exception of tubal factor (p<0.5). After controlling for covariates in the regression model, race was the most significant finding, with African-American race associated with a decreased live birth rate compared to white race (OR 0.73 95% CI 0.55 -0.98). Older patients were found to have lower live birth rate compared to younger recipients (one year increase in age OR 0.98 95% CI 0.97 – 0.99). Higher BMI was negatively associated with live birth rate (OR 0.99 95% CI 0.97 to 0.99). Women with a history of smoking had a higher live birth rate compared to those who did not smoke; however, the total number of smokers was small in the sample 188 (3.8%) (OR 1.34 95% CI 1.00 – 1.86). Patients with tubal factor did not have an appreciable difference in live birth rate in the final model (OR 0.99 95% CI 0.7 – 1.14).

CONCLUSIONS: More patients are choosing cryopreserved donor oocytes in donor egg cycles, yet data is scarce as to how to best counsel patients regarding best prognosis for an individual patient. Our study suggests that cryopreserved donor oocyte outcomes are associated with race, age, and BMI. Smoking does not appear to be negatively associated with live birth.

SUPPORT: none

P-414 4:30 PM Sunday, October 18, 2020

PREGNANCY OUTCOMES WITH GESTATIONAL SURROGACY COMPARED TO NON-SURROGACY FOR IN-VITRO FERTILIZATION CONCEPTION.

Melody A. Rasouli, MD, MBA,[1] Hailey E. Roberts, BS,[2] David N. Jackson, MD.[3] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]Loyola University Chicago, Chicago, IL; [3]High Risk Pregnancy Center, Las Vegas, NV.

OBJECTIVE: In vitro fertilization (IVF) often requires a gestational carrier (surrogate) to achieve parenting for intended couples. Our objective was to study the characteristics and outcomes of pregnancies with a designated gestational surrogate compared to non-surrogate IVF conceptions.

DESIGN: Retrospective case series.

MATERIALS AND METHODS: Designated gestational surrogate pregnancies managed in a single maternal fetal medicine center from January 2011 to March 2020 were eligible. Age matched IVF pregnancies were selected as controls in a 2:1 fashion. Comorbidities of surrogates, gravidity, parity, singleton vs twin gestation, estimated fetal weight (EFW) and abdominal circumference (AC) percentiles in second and third trimesters, fetal anomalies, abnormal ultrasound findings, cervical length, gestational age at delivery, mode of delivery and perinatal complications were reviewed. Descriptive statistical analysis, Fisher's test and chi-square were performed with a p value of <0.05 considered significant.

RESULTS: Thirty gestational surrogate IVF pregnancies were compared with 60 IVF controls. Gestational surrogates had higher mean gravidity than non-surrogacy IVF pregnancies, (4.75 vs 1.86, p= 0.0001). The rate of twin gestation was 60% among surrogacy pregnancies compared to 40% of controls (p= 0.3295). There were two monochorionic gestations after single embryo transfer in each group. Surrogates had a 17.6% rate of fetal cardiac and central nervous system anomalies identified on prenatal ultrasound compared to 5.8% of non-surrogacy IVF pregnancies (p= 0.1901). There was a significantly higher rate of abnormal placental ultrasound findings in the gestational surrogacy group compared to non-surrogacy IVF pregnancies (placenta previa, placental cysts, and presence of multiple placenta lakes) (p= 0.027). Among gestational surrogacy IVF pregnancies there was a trend towards a higher rate of pre-term delivery at 37% vs 21%, however not statistically significant (p= 0.06). Cesarean delivery among gestational surrogacy IVF pregnancies was 77%, compared to 41% of non-surrogacy IVF pregnancies (p = 0.018). Despite antepartal assessment, fetal demise was found at 35 weeks and 36 weeks in the gestational surrogacy IVF group (11.7%), while there were no losses in the non-surrogacy IVF group (p= 0.021).

CONCLUSIONS: In this case series, gestational surrogacy IVF pregnancies had high rates of twinning, abnormal ultrasound findings, cesarean delivery and intrauterine fetal demise. Our data suggests that pregnancies for intended parents through gestational carriers have an increased rate of adverse perinatal outcomes compared to age matched IVF controls in autologous gestations. This requires modified counseling and additional management over typical IVF pregnancies alone.

P-415 4:30 PM Sunday, October 18, 2020

PROMISING LIVE BIRTH RATES ARE SEEN WITH UNTESTED DONOR EMBRYOS.

Olivia Carpinello, MD,[1] B. Mitchell Bodily, MD,[2] Samad Jahandideh, PhD,[3] Morine Cebert, Ph.D., RN,[4] Joshua C. Combs, MD,[5] Micah J. Hill, DO,[5] Alan H. DeCherney, MD,[6] Kate Devine, MD.[3] [1]Program in Reproductive Endocrinology and Gynecology, NICHD, NIH, Bethesda, MD; [2]Uniformed Services University, Bethesda, MD; [3]Shady Grove Fertility, Washington D.C., DC; [4]University of Pennsylvania & Philadelphia VA Medical Center, Philadelphia, PA; [5]Walter Reed National Military Medical Center, Bethesda, MD; [6]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

OBJECTIVE: To describe the characteristics and reproductive outcomes of patients choosing to utilize donated embryos at a single infertility practice.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: A chart review was performed on patients who presented to a single infertility practice and utilized donated embryos from 2016-2018. Practice criteria for embryo donation included: embryos vitrified onsite at blastocyst stage on day 5 or 6, egg age <40 years old, sperm age <50 years old, no PGT-M/SR; however PGT-A euploid embryos were accepted. Embryos with an estimated 40-45% odds of LB per embryo, based on records review, and assuming no uterine factor, were permitted for donation. Descriptive statistics were used to evaluate patient characteristics and outcomes.

RESULTS: 198 donated embryo FET cycles with planned transfer to 141 unique patients were initiated. Mean recipient age at cycle start was 40.5 years. Mean number of previously completed IUI, IVF and FET cycles per recipient was 0.6, 0.7, and 0.7, respectively, with a mean of 2.1 (SD = 2.79) total prior treatment cycles per recipient. 13 cycles were ultimately cancelled, 10 of which were cancelled due to inadequate endometrial response. Another patient had no transfer because the single thawed embryo did not survive. 184 (93%) of the initiated donated embryo cycles were completed, and the mean egg age at the time of embryo creation was 29.8 years (range 22-38 years). The most common primary infertility diagnosis for recipients was diminished ovarian reserve (36.4%) with the second most common listed as "other" (27.2%). 1.6% of recipients had a diagnosis of uterine factor infertility. 28.4% of the 141 patients using donated embryos were single females and another 7.1% were same sex couples. Patients mostly identified as Caucasian (68.5%) or Black/African American (14.1%). A mean of 1.2 embryos were transferred each cycle. 14.7% of transfers were double embryo transfers, and 9.8% of clinical pregnancies were twin gestations. One patient with a singleton pregnancy underwent a therapeutic abortion at 11 weeks with no reason provided. Livebirth and ongoing pregnancy per transfer were 42.9%, and transfers were performed with mostly PGT untested embryos (95.7%). Mean age at delivery was 37.3 weeks gestation.

CONCLUSIONS: Use of donated embryos can provide a successful means to parenthood, particularly for those with diminished ovarian reserve. In the absence of PGT-A, FET of donated embryo was associated with a high live birth rate. Single embryo transfer should be recommended in order to minimize twin gestations.

P-416 4:30 PM Sunday, October 18, 2020

DOES ELEVATED PROGESTERONE ON DAY OF TRIGGER ASSOCIATE WITH BLASTOCYST PLOIDY IN EGG DONOR CYCLES? Priscilla Caldeira, MD,[1] Aline R. Lorenzon, PhD,[2] Ana Paula Aquino, MD,[3] Bruna Barros, BSc,[3] Eduardo L. A. Motta, MD, PhD,[4] Thais S. Domingues, MD, PhD.[5] [1]School of Medicine - University of São Paulo, Brazil; [2]Scientific Coordinator, Huntington Medicina Reprodutiva, Sao Paulo, Brazil; [3]Huntington Medicina Reprodutiva, São Paulo, Brazil; [4]Department of Gynecology, Paulista School of Medicine, Federal University of São Paulo, São Paulo, Brazil; [5]Huntington Medicina Reprodutiva, Sao Paulo, Brazil.

OBJECTIVE: Evaluate if high progesterone levels on day of trigger influences blastocyst ploidy and embryo quality parameters in egg donors cycles.

DESIGN: Retrospective cohort study from ICSI cycles using frozen donated oocytes that underwent embryo biopsy at blastocyst stage performed between April/2013 and February/2019 at Huntington Medicina Reprodutiva. Two groups were set according to progesterone (P4) level on day of trigger: group A if P4 <1.5 ng/mL (n=75 cycles: 57 donors – 69 recipients) and group B if P4 ≥1.5 ng/mL (N=184 cycles: 115 donors – 163 recipients).

MATERIALS AND METHODS: Donors were women under 35 years old, with regular menstrual cycles, no gynecological or other health diseases, IMC under 30 Kg/m^2 and normal karyotype. They received standard ovarian stimulation protocol with GnRH antagonist. Clinical parameters such as antral follicular count, FSH basal, total gonadotrophins dose and estradiol (E2) at trigger were analyzed. Number of eggs retrieved, mature oocytes (MII), number of ICSI, fertilization rate, number of blastocysts, number of top quality blastocyst, number of euploid/aneuploid blastocysts, euploid/aneuploid embryo rate and clinical pregnancy were compared between group A and B. T and Fisher tests were used for statistical analysis.

RESULTS: Group A mean age was 25.15±3.59 and group B 24.46±3.73 years old (p=0.19). Total gonadotropins used and basal FSH were not different between group A and B (2777.83±526.02 vs 2814.54±538.78, p=0.7363; 5.19±1.51 vs 5.22±1.47, p=0.3035). Antral follicular count was higher in group B than in A (22.95±10.65 vs 19.60±7.08, p=0.0301) and estradiol at trigger was higher in group A than in B (5255.00±6405.77 vs 5252.83±4346.33 vs, p=0.0340). Number of eggs retrieved, MII and number of ICSI performed were higher in group B than A (33.96±1.76 vs 28.01±11.78, p=0.0014; 24.84±11.74 vs 21.12±10.56, p=0.0082; 8.08±1.74 vs 7.61±1.63, p=0.0025). There were no differences between groups in oocytes post-thaw survival rate, fertilization rate, number of blastocysts and number of top-quality embryos (0.95±0.10 vs 0.98±0.17, p=0.2626; 0.83±0.14 vs 0.82±0.13, p=0.854; 3.60±1.52 vs 3.68±1.52, p=0.6671; 2.27±1.59 vs 2.28±1.43, p=0.8019). The mean of blastocyst biopsied per group were similar (3.15±1.33 versus 3.06±1.29, p=0.6998; n=236 group A and 563 group B). There was no difference between groups when comparing number of euploid embryos and euploid embryo rate (1.92±1.25 vs 1.92±1.13,p=0.9542; 0.31±0.20 vs 0.30±0.18, p=0.6257). Number of aneuploid embryos and aneuploid embryo rate were not different between groups (1.23±1.01 vs 1.14±0.94,p=0.5927; 0.21±0.19 vs 0.18±0.15, p=0.4363). There was no difference in clinical pregnancy rate (0.73 vs 0.82, p= 0.4765). Seminal parameters were similar between groups.

CONCLUSIONS: Our data showed that elevated progesterone levels on trigger's day is not associated with blastocyst aneuploidy rates or worst embryo quality parameters in egg donors cycles, in which the cofounder of maternal age is excluded from the analysis.

P-417 4:30 PM Sunday, October 18, 2020

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY IN DONOR OOCYTE IVF CYCLES: A MATCHED, SIBLING OOCYTE COHORT STUDY. Devora Aharon, MD,[1] Dmitry Gounko, MA,[2] Joseph A. Lee, BA,[2] Tanmoy Mukherjee, MD,[1] Alan B. Copperman, MD,[1] Lucky Sekhon, MD[2] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: The use of preimplantation genetic testing for aneuploidy (PGT-A) has been shown to improve live birth rate per embryo transfer (ET) and reduce pregnancy loss.[1] Whether PGT-A is beneficial in donor oocyte recipient cycles, with lower expected rates of aneuploidy, is less clear.[2-4] A major concern is the possible lower positive predictive value of PGT-A when the technology is used to screen young donor-oocyte derived embryos, which may reduce the number of healthy embryos available for transfer and/or cryopreservation. This study aims to compare the overall IVF cycle efficacy and efficiency in recipients of sibling donor oocytes who did and did not utilize PGT-A.

DESIGN: Retrospective, matched cohort study.

MATERIALS AND METHODS: The study included single embryo transfers in recipients of sibling oocytes from the same donor in which one recipient utilized PGT-A ("PGT-A" group) and the other recipient did not ("unscreened" group) from September 2016 to March 2020. Donors underwent controlled ovarian hyperstimulation and the retrieved oocytes were divided equally among the recipients. PGT-A was performed using Next Generation Sequencing. Baseline characteristics including age, BMI, endometrial thickness, use of donor sperm, fresh vs. frozen embryo transfer, embryo age, and embryo quality were compared between the groups. Outcomes included cycle efficiency, defined as percentage of fertilized oocytes that were transferred and/or cryopreserved, as well as clinical pregnancy, live birth, and pregnancy loss rates. Comparative statistics and linear and logistic regression were used for analysis.

RESULTS: The study included a total of 50 matched pairs, or 100 oocyte recipient cycles. Average oocyte age was 26.5±2.7 years. The groups were similar in terms of recipient age and BMI. The PGT-A group had a significantly lower endometrial thickness, lower rate of donor sperm use, higher proportion of frozen-thawed embryo transfers, and lower proportion of day 5 vs. day 6 embryos transferred compared to the unscreened group. With regards to embryo quality, the PGT-A group had significantly higher expansion grades, similar inner cell mass morphology grade, and a higher proportion of trophectoderm grade B. Cycle efficiency was similar between the groups (60.7±0.2% vs. 56.5±0.2%, p=0.44). On multivariate logistic regression, no significant differences were seen between the PGT-A and unscreened groups in clinical pregnancy rate (OR 0.85, 95% CI 0.26-2.73, p=0.79), live birth rate (OR 1.93, 95% CI 0.51-7.35, p=0.33), or pregnancy loss rate (OR 0.65, 95% 0.11-3.69, p=0.63) when controlling for confounders.

CONCLUSIONS: Our study which utilized a sibling donor oocyte matched model failed to demonstrate alterations in cycle outcome in cases with embryos that had undergone PGT-A. We did not observe a reduced number of embryos available for transfer or cryopreservation, suggesting that the use of PGT-A does not reduce treatment efficiency. Recipients who desire the use of PGT for sex selection or aneuploidy screening can be reassured that this technology is safe and will not reduce the number of embryos available for treatment.

UNDERSTANDING SELF-PERCEPTIONS AND RISK EXPERIENCES OF GESTATIONAL SURROGATE MOTHERS IN GESTATIONAL SURROGACY ARRANGEMENTS, THAILAND. Jutharat Attawet, PhD candidate. University of Technology Sydney, Sydney, NSW, Australia.

OBJECTIVE: This study aims to explore gestational surrogate mothers' self-perceptions and risk experiences during the process of gestational surrogacy arrangements in Thailand.

DESIGN: Qualitative descriptive design

MATERIALS AND METHODS: Fifteen Thai women who had gestational surrogacy experience were interviewed by telephone. An approximately 30-minute semi-structured interview was conducted per individual. During the interview, audio tape was used to record the conversation for the purpose of transcription and translation. Thematic analysis was applied to analyze the translated interviews.

RESULTS: 'Womb for work' was an overarching theme for Thai women deciding to become gestational surrogate mothers. Thai women perceived that their wombs could be turned into money and simultaneously assist a childless couple to complete their family. In doing this, Thai women were able to justify the exchange of 'womb for work.' For entry into commercial surrogacy arrangements, Thai women had to sign a contract, which they perceived as outlining their obligations and having to be followed without deviating. Thai women mostly entered the surrogacy process through a surrogacy agency, who they called a 'big boss.' Thai women perceived that the 'big boss' was a powerful person in the surrogacy arrangement, with whose instructions they had to comply during the process of the gestational surrogacy arrangement. The women reported that they mainly communicated with the 'big boss' and obtained surrogacy treatment information from the 'big boss.' Communicating between the Thai women and fertility professionals could be described as a 'triangle communication,' meaning they received surrogacy treatment information from the 'big boss' rather than directly communicating with the fertility professionals. Through the process, it was identified that some details, such as risks associated with multiple or potential infected embryo transfer, or complications of multiple pregnancy, were omitted. According to cultural norms, asking questions of a powerful person, such as the 'big boss' or fertility professionals, was an inappropriate behavior. Consequently, these self-perceptions of being inadequately empowered to ask questions about surrogacy treatment and their own health among the Thai women were creating a barrier to further knowledge about potential health risks involved in gestational surrogacy arrangements. It was therefore found that Thai women had limited understanding and knowledge of potential health risks involved in the process of gestational surrogacy arrangements, which could possibly have contributed to their experiences of making decisions regarding surrogacy treatment and accepting risks unintentionally.

CONCLUSIONS: Self-perceptions were found to be the barrier limiting gestational surrogate mothers from further seeking information from reliable sources—fertility professionals—which affected their understanding of health risks and decision-making in the process of surrogacy treatment.

SUBJECTIVE PSYCHOLOGICAL FACTORS ASSOCIATED WITH EGG DONORS UNDERGOING ADDITIONAL DONATIONS AFTER THEIR FIRST OOCYTE DONOR CYCLE.

Diane Tober, PhD,[1] Kevin S. Richter, PhD,[2] Shannon Kokjohn, MSc,[3] Christina M. Garibaldi, MS,[4] Raquel Cool, BA,[5] Kezia Mostak, MS,[4] Natalia Villegas, BS,[4] Cris Zubizarreta, BA,[4] Katarina Cook, BS,[4] Said Daneshmand, MD.[3]
[1]UCSF Institute for Health and Aging, San Francisco, CA; [2]Fertility Science Consulting, Silver Spring, MD; [3]San Diego Fertility Center, San Diego, CA; [4]University of California, San Francisco, San Francisco, CA; [5]We Are Egg Donors, Santa Cruz, CA.

OBJECTIVE: To determine psychological factors that influence egg donors' decisions to undergo repeat donation cycles.

DESIGN: Survey.

MATERIALS AND METHODS: Oocyte donors (n=318) in the US were surveyed regarding subjective psychological assessments of their experience as first-time donors, and the subsequent probability that they undergo additional donations after their first. Donors providing eggs to a friend or relative were excluded.

RESULTS: Egg donors were more likely to donate oocytes again if they considered their first experience with donation to be rewarding, if their expectations regarding egg donation were met, if potential short-term and long-term risks of donation were adequately explained by their clinic before treatment, and if they were satisfied with their clinic (Table). Donors who reported feeling regret (53.5% vs 84.8, $p<0.0001$, C^2), fear or anxiety (63.2% vs 87.9%, <0.0001, C^2), depression (61.4 vs 85.9%, <0.0001, C^2), or mood swings (68.3 vs 84.7%, $p=0.0012$, C^2) during or after their first donation were significantly less likely to undergo a second oocyte donation.

Proportion of egg donors choosing to do additional oocyte donations after their first donation, according to their subjective experiences of their first donation rated on a Likert scale, assessed using Kendall's test for significant association

CONCLUSIONS: Oocyte donors reporting comprehensive informed consent and high satisfaction with patient care were more likely to donate again.

SUPPORT: This study was supported by the University of California, San Francisco, Institute for Health and Aging; UCSF Individual Investigator Grant (#7501159); and funding from the National Science Foundation (#1828783).

6 YEARS OF DONOR OOCYTE TRANSFERS IN A SINGLE PROGRAM: WHAT HAVE WE LEARNED?.

Alexandra Peyser, M.D., Nicole Noyes, MD, Stephanie R. Brownridge, M.D., Mary Rausch, MD. Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Advances in IVF & oocyte cryopreservation technology have allowed for newer modalities in the field of donor oocyte (DE) such as the use of frozen oocytes purchased from banks (COM-O) & genetic testing of resultant embryos. The objective of our study was to analyze our program's DE data over a 6-year period to assess DE usage efficiency & trends over time & whether these changes have positively impacted pregnancy outcomes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: From 2014-2019, our program completed 462 DE transfers in 241 recipients (REC; avg 2-embryo ET/REC) using embryos derived from a total of 163 donors. We analyzed the data for the following: freshly-retrieved oocytes (FRESH-O) vs. COM-O, FRESH-ET (in retrieval or egg-thaw cycle) vs. FROZEN-ET of resultant frozen thawed embryos; SOLE (all oocytes to 1 REC) vs. SHARED (oocytes split between 2 REC) cycles, & usage of PGT-A or not. In addition, donor age & duration of freeze were analyzed. Primary outcome was ongoing pregnancy (>8 wks) + live birth rate (OP/LB). Chi Square was used with significance at $p< .05$.

RESULTS: A total of 368 FRESH-O (80%) and 94 COM-O (20%) were performed. Overall, FRESH-O ETs yielded a significantly higher OP/LB compared to COM-O ETs (44% vs. 30%, $p= .01$). Within the FRESH-O group, OP/LB was not different when comparing FRESH-ET vs. FROZ-ET (51% vs 41%, $p= .08$). Within FRESH-ETs, those using FRESH-O had a higher OP/LB compared to COM-O (51% vs. 27%, $p= .0007$). When comparing SOLE ETs (n= 169; avg # eggs: 17 MII) vs. SHARED ETs (n= 147; avg # eggs: 10 MII), OP/LB rates were 53% vs. 40% ($p= .02$); of note, 60/75 (80%) SOLE & 28/30 (93%) SHARED donors produced at least 1 OP/LB. The use of PGT-A did not positively impact OP/LB in DE cycles as a whole ($p= .9$). When excluding PGT-A cycles, SOLE ETs yielded a significantly higher OP/LB than SHARED (59% vs. 40%, $p= .002$). Length of freeze as well as donor age (21-32y) did not impact OP/LB outcomes ($p= .15$ and $p= .3$, respectively).

	Strongly agree	Somewhat agree	Neutral	Somewhat disagree	Strongly disagree	*P*-value
Donation was rewarding	87.1%	76.1%	75.0%	40.0%	40.0%	<0.0001
Expectations were met	88.5%	81.0%	73.3%	72.3%	40.9%	<0.0001
Short-term risks explained	89.0%	77.9%	70.6%	78.0%	64.7%	0.0009
Long-term risks explained	91.7%	87.0%	76.9%	78.3%	70.7%	0.0005
Satisfaction with clinic	90.1%	78.1%	77.3%	65.7%	56.7%	<0.0001

CONCLUSIONS: As judged by OP/LB, the use of SOLE, FRESH-O with FRESH-ET without PGT-A remains superior to newer DE treatment combinations. Specifically, the use of COM-O & PGT-A did not improve success. Young oocytes yield sufficient-quality embryos for LB without requiring genetic evaluation. DE considerations now go beyond OP/LB & include enhanced DE choice (COM-O), easier scheduling & coordination (FROZ-ET and COM-O) and lower cost (SHARED). That 32yo and 21yo DEs yield similar OP/LB is important when counseling women pursing fertility preservation to be their own "donors" in the future. Although changing DE practices may enhance patient experience and affordability, patients & providers must be cognizant that choices may not always favorably impact pregnancy outcome and may cause other longer-term ramifications.

P-421 4:30 PM Sunday, October 18, 2020

A COMPARISON OF THE CHANCE OF A SECOND LIVE DELIVERED PREGNANCY FROM DONATED OOCYTES BEFORE UTILIZING ALL EMBRYOS FORMED ACCORDING TO WHETHER THE SOURCE OF EGGS WERE INFERTILE DONORS OR PAID POTENTIALLY FERTILE DONORS. Laura X. Zalles, MD,[1] Jerome H. Check, M.D., Ph.D.,[2] Jung Choe, M.D.,[2] Carrie K. Wilson, B.A.,[3] Donna Summers, M.S.[3] [1]Cooper University Hospital, Camden, NJ; [2]Cooper Medical School of Rowan University, Camden, NJ; [3]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ.

OBJECTIVE: Certain states that have mandated coverage for in vitro fertilization-embryo transfer (IVF-ET) will pay for the whole IVF cost for donor oocyte cycles with the exception of actual payment to the donor or payment for frozen donor oocytes. If a recipient receives one half of the retrieved eggs from an infertile donor undergoing IVF, the recipient cost is zero. The question is whether this comes at a sacrifice for success rates compared to donated oocytes from a paid donor. We previously determined that there was no difference in live delivered pregnancy rates resulting from infertile donor oocytes following fresh transfer. However, it is possible that the initial fresh transfer would select the best quality embryos, and thus result in decreased success in a subsequent frozen (F) ET (FET) in those women trying for another baby. The purpose of this study was to compare pregnancy outcomes according to source of donated eggs in FET's after a successful delivery with fresh donated oocytes.

DESIGN: Retrospective comparative.

MATERIALS AND METHODS: We reviewed FET outcomes of women delivering a live baby on their fresh transfer using one of three sources of donor oocytes: infertile donor sharing half the eggs collected, paid donor with all eggs to one recipient, and paid donor with eggs split between two recipients. Infertile donors receive no payment but only pay for the ET. The category pregnancy rate/retrieval includes the pregnancy rate potentially using all embryos (fresh or frozen) and thus possibly several transfers from embryos formed in the first successful donor-oocyte cycle.

RESULTS: Live delivered pregnancy rates per transfer and retrieval in attempt for a second baby from embryos formed in first donor egg recipient cycle.

CONCLUSIONS: Power analysis found that for the 40% increased live delivered pregnancy rate to be significant the study would need to have 1.5 x more patients. If this difference is found to be true a couple would have to decide if this extra benefit is worth the increased expense.

P-422 4:30 PM Sunday, October 18, 2020

AN IMPROVED METHOD FOR ZIKA VIRUS SCREENING IN A GAMETE BANK SETTING. Corey Andrew Burke, BSc, CLS,[1] Dixie Howell, MHA,[1] Julio Cortes, BS,[2] Anne-Bine Skytte, MD,[1] Ruth Fernandez, AAS,[2] Suzy Pixley, BS.[2] [1]Cryos International - USA, Orlando, FL; [2]Unilab of Dade, Fort Lauderdale, FL.

OBJECTIVE: Can the use of an Emergency Use Authorized (EUA) test for Zika IgM antibodies strengthen FDA screening for Zika virus?

DESIGN: Prospectively collected Zika-virus IgM antibody tests have been analyzed during the out-break of the epidemic and the period thereafter for sperm and egg donors donating at Cryos International -USA between August 2016 and January 2020.

MATERIALS AND METHODS: Screening of Sperm donors for Zika IgM by InBios ZIKV Detect™ 2.0 IgM Capture ELISA was carried out at the beginning and closure of each batch of ten ejaculates or every 8 weeks. Egg donors were screened prior to beginning their cycle and again on the day of oocyte pick-up. Zika IgM levels are variable over the course of the infection and may be detectable near day four post onset of symptoms and persist up to approximately 12 weeks following initial infection. Testing was performed at Unilab of Dade.

RESULTS: One-thousand-three hundred-seventy-six tests were performed on one-hundred-forty-six donors. A total of sixteen donors tested positive or reactive. Eight donors (6 sperm, 2 egg) were reported as presumptive positive for Zika IgM. The remaining eight donors (7 sperm, 1 egg) were presumed to have a positive result due to interference from West Nile Virus or Dengue virus however none of these donors were confirmed positive to West Nile Virus or Dengue virus.

CONCLUSIONS: Zika virus infection during pregnancy may cause serious birth defects and developmental disability, including a condition called microcephaly. Other signs and symptoms of congenital Zika virus syndrome (CZVS) may appear later in infancy including seizures, irritability, problems swallowing, as well as hearing and sight abnormalities.

There is also strong scientific evidence that a Zika infection during pregnancy can cause Guillain Barre Syndrome (GBS). Symptoms of GBS include weakness of the arms and legs and, in severe cases, can affect the muscles that control breathing.

When the Zika outbreak first began in the United States in 2016 the FDA issued a screening policy requiring that a series of travel and lifestyle questions be asked of sperm and egg donors. At the same time Cryos International instituted a policy of using an EUA screening test for the Zika virus. Between August 2016 and January 2020 sixteen donors were found to be positive or possibly positive for Zika virus, one of these was confirmed by the state department of health by rt-PCR to have the virus. The remaining fifteen could not be confirmed to be positive or negative for the virus.

None of the donors tested answered yes to FDA questionnaires regarding travel to an infected area, sex with an infected. This raises concern about the effectiveness of using only lifestyle questions to screen for Zika virus. Due to the emerging nature of this virus, the testing methodology has not been fully validated. This study addresses the urgent need of ART facilities including gamete banks for reliable, clinically significant, accurate and accredited methods to screen gamete donors for Zika virus in order to the safety of donor gametes.

	Egg Donor Type		
	Infertile donor	Paid donor, 1 recipient	Paid donor, split between 2 recipients
Avg. age (yrs) of donor	31	29.5	28.7
No. of initial FET cycle*	27	57	56
No. of all subsequent FET cycles*	35	88	68
% live delivered/1st FET	40.7% (11/47)	43.9% (29/57)	35.7% (22/56)
% live delivered/all subsequent FET	51.8% (14/27)*	70.1% (40/57)	46.4% (26/56)

*p=.0837 comparing infertile donor source vs. paid donor 1 recipient, chi-square.

P-423 4:30 PM Sunday, October 18, 2020

INFANT BIRTH WEIGHT AND MATERNAL BMI: GENETIC VS EPIGENETIC CONTRIBUTIONS.

Pamela B. Parker, M.D., M.P.H., Sacha A. Krieg, M.D., Ph.D., David Lee, MD, Thomas O'Leary, PhD, Diana Wu, MD, Bharti Garg, MBBS, MPH, Paula Amato, MD. Oregon Health & Science University, Portland, OR.

OBJECTIVE: The prevalence of obesity is increasing worldwide. Obesity has been shown to have a negative effect on reproductive outcomes in both spontaneous and IVF pregnancies. Studies on the effect of maternal BMI on pregnancy success rates in donor oocyte IVF cycles are conflicting. Few studies have examined the effect of maternal BMI on neonatal outcomes. While increasing maternal BMI is associated with increased infant birth weight in both spontaneous and autologous IVF pregnancies, it is unclear whether this is primarily a genetic or epigenetic phenomenon. To our knowledge, this is the first study to examine the effect of donor BMI on infant birth weight in donor oocyte IVF cycles. The purpose of this study is to assess the relationship between infant birth weight and recipient and donor BMI in donor oocyte IVF cycles in order to determine the relative genetic (oocyte) and epigenetic (endometrial) contributions.

DESIGN: IRB-approved retrospective cohort study.

MATERIALS AND METHODS: We conducted a retrospective cohort study of 130 donor oocyte IVF cycles resulting in a singleton live birth at a single IVF center from 2012-2018. Pearson correlation coefficients were calculated to examine the relationship between recipient and donor BMI and infant birth weight. ANOVA was conducted to compare infant weight among various BMI subgroups. Linear regression was used to adjust for the type of embryo transfer (fresh vs frozen), diabetes or gestational diabetes status, hypertension in pregnancy, gestational age, and infant sex.

RESULTS: Recipients were >35 years of age on average and predominantly Caucasian. Decreased ovarian reserve was the most common etiology of infertility diagnosis. Forty-four percent of recipients were normal weight and 56% were overweight or obese. The mean age of oocyte donors was 26.7 ± 3.15 (Range 20-39) years. Seventy-eight percent of oocyte donors were normal weight and oocyte donors were predominantly Caucasian. There was no correlation between recipient BMI and infant birth weight (r=0; p=0.99). In contrast, there was a weakly positive, but non-significant, correlation between donor BMI and infant birth weight (r=0.02; p=0.76). This relationship persisted after adjusting for potential confounders.

CONCLUSIONS: Several studies have shown a clear association between maternal BMI and infant birth weight in autologous IVF cycles. In this study we examined the relative contribution of donor and recipient BMIs to infant birth weight in donor oocyte IVF cycles. The lack of correlation observed between recipient BMI and infant birth weight along with the weak although not significant correlation between donor BMI and infant birth weight suggests that oocyte or genetic components may play a greater role in infant birth weight compared to epigenetic or endometrial factors. This study is limited by the relatively small sample size and lack of information on paternal BMI. Future studies aim to examine metabolic health outcomes in oocyte donor-conceived children.

P-424 4:30 PM Sunday, October 18, 2020

THE EVOLVING LANDSCAPE OF DONOR EGG TREATMENT: SUCCESS, WOMEN'S CHOICE AND ANONYMITY.

Alexandra Peyser, M.D., Mary Rausch, MD, Stephanie R. Brownridge, M.D., Nicole Noyes, MD. Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: 40K+ babies are born in the US annually from the use of donor gametes; ∼¼ are eggs (DE). Notably, in 2017, ∼¼ of the women > 40y that succeeded using ART did so with DE. DE is thus, common practice today as more women delay childbirth in lieu of professional/personal pursuits, causing them to "age-out" of traditional ART. DE has evolved from synching a recipient's (REC) endometrium to a donor's fresh retrieval (FRESH-O) + multi-embryo FRESH-ET to; (non-synchronized) frozen-embryo transfers (FROZ-ET) &/or the use of commercially-bought, frozen DE (COM-O) ± the use of PGT-A; all meant to optimize DE outcomes. We sought to examine trends over time re: psychology, cost, choice, genetics and ease.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: From 1/2014-12/2019, we completed 462 DE transfers in 241 REC using a total of 163 donors (avg: 2-emb ET/REC). We analyzed donor characteristics & cycle repeats, &, over time, FRESH-O vs. COM-O, SOLE (1 REC) vs. SHARED (2 REC), FRESH-ET vs. FROZ-ET, PGT-A or not, single (SET) vs. double (DET) ET. Primary outcome was ongoing (> 8 wks) pregnancy + live birth rate (OP/LB). Stats: Chi Square was used.

RESULTS: Of donors, 98 (60%) were FRESH-O; 65 (40%) were COM-O. 29 (30%) FRESH-O donated greater than once (REPEAT) with embryos transferred to a total of 108 REC. On average, REPEATs had 3 retrievals (range 2-6), went to 4 REC (range 2-9) & their donations resulted in 7 ETs (range 2-23) creating 84 OP/LB; 3 per donor (range 1-9). A total of 74 "genetic half-siblings" were born to 76 REC from 23 donors. Assessing oocyte & ET type, FRESH-ETs using FRESH-O compared to COM-O yielded a higher OP/LB rate (51% vs. 27% p=.0007). In FRESH-O, OP/LB rates were similar in FRESH-ET & FROZ-ET (50% vs 41%, p=.08). For all DE cycles, PGT-A use increased over time (2014-16: 0.2%, 2018-19: 13%) with no OP/LB improvement (p=.9). 2-ETs led to a higher OP/LB compared to SET (50% vs. 37%, p=.007) but had a 15% twin rate. The program trended from 2-ET to SET over 6y (2014-2019), decreasing from 42% to 19% (p<.05); SET continues to dominate. As years progressed, we trended toward SOLE over SHARED and less COM-O due to SOLE's superior OP/LB per ET. Of note, 60/75 (80%) SOLE (17 eggs/REC) & 28/30 (93%) SHARED (10 eggs/REC) donors made at least 1 OP/LB.

CONCLUSIONS: ART continues to evolve. As OP/LB successes have become universally acceptable, primary treatment emphasis has expanded from best-pregnancy-rate-only to include healthy baby (and mother) & meeting patient concerns: cost, timing, ease, non-family genetic siblings. Trends in practice require continuous reevaluation. Moving away from 2-ET in favor of SET is mandatory. PGT-A's role in DE appears unnecessary except for carrier-state issues. The combo of SOLE, FRESH-O + readied REC continues to provide the best absolute OP/LB but COM-O and FROZ-ET add choice and convenience. Sharing donors, whether through FRESH-O or COM-O decreases cost & the # of supernumerary embryos but also increases the number of REC per donor, and therefore genetically-related offspring in the background of consumer testing unraveling anonymity. Donors and intended parents require full & appropriate counseling.

P-425 4:30 PM Sunday, October 18, 2020

SURVIVAL RATE OF MATURE DEVITRIFIED OOCYTES IN A DONOR PROGRAM.

Arnoldo Gonzalez, M.D.,[1] Julio C. Rosales, M.D.[2] [1]RESIDENTE SEGUNDO AÑO, Monterry, NL, Mexico; [2]IECH, Monterrey, NL, Mexico.

OBJECTIVE: To analyze the number of mature oocytes that survive devitrification classified into three groups by number of aspirated oocytes in a donor program

DESIGN: Retrospective, Observational.

MATERIALS AND METHODS: A retrospective, observational study was carried out between the period of 2014 to 2019 that includes 224 cycles of donors aged between 18 and 25 with antimulleriana hormone > 2.5 ng/ml, patients with polycystic ovary syndrome were excluded. A long protocol of agonist Leuprorelin 5UI d21 was administered, for ovarian stimulation FSHr was used, doses of 200 to 225 IU, final maturation was carried out with choriogonadotropin alfa 250 μg, follicular aspiration was performed 35 hours post trigger. Subsequently, they were classified by number of ovules in <15, 16-30 and 31 or more.

RESULTS: In the group of <15 oocytes, 510 were aspirated, being 401 MII (78.6%) and after devitrification 341 were recovered; Survival rate was 85%. In the group of 16-30 oocytes 2415 were aspirated, of which 1237 MII (51.2%) and 1047 were recovered; the survival rate was 84%. In the group of 31 or more, 990 oocytes were aspirated, of which 475 are MII (47.9%) and 371 were recovered; the survival rate was 78%.

CONCLUSIONS: In donor cycles for vitrified oocytes with a long agonist protocol, aspiration of 15 or fewer oocytes has the best survival rate, as well as a better percentage of usable mature eggs.

EGG DONOR PERCEPTIONS OF LONG-TERM ADVERSE OUTCOMES.

Diane Tober, PhD,[1] Kevin S. Richter, PhD,[2] Cristina Garibaldi, MS,[3] Kezia Mostak, MS,[3] Natalia Villegas, BS,[3] Cris Zubizarreta, BA,[3] Raquel Cool, BA,[4] Katarina Cook, BS,[3] Shannon Kokjohn, MSc,[5] Said Daneshmand, MD.[5] [1]UCSF Institute for Health and Aging, San Francisco, CA; [2]Fertility Science Consulting, Silver Spring, MD; [3]University of California, San Francisco, San Francisco, CA; [4]We Are Egg Donors, Santa Cruz, CA; [5]San Diego Fertility Center, San Diego, CA.

Number of donation cycles and average number of oocytes per donation cycles

Potential long-term risk of oocyte donation	Number of donors reporting condition	Frequency in oocyte donor population	Mean donation cycles with vs without condition	P-value (t-test)	Mean eggs per cycle with vs without condition	P-value (t-test)
Menstrual irregularities	73	30.0%	3.6 vs 3.5	NS	25.4 vs 25.0	NS
Hormonal irregularities	52	21.4%	3.5 vs 3.6	NS	28.3 vs 24.3	NS
Endometriosis	12	4.9%	2.5 vs 3.6	NS	24.6 vs 25.1	NS
PCOS	18	7.4%	3.3 vs 3.6	NS	27.4 vs 25.0	NS
Reproductive or other cancers	11	4.5%	2.5 vs 3.6	NS	21.6 vs 25.3	NS
Post-donation infertility	23	9.5%	3.1 vs 3.6	NS	25.7 vs 25.1	NS

OBJECTIVE: To examine egg donor self reports of perceived long-term adverse outcomes in relation to number of donation cycles and eggs produced per cycle

DESIGN: Survey.

MATERIALS AND METHODS: Oocyte donors (n=243) in the US were surveyed a year or more after their last oocyte donation regarding potential long-term risks associated with repeated oocyte donations. Potential risks evaluated included menstrual irregularities, hormonal irregularities, endometriosis, polycystic ovary syndrome (PCOS), reproductive cancer, and post-donation infertility. The mean number of donation cycles per donor was compared between egg donors reporting the occurrence, or not, for each potential risk and evaluated by t-test.

RESULTS: Past oocyte donors completed the survey from one to as many as 27 years (mean = 7.2, SD = 6.6, median = 4, interquartile range = 2 to 10) following their last oocyte donation cycle. Mean number of donation cycles and mean number of eggs retrieved per donation cycle did not differ significantly between those experiencing vs those not for each of the potential risks evaluated (Table).

CONCLUSIONS: Perceived experiences long-term adverse effects were higher than anticipated, but reports of long-term effects do not appear to be related to number of cycles or number of eggs produced per cycle.

SUPPORT: This study was supported by the University of California, San Francisco, Institute for Health and Aging; UCSF Individual Investigator Grant (#7501159); and funding from the National Science Foundation (#1828783).

P-427 4:30 PM Sunday, October 18, 2020

PRE-TREATMENT PREDICTORS OF EGG DONORS WHO WILL UNDERGO ADDITIONAL OOCYTE DONATIONS AFTER THEIR FIRST.

Diane Tober, PhD,[1] Kevin S. Richter, PhD,[2] Shannon Kokjohn, MSc,[3] Natalia Villegas, BS,[4] Cris Zubizarreta, BA,[4] Cristina Garibaldi, MS,[4] Kezia Mostak, MS,[4] Katarina Cook, BS,[4] Raquel Cool, BA,[5] Said Daneshmand, MD.[3] [1]UCSF Institute for Health and Aging, San Francisco, CA; [2]Fertility Science Consulting, Silver Spring, MD; [3]San Diego Fertility Center, San Diego, CA; [4]University of California, San Francisco, San Francisco, CA; [5]We Are Egg Donors, Santa Cruz, CA.

OBJECTIVE: To assess corresponding factors on probability an oocyte donor will undergo additional donations after their first donation.

DESIGN: Survey.

MATERIALS AND METHODS: Oocyte donors (n=318) in the US were surveyed regarding pre-donation characteristics, and the probability that they undergo additional donations after their first. Donors providing eggs to a friend or relative were excluded.

RESULTS: The frequency of second cycles after a first donation declined from 89% among women aged 18 to 22 years to 56% among women aged 30 to 36 years. The frequency of second cycles after a first donation declined from 91% among women with a high school, GED, or vocational education to 70% among women with a post-graduate degree (Master's or Ph.D.). Reported income and degree to which they were financially motivated to donate were not related to repeat donation. However, donors who were paid more were more likely to undergo multiple donations. Reported prior psychological conditions including anxiety, depression, and mood swings were unrelated to the frequency of repeat donation.

Probability of donors undergoing a second cycle after their first oocyte donation according to age, academic education level, and monetary compensation, assessed using Kendall's test for significant association.

Age at first donation	Sample size	Repeat donation	*P*-value
Less than 23 years	76	89.5%	0.0003
23 to 25 years	117	82.9%	
26 to 27 years	64	81.3%	
28 to 29 years	27	74.1%	
30 years or older	34	55.9%	
Academic education level	Sample size	Repeat donation	0.0007
High school, GED, or vocational school	77	90.6%	
Bachelor's degree	118	80.8%	
Graduate degree	87	70.1%	
Monetary compensation (inflation adjusted)	Sample size	Repeat donation	<0.0001
None	22	22.7%	
Less than $5,000	20	70.0%	
$5,000 to $6,999	120	84.2%	
$7,000 or greater	154	87.0%	

CONCLUSIONS: Higher monetary compensation was correlated with decisions to undergo repeat donation cycles.

P-428 4:30 PM Sunday, October 18, 2020

RECIPIENTS RECEIVING EGGS FROM INFERTILE DONORS SHARING HALF OF THE EGGS COLLECTED HAVE NO LESS CHANCE OF HAVING A LIVE DELIVERY COMPARED TO RECIPIENTS RECEIVING EGGS FROM A PAID DONOR.

Laura X. Zalles, MD,[1] Jerome H. Check, M.D., Ph.D.,[2] Jung Choe, M.D.,[2] Carrie K. Wilson, B.A.,[3] Donna Summers, M.S.[3] [1]Cooper University Hospital, Camden, NJ; [2]Cooper Medical School of Rowan University, Camden, NJ; [3]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ.

OBJECTIVE: Certain states that have mandated coverage for in vitro fertilization-embryo transfer (IVF-ET) will pay for the whole IVF cost for donor oocyte cycles with the exception of actual payment to the donor or payment for frozen donor oocytes. If a recipient receives one half of the retrieved eggs from an infertile donor undergoing IVF, the recipient cost is zero. The question is whether this comes at a sacrifice for success rates compared to fresh oocytes from a paid donor or frozen eggs from an egg bank. The purpose of this study was to compare pregnancy outcome according to source of donated eggs.

DESIGN: Retrospective comparative.

MATERIALS AND METHODS: We reviewed IVF cycle outcomes of women using one of four sources for donor oocytes: infertile donor sharing half the eggs collected, paid donor with all eggs to 1 recipient, paid donor with eggs split between 2 recipients, and frozen eggs from an egg bank.

	Egg Donor Type			
	Infertile donor	Paid donor, 1 recipient	Paid donor, split between 2 recipients	Thawed frozen from egg bank
Avg. age (yrs) of donor	31	29.5	28.7	25.5
No. of fresh transfers	356	473	506	26
No. of fresh and frozen transfers	614	979	892	41
% implantation	32.2%	33.1%	33%	31.1%
% live delivered/1st fresh transfer	47.5% (164/356)	47.4% (224/473)	48.2% (244/506)	38.5% (10/26)
% live delivered/retrieval	70.0% (249/356)	85.2% (403/473)	55%	46.2%

There was a trend for a significantly higher pregnancy rate per retrieval comparing source infertile donors vs. paid donor, 1 recipient (p= .064, chi-square).

Infertile donors receive no payment but only pay for their own embryo transfer. The category pregnancy rate/retrieval includes the pregnancy rate potentially using all embryos (fresh or frozen) and thus possibly several transfers from embryos formed in the first donor-oocyte cycle.

RESULTS: Live delivered pregnancy rates per transfer and retrieval according to source of donated eggs.

CONCLUSIONS: A couple receiving mandated coverage for donor egg cycles would have to decide if the 20% increased chance of a live baby using all embryos formed from a paid donor keeping all oocytes is worth the cost compared to an infertile donor source, which is free. Though the frozen egg group is small, it was least likely to result in a live delivery before having to pay for another group of frozen-thawed eggs, and thus was by far the most expensive option for couples with mandated coverage with paid donor recipient costing half of frozen-thawed eggs and paid split with 2 recipients ¼ the cost.

BIRTH OUTCOMES AMONG GESTATIONAL SURROGATES ACCORDING TO SURROGATE CHARACTERISTICS: THE INFLUENCE OF SURROGATE AGE AND PARITY.

Said Daneshmand, MD,[1] Kevin S. Richter, PhD,[2] Danielle Miller, RN, BSN,[1] Natasha Sam, BS Candidate,[1] Hanna L. Mulloy, MA,[1] Shannon Kokjohn, MSc.[1] [1]San Diego Fertility Center, San Diego, CA; [2]Fertility Science Consulting, Silver Spring, MD.

OBJECTIVE: To investigate whether commonly measured characteristics of gestational surrogates can be predictive of neonatal outcomes

DESIGN: Retrospective chart review

MATERIALS AND METHODS: Singleton and twin births among parous gestational surrogates from a single infertility treatment center were retrospectively reviewed. Gestational age at birth, birth weight, and frequency of caesarean section were evaluated according to surrogate age, height, body mass index (BMI), parity, and endometrial thickness. Potential associations were evaluated by linear or logistic regression analysis as appropriate.

RESULTS: Singleton gestational age at birth decreased by approximately 2 days with each additional previous birth (268.9 days, 265.3 days, 263.3 days, 262.2 days, and 259.1 days for 1, 2, 3, 4, and 5 previous births respectively, p=0.0025). There were weak trends toward greater gestational age and birth weight with increasing surrogate BMI that approached but did not reach statistical significance (p=0.11 and p=0.07). Twin birth weight per child declined significantly with increasing surrogate age (p=0.042), from 100 oz at 22 years down to 70 oz at 40 years (30% relative reduction in birth weight). Neither surrogate height nor endometrial thickness were associated with gestational age, birth weight, or frequency of caesarean section for either singletons or twins.

CONCLUSIONS: Gestational age of singleton births declined with increasing parity, although to a small extent likely to be of little clinical importance. Birth weight among a small cohort of twin surrogate births decreased substantially with increasing surrogate age, suggesting caution be exercised when considering transfer of multiple embryos to older surrogates. Larger studies of the influence of surrogate parity and age on neonatal outcomes are warranted.

Table. *P*-values for tests of association between surrogate characteristics and birth outcomes.

Singleton Births (n=127)					
Birth Outcome	Surrogate age, mean = 30 ± 5 years	Height, mean = 64.5 ± 2.3 inches	BMI, mean = 26.7 ± 4.2 kg/m^2	Parity, mean = 2.5 ± 1.5 births	Endometrial thickness, mean = 9.6 ± 1.8 mm
Gestational age at birth, mean = 265 ± 20 days	0.55	0.27	0.11	0.0025	0.63
Birth weight, mean = 123 ± 22 oz	0.72	0.71	0.07	0.30	0.42
Caesarean section frequency = 26%	0.20	0.18	0.66	0.46	0.81
Twin Births (n=20)					
Birth Outcome	Surrogate age, mean = 30 ± 6 years	Height, mean = 65.0 ± 2.2 inches	BMI, mean = 27.2 ± 3.2 kg/m^2	Parity, mean = 2.2 ± 1.2 births	Endometrial thickness, mean = 9.6 ± 2.2 mm
Gestational age at birth, mean = 244 ± 20 days	0.24	0.45	0.70	0.68	0.68
Birth weight, mean = 87 ± 20 oz	0.042	0.64	0.85	0.16	0.44
Caesarean section frequency = 71%	0.98	0.67	0.54	0.63	0.68

P-430 4:30 PM Monday, October 19, 2020

ROUTINE ENDOMETRIAL RECEPTIVITY ARRAY IN FIRST EMBRYO TRANSFER CYCLES DOES NOT IMPROVE LIVE BIRTH RATE.

Carrie Riestenberg, MD,[1] Lindsay Kroener, MD,[1] Kaycee Ching, BA,[2] Gayane Ambartsumyan, MD, PhD,[3] [1]University of California, Los Angeles, Los Angeles, CA; [2]Wayne State University School of Medicine, Detroit, MI; [3]Reproductive Partners Medical Group, Redondo Beach, CA.

OBJECTIVE: To report the rate of displacement of the window of implantation (WOI) in an infertile population without a history of implantation failure, and to compare the rates of live birth between patients who undergo personalized embryo transfer (pET) after ERA versus FET with standard timing.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: All patients who underwent their first single euploid programmed frozen embryo transfer at a private IVF center between January and December 2018 were assessed for inclusion. Natural cycle and min-stim FET cycles as well as cycles using egg donation were excluded. All patients were offered ERA prior to their first FET and the decision was made jointly with their physician. In those who elected, an endometrial biopsy with ERA was performed in a programmed mock cycle on day P+5. Results were interpreted as pre-receptive, receptive or post-receptive. In patients with pre-receptive or post-receptive biopsies, the duration of progesterone exposure was accordingly adjusted per manufacturer recommendations. FET cycle outcomes were compared between patients who underwent ERA with a subsequent pET and those who had FET with standard timing. The primary outcome was live birth rate. Secondary outcomes included positive hCG, clinical pregnancy, ongoing pregnancy, biochemical and miscarriage rates.

RESULTS: Of the 229 patients who underwent their first single euploid programmed FET during the study period, 147 (64.2%) elected to do ERA and 82 (35.8%) chose to proceed with FET with standard timing. ERA was receptive in 60/147 (40.8%) and non-receptive in 87/147 (59.2%). Non-receptive ERAs were pre-receptive in 81/87 (93.1%) and post-receptive in 6/87 (6.9%) of patients. Patients who opted to have ERA performed were significantly older (36.9 years vs 34.9 years, p=0.0001) and had fewer euploid embryos available for transfer (2.9+/-2.0 vs 4.3+/-2.4, p<0.0001). There were no differences in BMI, endometrial lining thickness or progesterone route used between the two groups.

Comparison was made between patients who underwent FET with standard timing to those who underwent biopsy and ERA, regardless of whether the duration of progesterone was changed based on ERA results. There were no differences in LBR (56.1% vs 56.5%, p=0.96), clinical pregnancy rate (65.9% vs 67.4%, p=0.82), rate of positive hCG (75.6% vs 79.6%, p=0.48), biochemical rate (14.5% vs 15.4%, p=0.88) or miscarriage rate (13.0% vs 15.2%, p=0.71) between groups. A subgroup analysis of only patients who had an ERA was performed to see if there was a difference in outcomes between patients who had receptive and non-receptive ERA results. Patients with receptive ERA results did not significantly differ from those with non-receptive ERA results with regards to LBR (50.0% vs 60.9%, p=0.19), clinical pregnancy rate (65.0% vs 69.0%, p=0.61), rate of positive hCG (78.3% vs 80.5%, p=0.75), biochemical rate (19.1% vs 14.3%, p=0.48), or miscarriage rate (23.1% vs 10.0%, p=0.08).

CONCLUSIONS: Our data does not support the routine use of ERA in an unselected patient population undergoing first programmed single euploid embryo transfer.

P-431 4:30 PM Monday, October 19, 2020

CLINICAL FACTORS ASSOCIATED WITH MONOZYGOTIC TWINNING AFTER SINGLE EMBRYO TRANSFER.

Margeaux Oliva, MD,[1] Devora Aharon, MD,[1] Joseph A. Lee, BA,[2] Alan B. Copperman, MD,[1] Lucky Sekhon, MD,[2] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: The current study aimed to identify clinical factors associated with monozygotic splitting after SET.

DESIGN: Retrospective case-control study

MATERIALS AND METHODS: Patients who underwent IVF with SET from 2002 to 2020 that resulted in monozygotic twinning (MZT) were compared to singleton gestations. Cycles with more than one embryo transferred were excluded. Student's t-test, chi-squared test and multivariate logistic regression were used for the analysis.

RESULTS: 3.1% (n=205) of pregnancies after SET resulted in MZT pregnancies. Patient age, BAFC, stimulation protocol, GND dose, E2 and P4 levels, number of oocytes retrieved and day of embryo development did not differ significantly between MZT and singleton pregnancies. Both groups had similar rates of utilizing donor oocytes, frozen transfer, ICSI, PGT-A, repeat trophectoderm biopsy and repeat vitrification-warming. Controlling for relevant confounders, embryos with increased TE grade (A vs. C: OR 3.11, CI 1.39-6.94) and female sex (OR 1.73, CI 1.09-2.72) had increased odds of MZT.

	MZT pregnancy (n=205)	Singleton pregnancy (n=6404)	p value
Patient age	37 ± 5.1	36.6 ± 5.1	.21
AMH	3.4 ± 3	3.8 ± 4.3	.36
BAFC	13.2 ± 8.1	13.4 ± 8	.75
BMI	24 ± 4.9	24.1 ± 4.5	.85
Stimulation protocol (%)			.55
GnRH antagonist	144 (75.4)	4546 (76)	
GnRH agonist	2 (1)	142 (2.4)	
Microflare	16 (8.4)	414 (6.9)	
OCP/Lupron	4 (2.1)	129 (2.2)	
Synthetic	17 (8.9)	596 (10)	
Other	8 (4.2)	155 (2.6)	
GND dose	3379.9 ± 1344.5	3372.8 ± 1297.5	.94
Donor oocyte (%)	26 (12.7)	816 (12.7)	.98
IVF cycle			.22

Expansion grade (%)			<.01
3	8 (4)	141 (2.3)	
4	92 (46.2)	3321 (53.4)	
5	67 (33.7)	1419 (22.8)	
6	31 (15.6)	1296 (20.8)	
ICM grade (%)			.16
A	141 (71.6)	4624 (75.9)	
B	45 (22.8)	1287 (21.1)	
C	11 (5.6)	179 (2.9)	
TE grade (%)			<.01
A	107 (54.3)	2695 (44.2)	
B	73 (37.1)	2418 (39.7)	
C	17 (8.6)	966 (15.9)	
Embryo sex			<.01
F	90 (63.8)	2267 (52.2)	
M	51 (36.2)	2080 (47.8)	

CONCLUSIONS: Our study showed that female embryos and blastocysts with favorable TE grade are more likely to split. Monozygotic splitting could be related to the rate of proliferation and differentiation of TE cells. Future studies are needed to determine the epigenetic drivers of monozygotic splitting and the molecular basis for the sexual dimorphism found in our study.

ARTIFICIAL INTELLIGENCE MACHINE LEARNING MODELING TO PREDICT SINGLE EUPLOID BLASTOCYST TRANSFER OUTCOMES.

Mary E. Haywood, PhD, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD, Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: An evidence-based algorithm for the probability of predicting successful live birth has significant clinical utility in counseling infertility patients regarding embryo transfer outcomes. Towards this objective, we examined an artificial intelligence (AI), machine learning classification model using patient clinical measurements and IVF cycle characteristics to assess the prognostic value in estimating treatment outcomes including live birth.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: In total, 3,368 consecutive, single, autologous, euploid frozen blastocyst transfers that occurred from 2009-2019 were included. Decision tree algorithms constructed classification models based on 17 clinical measurements (including ovarian reserve, BMI, embryo grade) and transfer outcomes: negative serum β-hcG (10 days after transfer), biochemical (consecutive positive serum β-hcG 10-12 days after transfer), non-viable implantation (visualized gestational sac and no fetal pole), miscarriage (visualized fetal heart tone followed by loss) and live birth. Data was randomly allocated, with 70% applied to training the AI machine learning model and 30% for prediction testing. Fisher's exact, Kruskal-Wallis, pairwise Wilcoxon, and Benjamini-Hochberg p-value adjustment were used to calculate statistical significance of individual parameters where appropriate, $p < 0.05$.

RESULTS: In the absence of β-hcG, no classification models were significant. Modeling β-hcG alone demonstrated an overall accuracy of 87.5% ($p < 0.0001$) and investigation of β-hcG distribution demonstrated significant pairwise differences between all outcomes ($p < 0.0001$ for all pairwise comparisons). Individual parameter evaluation of miscarriages revealed monozygotic twinning was 2.5x more likely to end in a miscarriage than any other outcome ($p < 0.05$). The addition of maternal age did not result in an increase in model predictive accuracy, emphasizing that the age-related reduction in reproductive efficiency is predominantly overcome with a euploid embryo transfer. Blastocyst quality increased accuracy to 88.0% ($p < 0.0001$), and together with β-hcG distributions, were stratified to create a live birth outcome probability table for clinical utilization. Analysis of blastocyst quality by outcome revealed 2.1x enrichment of high-grade blastocysts with a live birth (day 5 biopsy, Grade 3-5, AA or BA; p-adj < 0.0001). Negative, biochemical, and non-viable implantation outcomes had 2.1x, 1.9x and 1.8x fewer high-grade blastocysts respectively (p-adj < 0.0001, 0.001, 0.05) and negative outcome alone had 4.7x more day 7 biopsied blastocysts (p-adj < 0.0001).

CONCLUSIONS: Overall, clinical measurements evaluated in AI machine learning had poor predictive value in stratifying single, euploid blastocyst transfer outcomes, emphasizing the heterogeneity and biological complexity of infertility patients and their treatment. Nevertheless, classification using β-hcG distributions and blastocyst quality together displayed high predictive accuracy for live birth following a single euploid embryo transfer.

SEX-SPECIFIC EMBRYO CLEAVAGE KINETICS AND PERINATAL OUTCOMES AFTER BLASTOCYST TRANSFERS.

Suneeta Senapati, MD MSCE,[1] Dara S. Berger, PhD,[1] Charikleia Kalliora, MD, MSc,[1] Elizabeth Ruiz, BA, MHS,[1] Carmen Sapienza, PhD,[2] Christos Coutifaris, MD, PhD,[1] Monica Mainigi, MD,[1] [1]University of Pennsylvania, Philadelphia, PA; [2]Temple University, Philadelphia, PA.

OBJECTIVE: Extended embryo culture during in-vitro fertilization (IVF) is associated with an increased risk of adverse perinatal outcomes such as preterm delivery in fresh cycles. While utilization of vitrified/warmed blastocyst embryo transfers (FET) has increased, the impact of subtle differences in embryo development kinetics on perinatal outcomes is unknown. In addition, increasing evidence supports sex-specific variations in early human embryo development, suggesting the impact of extended embryo culture on perinatal outcomes may be dimorphic. Our objective was to determine the sex-specific association of embryo culture duration and adverse perinatal outcomes in FETs.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: All autologous vitrified/warmed blastocyst transfers from 1/1/2015-4/18/2020 at an urban academic center were identified. Cycles with previously frozen oocytes and mixed fresh/frozen transfer cycles were excluded. Embryos were cultured in CSCM media (Fujifilm Irvine Scientific) and cycles were analyzed according to days of embryo culture prior to vitrification: Day 5 (D5ET) vs Day 6 (D6ET). Logistic regression modeling was used to determine the association between duration of embryo culture and preterm delivery considering effect modification by fetal sex and adjusting for relevant confounders as appropriate. Secondary outcomes include rates of clinical pregnancy, live birth, preeclampsia, and low birth weight.

RESULTS: Of 1820 cycles in 1120 patients, there were 1345 D5ET (73%) and 475 D6ET (23%). D6ET patients were slightly older (D5ET 35.3 years vs D6ET 36.3 years, $p<0.05$) and PGT utilization was lower in D5ET compared to D6ET (28% vs 37%, $p<0.05$). There were no differences in race, ethnicity, maternal body mass index, and >80% were single embryo transfers in both groups. D5ET had a higher clinical pregnancy rate (D5ET 60.2% vs D6ET 47.6%, $p<0.001$) and of those who have delivered, a higher live birth rate compared to D6ET (D5ET 42% vs D6ET 32%, $p<0.0001$). Sex ratios were similar between the two groups (M:F D5ET 49:51 vs D6ET 45:55, $p=0.4$). There were no differences in gestational age at delivery, birth weight, or preeclampsia overall ($p>0.05$). Amongst singleton deliveries, D6ET had a higher incidence of preterm delivery (OR 1.85, 95% CI [1.04-3.27]). Moreover, fetal sex was an effect modifier in the relationship between duration of embryo culture and preterm delivery such that a lower incidence of preterm delivery was observed in D5ET females (10% D5ET for males vs 5% D5ET for females) whereas a higher incidence was noted in D6ET females (11% D6ET for males vs 17% D6ET for females).

CONCLUSIONS: Improvements in embryo culture and vitrification have revolutionized IVF success. However, the optimization of perinatal outcomes in pregnancies conceived after IVF remains elusive. Our data suggest that duration of culture may impact embryo development and perinatal outcomes in singletons, and this effect may be sexually dimorphic. Further studies are needed to understand the etiology for these observations and define modifiable factors that may improve pregnancy and perinatal outcomes.

DOES TROPHECTODERM BIOPSY FOR PREIMPLANTATION GENETIC TESTING AFFECT FETAL BIRTH WEIGHT OR RATE OF PRETERM DELIVERY? A SART CORS STUDY.

Papri Sarkar, MD,[1] Erika P. New, MD, MPH,[1] Sangita K. Jindal, Ph.D.,[2] Jean Tanner, PhD,[1] Anthony N. Imudia, MD,[1] [1]University of South Florida, Tampa, FL; [2]Albert Einstein College of Medicine / Montefiore Medical Center, Hartsdale, NY.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) is used as part of IVF treatment to select euploid embryos, and involves trophectoderm biopsy of blastocysts. The effects of possible trauma caused by biopsy of the blastocyst and implications on placental development are unknown. Therefore, the goal of our study was to evaluate if PGT-A is associated with adverse neonatal birth outcomes, including birthweight, small for gestational age (SGA), and preterm birth (PTB).

DESIGN: Retrospective study.

MATERIALS AND METHODS: Using the data from the national Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SART CORS), we identified 6,352 cycles which had single embryo transfer leading to a singleton live birth following frozen embryo transfer (FET) between 2014 and 2015. Our study group included cycles with PGT-A confirmed euploid embryos used for transfer, and our control group included all other FETs where non PGT-A tested embryos were used. We assumed that in the PGT-A group, euploid embryos were transferred and embryos with mosaicism or inconclusive results were discarded. The demographic and IVF cycle information were obtained from the corresponding linked fresh stimulation cycles. PTB was defined as delivery before 37 weeks' gestation and SGA was defined as birth weight less than 10th percentile for gestational age. Depending on the outcome, multivariable logistic or linear regression were used to estimate the association between SGA, PTB, or birthweight and PGT-A. Models were adjusted for patient's age, gravidity, history of PTB, smoking, infant sex, gestational age and number of oocytes retrieved.

RESULTS: From the initial cohort of 31,751 cycles, 6,352 cycles which had a singleton live birth following FET were included in the final cohort. A total of 3,482 (54.8%) had PGT-A confirmed euploid embryos and 2,870 (45.2%) had embryos selected based on morphology for transfer. No difference in birthweight (grams) was noted when FET was performed using PGT-A confirmed euploid embryos compared to non-tested morphologically selected embryos (3370.7 vs. 3354.5 grams, adjusted regression coefficient 11.4; 95% CI: -12.6; 35.3). As compared to morphologically selected embryos, performance of PGT-A did not increase the risk of SGA (3.9% vs. 4.1%, OR: 1.13; 95% CI: 0.86-1.50), low birth weight (1500-<2500 g) (5.8% vs. 5.5%, OR: 0.90; 95% CI: 0.66-1.21), or very low birthweight (1.3% vs. 1.0%, OR: 0.44; 95% CI: 0.44 (0.18-1.10). There was no increased risk of PTB associated with pregnancy resulting from PGT-A embryos vs. non PGT-A embryos (15.8% vs. 16.4%, OR: 0.94; 95% CI: 0.81-1.09).

CONCLUSIONS: In our study, trophectoderm biopsy for PGT-A did not increase the risk of adverse neonatal outcomes, including SGA or PTB in IVF pregnancies.

P-435 4:30 PM Monday, October 19, 2020

ORAL CONTRACEPTIVE PRETREATMENT DOES NOT ALTER LIVE BIRTH RATES IN PGT-A SCREENED FROZEN EMBRYO TRANSFER CYCLES.

Carlos Hernandez-Nieto, MD,[1] Joseph A. Lee, BA,[1] Tamar Alkon Meadows, MD,[1] Deborah Cassis-Bendeck, MD,[1] Martha Luna-Rojas, MD,[1] Alan B. Copperman, MD,[2] Benjamin Sandler, MD,[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: Oral contraceptives pills (OCPs) have been a long-standing adjuvant used for multiple purposes during ART treatment. Despite a widespread adoption of OCPs in many clinical settings, some studies have suggested that OCP utilization might exhibit a deleterious effect on IVF outcomes. Opponents have proposed the progesterone compound of OCPs may negatively affect endometrial receptivity[1]. Recently, one study showed pregnancy rates were negatively associated with OCP usage[2]. Furthermore, the utilization of OCPs has been associated with increased pregnancy loss rates in frozen embryo transfer (FET) cycles[3]. The majority of available published evidence about OCPs use has included data derived from fresh IVF cycle outcomes; however, data regarding the effect of OCPs pretreatment in euploid FETs is scarce. The objective of this analysis is to assess the effect of OCPs pretreatment on pregnancy rates in single euploid FET cycles.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: The study included patients who underwent a FET cycle from 2016-2020. PGT-A with *NGS was* performed in all cases. Cohorts were segregated in two groups based on OCPs pretreatment during the FET cycle: Group 1: OCP pretreatment; Group 2: Endometrial preparation cycles without OCP utilization. Patient demographics and IVF cycle outcomes were assessed. Comparative statistics, multivariate regression and an adjusted mixed model with a GEE were utilized for statistical analyses. A sample size of 388 FET's per group was calculated to ensure an 80% power to detect a difference of 10% on live birth rates (LBR) (α=0.05).

RESULTS: 1,405 single euploid FET cycles with OCP pretreatment were compared to 4,622 control cycles. Significant differences were found in patient and oocyte ages between cohorts. No differences were found in AMH, BMI, and endometrial thickness at FET among cohorts. Also, no differences were found in number of good quality embryos transferred, implantation, clinical pregnancy (CPR), LBR, and clinical loss (CLR) rates. Gestational age and birth weight at delivery were similar among groups. After adjusting for confounders there was no correlation between the days of OCP utilization and lower LBR (R2=0.06, p=0.15). Finally, after adjusting for age, BMI, AMH, embryo quality and endometrial thickness, no association was found between OCP utilization and lower odds of implantation (OR 1.22 CI95% 0.9-1.6, p=0.18); CPR (OR 0.76 CI95% 0.5-1.1, p=0.17); LBR (OR 0.81 CI95% 0.6-1.1, p=0.26) or CLR (OR 1.07 CI95% 0.6-1.6, p=0.73).

CONCLUSIONS: OCPs can safely be used for patient planning and to ensure that NGS results on analyzed embryos is available to support embryo selection decisions. Based on our findings, OCP pretreatment does not appear to affect implantation or live birth rates after the transfer of a euploid embryo within a synthetically prepared endometrium. Further studies focusing on endometrial genetic transcription patterns and their interactions with different hormonal preparations during the peri-implantation period should be performed in order to optimize and personalize the endometrial molecular microenvironment.

PERINATAL OUTCOMES IN BABIES BORN FOLLOWING BLASTOCYST VERSUS CLEAVAGE STAGE EMBRYO TRANSFER - A RETROSPECTIVE ANALYSIS OF 113,764 IVF/ICSI CYCLES.

Edwin Amalraj Raja, M Sc., PhD.,[1] Siladitya Bhattacharya, MD., FRCOG,[1] Abha Maheshwari, MD, FRCOG,[2] David J. McLernon, PhD,[1] [1]University of Aberdeen, Aberdeen, United Kingdom; [2]NHS Grampian, Aberdeen, United Kingdom.

OBJECTIVE: To compare perinatal outcomes in babies born following blastocyst (Day 5) versus cleavage stage (Day 2 or 3) embryo transfer.

DESIGN: A population-based cohort study using cycle to woman linked data from 2000 to 2017 in the United Kingdom Human Fertilisation and Embryology Authority register.

MATERIALS AND METHODS: In babies conceived through in-vitro fertilisation (IVF), we investgated the association between the day of embryo transfer (blastocyst versus cleavage stage) and gestational age, birth weight, congenital abnormality and healthy baby rate ($\geq$37 weeks, normal birth weight and no congenital abnormalities). Generalized Estimating Equation (GEE) models with robust standard errors were used to account for women

with more than one live birth episode while a log-binomial model was used for binary outcomes and multinomial model for birthweight outcomes.Maternal (age, cause of infertility, previous live birth status) and treatment factors (IVF versus ICSI, number of eggs collected and number of embryos transferred) were considered as confounders in multivariable models. Relative Risk (RR) and 95% Confidence Intervals (CI) were estimated. The analysis was repeated for twins and for singleton siblings conceived through either blastocyst or cleavage stage embryos. Comparison of siblings allowed us to assess the influence of day of embryo transfer whilst minimising the confounding effect of maternal factors.

RESULTS: There were 86, 630 singleton live births (28, 814 following blastocyst versus 57, 816 following cleavage stage ET), 21,940 twin live births (5,194 vs 16,746) and 5,384 sibling pairs. Singletons born following blastocyst transfer were more likely to be born preterm (<37 weeks) compared to those conceived from cleavage stage embryos (aRR 1.13; 95% CI 1.06, 1.19). However, they were more likely to be a healthy baby (aRR 1.01; 95%CI 1.01, 1.02), with a lower risk of having a congenital abnormalilty (aRR 0.63; 95%CI 0.57, 0.71) and high birth weight (>4500g) (aRR 0.92; 95%CI 0.87, 0.99). Twins born following had an increased risk of preterm birth (aRR 1.19; 95%CI 1.12, 1.28) and low birthweight (<2500g) (aRR 1.11; 95%CI 1.05, 1.17) compared to twins born following cleavage stage transfer. However, they had a decreased risk of congenital abnormality (aRR 0.80; 95%CI 0.67, 0.95) and being a healthy baby (aRR 0.85; 95%CI 0.82, 0.90) . There was no statistically significant difference in the risk of between siblings conceived from blastocyst and cleavage stage embryos.

CONCLUSIONS: Babies (both singleton and twins) born following blastocyst ET are more likely to be born preterm but are at a decreased risk of having a congenital abnormality compared to those following cleavage stage ET. However, these differences were not present when siblings were compared suggesting that maternal factors may be a greater influence than the day of embryo transfer. This provides reassurance to the default position of embryo transfer at blastocyst stage.

P-437 4:30 PM Monday, October 19, 2020

WEIGHING IN ON LIVE BIRTH RATE AFTER A SINGLE EUPLOID TRANSFER. Jill Karten, M.D.,[1] Baruch Abittan, M.D.,[2] Weiwei Shan, MS PhD,[3] Randi H. Goldman, M.D.,[2] Christine Mullin, M.D.[2] [1]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Northwell Health Department of Biostatistics, New Hyde PArk, NY.

OBJECTIVE: Prior studies have evaluated the effect of body mass index (BMI) on outcomes following euploid frozen embryo transfer (FET) with varying results, and have been limited by small sample sizes[i][ii][iii]. The purpose of this study was therefore to investigate whether BMI impacts pregnancy outcomes following euploid FET using a larger population that contains a greater proportion of patients with obesity.

DESIGN: Retrospective cohort study at an academic fertility center.

MATERIALS AND METHODS: Patients undergoing euploid FET between 2015 and 2019 were included. Preimplantation genetic testing for aneuploidy was performed by either array comparative genomic hybridization or next generation sequencing. Patients were stratified by BMI (kg/m^2) category according to WHO criteria. Differences in clinical outcomes, stratified by BMI, were initially compared using Chi square, Fishers exact tests or ANOVA where indicated. Logistic regression was then performed, controlling *a priori* for maternal age and history of miscarriage.

RESULTS: Most (78%) of the 1,421 patients included were normal or overweight BMI. No differences in outcomes were observed between patients with normal BMI vs. overweight BMI. When adjusted for other variables including age and previous miscarriage, there was a significant reduction in live birth (LBR) among patients with obesity compared to patients with normal or overweight BMI. In general, for every 1-unit increase in BMI above 30, the LBR following euploid FET decreased by 3.7% (with other variables held constant). Patients with obesity had a 40% lower likelihood of LBR following transfer of a euploid embryo compared to patients with normal weight (OR: 0.58 (CI: 0.39-0.86)).

CONCLUSIONS: Obesity is associated with a decreased likelihood of LBR following euploid FET and suggests that the negative impact of BMI on live birth may be independent of embryo genetics.

P-438 4:30 PM Monday, October 19, 2020

A DROP IN ESTRADIOL LEVELS POST-TRIGGER IN FRESH TRANSFER CYCLES DOES NOT NEGATIVELY IMPACT LIVE BIRTH OUTCOMES. Pietro Bortoletto, MD,[1] Phillip A. Romanski, MD,[1] Nigel Pereira, MD,[2] Zev Rosenwaks, M.D.[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Ronald O. Perlman and Claudia Cohen Center for Reproductive Medicine, New York, NY.

OBJECTIVE: To determine if a post-trigger drop in estradiol (E2) level negatively impacts live birth outcomes in women undergoing IVF with fresh embryo transfer (ET).

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: Inclusion criteria included women ages 18-44 years undergoing their first IVF cycle using a GnRH antagonist protocol followed by a fresh day 3 or 5 ET at our center between 2008 and 2018. We excluded women who received a pure GnRH agonist trigger. Women were stratified into groups based on change in their E2 level from day of trigger to post-trigger: E2 rise (>0 pg/mL difference) versus E2 drop ($\leq$ 0 pg/ml difference). Live birth rate was the primary outcome. Multivariable logistic regression was used to examine the association between the two E2 groups and live birth while controlling for confounders. Odds ratios (OR) with 95% confidence intervals (CI) for live birth were estimated.

RESULTS: A total of 7,660 women were included, of whom 7,076 (92.4%) had a rise in their post-trigger E2 level and 584 (7.6%) had a drop. The mean ($\pm$SD) E2 change was 34.7% (23.2) for those with a rise in their post-trigger E2 and 8.6% (7.2) for those with an E2 drop. An hCG only ovulatory trigger was used in 84.3% versus 87.5% of the patients in the E2 rise versus drop group, respectively. Cleavage stage embryo transfer was performed in 74% versus 84% of patients, respectively. The live birth rate was 37.8% versus 32.4% (p=0.009) for women with an E2 rise versus drop, respectively. In the regression model, women over the age of 37 had reduced odds of live birth compared to women <37 years of age (OR 0.48, CI 0.42-0.854). Those with a diagnosis of diminished ovarian reserve had reduced odds of live birth when compared to women with partners diagnosed with male-factor infertility (OR 0.81, CI 0.70-0.94). After controlling for the above factors, in addition to the number of mature oocytes retrieved and the number and developmental stage of embryos transferred, there were no

	Normal weight (BMI 18.5-24.9)	Overweight (BMI 25-29.9)	Class 1 obesity (BMI 30-34.9)	Class 2/3 obesity (BMI >35)	P value
N	767	343	190	121	
Age	35.3	36.6	36.7	36.8	<0.01
%Biochemical	9.6	7.6	10.0	10.7	0.63
%SAB	7.3	6.7	11.6	9.9	0.23
%Live Birth	52.4	49.6	38.9	38.0	<0.01

differences in the odds of live birth when comparing patients with an E2 rise versus drop (OR 1.0, CI 0.83-1.21). Using the same regression model, there was no percent E2 drop (-5% to -35%) threshold identified in which the live birth outcome would have been negatively affected.

CONCLUSIONS: A drop in E2 level post-trigger does not negatively impact the live birth outcome in women undergoing fresh embryo transfer during an IVF cycle after controlling for relevant clinical and cycle level variables.

P-439 4:30 PM Monday, October 19, 2020

A COMPARATIVE EVALUATION OF NOVEL SUB-ENDOMETRIAL AND INTRAUTERINE PLATELET RICH PLASMA TREATMENT FOR WOMEN WITH RECURRENT IMPLANTATION FAILURE (RIF).

Noushin abdul Majiyd, MD, MRCOG , MRCPI, FRM,[1] Sankalp Singh, MRCOG,[2] Chaitra Thunga, MS, DNB,[2] Mohamed Ashraf, M.D, D.G.O, DPS,[1] Swati Singh, MD, DNB,[1] Reema Basheer, MD, FRM,[1] Raiza Ashraf, MBBS, MSC,[1] Kannamannadiar Jayaprakasan, Ph.D.,[3] [1]INDIA, thrissur, India; [2]craft hospital, kodungallur, India; [3]Department of Obstetrics and Gynaecology, Derby, United Kingdom.

OBJECTIVE: Sub endometrium is considered as the niche area for growth factor (GF) & cytokine production[1] . Aim of the study was to compare the effectiveness of treatment with autologous activated platelet rich plasma (PRP), administered either to sub-endometrium (SE-PRP) or to endometrial surface (intrauterine; IU-PRP) against controls.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: The study was undertaken from Jan 2019-20. Women aged <40 years with history of unexplained RIF undergoing Frozen Embryo transfer (FET) were recruited. **Exclusion criteria** included women with BMI ≥ 30 kg/m2, untreated uterine abnormalities, untreated hydrosalpinges, low ovarian reserve, thrombophilia, uncontrolled endocrinopathy , severe male factor infertility, difficult embryo transfer, only poor quality embryos available & couple with chromosomal abnormalities.

INTERVENTION: SE-PRP- 4 ml PRP was injected into the sub endometrial space trans vaginally via Embryo transfer catheter under ultrasound guidance in the luteal phase of previous cycle of FET (n=33). **IU-PRP**- Intrauterine infusion of 1 ml PRP was done during FET cycle when endometrium was 7 mm (n=109). **Controls** underwent standard FET with no intervention (n=154).

All patients were given the option to choose either SE- PRP, IU-PRP or no intervention with an informed consent.

PRP PREPARATION : Both SE-PRP and IU-PRP groups were given colony stimulating factor (G-CSF) 300 μg subcutaneous for 3 days to boost WBC & GF production[2]. The next day 60 ml blood was drawn & PRP was prepared using by double centrifugation (FDA approved Regen kit) . Post PRP preparation platelets rose to a range of 10-15 L/μl. Activation of PRP was done with freeze thaw technique using liquid nitrogen[3] . PRP was prepared at 20-22°C & infused within 10 min of preparation to maintain efficacy.

For the FET-Endometrium was prepared by hormone replacement treatment (HRT) protocol. Estradiol valerate was started on day 2/3 of cycle at dose of 6mg & once endometrium was ≥8mm progesterone vaginal pessary 400 mg twice daily was offered for luteal support.

Statistical analysis was done with SPSS (version 20) using ANOVA (bonferroni test) & chi-square tests.

Main outcome measures : Ongoing pregnancy or live birth rate (OPR/LBR); Clinical pregnancy rate (CPR), and miscarriage rate (MR).

RESULTS: Baseline characteristics (Age , BMI , AMH, NUMBER OF FET ATTEMPT, NUMBER AND QUALITY OF EMBRYOS TRANSFERRED[4]) were similar in all the groups. OPR/LBR was higher (P<0.01) in the SE-PRP (13/33; 39.4%) and IU-PRP (45/109; 41.3%) than in the control group (34/154; 22.1%). OPR/LBR was similar between SE-PRP vs IU-PRP (P=0.85). CPR showed a similar trend (P<0.01) with a higher rate in the SE-PRP (17/33; 51.5%) and IU-PRP (57/109; 52.3%) than the controls (52/154; 33.8%). There was no statistical difference in the CPR between SE-PRP vs IU-PRP (P=0.94). MR was similar in all three groups (4/33; 12.1%, 12/109; 11% and 18/154 ; 11.7% respectively).

CONCLUSIONS: In women with history of RIF, PRP treatment appears to improve FET outcome with increase in OPR/LBR. However, SE-PEP treatment do not offer any advantage over lesser invasive IU-PRP treatment.

SUPPORT: Nothing to disclose.

SEARCHING FOR THE OPTIMAL NUMBER OF OOCYTES TO REACH A LIFE BIRTH AFTER *IN VITRO* FERTILIZATION: A SYSTEMATIC REVIEW WITH META-ANALYSIS.

Nathalie Sermondade, M.D., Ph.D.,[1] Charlotte Sonigo, M.D., Ph.D.,[2] Naouel Ahdad-Yata, M.D.,[3] Maud Pasquier, M.D.,[4] Eloise Fraison, M.D.,[5] Michael Grynberg, M.D., Ph.D.[6] [1]Hopital Tenon, Paris, France; [2]Hopital Antoine Beclere, Clamart, France; [3]Hopital De Meaux, Meaux, France; [4]Centre Hospitalier Intercommunal De Creteil, Creteil, France; [5]Hospices Civils De Lyon, Bron, France; [6]Hopital Antoine Beclere, Clamart, France.

OBJECTIVE: Several lines of evidence indicate that number of oocytes represents a key point for in vitro fertilization (IVF) success. However, consensus is lacking regarding the optimal number of oocytes for expecting a live birth. The present study aims to investigate the relationship between the number of oocytes and both the live birth rate after fresh embryo transfer (LBR) and cumulative live birth rate (CLBR).

DESIGN: A systematic review and independent meta-analyses.

MATERIALS AND METHODS: Literature search in MEDLINE, EMBASE and Cochrane Library was performed for studies published between January 01, 2004 and August 31, 2019, combining the Medical Subject Headings and text words for 'IVF', 'ICSI', 'fertility preservation' 'oocytes number' and 'live birth'. Studies that only reported results on infertile couples undergoing Prenatal Genetic Screening cycles, or oocyte donation cycles, were excluded. Two independent reviewers carried out study selection, quality assessment using the adapted Newcastle-Ottawa Quality Assessment Scales, bias assessment using ROBIN-1 tools, and data extraction according to Cochrane methods. Independent analyses were planned according to the type of oocytes (retrieved and mature) and to the outcome (LBR and CLBR). Mean-weighted threshold of optimal oocyte number was estimated from documented thresholds followed by a one-stage meta-analysis, using R software, dosresmeta package and restricted cubic splines, on articles with documented or estimable relative risks.

RESULTS: After review of 843 records, 62 full-text articles were assessed for eligibility. A total of 35 studies were available for the quantitative syntheses. Sixteen and 15 studies were included in the meta-analyses evaluating the relationship between the number of retrieved oocytes and LBR or CLBR, respectively. Given the limited number of investigations considering mature oocytes, association between the number of metaphase II oocytes and IVF outcomes could not be investigated.

Concerning LBR, 7 (35.0%) studies reported a plateau effect, corresponding to a weighted mean of 14.4 oocytes. The pooled dose-response association between the number of oocytes and LBR showed a non-linear relationship with a plateau beyond 15 oocytes.

For CLBR, 4 (20.0%) studies showed a plateau effect, corresponding to a weighted mean of 22.9 oocytes. The meta-analysis on the relationship between the number of oocytes and CLBR also found a non-linear relationship, with a slight but sustained increase in CLBR beyond 14 oocytes.

All analyses showed a statistically significant deviance criterion (p<0.01) and a high coefficient of determination (R^2 > 90% for all meta-analyses). Sensitivity analyses were not able to decrease deviance.

CONCLUSIONS: This first meta-analysis on the topic indicates a non-linear relationship between the number of retrieved oocytes and both LBR and CLBR. Above a threshold of 15 oocytes, the LBR following fresh transfer plateaus. On the contrary, for CLBR, our findings suggest a slight increase beyond 14 oocytes. Sub-groups analyses are currently performed in order to assess the influence of female age.

THE PREDICTIVE VALUE OF ESTRADIOL LEVEL IN EUPLOID NATURAL CYCLE FROZEN EMBRYO TRANSFER PREGNANCY OUTCOMES. Brindha Bavan, MD,[1] Jasmyn K. Johal, MD, MS,[2] Wendy Y. Zhang, BS,[3] Matthew J. Sahagun, BS, MA,[4] Amin A. Milki, MD,[1] Anna Sokalska, MD, PhD,[1] [1]Stanford Fertility and Reproductive Medicine Center, Sunnyvale, CA; [2]Stanford University, Dept of Obstetrics & Gynecology, Stanford, CA; [3]Stanford University School of Medicine, Stanford, CA; [4]California State University East Bay, Dept of Statistics & Biostatistics, Hayward, CA.

OBJECTIVE: To determine whether estradiol (E2) level on the day of LH surge/hCG trigger in euploid natural cycle frozen embryo transfers (NC-FET) is associated with pregnancy outcomes

DESIGN: IRB-approved retrospective cohort study.

MATERIALS AND METHODS: All NC-FET with euploid blastocysts performed at a single academic institution from May 2016 to March 2019 were reviewed. Demographic data including age, BMI, parity, race, smoking status, and SART diagnosis were collected. All patients underwent uterine cavity evaluation with correction if needed prior to NC-FET. Standard protocol for NC-FET included hCG trigger when the dominant follicle was $\geq$18 mm and the endometrial lining was $\geq$7 mm. NC-FET was performed 6 days after spontaneous LH surge (augmented with hCG trigger) or 7 days after hCG trigger alone. E2 (pg/mL) was evaluated on the day of hCG trigger. Vaginal progesterone was started 3 days before NC-FET. NC-FET with E2 $<$200 were compared to NC-FET with E2 $\geq$200. The primary outcomes of interest were clinical pregnancy rate (CPR, defined as intrauterine gestation with positive fetal cardiac activity) and live birth rate (LBR). *The R Project for Statistical Computing* was used to complete independent t-tests for continuous variables, chi-square tests for categorical variables, and logistic regressions for outcome variables.

RESULTS: A total of 441 NC-FET were analyzed. Mean age at transfer was 36.5 $\pm$SD 3.8 years, and mean BMI was 25.0 $\pm$SD 4.8 kg/m^2. The majority of patients were nulliparous (63%), Asian (51%) or White (39%), and never smokers (95%). Mean E2 on the day of spontaneous LH surge/hCG trigger was 274 $\pm$SD 121. The overall CPR was 65%, and the overall LBR was 61%. There were 134 NC-FET with E2 $<$200 and 307 NC-FET with E2 $\geq$200. Demographic variables did not significantly differ between the 2 groups, except for mean BMI, which was 26.2 in the E2 $<$200 group vs. 24.4 in the E2 $\geq$200 group, p$<$0.01. CPR was 58% for cycles with E2 $<$200 vs. 68% for cycles with E2 $\geq$200, p=0.04; LBR was 52% for cycles with E2 $<$200 vs. 65% for cycles with E2 $\geq$200, p=0.01. In a logistic regression controlling for age at transfer, BMI, parity, race, smoking status, endometrial thickness, and embryo grade, E2 $\geq$200 still predicted an increased CPR (OR 1.74 [CI 1.11, 2.72]) and an increased LBR (OR 1.94 [CI 1.25, 3.03]).

CONCLUSIONS: The focus before proceeding with NC-FET has traditionally been dominant follicle size and endometrial thickness. E2 level may also play an important role in preparing the endometrium for implantation and pregnancy, as suggested by a study of 101 untested, cleavage-stage NC-FET (1). The strength of our study lies in its larger cohort size and inclusion of only NC-FET with euploid blastocysts. In our patient population, E2 $\geq$200 at the time of hCG trigger in NC-FET predicted an increased CPR and LBR, both with statistical significance. These findings support delaying hCG trigger if E2 $<$200 in the absence of an LH surge, even when criteria for dominant follicle size and endometrial thickness are met. When an LH surge occurs and delaying hCG trigger is not possible, providers may consider postponing NC-FET to another cycle when E2 level might be more optimal.

P-442 4:30 PM Monday, October 19, 2020

MINIMAL STIMULATION USING GONADOTROPIN-RELEASING HORMONE ANTAGONIST IS ASSOCIATED WITH HIGHER LIVE BIRTH RATES: A NATIONAL STUDY OF 13,050 CYCLES. Emily G. Hurley, MD,[1] Fangbai Sun, MPH,[2] Heping Zhang, PhD,[2] Alex J. Polotsky, M.D., M.S.,[3] Julie Sroga Rios, MD,[1] [1]University of Cincinnati, West Chester, OH; [2]Yale University School of Public Health, New Haven, CT; [3]University of Colorado Anschutz Medical Campus, Aurora, CO.

OBJECTIVE: Minimal stimulation for in vitro fertilization (IVF) is advocated for reduced costs and lower rates of side effects. However, the preferred clinical protocol remains undetermined. In order to optimize patient outcomes, it is necessary to establish if the use of gonadotropin-releasing hormone (GnRH) antagonist during minimal stimulation IVF cycles improves live birth rate.

DESIGN: Historical cohort study from the Society for Assisted Reproductive Technology Clinic Online Reporting System.

MATERIALS AND METHODS: The database was queried for all fresh autologous oocyte cycles designated as minimal stimulation from 2014-2016. Cycles were categorized by the use of GnRH antagonist vs. no suppression. Cycles were excluded if an agonist flare or agonist suppression was used or if live birth was not reported. Live birth was the primary outcome. Secondary outcomes included total dose of gonadotropin, number of cryopreserved embryos and cycle cancelation rate. Wilcoxon's rank-sum test was used for continuous variables, and Chi-square test was used for categorical variables. P$<$0.05 was considered significant.

RESULTS: A total of 6,750 patients undergoing 13,050 cycles were included. Patient age ranged from 19-54 years, median 41 (IQR 37, 44) and anti-mullerian hormone (AMH) ranged from undetectable (0) to 40 ng/mL, median 0 (IQR 0.0-0.2). GnRH antagonist use was associated with a significantly higher total gonadotropin dosage (median 975.0 [IQR 600.0, 1575.0] vs. median 660.0 [IQR 375.0, 975.0]), p$<$0.001, lower cycle cancelation rate (11.3% vs. 13.6%), p$<$0.001, and higher live birth rate (4.3% vs. 2.1%), p$<$0.001, when compared to no antagonist suppression. GnRH antagonist use was associated with a significantly higher live birth rate in women 35 years or age or older and AMH $<$1 (Table). Overall, as historically reported, the live birth rate with minimal stimulation was dramatically lower than that of conventional IVF, regardless of the use of suppression.

	With Antagonist Suppression (n=5984)	Without Antagonist Suppression (n=7066)	P value
Dosage of FSH	975.0 (600.0, 1575.0)	660.0 (375.0, 975.0)	<0.001
Embryos cryopreserved	1.0 (0.0, 2.0)	0.0 (0.0, 1.0)	<0.001
Cycle canceled	11.3%	13.6%	<0.001
Live birth			
Overall	4.3%	2.1%	<0.001
AMH < 1	4.9%	2.6%	0.004
AMH ≥ 1	10.7%	11.9%	0.512
Age < 35	12.3%	12.4%	0.989
Age ≥ 35	2.7%	0.9%	<0.001

CONCLUSIONS: The use of GnRH antagonist suppression during minimal stimulation IVF cycles is associated with an improved live birth rate, especially in older women and in women with diminished ovarian reserve. Although GnRH antagonist use may increase medication costs, it significantly decreases cancelation rate and increases number of embryos cryopreserved and should be encouraged for all minimal stimulation IVF cycles.

SIMILAR OVARIAN RESPONSE WITH INDIVIDUALIZED FOLLITROPIN DELTA DOSING REGIMEN IN JAPANESE AND NON-JAPANESE IVF/ICSI PATIENTS. Osamu Ishihara, MD, PhD,[1] Anders Nyboe Andersen, MD, PhD,[2] Scott M. Nelson, MD, PhD,[3] Joan-Carles Arce, MD, PhD,[4] [1]Saitama Medical University, Saitama, Japan; [2]Rigshospitalet, Copenhagen, Denmark; [3]University of Glasgow, Glasgow, United Kingdom; [4]Ferring Pharmaceuticals, Copenhagen, Denmark.

OBJECTIVE: To compare across populations from different geographies the ovarian response associated with the individualized follitropin delta dosing regimen.

DESIGN: Post-hoc analysis of two randomized, controlled, assessor-blind, multi-center, efficacy trials with follitropin delta (Rekovelle, Ferring

Pharmaceuticals) in IVF/ICSI patients conducted in Japan and outside Japan (11 countries in Europe, North- and South America) (NCT03228680; NCT01956110).

MATERIALS AND METHODS: A total of 170 and 665 women, respectively, underwent controlled ovarian stimulation with follitropin delta in the trials in Japan and outside Japan. The two trials had similar eligibility criteria, and the Japanese and non-Japanese patients were comparable in age (mean 34.2 vs 33.4 years) and serum AMH (mean 20.9 vs 19.4 pmol/L) but not in body weight (mean 54.5 vs 64.7 kg). In both trials, the follitropin delta dosing regimen was individualized by the woman's serum AMH and body weight (AMH <15 pmol/L [<2.1 ng/mL]: 12 μg; AMH $\geq$15 pmol/L [$\geq$2.1 ng/mL]: 0.10-0.19 μg/kg; maximum 12 μg; minimum 6 μg for the Japanese trial), and the daily dose was fixed throughout stimulation. Elecsys® AMH / AMH Plus, Roche Diagnostics was used. Stimulation was carried out in a GnRH antagonist cycle, with identical triggering criteria. Mean values and proportions were compared between trials using t-tests and Fisher's exact tests.

RESULTS: Stimulation with the individualized follitropin delta dosing regimen resulted in a comparable number of oocytes retrieved in Japanese and non-Japanese IVF/ICSI patients, with a mean of 9.3±5.4 and 9.6±5.8, respectively, among all patients who started stimulation. Cycle management parameters were not significantly different between populations, with cycle cancellation due to poor ovarian response occurring for 1.2% and 3.8% in the Japanese and non-Japanese population, and excessive ovarian response leading to triggering with GnRH agonist in 1.2% and 1.5%, respectively. Among patients with AMH <15 pmol/L, the mean number of oocytes retrieved with follitropin delta was 7.2±3.7 in the Japanese population and 7.5±4.6 in the non-Japanese population, and the proportion of patients with <4 oocytes was 11.6% and 11.8%, respectively, with no significant differences between populations. Among patients with AMH $\geq$15 pmol/L, the average oocyte yield with follitropin delta was comparable with 10.8±5.9 and 11.2±6.2 in the Japanese and non-Japanese women, respectively. In this population, 22.0% of the Japanese women and 27.9% of the non-Japanese women had $\geq$15 oocytes, and 8.0% and 10.1%, respectively, had $\geq$20 oocytes, with no significant differences between populations.

CONCLUSIONS: The performance of the individualized follitropin delta dosing regimen in terms of ovarian response was consistent across trials conducted in Japan and outside Japan. This investigation documents that personalizing the follitropin delta dose based on AMH and body weight provides a predictable ovarian response among different populations, with very comparable results between Japanese and non-Japanese IVF/ICSI patients across AMH levels.

PREGNANCY OUTCOMES IN LETROZOLE OVULATION INDUCTION FROZEN-THAWED EMBRYO TRANSFER CYCLES AS COMPARED TO NATURAL AND PROGRAMMED CYCLES.

Prachi N. Godiwala, MD, Reeva B. Makhijani, MD, Chantal Bartels, MD, Alison Bartolucci, PhD, Daniel R. Grow, MD, John Nulsen, MD, Claudio A. Benadiva, MD, Lawrence Engmann, MD, Center for Advanced Reproductive Services, University of Connecticut School of Medicine, Farmington, CT.

OBJECTIVE: The optimal endometrial preparation for frozen-thawed embryo transfer (FET) cycles is controversial and variable among IVF centers. Our aim is to compare pregnancy outcomes between letrozole ovulation induction FET cycles, natural FET cycles and programmed FET cycles in a US-based population.

DESIGN: Single academic center retrospective cohort study.

MATERIALS AND METHODS: 2310 cycles consisting of patients <43 years utilizing embryos created from autologous oocytes between 2015-2020 were included. Blastocyst embryo transfer occurred 6 days after a natural LH surge to >20 mIU/mL in natural and letrozole cycles, or 6 days after the initiation of intramuscular progesterone in programmed cycles. The primary outcome was the ongoing pregnancy rate (OPR), and secondary outcomes included pregnancy rate (PR), implantation rate (IR), clinical pregnancy rate (CPR), and clinical loss rate (CLR). Chi-square test for categorical data and one-way ANOVA for continuous data was used with Bonferroni correction for multiple comparisons. Multiple logistic regression analysis was performed adjusting for age, BMI, anovulation diagnosis, number of embryos transferred and utilization of preimplantation genetic testing for aneuploidy (PGT-A). A two-sided p-value of <0.05 was considered statistically significant.

RESULTS: There was a higher proportion of patients with a diagnosis of anovulation in both letrozole and programmed FET cycles compared with natural cycles ($p < 0.01$). Patients undergoing programmed FET cycles were more likely to be younger, have a higher BMI, and to have more embryos transferred compared to patients undergoing natural FET and letrozole FET cycles ($p < 0.01$). The OPRs and CPRs were similar between the groups, while the CLRs were higher in the programmed compared with natural and letrozole FET cycles. After adjusting for potential covariates, the probability of clinical loss was still significantly higher in programmed cycles compared with natural and letrozole FET cycles (aOR 1.58; 95% CI, 1.15-2.12; $p < 0.01$).

Outcome	Natural FET (n = 1135)	Letrozole FET (n = 88)	Programmed FET (n = 1087)	p value
PR (%, n)	77.8 (883/1135)	78.4 (69/88)	79.9 (869/1087)	0.46
IR (%, n)	62.1 (877/1413)	63.4 (64/101)	62.1 (903/1455)	0.96
CPR (%, n)	68.8 (781/1135)	67.0 (59/88)	69.5 (755/1087)	0.87
OPR (%, n)	60.4 (686/1135)	59.1 (52/88)	56.9 (619/1087)	0.25
CLR (%, n)	11.5 (90/781)	11.9 (7/59)	17.5 (132/755)	<0.01

CONCLUSIONS: Letrozole ovulation induction may be a better alternative to programmed FET cycles particularly for anovulatory patients in view of the lower clinical loss rate.

THE ASSOCIATION OF ENDOMETRIAL THICKNESS AND ENDOMETRIAL TYPE WITH IVF OUTCOMES IN A SHARED OOCYTE DONOR-RECIPIENT MODEL.

Devora Aharon, MD,[1] Guillaume Stoffels, MA,[1] Dmitry Gounko, MA,[2] Jessica Overbey, DrPH,[1] Joseph A. Lee, BA,[2] Alan B. Copperman, MD,[1] Erkan Buyuk, MD,[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: The effect of endometrial thickness and type on pregnancy outcomes of ART cycles is controversial.[1-2] A challenge in evaluating the role of the endometrial characteristics is the inability to completely control for the impact of egg quality in patients who have difficulty achieving an "adequate lining."[2] Assessing transfer outcomes among shared recipients of the same oocyte donor allows for a more precise assessment of the role of endometrial characteristics in embryo transfer outcomes. The objective of this study is to evaluate the impact of endometrial thickness and type on ART cycle outcomes among shared oocyte donor recipients.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Shared recipients of the same oocyte donor cycle from July 2002 through May 2019 were included in the study. Endometrial thickness and type at progesterone start were analyzed. Demographic and cycle characteristics and outcomes were compared among recipients with an endometrial thickness of < 7 vs. ≥ 7mm, and among recipients with an endometrial type of 1 compared to types 2 and 3. Comparative statistics were used to compare the groups. Mixed effects logistic regression was used to analyze the impact of endometrial thickness and endometrial type on clinical pregnancy (CP) and live birth (LB) rate among shared recipients of the same donor cycle, accounting for repeated recipients and donors. Potential confounders considered were recipient age, donor age, days of estradiol administration, embryo quality, frozen embryo, euploid embryo, number of embryos transferred, and embryo age. A threshold value for endometrial thickness associated with improved odds of LB was calculated using an area under the curve model.

RESULTS: A total of 2075 oocyte recipient transfer cycles from shared donors were identified and included in the study. 468 donors and 1364 recipients were included in the analysis. Recipients with endometrium $<$7mm (N=73) had a significantly lower LB rate compared to recipients with lining $\geq$7mm (N=2000) (31.5% vs. 48.7%, p=0.0039). There were no significant differences in CP and LB rates among type 1 (N=947) compared to type 2/3 (N=1055) endometrial lining. Increased endometrial thickness was significantly associated with CP (OR 1.08, 95% CI 1.02-1.14, p=0.004) and LB rates (OR 1.07, 95% CI 1.02-1.13, p=0.008) after controlling for confounders. The thickness threshold that simultaneously maximized sensitivity and specificity for LB was 10 mm, with an average probability of LB of 0.48 and sensitivity and specificity of 0.59 and 0.62, respectively. The model AUC was 0.65.

CONCLUSIONS: When controlling for the oocyte factor using a shared donor model, patients with endometrial thickness of $\geq$7mm had increased LB rate, however a thicker lining was associated with better outcomes, with LB rate optimized at a threshold of 10 mm. This data will be used to generate a multi-dimensional model to optimize synchronization and endometrial preparation to maximize the likelihood of implantation and positive reproductive outcome.

CHANGE IN PROGESTERONE LEVEL DURING IVF STIMULATION PREDICTS LIVE BIRTH RATE FOLLOWING FRESH EMBRYO TRANSFER.

Serin I. Seckin, MD,[1] Dawn A. Kelk, PhD, HCLD,[2] Victoria G. Wesevich, MD,[3] Amanda Nicole Kallen, MD,[3] Pinar H. Kodaman, MD/PhD,[3] [1]Icahn School of Medicine at Mount Sinai West/St. Luke's, New York, NY; [2]Yale University, Orange, CT; [3]Yale School of Medicine, New Haven, CT.

OBJECTIVE: Prematurely elevated progesterone levels at time of hCG/GnRH agonist trigger can lead to a developmentally advanced endometrium relative to the fresh embryo that is subsequently transferred. Embryo implantation may be compromised in the setting of this asynchrony. Our objective is to examine the peak progesterone level at the time of trigger in addition to the change in progesterone levels (ΔP) between baseline and trigger to determine optimal cutoff values for progesterone and ΔP as well as to assess their effects on pregnancy outcome following IVF with fresh embryo transfer.

DESIGN: Single-center prospective cohort study

MATERIALS AND METHODS: A total of 292 patients $<$42 years of age undergoing fresh IVF cycles with an antagonist protocol were included in the study. Exclusion criteria included patients using donor oocytes, gestational carriers, and patients who had preimplantation genetic testing of embryos. The peak progesterone level and ΔP were modeled in relation to prediction of clinical pregnancy rate (CPR) and live birth rate (LBR), controlling for age, BMI, number of embryos transferred, and endometrial thickness. Data was analyzed using the Python Statsmodels library to build a multivariable logistic regression model after standard scaling the data and classifying ΔP as high or low.

RESULTS: The CPR and LBR in the dataset were 53.4% and 46.3 %, respectively. Comparative models demonstrated that a ΔP cut-off of 0.9 ng/ml was more predictive than using peak progesterone level alone in predicting CPR (p=0.025, 95% CI -5.27, -0.035) and LBR (p=0.026, 95% CI -0.564, -0.036). Patients who had a $<$0.9 ng/ml rise in progesterone were 2.5 times and 2.7 times more likely to achieve clinical pregnancy and live birth, respectively.

CONCLUSIONS: The relative change in progesterone level from baseline to trigger (ΔP) is more predictive in determining pregnancy outcome following fresh ET as compared to peak progesterone level alone. As progesterone assays vary between laboratories, the threshold for an optimal serum progesterone level may also vary. Therefore, incorporating the ΔP level may be helpful in assessing hormone levels prior to making the decision to proceed with fresh embryo transfer.

	CPR	LBR
Overall Outcome	53.4%	46.3%
Odds Ratio for pregnancy outcome ΔP$<$0.9	2.5	2.7
Outcome ΔP$>$0.9	66.6%	73.4%
Logistic Coefficient p-value ΔP$>$0.9	0.025	0.026
Logistic Coefficient 95% Confidence Interval ΔP$>$0.9	(-5.27, -0.035)	(-0.564, -0.036)

P-447 4:30 PM Monday, October 19, 2020

IMPACT OF IN VITRO FERTILIZATION AND PREIMPLANTATION GENETIC TESTING ON THE SEX RATIO IN THE UNITED STATES.

Kathryn L. Shaia, MD, MHA,[1] Tracy Truong, MS,[2] Carl F. Pieper, DrPH,[2] Anne Z. Steiner, MD, MPH,[3] [1]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC; [2]Department of Biostatistics & Bioinformatics, Duke University Medical Center, Durham, NC; [3]Duke University, Durham, NC.

OBJECTIVE: The sex ratio (SER) is defined as the ratio of males to females in the population. In vitro fertilization (IVF) and preimplantation genetic testing (PGT) have each been shown to increase the probability of delivering a male offspring. We sought to investigate the impact of increasing

Table 1Simulation results of SER at birth and SER in the population at 10, 20, and 30 years with varying IVF and PGT rates

% IVF Births	% PGT	US SER at birth	US SER at 10 years	US SER at 20 years	US SER at 30 years
1%	50%	1.050343	0.9785819	0.9862770	0.9931707

utilization of IVF and PGT on the sex ratio in the United States (US) population.

DESIGN: Simulation model.

MATERIALS AND METHODS: Population data, population SER, SER at birth, and birth and death rates for 2017 were obtained from the Central Intelligence Agency, Centers for Disease Control and Prevention, and the US Department of Health and Human Services. Based on an analysis of Society for Assisted Reproductive Technology (SART) data from 2014-2016, the sex ratio at birth for IVF with PGT was calculated as 1.10 and without PGT as 1.07. The simulation was conducted while varying the IVF and PGT utilization in the US to predict the SER at birth as well as the population SER after 10, 20, and 30 years.

RESULTS: In 2017, the population SER was 0.97, and the SER at birth was 1.05. The simulation results are shown in Table 1. Increasing utilization of IVF and PGT had minimal impact on the SER at birth. However, over time the SER in the population increased from 0.97 to 0.99, or 2 more males for every 100 persons.

CONCLUSIONS: Increased utilization of IVF and PGT would have minimal impact on the population SER at birth but would significantly alter the population SER in the US over time.

EVALUATING THE ABILITY OF AN OOCYTE TO REPAIR FRAGMENTED SPERM CHROMATIN.

Derek Keating, B.A., Alessandra Parrella, M.Sc., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To assess the ability of human oocyte repair mechanisms to fix sperm chromatin defects following intracytoplasmic sperm injection (ICSI) insemination in relation to cytoplasmic maturity.

DESIGN: From 2006-2020, ejaculates from 246 men were assessed for sperm chromatin fragmentation (SCF). These men underwent ICSI with their female partners using ejaculated spermatozoa. To understand the impact of nuclear maturity on oocyte repair mechanisms, the proportion of metaphase-II (MII) oocytes obtained at retrieval was used to infer cytoplasmic readiness. We then assessed clinical outcomes according to the proportion of mature oocytes at the time of denudation.

MATERIALS AND METHODS: Samples from consenting couples were screened for SCF levels by terminal deoxynucleotidyl dUTP transferase nick-end labeling (TUNEL) using a commercial kit. A minimum of 500 spermatozoa were assessed per patient, and an SCF of $<15\%$ was considered normal. From the retrieved cohort, the proportion of MII oocytes at the time of ICSI was reported and used for this assessment. ICSI was performed in the standard fashion. Female age was limited to ≤ 37 years to control for confounding female factors. A clinical pregnancy was defined as the presence of a fetal heartbeat.

RESULTS: A total of 259 couples underwent 445 ICSI cycles. Of these, 134 couples underwent 234 cycles yielding an optimal ($\geq 80\%$) oocyte maturity, and 125 couples underwent 211 cycles with a suboptimal ($<80\%$) maturity. The average SCF was $9.3\pm3\%$ within threshold and $24.1\pm10\%$ above threshold ($P<0.0001$).

Characteristics of SCF did not affect clinical outcome within the optimal oocyte maturity cohort in terms of fertilization (74.2% vs. 71.0%), implantation (23.4% vs. 23.1%), and clinical pregnancy rates (CPR; 34.4% vs. 39.3%).

However, in the suboptimal maturity cohort, an abnormal SCF yielded compromised implantation compared to those within threshold (10.7% vs. 20.2%; $P<0.05$).

To validate our findings, we looked only at men with abnormal SCF. The suboptimal oocyte cohort had comparable fertilization rates (71.0% vs. 72.5%) but compromised embryo implantation (23.1% vs. 10.7%; $P<0.05$) and CPRs (39.3% vs. 20.0%; $P<0.05$). No differences were observed in couples with normal SCF independent of oocyte maturity levels.

CONCLUSIONS: This study describes the role of the oocyte in repairing fragmented sperm chromatin in relation to cytoplasmic maturity. Oocyte DNA repair is a dynamic process that, rather than being intrinsic to the oocyte, is linked to the particular ovarian superovulation protocol used.

P-449 4:30 PM Monday, October 19, 2020

RATIO OF HUMAN MENOPAUSAL GONADOTROPIN (HMG) TO RECOMBINANT FOLLICLE STIMULATING HORMONE (RFSH) DOSAGE PREDICTS PREMATURE PROGESTERONE ELEVATION AND LIVE BIRTH RATE IN FRESH IVF CYCLES.

Victoria G. Wesevich, MD,[1] Dawn A. Kelk, PhD, HCLD,[2] Serin I. Seckin, MD,[3] Pinar H. Kodaman, MD/PhD,[1] Amanda Nicole Kallen, MD,[1] [1]Yale School of Medicine, New Haven, CT; [2]Yale University, Orange, CT; [3]Icahn School of Medicine at Mount Sinai West/St. Luke's, New York, NY.

OBJECTIVE: Premature progesterone rise during IVF stimulation reduces endometrial receptivity and is associated with decreased pregnancy rates following embryo transfer (ET). To our knowledge, no data exists regarding the appropriate ratio of hMG (which has 1:1 LH:FSH activity) to rFSH (which has FSH activity alone) to improve pregnancy outcomes. Our objective is to determine if an optimal ratio of hMG:rFSH can be identified that best predicts a reduced risk of elevated serum progesterone levels and change in progesterone (ΔP) during IVF stimulation, and to determine whether this ratio can also predict pregnancy outcomes following fresh ET.

DESIGN: Single-center prospective cohort study

MATERIALS AND METHODS: A total of 292 women between the ages of 21-42 years undergoing fresh antagonist IVF cycles were included. Exclusion criteria were use of donor oocytes, gestational carriers, and preimplantation genetic testing cycles. The ratios of hMG to rFSH were modeled in relation to prediction of peak progesterone level on day of hCG administration (peak P), clinical pregnancy rate (CPR), live birth rate (LBR), and miscarriage rate. Since we have recently shown that a greater increase in serum progesterone level (ΔP) between stimulation start and time of hCG trigger negatively influences pregnancy outcomes, we also analyzed hMG:rFSH ratios in relation to ΔP. Our analysis controlled for age, BMI, number of embryos transferred, and endometrial thickness. Data was analyzed using the Python Statsmodels library to build a multivariable logistic regression model after standard scaling the data and classifying hMG:rFSH as "within" versus "outside" the "optimal" ranges identified.

RESULTS: Overall CPR, LBR and miscarriage rates were 53.4%, 46.3 %, and 7.9% respectively. Comparative models demonstrated that an hMG:rFSH ratio of 0.6-1.4 was predictive of both peak P (p=0.014, 95% CI -0.259, -0.029) and ΔP (p=0.022, 95% CI -0.228, -0.017) during IVF stimulation. Additionally, for CPR, the best outcomes were seen within the range of hMG:rFSH ratios 0.3-0.4 [75.6% vs 62.5% within and outside of the range, respectively, (p=0.032, 95% CI 0.069, 1.505)]. For LBR, the best outcomes were seen within the ratio range of 0.3-0.6 hMG:rFSH, LBR of [55.4% vs 41.4% (p=0.023, 95% CI 0.081, 1.079)]. Miscarriage rates outside of the ratio range of 0.3-0.6 were significantly higher, [17.7% vs 6.7% (p=0.049, 95% CI 0.099, 0.110)].

CONCLUSIONS: We have shown that the relative dosing of hMG:rFSH in fresh IVF cycles predicts subsequent progesterone levels (both peak P and ΔP), and that the use of an optimal hMG:rFSH dosing ratio is associated with the highest likelihood of CPR, LBR, and lowest miscarriage risk. Thus, use of an appropriate ratio of hMG:rFSH, and specifically incorporating LH activity, should be considered in all fresh IVF cycles in order to achieve optimal outcomes.

SYSTEMIC CATEGORIZATION OF OOCYTE GRANULATION PATTERNS AND THEIR PREDICTIVE VALUE FOR IVF OUTCOMES.

Jianjun Hu, MD,[1] Lin Zhang, MD,[1] David F. Albertini, PhD, MS,[1] Emanuela Molinari, PhD,[1] David H. Barad, MD, MS,[1] Norbert Gleicher, MD,[2] [1]Center for Human Reproduction, New York, NY; [2]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY.

OBJECTIVE: Since oocyte quality sits upstream from embryo quality and, therefore, may be a superior predictor of embryo quality, to investigate for the first time in oocytes as potential predictors IVF outcomes4 patterns of cytoplasmic granulations.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Based on size and distribution of cytoplasmic granules of MII oocytes in IVF cycles with intracytoplasmic sperm injection in years 2017-2019, we systematically categorized cytoplasmic granulation of oocytes after assigning them to 4 granulation patterns: (i) fine; (ii) central; (iii) dispersed; and (iv) a pattern we termed uneven. We then statistically assessed their association with fertilization (2PN, <2PN, >2PN), final disposition (usable rates), pregnancy, and live birth rates. Analyses were done in fresh autologous oocytes, for *in vitro*matured autologous oocytes, as well as fresh and thawed donor oocytes. In fresh oocytes, fertilization analysis was also performed in age groups (<=30, 31-35, 36-39, 40-42, ≥43 years) to verify reliability and independence of this categorization system. Two methods, embryos/oocytes count-based method and a more stringent scoring-based method, were used to determine the contribution of embryos/oocytes that resulted in pregnancy.

RESULTS: In fresh autologous MII oocytes, fine granulation demonstrated highest normal fertilization (2PN, 90.3%, n=620); central granulation was the most uncommon pattern and demonstrated slightly lower 2PN rate (85.6%, n=312, P<0.05 vs. fine granulation); Uneven granulation had a lower 2PN rate (76.3%, n=1135, p<0.001, with increased <2PN and >2PN rates vs. fine granulation); Strikingly, dispersed granulation demonstrated the lowest 2PN rate (56.4%, n=543, P<0.001 compared to all other patterns). Fertilization rates showed similar trends among age different groups, suggesting that granulation patterns were relatively (butnot absolutely) independent of age. In fresh autologous oocytes, dispersed granulation had the lowest pregnancy rate [9.1% (14/154), vs. 21.3% (60/282) in fine granulation,P=0.001; vs. 19.8% (82/415) in uneven granulation,P=0.002] and the lowest live birth rate [3.9% (6/154), vs. 12.8% (36/282) in fine granulation, P<0.01; vs. 10.0% (12/120) in central granulation, P<0.05; vs. 12.8% (53/415) in uneven granulation, P<0.0].Similar differences were also found in fresh and thawed donor oocytes.

CONCLUSIONS: Systemic categorizationof cytoplasmic granulation in human oocytes appears to represent a reliable, and in fresh, thawed, even *in vitro*matured oocytes by fertilization rates validated method of ultimate embryo selection and, potentially, pregnancy and live birth prediction, mostly independent of age. Two follow-up studies are underway: (i) On a physiological level, a determination of what these granulations represent; and on a clinical level how they relate to pregnancy and live birth rates at different ages?

SUPPORT: Intramural funds from The Center for Human Reproduction and Foundation for Reproductive Medicine.

P-451 4:30 PM Monday, October 19, 2020

GNRH ANTAGONIST-INDUCED HYPOTHALAMIC SUPPRESSION AS A PREDICTOR OF SUBOPTIMAL RESPONSE TO GNRH AGONIST TRIGGER.

Christine Yang, MD,[1] Phillip A. Romanski, MD,[2] Pietro Bortoletto, MD,[2] David Reichman, MD,[2] Zev Rosenwaks, M.D.[2] [1]Weill Cornell Medicine, New York City, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine if iatrogenic hypothalamic suppression during a GnRH antagonist IVF cycle is a risk factor for suboptimal response to GnRH agonist trigger.

DESIGN: Retrospective cohort study of GnRH antagonist IVF cycles triggered with 4 mg GnRH agonist alone or in combination with hCG. Hypothalamic suppression was defined as an LH level <1.0 (mIU/mL). Patients were stratified based on the following LH levels: >1.0 at cycle start and at trigger (control), <1.0 only at trigger (iatrogenic suppression), <1.0 at cycle start and at trigger (moderate endogenous suppression), and <1.0 only at cycle start (mild endogenous suppression).

MATERIALS AND METHODS: The primary outcome was the proportion of patients with post-trigger LH levels <15. The secondary outcome was the proportion of patients with post-trigger LH levels <50. Logistic regression, adjusted *a priori* for age and use of oral contraceptive priming for the IVF cycle, was used to estimate the odds ratio with a 95% confidence interval among the groups (OR (CI)). The timing of the trigger administration was determined by the treating physician.

RESULTS: A total of 5,702 cycles were included (control group: 2,492; iatrogenic suppression: 2,653; moderate hypothalamic suppression: 434; and mild hypothalamic suppression: 123). The mean ± standard deviation post-trigger LH levels (mIU/mL) for each group was: control 110.4 ± 49.8; iatrogenic suppression 100.9 ± 47.0; moderate hypothalamic suppression 54.7 ± 35.0; and mild hypothalamic suppression 81.2 ± 47.1. When evaluating the proportion of patients with a post-trigger LH <15, there were no differences between the control and iatrogenic suppression groups (0.6 vs. 0.5%; OR 0.90; 0.43-1.90). However, there was a significant difference in the proportion of patients with post-trigger LH <50 between these two groups (9.5 vs. 12.6%; OR 1.45; 1.21-1.74). When compared to the control group, the moderate endogenous suppression group was significantly more likely to have a post-trigger LH <15 (0.6 vs. 9.7%; OR 17.87; 9.48-33.66) and post-trigger LH <50 (9.5 vs. 51.4%; OR 10.62; 8.36-13.50). When compared to the control group, the mild endogenous suppression group was also significantly more likely to have a post-trigger LH <15 (0.6 vs. 3.4%; OR 4.51; 1.28-15.93) and a post-trigger LH <50 (9.5 vs. 32.5%; OR 4.46; 2.98-6.66).

CONCLUSIONS: Patients with evidence of hypothalamic suppression at the start of an IVF cycle are at high risk for a suboptimal response to GnRH agonist trigger. In patients who become iatrogenically suppressed during the IVF cycle, the risk of post-trigger LH <15 is similar to non-suppressed patients. Therefore, GnRH agonist-only trigger should be approached with caution in patients with an LH <1.0 at cycle start. Gonadotropin dosing in such cycles should be carefully dosed in order to mitigate ovarian hyperstimulation risk.

USE OF PROPENSITY SCORE MATCHING TO ASSESS THE ENDOMETRIAL RECEPTIVITY ASSAY (ERA) IN OPTIMIZING EMBRYO TRANSFER OUTCOMES.

Keri Bergin, MD,[1] Yael Eliner, MD, MPH Candidate,[2] Denis A. Vaughan, MD,[3] Denny Sakkas, PhD,[3] Daniel W. Duvall, Jr., BA,[3] Sonia Elguero, MD,[4] Alan S. Penzias, M.D.[5] [1]Albany Medical Center, Albany, NY; [2]MPH Candidate, Boston, MA; [3]Boston IVF, Waltham, MA; [4]Boston IVF, Loundonville, NY; [5]Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, MA.

OBJECTIVE: The increasing utilization of frozen embryo transfer (FET) has intensified the need to assess outcomes and refine protocols. The timing of embryo transfer is of paramount importance, with commercially available endometrial transcriptomic profiling (Endometrial Receptivity Assay, ERA) purported to improve FET outcomes. The primary objective of this study was to utilize propensity score matching to compare FET outcomes in patients who had undergone ERA biopsy to a control group.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All cycles with FET between January 2014 and March 2019 at a university-affiliated IVF center were reviewed. Data from 163 and 5671 patients with and without ERA assessment, respectively, were assessed. Propensity score matching (PSM) was performed based on the following variables: age at oocyte retrieval, number of oocytes retrieved, total number of prior cycles, preimplantation genetic screening, number of embryos transferred, FET protocol, infertility diagnosis, gravidity, body mass index, age at FET, oocyte retrieval date, use of ICSI. 161 ERA patients were successfully matched to 320 of the 5671 non-ERA patients in a 1:2 matching ratio. A conditional logistic regression was performed on the matched data to compare the live birth rates in each group.

RESULTS: After propensity score matching, there was no significant difference in patient characteristics between the groups, creating similar cohorts. For example, the frequency of PGT-A use was significantly different between groups initially (76.7% vs 33.5% in PGT-A vs controls respectively, P =<.0001). Following propensity score matching the use of PGT-A was similar in both groups (Table 1). The overall propensity score had a mean difference of 0.021 between groups. A total of 100/161 (62.1%) ERA patients and 200/320 (62.5%) non-ERA patients achieved live birth over the course of their treatment. 76/161 patients (47.2%) were noted to be non-receptive on ERA.

CONCLUSIONS: In this study, overall live birth rates were similar, irrespective of ERA use. While propensity score matching is a useful tool to match patients in a retrospective setting, there may be inherent differences between groups that cannot be controlled for. Further studies are required to define the patient cohort who may benefit from ERA prior to embryo transfer.

Table 1Example of Patient Characteristics before and after PSM

	Before PSM			After PSM		
	ERA (n=163)	Non-ERA (n=5671)	P value	ERA (n=161)	Non-ERA (n=320)	P value
Age at Retrieval, Mean (SD)	36.2 (3.7)	35.0 (4.0)	0.0002	36.2 (3.7)	36.4 (3.9)	0.44
Cycle Number, Mean (SD)	5.5 (2.5)	3.4 (1.9)	< .0001	5.4 (2.5)	5.2 (2.6)	0.35
PGT-A, n (%)	125 (76.7)	1900 (33.5)	< .0001	124 (77.0)	242 (75.6)	0.74

THE EFFECT OF ENDOMETRIAL THICKNESS ON LIVE BIRTH OUTCOMES IN WOMEN UNDERGOING HORMONE REPLACED FROZEN EMBRYO TRANSFER (HR-FET).

Rachel A. Martel, BA,[1] Jennifer K. Blakemore, MD,[2] James A. Grifo, MD, PhD,[3] [1]NYU Grossman School of Medicine, Manhattan, NY; [2]NYU Langone Prelude Fertility Center, New York, NY; [3]NYU Langone School of Medicine, New York, NY.

OBJECTIVE: Endometrial development is an important factor in healthy placentation. Recent evidence demonstrates that endometrial thickness may correlate with live birth (LB) outcomes after In Vitro Fertilization cycles with a fresh embryo transfer [1]. Our objective was to determine the impact of endometrial thickness on LB outcomes and obstetric complications after HR-FET.

DESIGN: Retrospective cohort study of all patients with a singleton LB from a single euploid HR-FET cycle between 1/2017 and 12/2018.

MATERIALS AND METHODS: All patients with a singleton LB after single euploid embryo transfer (by array CGH or Next Generation Sequencing) in a HR-FET cycle in the study period were reviewed. HR-FET cycles were defined by treatment of oral estradiol (E2) daily until E2 >150pg/mL and the endometrium measured a goal of at least 7mm, followed by progesterone; either 50-75mg intramuscular in oil or vaginal suppository. Embryo transfer was performed on the 6th day of progesterone administration. Patients with missing data were excluded from analysis**.** Primary outcomes were 1) birthweight and 2) obstetric complication rate. The composite obstetric complication outcome was defined by inclusion of any of the following: pre-eclampsia or gestational hypertension, HELLP syndrome, abnormal placentation and umbilical cord anomalies, or intrauterine growth restriction. SPSS (v 25.0) was used for statistical analysis including Students t-test, Mann-Whitney U for non-parametric variables, chi-squared, Spearman's rho correlation and logistic regression where appropriate, with $p<0.05$ considered significant.

RESULTS: 492 patients were included. The mean age of patients at HR-FET was 37.14 ±4.49 years and 86.8% of patients had no or minor medical conditions. Median endometrial thickness prior to transfer was 8.6 mm (range 6.0 – 20.0). The mean gestational age (GA) at LB was 38.8 ±2.2 weeks with a mean birthweight of 3,287±590.5 grams. Endometrial thickness was significantly correlated with birthweight ($p<0.03$). When patients were dichotomized into two groups, those with endometriums below or above 7mm, babies born from endometriums <7mm were 1) born earlier (257 ±24.6 vs 273.0±15.0, $p<0.001$) and 2) born at lower birthweights (2455±770.5 vs 3307.2±572.3, $p<0.001$). Notably, in a subgroup analysis of all babies born at term (> 37 weeks), endometrial thickness was not significantly associated with being small for gestational age ($p=0.318$). 7.7% (n=38) of patients had an obstetric complication. Endometrial thickness was not significantly associated with obstetric complications ($p=0.205$), even with adjustments for age and medical history ($p=0.274$). Furthermore, there was no difference in complication rate between patients with an endometrial thickness under as compared to over 7mm (10% vs 8.3%, $p=0.591$).

CONCLUSIONS: Endometrial thickness may be a valuable predictor of placental health and birthweight. Further study is needed to examine the relationship with individual obstetric complications as well as the relationship to endometrial thickness in natural frozen embryo transfer cycles.

LOW EUPLOIDY RATE DOES NOT AFFECT CLINICAL OUTCOMES IN IVF PGT CYCLES WITH SINGLE EMBRYO TRANSFER (SET) - A 2391 SETS REVIEW.

Oleksii O. Barash, Ph.D., Kristen Ivani, Ph.D., H.C.L.D, Deborah Wachs, MD, Louis N. Weckstein, MD. Reproductive Science Center of the San Francisco Bay Area, San Ramon, CA.

OBJECTIVE: Recent publications have demonstrated significant improvement in IVF treatment outcomes by implementing NGS/SNP-based preimplantation genetic testing (PGT) while transferring fewer embryos. Euploidy rates can vary significantly even for the same patient from cycle to cycle. The objective of this study was to evaluate clinical pregnancy rates in IVF cycles with low euploidy rates.

DESIGN: A retrospective study of IVF PGT outcome data from blastocysts biopsied on day 5 or day 6 was conducted to identify differences in clinical pregnancy rates.

MATERIALS AND METHODS: 1646 cycles (13869 embryos, 6.2 ± 3.81 per cycle) of IVF PGT treatment where at least one euploid embryo was available between January 2013 and January 2020 were included in the study. 2391 single embryo transfers (SET) were performed (average maternal age – 36.2 ± 4.7). All SETs were divided in 4 groups based on euploidy rates: 1-25% (192 SETs), 26-50% (819 SETs), 51-75% (774 SETs), and 75-100% (606 SETs). All embryos were vitrified after biopsy, and selected embryos were subsequently thawed for a hormone replacement frozen embryo transfer cycle. Clinical pregnancy rate (PR) was defined by the presence of a fetal heartbeat at 6 - 7 weeks of pregnancy.

RESULTS: Analysis of the data showed no statistically significant difference in clinical pregnancy rates between the group with lowest (1-25%) and the group with highest euploidy rates (76-100%): 65.63% (126/192) vs 65.18% (395/606), respectively, $\chi^2 = 0.013$, OR = 1.02, CI = 0.725 – 1.435, $p<0.05$. Even in the group of patients with 100% euploidy rate (average age 34.4 ± 4.9) the clinical pregnancy rate was not statistically different – 63.5% (233/367, $p<0.05$). For some patients low euploidy rates were manifested also in a small number of euploid embryos available for transfer – 29.7% (489/1646) of patients in our study had only one euploid embryo. At the same time, no statistically significant difference was found in the clinical pregnancy rates in the cycles where only one euploid embryo was available versus IVF PGT cycles where four or more euploid embryos were available for a transfer: 65.24% (319/489) vs 66.96% (675/1008), respectively, $\chi^2 = 0.507$, OR = 0.926, CI = 0.737 – 1.162, $p<0.05$.

CONCLUSIONS: Analysis of the data proved that low euploidy rate does not affect clinical outcomes in IVF PGT cycles with single embryo transfer.

Single embryo transfer should be imperative in PGT cycles regardless of the euploidy rate or the total number of euploid embryos available for transfer.

P-455 4:30 PM Monday, October 19, 2020

THE PRESENCE OF CESAREAN SECTION SCAR DIVERTICULUM IS DETRIMENTAL TO THE REPRODUCTIVE OUTCOME OF FRESH AND FROZEN EMBRYO TRANSFER AFTER IN VITRO FERTILIZATION/INTRACYTOPLASMIC SPERM INJECTION. Ling Huang, MD,[1] Sunxing Huang, MD,[1] Yubin Li, Professor,[1] Minghui Chen, Professor,[1] Lingli Long, MD,[2] Canquan Zhou, Professor,[1] [1]Reproductive Medicine Center, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Translation Medicine Center, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: The primary purpose of our study was to investigate the influence of cesarean scar diverticulum on the reproductive outcome of fresh and frozen embryo transfer after in vitro fertilization/intracytoplasmic sperm injection. The secondary aim of our study was to assess the impact of endometrial cavity fluid on the reproductive outcome of embryo transfer among patients with an existing cesarean scar diverticulum.

DESIGN: This was a retrospective cohort study. 1275 patients who had a history of cesarean delivery between January 2013 and December 2018 at our Institute of Reproductive Medicine were included. The study included 847 cycles of fresh embryo transfer and 1213 cycles of frozen embryo transfer. According to the results of transvaginal gynecological ultrasound, the patients were divided into two groups: cesarean scar diverticulum group(n=169) and cesarean delivery without diverticulum group(n=1106). According to the presence of endometrial cavity fluid during the endometrial preparation process of frozen embryo transfer, patients with the cesarean scar diverticulum were divided into two subgroups: endometrial cavity fluid group(n=36) and non-endometrial cavity fluid group(n=108).

MATERIALS AND METHODS: The basic characteristics, pregnancy outcome and delivery outcome of the included patients were collected from the database of our institute and compared. Binary logistic regression analysis was performed to adjust confounding factors when the baseline demographic variables of two groups of patients were significantly different. The propensity score was computed by accounting for the effect of confounding factors. Propensity scores were matched 1:1 using the nearest neighbor matching method. The matched data set was used in logistic regression.

RESULTS: There were no significant differences in the baseline variables between the cesarean scar diverticulum group and the control group. The implantation rate, clinical pregnancy rate and live birth rate of fresh embryo transfer in the cesarean section diverticulum group was significantly lower than the control group(19.6% vs 32.5%,p=0.001; 25.7% vs 43.0%,p=0.001; 17.8% vs 31.6%,p=0.004). The implantation rate, clinical pregnancy rate and live birth rate of frozen embryo transfer in the cesarean section diverticulum group was also significantly lower than the control group(27.1% vs 34.5%,p=0.015; 32.7% vs 41.2%,p=0.021; 23.5% vs 31.4%,p=0.021). 21.20% cycles of frozen embryo transfer among the cesarean section scar diverticulum group developed endometrial cavity fluid during endometrial preparation. The baseline variables were similar between the endometrial cavity fluid and non-endometrial cavity fluid group after propensity score matching. The odds of clinical pregnancy and miscarry were similar between two subgroups before and after adjustment for covariates (adjusted OR0.45(0.18-1.12), P=0.086; adjusted OR 0.75(0.14-3.95), P=0.736).

CONCLUSIONS: The presence of cesarean section scar diverticulum was detrimental to embryo implantation and had a bad impact on reproductive outcomes of fresh and frozen embryo transfer.

P-456 4:30 PM Monday, October 19, 2020

THE DEGREE OF BLASTOCYST EXPANSION POST-WARMING STRONGLY PREDICTS CLINICAL OUTCOMES IN SINGLE FROZEN EMBRYO TRANSFER CYCLES (SFET). Ahmad Morsi Abu Maizar, M.Sc,[1] Diane Wright, PhD,[2] Richard Marrs, MD,[1] Guy E. Ringler, MD,[1] Kelly J. Baek, MD,[1] Karine Chung, MD,[1] Matthew David VerMilyea, PhD,[3] [1]California Fertility Partners, Los Angeles, CA; [2]Ovation Fertility, Houston, TX; [3]Ovation Fertility, San Antonio, TX.

OBJECTIVE: To determine whether the degree of blastocyst re-expansion post warming affects the Clinical Pregnancy Rate (CPR) in PGT-A tested Embryo Transfer cycles.

DESIGN: Retrospective analysis of data from a single private fertility clinic

MATERIALS AND METHODS: CPR of 519 frozen PGT-A tested euploid blastocyst was evaluated for sFET cases during 2018-2019. CPR was determined by the presence of a positive fetal heartbeat (FHB) at 7 weeks. As a standard lab protocol, all fertilized oocytes underwent uninterrupted extended culture in FujiFilm Irvine Scientific Media CSCM-NXC and CSCM-NX until biopsy on day 5, 6 or 7. Transfers were performed using vitrified/warmed blastocysts. Blastocyst warming was performed on the day of the sFET and re-expansion was checked at the time of transfer. A standardized expansion guide was created, and embryologists were trained to use it to examine and document the degree of re-expansion post warming. Re-expansion evaluations were subdivided into five intervals; 0%, 25%, 50%, 75% and 100%. Data was analyzed by mean time difference for blastocyst re-expansion (time difference between the first and the second check), the patients' age, the egg source (donor vs patient) and the embryo recipient (gestational carrier vs patient). Statistical analysis was performed using Chi-square ($P < 0.05$). A multivariable linear regression analysis was also performed to adjust for confounders such as age.

RESULTS: Our data show that embryos with > 50% re-expansion post warming have a significantly higher CPR when compared to embryos with < 50% re-expansion (63% vs 21% respectively, P= 0.002). Furthermore, the difference was more substantial with embryos with < 25% re-expansion compared to embryos that achieved >= 50% re-expansion (25% vs 71%, p=0.001) Table 1. There was no correlation between patients' age and the degree of re-expansion (P=0.995). In addition, there was not an association between the degree of expansion and the egg source (P= 0.913) or embryo recipient (P= 0.879) categories. Finally, the mean time difference from thaw did not influence the CPR when correlated with the degree of expansion (P=0.824).

CONCLUSIONS: Our data suggest that the degree of embryo re-expansion post warming could serve as a strong predictor of clinical pregnancy in frozen embryo transfers of euploid blastocysts. Furthermore, our data suggests that a minimum of 25% of re-expansion may be a good indicator to predict the embryo's implantation potential.

TABLE 1. The clinical pregnancy rate in each expansion interval. Each subscript letter denotes a subset of Expansion (%) categories that do not differ significantly from each other at the 0.05 level.

Expansion (%)	Transfer Count(n)	FHB(n)	CPR
0	14	2	$14\%_{a}$
25	20	5	$25\%_{a,b}$
50	28	20	$71\%_{c}$
75	49	30	$61\%_{c}$
100	408	256	$63\%_{c}$
Total	519		

SUPPORT: None.

EAST ASIAN WOMEN EXPERIENCE LOWER RATES OF LIVE BIRTH THAN CAUCASIAN WOMEN AFTER SINGLE FRESH BLASTOCYST TRANSFER BUT HAVE SIMILAR OUTCOMES AFTER FROZEN TRANSFER. Anne E. Martini, DO,[1] Samantha Kodama, MD, MPH,[2] Tommy Na, BS, BA,[3] Samad Jahandideh, PhD,[4] Micah J. Hill, DO,[5] Alan H. DeCherney, MD,[1] Kate Devine, MD,[4] Frank E. Chang, MD,[4] [1]National Institute of Child Health and Human Development, NIH, Bethesda, MD; [2]Medstar Washington Hospital Center/Georgetown University Hospital, Washington, DC; [3]University of Richmond, Richmond, VA; [4]Shady Grove Fertility Center, Rockville, MD; [5]Walter Reed National Military Medical Center, Bethesda, MD.

OBJECTIVE: To compare live birth rates after autologous fresh or frozen single embryo transfers (SET) in East Asian and Caucasian women.

DESIGN: Retrospective cohort

MATERIALS AND METHODS: Autologous SETs of fresh or vitrified/warmed blastocysts in East Asian and Caucasian patients from 2015-2018 were analyzed. Fresh and frozen transfers were analyzed separately.

	East Asian	Caucasian	P-value	P-value (adjusted)
Fresh				
Cycles (n)	265	4359		
Age (y)	36.3 ± 4.7	34.5 ± 5.1	<0.001	
E2 on day of trigger (pg/mL)	2862.1 ± 1658.2	2421.1 ± 1409.4	<0.001	
Follicles >14mm on day of trigger	8.5 ± 5.7	9.1 ± 6.4	NS	
E2/follicle (pg/mL)	329.8 ± 115.3	258.4 ± 95.2	<0.001	
Oocytes retrieved	15.0 ± 9.4	17.2 ± 10.3	0.001	
Fertilization (%)	76.0	78.0	NS	
Positive hCG/transfer (%)	50.6	63.0	<0.001	0.008
Clinical pregnancy/transfer (%)	42.6	54.3	<0.001	0.001
Live birth/transfer (%)	34.0	45.4	<0.001	0.001
Frozen				
Cycles (n)	280	7482		
Age (y)	38.3 ± 4.0	36.2 ± 4.9	<0.001	
E2 at last lining check (pg/mL)	734.16 ± 619.35	755.69 ± 782.58	NS	
Cycles using PGT-A (n (%))	260 (92.9)	2985 (39.9)	<0.001	
Positive hCG/transfer (%)	74.3	67.4	0.02	NS
Clinical pregnancy/transfer (%)	64.6	58.1	0.03	NS
Live birth/transfer (%)	47.5	45.5	NS	NS
Live birth/euploid transfer (%)	47.3	48.1	NS	NS

Mean ± SD unless otherwise stated

Unadjusted comparisons were evaluated by t-test or chi-square. Generalized estimating equations (GEEs) were used to account for repeat cycles and to adjust for age, body mass index (BMI), diagnosis, cycle number, and use of preimplantation genetic testing for aneuploidy (PGT-A).

RESULTS: In fresh and frozen cohorts, East Asians were older (P<0.001 for each), had more prior IVF cycles (P=0.009 and P<0.001), and lower BMI (P <0.001 for each). In fresh cycles, estradiol (E2) on day of trigger was higher in East Asians (P <0.001) despite similar numbers of follicles ≥14mm and fewer oocytes retrieved (P=0.038). Live birth per fresh transfer was significantly lower in East Asians in both unadjusted and adjusted analyses (P<0.001). There was no difference in the odds of live birth from FET between East Asians or Caucasians, whether or not PGT-A was used; however, it is notable that 93% of FETs in East Asians used PGT-A compared with 40% in Caucasians (P<0.001).

CONCLUSIONS: East Asians were 10% less likely to achieve a live birth after transfer of a single fresh (untested) blastocyst. Data revealed no difference in live birth from single blastocyst FET; however, 93% of blastocysts transferred among East Asians were PGT-A normal. While prior data have indicated no difference in rates of aneuploidy in this population[1], the current study suggests that embryo quality may contribute to worse fresh ART outcomes observed among East Asians. The impact of higher estradiol concentration on the endometrium may also play a role.

P-458 4:30 PM Monday, October 19, 2020

SIMILAR DOSE-RESPONSE PROFILES FOR FOLLITROPIN DELTA IN JAPANESE AND NON-JAPANESE IVF/ICSI PATIENTS. Osamu Ishihara, MD, PhD,[1] Joan-Carles Arce, MD, PhD,[2] [1]Saitama Medical University, Saitama, Japan; [2]Ferring Pharmaceuticals, Copenhagen, Denmark.

OBJECTIVE: To compare the ovarian response to different doses of follitropin delta between the Japanese and non-Japanese population.

DESIGN: Post-hoc analysis of two randomized, controlled, assessor-blind, multi-center, dose-response trials with follitropin delta (Rekovelle, Ferring Pharmaceuticals) in IVF/ICSI patients conducted in Japan and Europe (NCT02309671; NCT01426386).

MATERIALS AND METHODS: The two trials had similar eligibility criteria. A total of 117 Japanese women (mean 33.8 years) were randomized to one of three fixed daily doses of follitropin delta – 6 μg (low), 9 μg (medium) or 12 μg (high) – in the Japanese trial, and 222 non-Japanese women (mean 32.7 years) were randomized to one of five fixed daily doses of follitropin delta – 5.2 μg (low), 6.9 μg, 8.6 μg (medium), 10.3 μg or 12.1 μg (high) – in the European trial. In both trials, randomization was stratified according to AMH (5.0-14.9 pmol/L [0.7-<2.1 ng/mL]; 15.0-44.9 pmol/L [2.1-6.3 ng/mL]). The dose-response relationship between the two populations was compared using ANCOVA with Japanese/non-Japanese and AMH strata as factors, and log(dose) as covariate.

RESULTS: A significant (p<0.01) dose-response relationship between follitropin delta dose and number of oocytes retrieved was established for both Japanese and non-Japanese patients, including for each AMH strata. The dose-response relationship was not significantly different between populations, and a doubling of the follitropin delta dose was estimated to lead to an increase of 4.7 oocytes [95% CI: 2.60-6.76] in Japanese patients and 5.5 oocytes [95% CI: 3.95-7.06] in non-Japanese patients. The number of oocytes retrieved was higher for AMH ≥15 pmol/L than AMH <15 pmol/L, with an average difference of 3.4 and 4.0 oocytes, respectively, in the Japanese and non-Japanese patients. Regarding excessive response, there was no significant difference between the Japanese and non-Japanese populations with respect to the proportion of patients having ≥15 oocytes retrieved after stimulation with follitropin delta at low (5% vs 5%), medium (15% vs 14%) or high (28% vs 32%) doses. Concerning the ovarian hormone response, a doubling of the follitropin delta dose in the Japanese patients led to estimated increases of 1.6-fold [95% CI: 1.29-2.03] in inhibin B on stimulation day 6 as well as 1.8-fold [95% CI: 1.33-2.55] in estradiol and 2.0-fold [95% CI: 1.42-2.71] in inhibin A at end of stimulation. Comparable observations were made in the non-Japanese patients with increases of 1.8-fold [95% CI: 1.51-2.09], 1.8-fold [95% CI: 1.48-2.15] and 1.8-fold [95% CI: 1.50-2.16], respectively, for inhibin B on stimulation day 6, and estradiol and inhibin A at end of stimulation.

CONCLUSIONS: The ovarian dose-response to follitropin delta was comparable for Japanese and non-Japanese IVF/ICSI patients. The number of oocytes retrieved vary substantially in Japanese patients depending on AMH level. Therefore, serum AMH levels should be considered when selecting gonadotropin doses for Japanese patients, as already introduced with the individualized follitropin delta dosing regimen outside Japan.

DOES CRYOPRESERVATION AFFECT THE IMPLANTATION POTENTIAL OF BLASTOCYSTS DERIVED FROM VITRIFIED/WARMED OOCYTES?. Hadi Ramadan, M.D.,[1] Tarita Pakrashi, MD, MPH,[1] Andrea Ries Thurman, MD,[1] Kimball O. Pomeroy, Ph.D.,[2] Gerard Celia, Jr., PhD,[3] [1]Eastern Virginia Medical School, Norfolk, VA; [2]The World Egg Bank, Phoenix, AZ; [3]EVMS, Norfolk, VA.

OBJECTIVE: Vitrified, or "frozen", donor eggs (VDE) can either be fertilized and cultured for fresh transfer (group 1), or fertilized and cryopreserved for transfer in a "frozen embryo transfer" cycle (FET, group 2). This study compared implantation rates between the two groups.

DESIGN: A retrospective cohort study analyzing 800 frozen donor egg cycles from a commercial egg bank. Cycles were limited to single embryo transfers (ET) without preimplantation genetic testing (PGT).

MATERIALS AND METHODS: The data was analyzed using the Chi-squared test for categorical variables and the Wilcoxon-Mann-Whitney test for non-parametric continuous variables. P-values <0.05 were regarded as statistically significant. SAS version 9.4 was used for the analysis.

RESULTS: 600 cycles met the inclusion criteria (200 were excluded due to PGT or multiple embryo transfers). There were 409 cycles in group 1 and 191 cycles in group 2. Implantation rate was not significantly different between the two groups (38.63% vs 32.46% p=0.14). Mean embryo age was higher in group 2 (5.1 vs 5.4 days, p< 0.01).

CONCLUSIONS: Contrary to experiences with slow-cooling, a growing body of evidence shows vitrification to have no negative effect on embryo potential, even when subject to multiple vitrify/thaw cycles. To date, however, no investigation has looked at the possible compounding effect of vitrification when applied at two distinct stages: oocyte and embryo. In this study we compared implantation of VDE cycles transferred in fresh versus FET cycles to determine if such an effect exists. Although embryos used in FET cycles were statistically older, as would be expected due to extended culture, no difference was detected between the groups in terms of implantation. Unexpectedly, the data demonstrated a trend toward lower implantation in the FET group, which stands contrary to trends observed with fresh oocyte/FET cycles. While not significant at this power, a larger study should be undertaken to determine the validity of this effect and whether it represents a clinical concern when planning patient cycles.

USING SPERM DOUBLE-STRANDED DNA TO PREDICT EMBRYO PLOIDY. Derek Keating, B.A., Alessandra Parrella, M.Sc., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To demonstrate how the presence of double-stranded DNA breaks (dsDNA) in spermatozoa can be used to predict embryo ploidy.

DESIGN: Over the last 12 months, a prospective pilot study was carried out on semen samples to assess dsDNA levels. These samples were also concurrently assessed to determine total DNA damage. A correlation between the two assays was established. Couples were divided into two groups according to the adopted dsDNA threshold, and clinical outcomes were recorded and compared.

MATERIALS AND METHODS: Consenting men had their ejaculates screened for dsDNA rates utilizing an in-house protocol of the neutral Comet assay, assessing at least 200 spermatozoa. Concurrently, samples were assessed by terminal deoxynucleotidyl dUTP transferase nick-end labeling (TUNEL) with a commercial kit, screening at least 500 spermatozoa. ICSI was performed in the standard fashion. Resulting blastocysts were biopsied on day 5 or 6 post-insemination for preimplantation genetic testing for aneuploidy (PGT-A) using next-generation sequencing.

RESULTS: The initial pilot study reported an average total DNA fragmentation by TUNEL of 11.3±6% and a dsDNA average of 2.2±3% by neutral Comet assay. The results of TUNEL and dsDNA presented with a linear correlation (R^2=0.96; P<0.05), and dsDNA values were extrapolated. After establishing a threshold of 3%, 231 couples treated in 381 ICSI/PGT-A cycles were compared according to above or below threshold.

A total of 173 couples (maternal age, 37.2±4 years; paternal age, 38.9±5 years) with normal dsDNA levels underwent 296 ICSI cycles, yielding a fertilization rate of 76.9%; 1,562 embryos were screened by PGT-A. This resulted in 574 normal (36.7%), 827 abnormal (52.9%), and 161 mosaic embryos (10.3%). There have been 171 frozen embryo transfers (FET) of euploid blastocysts thus far, with a 51.6% implantation rate and a 55.6% clinical pregnancy rate (CPR).

A total of 48 couples with abnormal dsDNA levels underwent 85 ICSI cycles. They had a comparable maternal age of 38.0±5 years, but a much older male partner (43.2±8 years; P<0.0001). They achieved a fertilization rate of 72.7% (P<0.01), with 375 embryos biopsied for PGT-A. A total of 115 were euploid (30.7%; P<0.05), 222 were aneuploid (59.2%; P<0.05), and 38 were mosaic (10.1%). Interestingly, FET cycles from these cases trended toward lower implantation (43.9%) and CPRs (47.4%).

CONCLUSIONS: This study confirmed the relevance of dsDNA on structural chromosomal abnormalities and therefore the proportion of euploid embryos. Examining dsDNA of the male gamete can provide important information on the prospects of successful embryo implantation.

P-461 4:30 PM Monday, October 19, 2020

CLINICAL PARAMETERS AND PREDICTORS OF MONOZYGOTIC TWINS (MZT) AFTER SINGLE FROZEN EMBRYO TRANSFER (FET). Amelia G. Kelly, MD, Jennifer K. Blakemore, MD, Caroline McCaffrey, PhD, James A. Grifo, MD, PhD NYU Langone School of Medicine, New York, NY.

OBJECTIVE: FET and lab protocols regularly evolve, which may impact rates of MZT. We evaluated clinical factors in single embryo FET and rates of MZT.

DESIGN: Retrospective cohort study of all patients who underwent a single embryo FET between 1/2016 and 12/2018.

MATERIALS AND METHODS: All FETs in the study time-period were reviewed, and all documented clinical intrauterine pregnancies were included. The primary outcome was the number of MZT. Independent variables included use of Eglue (culture media with increased hyaluronon introduced in the lab on 7/17/17), cycle type, use of ICSI, use of PGT, embryo expansion, inner cell mass (ICM) and trophectoderm (TE) grades, day of blastocyst biopsy/vitrification (B/V), patient age and endometrial thickness (EE). Cycle type was defined as: 1) programmed (PRG) - daily oral estradiol for ≥10 days or until the EE measured greater than 7mm, followed by intramuscular progesterone in oil or 2) natural (NAT) - monitoring until a dominant follicle reached 18mm and ovulation was confirmed and/or triggered with the use of a compounded hCG. Statistical analyses included comparison of means, chi-squared, and multivariate logistic regression with p<0.05 considered significant.

RESULTS: 1621 cycles met inclusion criteria, and 31 resulted in MZT pregnancies (1.9%). Overall, Eglue was used in 877 (54.1%) cycles. 1386 (85.5%) cycles were PRG and 236 (14.4%) were NAT. PGT and ICSI were used in 1425 (87.9%) and 579 (35.7%) of cycles, respectively. The mean patient age at FET was 37.4±4.5 and the mean EE was 9.1±3.0cm and neither patient age (37.5±4.7 MZT vs 37.2±4.5 No MZT, p=0.90) nor EE (9.3±1.8 MZT vs 9.1±2.9 No MZT, p=0.60) were different between groups. The ICM grade (p=0.93), TE grade (p=0.56), expansion (p=0.74), and day of blastocyst B/V (p=0.93) were similar between the groups. Table 1 shows the MZT rate by clinical parameter. After controlling for age, EE, cycle type, embryo grade, day of B/V, ICSI and PGT, the use of Eglue still resulted in fewer MZT (B 1.2, p<0.01). Interestingly, PGT was no longer statistically significant (B -17.6, p=1.0). A regression using the same parameters with PGT only cycles showed that Eglue was still associated with a reduction in MZT (B-1.2, p<0.01), independent of all other unassociated parameters.

CONCLUSIONS: The rate of MZT after FET is reduced by the use of Eglue and is not affected by cycle type or other clinical parameters. The use of PGT needs to be further investigated as a risk factor for MZT.

TABLE 1. MZT after FET by Clinical Parameter

	No MZT (n=1590)	MZT (n=31)	p
Eglue	866 (54.5%)	11 (35.5%)	0.04
No Eglue	724 (45.5%)	20 (64.5%)	
PRG Cycle	1361 (85.6%)	25 (80.6%)	0.44
NAT Cycle	228 (14.3%)	6 (19.4%)	
ICSI	567 (35.7%)	12 (38.7%)	0.73
No ICSI	1023 (64.3%)	19 (61.3%)	
PGT	1394 (87.7%)	31 (100%)	0.04
No PGT	196 (12.3%)	0 (0%)	

P-462 4:30 PM Monday, October 19, 2020

DISPARITIES IN ART LIVE-BIRTH OUTCOMES FOR HISPANIC AND ASIAN WOMEN COMPARED TO WHITE NON-HISPANIC WOMEN. Alexander Kotlyar, MD,[1] Burcin Simsek, Ph.D.,[2] David B. Seifer, MD,[3] [1]Yale School of Medicine, Oange, CT; [2]University of Pittsburgh, Pittsburgh, PA; [3]Yale University, Orange, CT.

OBJECTIVE: To determine if disparities exist in ART outcomes for Hispanic and Asian women compared to white, non-Hispanic (WNH) women.

DESIGN: Retrospective, cohort study and comparison of reported outcomes in the SARTCORS database for 2014-2016.

MATERIALS AND METHODS: Analysis of 2014-2016 SARTCORS database for member clinics that performed at least 50 cycles of ART and reported race/ethnicity in more than 95% of cycles. 60,657 cycles using autologous, fresh, non-donor embryo cycles were analyzed of which 4,544 cycles were from Hispanic women, 11,987 cycles were from Asian women and 44,126 cycles were from WNH women.

RESULTS: In comparison to cycles in WNH women, cycles in Hispanic and Asian patients were generally in older women ($p<0.001$). Concerning causes of infertility, cycles from Hispanic women were more often associated with a history of endometriosis compared to those in WNH women ($p=0.033$). Additionally, Hispanic patients were more than twice as likely to exhibit tubal factor infertility compared WNH women ($p<0.001$). Cycles in Asian women were not associated with greater tubal factor infertility; however, diminished ovarian reserve (DOR) was greater in cycles with Asian women compared to WNH women ($p<0.001$). ART cycles in Asian and Hispanic women, exhibited lower rates of clinical intrauterine gestation (CIG) ($p<0.001$) and live birth (LB) per cycle-start ($p<0.001$) compared to cycles in WNH women. Multivariate logistic regression demonstrated that cycles from Asian and Hispanic women were less likely to have a LB than white women for their initial cycle (OR 0.86; $p=0.004$, OR 0.69; $p<0.001$, respectively). These findings were independent of age, parity, BMI, etiology of infertility, use of ICSI or number of embryos transferred.

CONCLUSIONS: Race/ethnicity continues to be an independent prognostic factor for LB for ART. Substantial outcome disparities exist among ART cycles in Asian and Hispanic women compared to WNH women. This may be in part due to the increasing proportion of older age in Asian and Hispanic women which may be accompanied by DOR as compared to WNH women. Additional analysis of trends among Asian and Hispanic patients is warranted to eventually remedy disparities in outcomes in ART treatment.

P-463 4:30 PM Monday, October 19, 2020

ENDOMETRIAL BCL6 EXPRESSION IS NOT ASSOCIATED WITH IMPLANTATION OUTCOMES. Amber M. Klimczak, MD,[1] Nola S. Herlihy, MD,[1] Cynthia S. Scott-,[2] Brent M. Hanson, MD,[3] Julia G. Kim, MD, MPH,[3] Ashley W. Tiegs, MD,[3] Emily K. Osman, MD,[3] Shiny Titus, PhD,[2] Emre Seli, M.D.,[3] Richard Thomas Scott, Jr., MD,[3] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: B-cell CLL/lymphoma 6 (*BCL6*) is a proto-oncogene that is overexpressed in the secretory endometrium of women with endometriosis. It has been postulated that BCL6 may serve as a surrogate marker for occult endometriosis, as well as a predictor of endometrial dysfunction and poor implantation. Therefore, BCL6 expression has been proposed as an adjunct test for women undergoing IVF. However, this test has not yet been validated in the general IVF population. The aim of this study was to determine whether increased endometrial BCL6 expression is associated with implantation failure in women undergoing IVF.

DESIGN: Case-control study.

MATERIALS AND METHODS: Endometrial biopsies were collected from women (n=50) undergoing ART, during the mid-secretory phase. In vitro fertilization was performed followed by trophoectoderm biopsy, preimplantation genetic testing for aneuploidy, embryo cryopreservation, and a warmed euploid embryo transfer in a subsequent cycle. Samples underwent paraffin embedding and sectioning, followed by immunohistochemistry for BCL6 using mouse monoclonal primary antibody (GI191E/A8, Sigma) and goat anti-mouse secondary antibody (Sigma). Lymph nodes served as positive controls, while slides stained with only secondary antibody served as negative controls. Two independent investigators blinded to cycle outcome performed semi-quantitative analysis of immunohistochemical staining intensity. Each slide was given a mean HSCORE calculated using the formula $= \sum Pi\ (i+1)/100$ where i= staining intensity ranging from 0-4 (not present-very strong) and Pi= percentage of stained epithelial cells for each intensity (0-100%). BCL6 expression was deemed positive if the HSCORE was >1.4 as previously defined by ROC curve analysis for the diagnosis of endometriosis (1). Additionally, an overall fluorescence intensity of each section was calculated using ImageJ software.

RESULTS: Twenty-seven patients with sustained implantation and 23 patients that failed implantation were included. Patient age, day 3 FSH, AMH, BMI, day of blastulation, and embryo grade did not significantly differ between the two groups. Mean HSCOREs did not significantly differ between the groups ($P=0.75$). Using the previously established BCL6 expression cut-off of positive >1.4, 8/15 samples were positive for BCL6 in the no implantation group, while 7/20 were positive in the sustained implantation group (OR: 1.52 CI [0.45-5.14]). A chi-square test showed that there was no significant association between BCL6 expression and implantation $x^2(2, N=50) = 0.46$, $p=0.49$. Overall fluorescence intensity did not significantly differ between the two groups ($P=0.33$).

CONCLUSIONS: The proportion of patients with BCL6 positivity did not differ between those who achieved sustained implantation and those who did not. While the odds of having aberrant BCL6 expression is increased in patients with no implantation, the confidence interval is wide. Physicians should take caution when implementing BCL6 expression as a diagnostic tool for clinical decision-making.

P-464 4:30 PM Monday, October 19, 2020

DICHORIONIC TWINS WITH PREECLAMPSIA CONCEIVED VIA ASSISTED REPRODUCTIVE TECHNOLOGY DO NOT YIELD HIGHER RATE OF FETAL GROWTH RESTRICTION. Evelina Manvelyan, MD,[1] Baruch Abittan, M.D.,[2] Matthew Blitz, MD,[3] Randi H. Goldman, M.D.[2] [1]Northwell Health at Southside Hospital, Bay Shore, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Pregnancies complicated by preeclampsia are more likely to result in fetal growth restriction (FGR). Twin gestations increase the likelihood of obstetric complications and are independently associated with FGR. Preeclampsia complicates dichorionic twin gestations conceived using in vitro fertilization (IVF) nearly twice as often as spontaneous dichorionic twins.

We previously reported significant placental differences in dichorionic twin pregnancies impacted by preeclampsia based on whether the pregnancy was achieved using IVF or spontaneously conceived. The objective of this study was to determine whether rates of FGR and fetal growth discordance (FGD) differ in dichorionic twin pregnancies complicated by preeclampsia if conceived using IVF.

DESIGN: A retrospective cohort study of dichorionic twin gestations complicated by preeclampsia conceived spontaneously and with IVF at a tertiary care university hospital from 2011-2016.

MATERIALS AND METHODS: Patients aged 18-45 years with dichorionic twin gestations complicated by preeclampsia who conceived spontaneously or with IVF (+/- ICSI) were evaluated. Patients with chronic hypertension, pre-gestational, or gestational diabetes were excluded. Two tailed student's t-tests and Welch's tests were used for data analyses.

RESULTS: Of 423 twin gestations, 122 pregnancies were suitable for analysis after application of inclusion/exclusion criteria. Sixty patients spontaneously conceived pregnancies (non-IVF group) and 62 conceived via IVF. Patients in the IVF group were significantly older and less parous. No significant differences were found in fetal weight or APGAR scores of either fetus A or B. There were no differences in FGD or FGR for fetus A. More than twice as many fetus Bs had FGR in the non-IVF vs. IVF group, a nearly significant difference (Table).

CONCLUSIONS: Dichorionic twin pregnancies conceived using IVF and complicated by preeclampsia do not demonstrate higher rates of FGD or FGR compared with spontaneously-conceived pregnancies, despite the differences in placental morphology. There was a higher rate of FGR for fetus B

in the non-IVF group that approached significance. This should be further studied.

INCREASING MICROBIAL DIVERSITY AND LACTOBACILLUS DOMINANCE OF GENITOURINARY, GASTROINTESTINAL, AND REPRODUCTIVE TRACTS DO NOT ASSOCIATE WITH REPRODUCTIVE OUTCOMES AFTER EUPLOID SINGLE EMBRYO TRANSFER. Nola S. Herlihy, MD,[1] Xin Tao, Ph.D,[2] Yiping Zhan, Ph.D,[2] Chaim Jalas, N/A,[2] Amber M. Klimczak, MD,[3] Brent M. Hanson, MD,[3] Julia G. Kim, MD, MPH,[3] Emily K. Osman, MD,[3] Ashley W. Tiegs, MD,[3] Emre Seli, MD,[3] Richard Thomas Scott, Jr., MD,[3] Jason M. Franasiak, MD,[3] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: To analyze preliminary data from a large scale observational study seeking to characterize the global microbiome of infertile patients, including the oral cavity, urinary tract, gastrointenstinal tract, vagina and cervix, and determine its relationship with pregnancy outcomes following euploid single embryo transfer (SET).

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Patients met inclusion criteria if they were undergoing IVF with pre-implantation genetic testing (PGT-A) with plans for euploid SET. Those who had recently used antibiotics and who had failed more than one previous IVF cycle were excluded. Patients underwent ovarian stimulation and oocyte retrieval according to standard practice. Five samples, buccal, vaginal, cervical, and rectal swabs, as well as a urine sample were obtained on the day of retrieval. Patients underwent euploid SET in a subsequent cycle and pregnancy outcomes were recorded, with sustained implantation (fetal heartbeat at discharge) serving as the primary outcome. All samples underwent DNA isolation and next generation sequencing of the V4 region of the bacteria-specific 16S rRNA gene with the Illumina NextSeq. Operational taxonomic units (OTUs) were assigned using the RDP classifier with confidence cutoffs of 0.8. Shannon Diveristy Index (SDI) was calculated for each sample and SDI values were compared for those with and without on-going implantation. For each of the five sample types, logistic regression was used to test the top genera assigned for association with sustained implantation. Samples were characterized as Lactobacillus dominant (LBD, $\geq$ 90%) and not (NLBD), and logistic regression was performed to test for association with sustained implantation.

RESULTS: Sixty patients who underwent euploid SET were included, of which OTUs were assigned for 35 buccal, 53 urine, 36 GI, 60 vaginal, and 59 cervical samples. SDI was highest for the GI tract samples, and was not significantly correlated with sustained implantation for any of the five sample types. The top genera calls for the urine, vaginal, and cervical samples were Lactobacillus, while the top call for the buccal and GI tract samples were Streptococcus and Prevotella respectively. The top fraction of genera calls for each sample type did not correlate with sustained implantation. Samples characterized as LBD (27 urine, 40 vaginal, and 35 cervical samples) did not demonstrate positive correlation with sustained implantation.

CONCLUSIONS: This is the first large scale study to analyze the global microbiome of infertile patients with respect to pregnancy outcomes. Preliminary data do not demonstrate correlation between microbial diversity and sustained implantation or reveal any specific bacterial dominance pattern correlated with sustained implantation, however our ability to detect a difference is limited by a small initial sample size. Recruitment for the study is ongoing.

P-466 4:30 PM Monday, October 19, 2020

PROGESTERONE LEVEL ON THE DAY OF TRIGGER AND FRESH EMBRYO TRANSFER. Mohamad Irani, MD,[1] Brandon Maddy, MD,[2] Simone C. Elder, MD,[3] Fabiana Kreines, MD,[4] Vinay Gunnala, MD,[5] Daylon James, PhD,[6] David Reichman, MD,[6] Zev Rosenwaks, M.D.[6] [1]Advanced Fertility Center of Chicago, Chicago, IL; [2]Mayo Clinic, College of Medicine and Science, Rochester, MN; [3]New York Presbyterian/Weill Cornell Medicine, New York, NY; [4]New York University, New York, NY; [5]Southwest Fertility Center, Phoenix, AZ; [6]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: There is no consensus on whether serum progesterone (P4) levels should be measured during IVF cycles. Studies that have suggested the benefit of measuring P4 have identified different thresholds above which there may be a reduction in implantation rates (IRs). However, the majority of these studies did not adjust for critical confounding factors. Therefore, we investigated whether serum P4 levels on the day of trigger influence the implantation potential of embryos by including only young women who had transfers of good-quality blastocyst(s) on day 5. Of note, progesterone levels did not influence the decision to proceed with embryo transfer because it was measured after the completion of cycles using stored serum collected on the day of trigger.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All fresh IVF-ET cycles performed at our center between January 2014 and December 2017 were reviewed. We included women $\leq$35 years who had transfers of good-quality blastocysts on day 5. Good-quality was defined as $\geq$2BB (2-6BB, 2-6AA, 2-6AB, 2-6BA) according to Gardner's grading system. The IR and live birth rate (LBR) were compared between patients at different P4 thresholds on the day of trigger. χ^2 and Fisher's exact tests were used for categorical variables. Student's *t* test was used for parametric data. Odds ratios (OR) with 95% confidence intervals (CI) were calculated. Values were expressed as mean $\pm$ standard deviation.

RESULTS: A total of 739 fresh IVF cycles for women who had a transfer of 1 or 2 good-quality blastocysts on day 5 were included. Their mean age was 31.7 $\pm$ 2.8 years, their body mass index was 23.5 $\pm$ 3.8 kg/m^2, and the number of oocytes retrieved was 16.9 $\pm$ 7.0. Women who had a serum P4 level $\geq$2 ng/mL on the day of trigger had a significantly lower LBR (10% vs. 58.2%; P=0.003) and IR (15% vs. 59.6%, respectively; P=0.002) compared to women whose P4 levels were <2 ng/mL. The difference in LBR remained significant after adjusting for the number of embryos transferred (adjusted OR = 12.5; 95% CI = 1.7-91.2). A P4 level <1.5 ng/mL was associated with a comparable LBR (58.5% vs. 52.6%, respectively; P=0.4) and IR (60.3% vs. 47.4%, respectively; P=0.2) to those of women with P4 levels of 1.5-2 ng/mL. Of note, women with a P4 $\geq$2 ng/mL had a comparable estradiol level on the day of trigger (1947 $\pm$ 711 vs. 2224 $\pm$ 865 pg/mL, respectively; P=0.3) and number of oocytes harvested (14.4 $\pm$ 6.4 vs. 16.9 $\pm$ 7.1, respectively; P=0.2) to those of women with a P4 <2 ng/mL.

CONCLUSIONS: An elevated serum P4 level ($\geq$2 ng/mL) on the day of trigger decreases embryo implantation potential during fresh transfer. Elevation of the P4 level during stimulation does not correlate with the estradiol level or the number of oocytes retrieved. Therefore, these parameters do not predict elevation in the P4 level, which should be measured to identify women who may benefit from freeze-all embryos due to embryo–endometrium dyssynchrony.

P-467 4:30 PM Monday, October 19, 2020

DOES TROPHECTODERM BIOPSY NEGATIVELY IMPACT OBSTETRIC OUTCOMES IN WOMEN <35 YEARS OF AGE?. Ruth Moges, MS,[1] Pietro Bortoletto, MD,[2] Phillip A. Romanski, MD,[2] Glenn Schattman, MD,[1] [1]Weill Cornell Medicine, New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To describe if trophectoderm biopsy for PGT negatively impacts obstetric outcomes in women under the age of 35 transferring a single embryo in the natural cycle.

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: We included women under the age of 35 undergoing their first IVF cycle at our center who then underwent a natural cycle FET of a single embryo which resulted in a live birth beyond 24 weeks. We excluded twin gestations. Women were stratified into two groups: PGT-A versus no PGT-A testing. The primary outcomes were gestational age (weeks) and weight (grams) at birth. The secondary outcomes were late preterm birth (34 to under 37 weeks) and mode of delivery. Chi-square and students t-test were performed. A p-value of <0.05 denoted statistical significance.

RESULTS: In total, 205 live births were included, n=116 in the PGT group and n=89 in the non-PGT group. Patient and cycle characteristics are displayed in table 1. There were no differences in mean gestational age at birth between the non-PGT and PGT group (38.7 versus 38.8 weeks, p=0.671). The birth weight was significantly higher in the PGT group compared to the non-PGT group (3379.3 versus 3191.8, p=0.020). The rate of late preterm birth was similar between the non-PGT and PGT group (5.7 versus 7.8%, p=0.338). The cesarean section rate was similar between the non-PGT and PGT group (31.8 versus 40.7%, p=0.199).

CONCLUSIONS: In women under the age of 35 who have a singleton live birth following single embryo transfer in the natural cycle, trophectoderm biopsy does not appear to portend detrimental obstetric outcomes. Further studies are needed to elucidate the relationship between trophectoderm biopsy on maternal complications in a cohort of young women in which a corpus luteum is present.

PREDICTING SUCCESSFUL CONVENTIONAL *IN VITRO* FERTILIZATION WITH A MACHINE LEARNING APPROACH BASED ON MARKERS OF CAPACITATION. Stephanie Gunderson, MD,[1] Nicholas C. Spies, MD,[2] Lis C. Puga Molina, PhD,[2] Emily S. Jungheim, MD, MSCI,[3] Joan Riley, PhD, HCLD,[4] Celia M. Santi, PhD MD,[2] [1]Washington University, St Louis, MO; [2]Washington University In Saint Louis, Saint Louis, MO; [3]Northwestern Feinberg School of Medicine, Chicago, IL; [4]Washinton University School of Medicine, St. Louis, MO.

OBJECTIVE: To fertilize an oocyte, spermatozoa must capacitate, during which their membrane potential (Em) becomes hyperpolarized and their intracellular pH (pHi) increases. In normospermic males, absolute values of sperm Em and pHi positively correlate with conventional *in vitro* fertilization (IVF) success rates. The objective of this study was to develop a machine learning algorithm using spermatozoa Em and pHi as well as other clinical parameters to predict success of conventional IVF in normospermic couples.

DESIGN: This was a single-institution, Institutional Review Board-approved study of normospermic couples undergoing IVF from September 12, 2018, to September 23, 2019. Couples were excluded if they used frozen sperm, had known male factor infertility, or underwent intracytoplasmic sperm injection only. Data from 76 participants were included in the analysis.

MATERIALS AND METHODS: After being capacitated in commercial IVF media, sperm were incubated with the pH-sensitive fluorescent probe BCECF-AM and with the Em-sensitive probe DISC3 5-AM. Fluorescence was detected by flow cytometry (FACSCanto II TM cytometer). Data from single, live sperm were analyzed with FACS Diva and FlowJo software. Sperm pHi and Em were obtained by linearly interpolating the median fluorescence values to calibration curves. A gradient boosted machine (GBM) classifier was trained with clinical data including age, body mass index, gravidity/parity, and clinical diagnoses, as well as sperm Em and pHi from 58 patients. The classifier was trained to identify patients who would have successful conventional IVF, defined as a fertilization ratio (number of fertilized oocytes [2 pronuclei]/number of mature oocytes) greater than 0.66. The classifier was then validated on an independent set of data from 18 patients.

RESULTS: Couples with a fertilization ratio <0.66 had similar demographic characteristics as couples with a fertilization ratio >0.66, except that female partners in the >0.66 group were significantly older than those in the <0.66 group (34.7±4 years, n=45, vs. 32.7±4.1, n=31, P=0.04) and patients in the >0.66 group had more living children. In receiver operator characteristic analysis of the prediction algorithm, the area under the curve for predicting successful conventional IVF was 0.831. The algorithm had an accuracy of 0.833, sensitivity of 0.857, and specificity of 0.818. The two parameters that were most predictive of conventional IVF success were sperm Em and pHi.

CONCLUSIONS: A machine learning algorithm could be trained to use clinical parameters and sperm capacitation markers to accurately predict success of conventional IVF in normospermic couples.

GESTATIONAL CARRIER PREGNANCY OUTCOMES FROM FROZEN EMBRYO TRANSFER (FET), DEPENDING ON THE NUMBER OF EMBRYOS TRANSFERRED AND PRE-IMPLANTATION GENETIC TESTING: A RETROSPECTIVE ANALYSIS. Amalia Namath, M.D.,[1] Samad Jahandideh, PhD,[2] Kate Devine, MD,[2] Jeanne E. O'Brien, MD, MSc,[3] [1]Georgetown University School of Medicine, Washington, DC; [2]Shady Grove Fertility, Washington D.C., DC; [3]Shady Grove Fertility Center, Rockville, MD.

OBJECTIVE: Economic and social factors may motivate intended parents (IPs) to request pre-implantation genetic testing for aneuploidy (PGTA) and/or two embryo transfers when using a gestational carrier (GC). We sought to compare gestational age (GA), birth weight (BW), and live-birth rates (LBR) in GCs after the transfer of one or two frozen embryo(s) (FET) with and without PGTA.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: All blastocyst transfers to GCs at our center from 2009-2018 were included. All transferred blastocysts were graded BB or better, vitrified and warmed. Primary outcome was live birth ($>$24 weeks) per transfer with and without PGTA. Secondary outcomes were GA and BW per live-birth. Statistical analysis using Chi Square test and t test were used, with a $p<0.05$ considered statistically significant.

RESULTS: 583 GC cycles were available for analysis. Mean GA and BW were significantly greater from single embryo transfer (SET) live-births (LB) versus double FET ($p<0.001$ for both). However, LBR was greater with double FET ($p<0.001$) (Table). The rate of multiple births was 1.9% for SET compared to 20.0% for double FET. Only 3.8% of LB from SET had low BW and only 0.6% had very low or extremely low BW. In comparison, 12.5% of double FET LB were low BW (p=0.02). Only 13.4% of SET LB were preterm, compared with 40% in double FET ($p<0.001$).

A total of 194 PGTA-tested cycles and 389 cycles without were available for analysis. Overall, LBR was not significantly different between PGTA and no PGTA groups (41.2% vs. 43.7%, p=0.9).

CONCLUSIONS: Economic factors and a desire for 'efficient' family building may incentivize two embryo transfers when the IPs' treatment plan involves a GC. This data indicates that transfer of two embryos to a GC was associated with a significant reduction in GA and BW, with more preterm and lower BW LB compared to SET. The outcomes of low BW and preterm birth are not justified by the observed modest increase in LBR.

The use of PGTA did not appear to improve LBR. This analysis must be interpreted with caution owing to the small sample of patients using

PGTA. Even if no benefit in terms of LB per transfer, PGTA may have value in the setting of GC FET, given that it may encourage elective SET and assist in GC recruitment.

Clinical Outcomes	One FET	Two FET	P value
BW (grams) (Mean ± SD)	3468 ± 559	2945 ± 750	<0.001
Low BW (<2500g)	3.8%	12.5%	0.02
Very low BW (<1500g)	0.6%	5%	0.08
Extremely low BW (<1000g)	0.6%	3.8%	0.2
GA (weeks)* (Mean ± SD)	37.87 ± 1.75	36.29 ± 3.25	<0.001
Preterm (<37 weeks)	13.4%	40%	<0.001
Very preterm (<32 weeks)	0.6%	6.3%	0.03
Extremely preterm (<28 weeks)	0.6%	3.8%	0.2
LBR	157 (36.8%) N: 427	80 (51.3%) N: 156	<0.001

LBR	PGTA	Non-PGTA	P value
Single and two blastocyst FET, combined	80 (41.2%) N: 194	157 (43.7%) N: 389	0.9

P-470 4:30 PM Monday, October 19, 2020

THE USE OF COMBINED HORMONAL CONTRACEPTIVE FOR IN-VITRO FERTILIZATION CYCLE PRIMING IS NOT ASSOCIATED WITH DECREASED PREGNANCY RATE IN FROZEN EMBRYO TRANSFER CYCLES. Kristy Cho, MD, FRCSC,[1] Chen Jing, MSc,[2] Niamh Tallon, MB BCh BAO, FRCSC,[3] [1]Division of Reproductive Endocrinology and Infertility, University of British Columbia, Vancouver, BC, Canada; [2]Biostatistic, Olive Fertility Centre, Vancouver, BC, Canada; [3]Division of reproductive endocrinology and infertility, University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: Oral contraceptive pills (OCP) and luteal phase estradiol are frequently used prior to GnRH-antagonist protocols for better cycle scheduling (1). The recent ESHRE guideline on ovarian stimulation stated that priming before IVF with estrogen or progesterone was acceptable, but discouraged the use of OCP due to reduced live birth rate (2).

The study objectives are to evaluate the cycle outcomes from IVF preceded by OCP priming compared to estradiol pretreatment and to determine if there is a role for OCP priming for those undergoing frozen embryo transfers.

DESIGN: A retrospective cohort study from a university-affiliated fertility centre. Inclusion: all IVF antagonist cycles with ICSI from Jan 2016 to Jun 2019. Exclusion: protocol deviation or treatment cancellation.

MATERIALS AND METHODS: The most common indications for OCP priming included ovulatory dysfunction and endometriosis. In the OCP group, patients utilized 30 mcg ethinyl estradiol and 150 mcg desogestrel daily starting in the preceding cycle for 21-35 days followed by a 5 days pill-free period. In the estradiol group, 17β-estradiol 2 mg was taken twice a day for 7-10 days starting in the luteal phase. Gonadotrophin dose was individualized. Follicular maturation was achieved with HCG, agonist, or dual trigger when >/=3 follicles had mean diameters of >/= 17 mm. Retrieval was performed at 36 hours. Embryos were biopsied on day 5-7. A single euploid embryo was replaced on day 5-7 of progesterone. Differences between groups were compared using a Mann-Whitney-Wilcoxon or Chi-square test.

RESULTS: There were 2237 cycles by 1958 patients; 27% of cycles utilized OCP priming. The average age in the OCP group was 34 years old compared to 36.5 in the estradiol group (P<0.01). AMH was reported in 43% of patients and was higher in the OCP group (3.7 vs 2.2 ng/mL, P<0.01). The gonadotrophin dose was higher in the estradiol group (P<0.01). However, the number of oocytes (15.2 vs 12.5), normal fertilization (72% vs 70%), blastulation rate (50% vs 44%), and number of blastocysts (4.6 vs 3.3) were higher in the OCP group (P all< 0.01). After adjusting for age and AMH with linear regression for the 978 cycles with recorded AMH (24% with OCP prime), significantly higher number of oocytes (13.8 vs 11.9, P=0.002) and mature oocytes (11.3 vs 9.3, P=0.05) were still noted in the OCP group. There were no longer differences in the number of embryos, the normal fertilization rate, or the blastulation rate (p> 0.2).

There were 866 euploid embryo transfer cycles (28% with OCP prime). There were no significant differences in implantation (77% vs 76%) or ongoing pregnancy rates (56 vs 54%) between those who had a transfer after OCP compared to estradiol primed stimulation cycles (p all >0.6).

CONCLUSIONS: There were no differences in pregnancy outcomes from euploid embryo transfer after OCP primed antagonist cycles compared to estradiol pretreatment. In fact, the use of OCP pretreatment was associated with increased oocyte yield, keeping in mind demographics differences. Thus, OCP priming should still be considered in specific populations, such as those with oligoovulation or adequate ovarian reserve.

P-471 4:30 PM Monday, October 19, 2020

THE TRANSFER OF EUPLOID COMPLETELY HATCHED BLASTOCYSTS IS ASSOCIATED WITH POORER CLINICAL OUTCOMES. Carlos A. Guerrero, Ph.D., Jennifer A. Rodriguez, B.Sc., Daniel Skora, M.D., Rebecca A. Chilvers, M.D., Satin S. Patel, M.D., Jerald S. Goldstein, M.D. Fertility Specialists of Texas, Frisco, TX.

OBJECTIVE: The handling, use and transfer of completely hatched blastocysts is becoming more common due to an increased demand for aneuploidy screening. The objective of this study was to evaluate clinical outcomes for single frozen embryo transfers using euploid completely hatched blastocysts versus euploid expanded/hatching blastocysts.

DESIGN: Retrospective analysis of data collected from January 2017 through January 2020. Patients were divided into two treatment groups based on the developmental stage prior to frozen embryo transfer. Group A) Expanded/Hatching blastocysts (ExBL/HgBL) and B) Completely hatched blastocysts (HBL). Clinical and laboratory end points were analyzed using t-test and Chi-square test as appropriate.

MATERIALS AND METHODS: Patients ≤38 years old (n=835) undergoing single frozen embryo transfer with euploid blastocysts were used in this study. Blastocysts were biopsied on days 5/6 and aneuploidy testing was performed via NextGen Sequencing. Blastocysts were warmed and cultured for 2-4h before embryo transfer. Low quality euploid blastocysts (<BB) were excluded from this study.

RESULTS: There was a lower positive β-hCG, clinical pregnancy and live birth/ongoing pregnancy rate when transferring HBL compared with ExBL/HgBL (Table 1). No difference was noted between treatment groups for patient age and blastocyst quality. Furthermore, no significant difference in clinical outcomes was noted when transferring Day 5 or Day 6 blastocysts.

TABLE 1. Effect of blastocyst developmental stage on clinical outcomes.

Blastocyst Stage	N	Avg. Age	Positive β-hCG Rate	Clinical Pregnancy Rate (+ heartbeat)	Live Birth/Ongoing Pregnancy Rate
ExBL/HgBL	633	32.2 [a]	480/633 (76%) [a]	416/633 (66%) [a]	390/633 (62%) [a]
HBL	202	32.1 [a]	137/202 (68%) [b]	112/202 (55%) [b]	102/202 (50%) [b]

[a,b] Different superscripts within columns indicate significant differences (P<0.05)

CONCLUSIONS: These findings suggest that euploid completely hatched blastocysts have lower clinical success rates than euploid expanded/hatching blastocysts. Completely hatched blastocysts may be more susceptible to the vitrification/warming process and more prone to mechanical damage during the embryo transfer procedure due to the absence of the zona pellucida. Protocols may need to be tailored to reduce the risk of damage during the embryo transfer procedure when transferring fully hatched blastocysts.

IS THERE A CRITICAL ENDOMETRIAL LINING THICKNESS FOR SUCCESSFUL IMPLANTATION IN A PROGRAMMED CYCLE?.

Michael Saad-Naguib, MD,[1] Douglas Timmons, MD, MPH,[2] Leila R. Grass, BS,[3] Jose A. Carugno, MD,[2] Marcelo J. Barrionuevo, MD,[3] Steven J. Ory, MD,[3] Kathleen A. Miller, DHSc,[3] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami, Miami, FL; [3]IVF Florida Reproductive Associates, Margate, FL.

OBJECTIVE: The relationship of endometrial thickness to implantation rates has been debated since 1989 [1,2]. Some studies have suggested a specific cutoff of 7- 8 mm or greater correlates with a statistically significant improvement in pregnancy rates [3,4 5]. A meta-analysis including only fresh cycles concluded that current data indicates that endometrial thickness has a limited capacity to predict implantation rates[6]. Programmed cycles with a different hormonal milieu than fresh cycles might offer a different implantation potential. This study was undertaken to determine the optimal endometrial thickness in a programmed cycle.

DESIGN: An IRB approved retrospective cohort study from a single private IVF center.

MATERIALS AND METHODS: 909 autologous first frozen embryo transfer cycles with a single euploid embryo (euSFET) were analyzed from January 2014 to February 2020. The first objective was to determine if euSFET removes the age-related decline in sustained implantation rate (SIR) defined as ongoing pregnancy rate >20 weeks gestation. SIRs were compared between SART age groups (< 35, 35-37, 38-40, and > 41) using a Chi-Square test or a Fisher's exact test, if assumptions were not met. Logistic regression was used to determine the odds ratios for SIR between endometrial thickness and SIR. Endometrial thickness was divided into the following groups: < 7mm, 7-8mm, 9-12mm, and > 12mm. A receiver operating curve (ROC) was created to identify the optimal endometrial thickness for implantation.

RESULTS: The effect of age on SIR with euSFET was not found to be significant at any level: 60% < 35 group (n=361), 60% in 35-37 group (n=220), 56% in 38-40 group (n=223), and 55% in >41 group (n=105), respectively.

Increasing endometrial thickness appears to have a positive effect on SIR: 46.67%, < 7mm (n=30), 51.5%, 7-8mm (n=266), 62.02% 9-12mm (n=445), and 63.9% > 12mm (n=168). Odds of implantation were 1.21 (95%CI: (.57, 2.59)) times higher in the 7-8mm group, 1.87 (95%CI: (.89, 3.92)) times higher in the 9-12mm group, and 2.00 (95%CI: (.92, 4.39)) times higher in the > 12mm group. Endometrial thickness over 12mm demonstrated a marked improvement in SIR (p = .08). ROC shows 8.35 mm to be the optimal thickness for a successful SIR.

CONCLUSIONS: This data demonstrates that endometrial thickness has a positive effect on SIR in euSFET in programmed cycles. Carefully controlled trials are needed to further demonstrate the effect of endometrial thickness on SIR.

Table 1

Effect of age on SIR			
Age group	N	SIR	P
< 35	361	60%	0.84
35-37	220	60%	0.85
38-40	223	56%	0.33
> 41	105	55%	0.37

Effect of endometrial thickness on SIR				
ET group	N	SIR	P	OR (95% CI)
< 7 mm	30	46.40%	0.72	.88 (.43, 1.79)
7-8mm	266	51.50%	0.62	1.21 (.57, 2.59)
9-12mm	445	62.02%	0.1	1.87 (.89, 3.92)
> 12mm	168	63.90%	0.08	2.00 (.92, 4.39)

OVERCOMPENSATING? THE USE OF ICSI FOR NON-MALE FACTOR INFERTILITY DOES NOT IMPROVE LIVE BIRTH RATE IN A MATCHED PATIENT POPULATION.

Tanya L. Glenn, MD,[1] Dawn A. Kelk, PhD, HCLD,[1] Michael Wininger, PhD,[2] David B. Seifer, MD,[1] [1]Yale University, Orange, CT; [2]Yale School of Public Health, West Haven, CT.

OBJECTIVE: The current ASRM guidelines recommend the utilization of ICSI be confined to couples with male factor infertility. ICSI should not be used routinely, but commonly is. Due to potential increases in complications from ICSI, such as increased handling of gametes, it is imperative to analyze if outcomes differ with the use of ICSI for non-male factor infertility (NMF).

TABLE #1. Contingency Tables

	<35 y/o (n=154)		35-38 y/o (n=72)		>38 y/o (n=56)	
	LBR, (n)	No LBR, (n)	LBR, (n)	No LBR, (n)	LBR, (n)	No LBR, (n)
ICSI	47.4% (36)	52.6% (40)	61.1% (22)	38.9% (14)	34.5% (10)	65.5% (19)
IVF	55.1% (43)	44.9% (35)	47.2% (17)	52.8% (19)	37.0% (10)	63.0% (17)

The primary hypothesis was that there is an association between the treatment (IVF/ICSI) and outcome (LBR) for NMF.

DESIGN: A propensity-matched cohort study comparing fresh NMF cycles utilizing ICSI versus IVF in a single academic institution from 2015-2018.

MATERIALS AND METHODS: A bi-directional selection process through optimization Akaike Information Criterion was used to match the ICSI and IVF groups. The number of embryos transferred, number of two pronuclei, diminished ovarian reserve status, and age were highly influential and thus included in a propensity-match across the two cohorts. Our analysis was then stratified by age-group (<34, 35-38, and >39 years).

RESULTS: The propensity-matched dataset found the best-matched 141 ICSI versus 141 IVF patients. The Cochrane-Mantel-Haenszel test showed no significant effect of ICSI when stratified across the three age groups (P = 0.840). The Breslow-Day test showed no significant effect between the three age groups (P=0.313; Table 1). The difference in fertilization rates from total oocytes retrieved, as well as the total number of usable embryos were not significant (P=0.54, P=0.23, respectively).

CONCLUSIONS: We conclude that ICSI does not significantly alter LBR when utilized for NMF, as the results provide insufficient evidence to reject the null hypothesis. The major strength of this study is the use of a propensity-matched population. Other strengths include a multi-year analysis and reduced confounders by isolating to fresh cycles. Limitations include the low number of matched cycles, patient factors not included in the analysis, such as cycle number or IVF protocol, and the non-randomized nature. However, a power calculation determined that a randomized control trial would require over 2000 participants, which is not practical. It is also pertinent to highlight the apparent statistical equivalence in LBR with the use of ICSI for NMF. Therefore, the use of non-essential ICSI puts unnecessary financial burden on the patient, extra demand on the embryology lab, and incurs potential adverse effects of ICSI without a significant alteration in LBR.

OVARIAN RESERVE, RESPONSE, BLASTOCYST DEVELOPMENT AND PREGNANCY RATES IN OPERATED AND NON-OPERATED ENDOMETRIOMA CASES: A COMPARISON WITH AGE MATCHED UEI CASES. Beril Yuksel, MD, Assoc. Prof., Semra Kahraman, MD Prof. Istanbul Memorial Sisli Hospital, Istanbul, Turkey.

OBJECTIVE: The aim of this study was to evaluate the effect of endometriosis on cycle characteristics in operated and non-operated cases when compared with age matched UEI cases.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We retrospectively analyzed 2500 patients with endometriosis who attended to Istanbul Memorial Hospital, ART and Genetics Center between January 2011 and December 2019. We compared cycle characteristics and ovarian reserve of operated (OE) and non-operated endometrioma (NOE) cases. The control group was comprised of age-matched (<35, 35-37, 38-40) unexplained infertile (UEI) cases.

RESULTS: A total of 2500 OE and NOE cycles, with 2140 cycles, age ≤40 were compared with 2353 cycles of UEI in the same age group. The mean AMH levels and the number of retrieved, mature and fertilized oocytes were significantly lower in OE and NOE cases when compared to UEI. The maturation (MR), fertilization (FR) and blastulation rates (BR) were comparable between NOE and OE cases. However, MR and BR were higher than in UEI controls between the ages of 35-40, both in overall and NOE cases (Table 1). Top - good quality (TQ-GQ) blastocyst rates were also higher in NOE patients when compared to UEI (47.8% vs 47.2%, p<0.05). However, the rates of TQ-GQ blastocysts were lower in NOE when compared to OE cases (47.8% vs 48.9%, p<0.05). The biochemical (BPR) , clinical (CPR) and ongoing pregnancy rates (OPR) were comparable between overall endometriosis, NOE and UEI controls, but the rates were significantly lower in OE when compared to NOE cases (BPR: 50.8% vs 45.2; CPR: 45.9% vs 38.7% and OPR: 38.3% vs 33.2%, p<0.05).

CONCLUSIONS: Endometriosis, even in NOE cases, results in significant reduction in ovarian reserve and ovarian response compared to UEI. However, neither the TQ-GQ blastocyst nor the pregnancy rates are affected.

SUPPORT: None.

IVF OUTCOMES AFTER BARIATRIC SURGERY. Katherine M. Baker, MD,[1] Laura E. Dodge, Sc.D., M.P.H.,[2] Kim L. Thornton, MD,[3] [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [3]Boston IVF, Waltham, MA.

OBJECTIVE: Increasing numbers of obese reproductive-age women are undergoing bariatric surgery to achieve and sustain weight loss to improve fecundability and in vitro fertilization (IVF) outcomes. Despite this, limited data is available regarding IVF outcomes in patients undergoing bariatric surgery. The aim of this study was to describe a cohort of patients who underwent IVF after pursuing bariatric surgery. This information will serve to counsel patients who have undergone or are contemplating undergoing bariatric surgery to improve their IVF outcomes.

DESIGN: Retrospective cohort study from the reproductive endocrine division at our academic teaching hospital.

MATERIALS AND METHODS: Patients whose first IVF cycle at our center began between 2008 and December 2013 and who underwent bariatric surgery before starting infertility treatment were included; outcomes were assessed through 2019. Patient characteristics and cycle details were obtained from electronic medical records. Descriptive statistics were used to describe patient demographic and treatment characteristics and IVF outcomes.

TABLE 1. Maturation (MR), fertilization (FR) and blastulation rates (BR) in cases of endometriosis, OE and NOE compared to UEI controls (**p<0.05 is considered statistically significant, Mann-Whitney U test*)

	MR			FR			BR

	NOE	**OE**		**NOE**	**OE**		**NOE**	**OE**	**p**
< 35 y	0.82 ± 0.1	0.84 ± 0.1	*	0.83 ± 0.2	0.80 ± 0.2	*ns*	0.50 ± 0.3	0.52 ± 0.3	*ns*
35-37	0.85 ± 0.1	0.84 ± 0.1	*ns*	0.81 ± 0.2	0.79 ± 0.2	*ns*	0.52 ± 0.3	0.55 ± 0.3	*ns*
38-40	0.87 ± 0.1	0.88 ± 0.1	*ns*	0.77 ± 0.2	0.82 ± 0.2	*ns*	0.54 ± 0.3	0.59 ± 0.3	*ns*

RESULTS: Forty-five eligible patients underwent 151 cycles (median: 2.0, interquartile range [IQR]: 1.0–4.0). Eighty-percent of patients had undergone gastric bypass, 7 (15.5%) had undergone gastric banding, and 2 (4.4%) had undergone a gastric sleeve procedure. At the start of their first cycle, median age was 38.6 years (IQR: 35.9–40.8), and median BMI was 33.6 (IQR: 29.0–39.3). At the time of the first IVF cycle, the median time since surgery was 3.9 years (IQR: 2.0–7.2), and the median weight loss was 100.0 pounds (IQR: 70.0–137.5). Among all cycles, pregnancy was achieved in 55 (36.4%), with 35 of 45 (77.8%) patients achieving at least one pregnancy, and 27 (17.9%) resulted in live birth, with 20 patients (44.4%) achieving at least one live birth. Of the 55 pregnancies, there were 16 (29.1%) biochemical pregnancies, 9 (16.4%) miscarriages, and 3 (5.5%) ectopic pregnancies. Of those who were known to be anovulatory prior to surgery (n=18), 27.8% regained ovulatory function following surgery. Pregnancies were similar between people who lost <100 pounds (n=13; 14 pregnancies among 43 cycles [32.6%]) and those who lost ≥100 pounds (n=23; 28 pregnancies among 80 cycles [35.0%]). Among all cycles, compared to people who lost <100 pounds, people who lost ≥100 pounds were less likely to experience biochemical pregnancy (21.4% vs. 28.6%, respectively) and miscarriage (10.7% vs. 21.4%, respectively) and more likely to experience ectopic pregnancy (10.7% vs. 0%, respectively) and live birth (57.1% vs. 50.0%).

CONCLUSIONS: At our center, patients who have undergone bariatric surgery prior to infertility treatment had favorable IVF outcomes. Our existing cohort is currently being expanded to allow for more robust analysis of outcomes with regards whether the type of surgery, timing of surgery relative to IVF, or absence or presence of comorbidities impacts IVF outcome.

MITOCHONDRIAL DNA COPY NUMBER OF CUMULUS CELLS IS NOT LINKED TO EMBRYO IMPLANTATION IN GOOD PROGNOSIS IVF PATIENTS. Weiwei Liu, MD, Chongqing, China.

OBJECTIVE: To explore the mitochondrial DNA (mtDNA) copy number of cumulus cells (CCs) could be used as a biomarker of the potential of embryo implantation in good prognosis IVF patients?

DESIGN: This was a prospective cohort study on good prognosis IVF patients from a large reproductive medicine centre. A total of 392 embryos from 61 cycles (including 31 implanted and 30 non-implanted cycles) were enrolled in the study.

MATERIALS AND METHODS: The corresponding CCs mtDNA copy number of embryos was tested by real-time quantitative PCR. The corresponding CCs mtDNA copy numbers were compared between implanted and non-implanted embryos and also compared between high-quality and poor-quality embryos. Then, mitochondrial membrane potentials of the corresponding CCs were compared between high-quality and poor-quality embryos to verify the above experiment's findings.

RESULTS: For the same population, the mean CCs mtDNA copy numbers for implanted and non-implanted embryos were 255.61±81.02 and 254.50±73.29, and those for high-quality and poor-quality embryos were 266.02±98.56 and 295.71±70.64, respectively. There was no difference in CCs mtDNA copy number between implanted and non-implanted embryos or between high-quality and poor-quality embryos. The mitochondrial membrane potential assay was assessed by JC-1, and the quantitative analysis revealed that the ratio of red to green fluorescence did not differ significantly between high-quality and poor-quality groups.

CONCLUSIONS: Measurement of CC mtDNA copy number might not provide any advantage to embryo prioritisation in good prognosis IVF patients. Any suggested link between CCs mtDNA copy number and embryo implantation requires further validation.

P-477 4:30 PM Monday, October 19, 2020

FOLLICLE FLUSHING DOES NOT IMPROVE LIVE BIRTH AND REDUCES OOCYTE YIELD: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS (RCTS). Anne E. Martini, DO,[1] Ariel Dunn, MD,[2] Lauren Wells, BS,[3] Nanette Rollene, MD,[2] Rhiana D. Saunders, MD,[2] Mae W. Healy, DO,[2] Nancy Terry, BS, MLS,[4] Alan H. DeCherney, MD,[1] Micah J. Hill, DO,[2] [1]National Institute of Child Health and Human Development, NIH, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]Uniformed Services University of the Health Sciences, Bethesda, MD; [4]National Institutes of Health Library, Bethesda, MD.

OBJECTIVE: To determine whether follicle flushing during oocyte retrieval improves live birth or secondary outcomes in ART.

DESIGN: Systematic review and meta-analysis

MATERIALS AND METHODS: Literature searches were performed for RCTs evaluating follicle flushing in ART (PubMed, EMBASE, Cochrane Database, Web of Science). Inclusion criteria were full-text, English language RCTs published from 1989-2020 comparing follicle flushing with conventional oocyte retrieval. Primary outcome was live birth. Secondary outcomes were clinical and ongoing pregnancy, total and mature oocytes (MII) retrieved, and operating time. Dichotomous and continuous outcomes were reported as risk ratio (RR) and mean difference (MD) respectively. Funnel plots were used to assess publication bias. Random effect models were utilized due to significant clinical heterogeneity between studies. Sensitivity analyses were performed to account for differences in patient population (normal vs poor responders), stimulation protocol, ovulation trigger type, number and volume of flushes, infertility diagnosis, flushing needle type, and random vs fixed effects models.

RESULTS: Ten RCTs met inclusion criteria totaling 922 subjects. Funnel plots revealed no publication bias. Five studies with 734 subjects reported live birth. No difference in live birth was demonstrated between follicle flushing and direct aspiration (RR 1.01, 95% CI 0.78-1.32, I^2=0%). Clinical pregnancy (RR 1.04, 95% CI 0.77-1.40) and ongoing pregnancy (RR 1.08, 95% CI 0.75-1.57) were also not improved with flushing. Total oocyte (MD -0.57, 95% CI -0.95 to -0.20) and MII yield (MD -0.36, 95% CI -0.71 to -0.01) were lower with flushing compared to direct aspiration. Sub-analysis of poor responders also demonstrated lower MII yield with flushing (MD -0.34, 95% CI -0.75-0.08). Procedure time was increased with flushing by 2 minutes in poor responders and 9 minutes in normal responders (P<0.05). Other sensitivity analyses did not reveal any changes.

CONCLUSIONS: Follicle flushing during oocyte retrieval increases procedure time and does not improve live birth or secondary ART outcomes. Oocyte yield is significantly reduced with flushing, although by less than one oocyte. The randomized data do not support the use of follicle flushing as an intervention in ART.

THE ASSOCIATION BETWEEN TYPE OF PROGESTERONE SUPPLEMENTATION AND MISCARRIAGE RISK IN WOMEN WITH A POSITIVE PREGNANCY TEST FOLLOWING EMBRYO TRANSFER: A RETROSPECTIVE COHORT STUDY. Talya Shaulov, MD, MSc,[1] Nadège Zanré, MSc,[2] Simon Phillips, PhD,[1] Louise Lapensée, MD[1] [1]Ovo Clinic, Montréal, QC, Canada; [2]University of Montreal, Montreal, QC, Canada.

OBJECTIVE: The aim of this study was to investigate the association between type of progesterone supplementation after a positive pregnancy test and miscarriage in in vitro fertilization (IVF), and to determine if switching from intramuscular (IM) progesterone to vaginal progesterone after a positive pregnancy test is associated with higher miscarriage risk.

DESIGN: Retrospective cohort study in a private university-affiliated fertility clinic in Montreal, Canada.

MATERIALS AND METHODS: Women aged 18 to 50 at the time of embryo transfer (ET), with a positive pregnancy test following ET between 2013 and 2016, were included. Only first IVF pregnancies were included. Biochemical pregnancies as well as pregnancies from oocyte donor, surrogacy, natural fresh or natural frozen cycles were excluded. A total of 1988 women with complete data on exposure and outcome were included in the analysis. The two groups of women studied are those who stayed on IM progesterone following a positive pregnancy test and those who switched to vaginal progesterone after a positive test. The main outcome measured was the risk of miscarriage < 24 weeks gestation as a proportion of non-biochemical pregnancies after fresh or frozen ET.

RESULTS: Among baseline characteristics, a higher number of prior miscarriages, as well as a higher number of prior failed embryo transfers and frozen cycles (vs fresh) were associated with continued IM progesterone use (p values 0.006, <0.001, 0.011, respectively). With regards to the primary outcome, miscarriage risk < 24 weeks, 22.4% (274/1221) of patients in the IM progesterone group experienced a miscarriage compared with 20.7% (159/767) in the vaginal progesterone group. A univariate analysis revealed an unadjusted OR of 0.90 (95%CI 0.73 to 1.13, p=0.369) for the association between progesterone type and miscarriage. A multivariable logistic regression model adjusting for potential confounders (age at oocyte retrieval, body mass index, ovarian reserve, parity, prior miscarriages, duration of infertility, cause of infertility, prior failed ETs, number of good quality embryos produced in fresh IVF cycle, type of ET cycle (fresh or frozen), number of embryos transferred and stage of embryo(s) transferred) revealed an adjusted OR (aOR) of 1.00 (95%CI 0.79 to 1.23, p=0.974). There was evidence for an effect modification by antral follicle count: among patients with <13 antral follicles, users of vaginal progesterone had a lower odds of miscarriage compared to users of IM progesterone (aOR 0.64, 95%CI 0.43 to 0.97, p=0.036).

CONCLUSIONS: This study suggests that switching from IM progesterone to vaginal progesterone after a positive pregnancy test following an ET is not associated with a change in miscarriage risk. Considering that IM progesterone imposes substantial discomfort, this study offers clinicians and patients comforting results and some flexibility in treatment protocols. Further prospective studies are necessary to corroborate results of this study, and to investigate this association in different patient or cycle subgroups, such as by fresh or frozen cycles or by level of ovarian reserve.

P-479 4:30 PM Monday, October 19, 2020

THE EFFECT OF ANTIBIOTIC ADMINISTRATION ON NATURAL CYCLE FROZEN EMBRYO TRANSFERS. Jasmyn K. Johal, MD, MS,[1] Isabel Beshar, MPhil,[1] Brindha Bavan, MD,[2] Amin A. Milki, MD,[2] [1]Stanford University, Dept of Obstetrics & Gynecology, Stanford, CA; [2]Stanford Medicine Fertility and Reproductive Health Services, Sunnyvale, CA.

OBJECTIVE: To assess whether withholding antibiotics prior to transfer impacts the success of natural cycle frozen embryo transfers (NC-FET)

DESIGN: IRB-approved retrospective cohort study

MATERIALS AND METHODS: All NC-FET with euploid blastocysts performed by a single provider at an academic institution from 3/2017- 3/2020 were reviewed. Standard protocol for NC-FET included hCG trigger when the dominant follicle was ≥18 mm and endometrial lining was ≥7 mm to time the transfer. NC-FET performed after 1/2019, which did not include antibiotic administration, were compared to a similar number of NC-FET performed prior to 1/2019, which included routine administration of doxycycline 100 mg BID starting two days prior to transfer through the evening of ET. Our three outcomes of interest were +bHCG, clinical pregnancy rate (CPR, defined as the presence of a gestational sac on ultrasound), and live birth (LB) or ongoing pregnancy rate (OPR, defined as pregnancies >13 weeks). Based on an a priori power analysis, our sample size was sufficient to detect a 5% difference. Demographic information and pregnancy outcomes were recorded in a secure database and analyzed in SAS with Wilcoxon ranked sum tests for non-parametric continuous data, chi-squared statistical analyses for categorical variables, and logistic regressions for outcome variables.

RESULTS: 125 NC-FET were included in each group. The overall mean age at transfer was 36.3 years and mean BMI was 24 kg/m2. Baseline characteristics, including age, BMI, and SART diagnosis, were similar between the two groups. Most patients were nulliparous (60%) women of Asian or Caucasian descent (93.4%). We found no significant difference in +bHCG (74% vs. 72.8%, p=0.83), CPR (65.9% vs 68%, p=0.72), and LB-OPR (62.6% vs 64%, p=0.82) for NC-FET with antibiotic administration and those without, respectively. After controlling for patient age, BMI, race, parity, SART diagnosis, endometrial thickness, and embryo grade in a logistic regression model, antibiotic administration still had no effect on +bHCG (OR 0.62[0.27, 1.40], CPR (OR 0.55[0.25, 1.23]), or LB-OPR (OR 0.56[0.26, 1.21].

CONCLUSIONS: While antibiotics had commonly been administered prior to ET to reduce microbial contamination, the effect on pregnancy outcomes in previous retrospective studies and randomized control trials has been inconsistent (1-3). The strength of our study is that it compared very similar populations using euploid frozen embryos in natural cycles, all performed by the same physician using the same technique. We found that withholding antibiotics does not reduce pregnancy success. Given the risks of antibiotics, including side effects and widespread antibiotic resistance, our findings support the current policy of withholding their use in frozen embryo transfer.

REPEATED IMPLANTATION FAILURE AND WINDOW OF IMPLANTATION TESTING: A WINNING DUET TO IMPROVE LIVE BIRTH RATE. Frida Entezami, MD,[1] Delphine Haouzi, PhD,[2] Alice Ferrieres-Hoa, MD,[2] Sophie Brouillet, PharmD, PhD,[3] Claire Vincens, MD,[4] Sophie Bringer-Deutsch, MD,[4] Emmanuelle Vintejoux, MD,[3] Samir Hamamah, MD, PhD,[3] [1]American Hospital of Paris, Neuilly-sur-Seine, France; [2]Inserm U1203, CHU Montpellier, St-Eloi Hospital, Montpellier, France; [3]Arnaud de Villeneuve Hospital, CHU Montpellier, Montpellier, France; [4]ART-PGD department, Arnaud de Villeneuve Hospital, CHU Montpellier, Montpellier, France.

OBJECTIVE: Outcome benefits on live birth rate in patients with repeated implantation failure (RIF) after customized embryo transfer based upon identification of endometrial receptivity window by transcriptomic approach.

DESIGN: This is a french prospective multicenter trial. Endometrial biopsies were performed during the implantation window 7-9 days after the LH surge in natural cycle or 5-9 days after progesterone administration under HRT. According to transcriptomic testing result of the biopsy, blastocysts were transferred in the subsequent frozen embryo transfer cycle (FRET), at the specific day where endometrium was identified as receptive. For cleavage stage D2/D3 embryos transfers were performed 72/48 hours before the specific cycle day where endometrium was identified as receptive.

MATERIALS AND METHODS: From 2015 to 2018 a total of 217 RIF patients (4.4±1.9 failed fresh/frozen transfers of 6.4±3.6 embryos) were enrolled. Genomic testing of endometrial biopsies was performed under natural/HRT cycles and mRNA expression of genes predictive of receptivity was established by RT-qPCR. Customized embryo transfer (n=157 patients) was

performed in a subsequent FRET cycle based upon these results. Clinical pregnancy and live birth rates (LBR) were compared to control RIF patients with standard FRET in natural/HRT cycles (n=60 patients).

RESULTS: Customized embryo transfer using the genomic testing strategy yielded spectacular increase in outcome for 157 RIF patients (age 37.2±4.3 years). Comparison of the results between the study group and the control group showed significantly higher rates for implantation (22.7% vs 7.2%, p=0.0001), clinical pregnancy (38.8% vs 15.0%, p=0.0006), ongoing pregnancy (36.3% vs 8.3%, p=0.00002) and live birth rates (31.8% vs 8.3%, p=0.0002). Analyses of endometrial receptivity status revealed mostly a delay both in natural and HRT cycles, between 1 to 3 days. Most patients achieved pregnancy after the first customized FRET (70%). Better clinical pregnancy and live birth rates were obtained with blastocyst transfer compared to cleavage stage transfers (respectively 36.3% vs 22.5% and 29.5% vs 14.0%). Whatever the day of transfer, results were significantly higher in the study group compared to the control group, with ongoing pregnancy rate for transfer of cleavage-stage embryos of 21.1% compared to 4.5% in the control group (p=0.03). In blastocyst transfer group ongoing pregnancy rate of 33.9% was significantly higher than 8.6% in the control group (p=0.003).

CONCLUSIONS: In RIF patients customized embryo transfer according to endometrial transcriptomic testing improves dramatically the clinical outcome by increasing almost four-fold the LBR. In our study, the majority of RIF patients displayed a delay in their receptivity window of 1 to 3 days, revealing a potential cause for their previous implantation failures. The transcriptomic window of implantation testing alone, and without any embryo genetical testings for aneuploidy, is able to enhance significantly the clinical outcome and should be advised to rescue LBR for patients with multiple RIF.

IDENTIFYING THE GAMETE RESPONSIBLE FOR ICSI FERTILIZATION FAILURE. Stephanie Cheung, B.S., Philip Xie, B.S., Alessandra Parrella, M.Sc., Derek Keating, B.A., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To identify and effectively treat the gamete responsible for complete ICSI fertilization failure.

DESIGN: A total of 114 couples treated at our center during the last 20 years who had a ≤10% ICSI fertilization rate were identified. Seventy-six men were screened for the presence of PLCζ. Those with a PLCζ presence were considered to have oocyte-related oocyte activation deficiency (o-OAD; n=52) and were treated by standard ICSI with a tailored stimulation protocol. Men with PLCζ absence were further screened by a mouse oocyte activation test (MOAT) and were considered to have sperm-related OAD (s-OAD; n=24). Some of these men (n=4) underwent a genomic evaluation by NGS. These couples then underwent subsequent ICSI cycles with assisted gamete treatment (AGT). ICSI outcome was compared between the study cohort and historical cycles from the same couple.

MATERIALS AND METHODS: Consenting couples with female partners ≤37 years of age and male partners with a sperm concentration of ≥1x10^6/ml who had a ≤10% fertilization rate, despite injecting ≥3 oocytes, were included (IRB 0712009553). PLCζ assessment was performed, confirmed by MOAT and DNA/RNAseq. In subsequent cycles, couples with o-OAD were treated by modulating *in vivo/vitro* maturation time, while s-OAD cases were treated by exposing both gametes to calcium ionophore. Clinical outcomes were compared.

RESULTS: A total of 114 couples (maternal age, 33.8±4 yrs; paternal age, 36.9±5 yrs) with a 9.1% ICSI fertilization rate were identified. Of all men screened for PLCζ, 52 were identified as having o-OAD. These 52 couples underwent subsequent ICSI cycles with tailored superovulation, yielding significantly higher fertilization (59.0% vs. 2.1%; P<0.0001) and clinical pregnancy (28.6% vs. 0%; P<0.0001) rates compared to their respective historical cycles. Thirty clinical pregnancies resulted in 25 deliveries and 5 pregnancy losses. A total of 32 babies were born, 15 boys and 17 girls, with no congenital malformations.

Twenty-four couples (maternal age, 35.6±5 yrs; paternal age, 39.8±6 yrs) in which the male partners had the absence of PLCζ were then screened by MOAT and considered to have s-OAD. In some of these men, DNAseq identified a PLCZ1 deletion, corroborating the initial screening results. Deletions of genes associated with spermiogenesis and embryo development (PIWIL1, BSX, NLRP5), as well as the absence of the subacrosomal perinuclear theca (PICK1, SPATA16, DPY19L), were found. For these couples, AGT provided higher fertilization (42.1% vs. 9.1%; P<0.05) and clinical pregnancy rates (36% vs. 0%; P<0.05) compared to their historical cycles. Six patients have successfully delivered, with children currently displaying normal development at 3 years of age.

CONCLUSIONS: This is the first attempt to identify a gamete-specific OAD in couples with complete ICSI fertilization failure. Couples with o-OAD can be successfully treated in a subsequent cycle by modifying the superovulation protocol, thus preventing AGT overuse. For couples with s-OAD confirmed by detailed genomic analysis, AGT treatment proved paramount in fulfilling their desire to have a child.

THE EFFECT OF THE ORAL OXYTOCIN ANTAGONIST, NOLASIBAN, ON PREGNANCY RATES IN WOMEN UNDERGOING EMBRYO TRANSFER FOLLOWING IVF. Georg Griesinger, MD, PhD,[1] Jacques Donnez, PhD, MD,[2] Andrew Humberstone, PhD,[3] Paul Terrill, PhD,[4] Oliver Pohl, DVM, MPH, MSc,[5] Elizabeth Garner, MD, MPH,[6] Ernest Loumaye, MD, PhD,[3] [1]University Hospital Schleswig-Holstein, Lübeck, Germany; [2]Catholic University of Louvain, Brussels, Belgium; [3]ObsEva SA, Plan-les-Ouates, Switzerland; [4]Cytel Inc, London, United Kingdom; [5]ObsEva, Plan-les-Ouates, Switzerland; [6]ObsEva Inc, Boston, MA.

OBJECTIVE: To summarize data from three randomized clinical trials in women undergoing IVF and a mechanism of action (MoA) study in healthy volunteers of nolasiban, an oral oxytocin receptor antagonist, being developed to improve pregnancy and live birth rates in women undergoing fresh embryo transfer following IVF.

DESIGN: The first clinical trial was a randomized, double-blind, parallel group, dose-ranging Phase 2 trial comparing single oral doses of 100, 300 and 900 mg nolasiban to placebo in women undergoing fresh Day 3 embryo transfer (ET) following IVF or ICSI. The subsequent two Phase 3 trials were randomized, double-blind, parallel group, trials comparing a single oral dose of 900 mg nolasiban to placebo in women undergoing fresh single embryo transfer on Day 3 or Day 5 post-OPU. A meta-analysis of ongoing pregnancy rate in the nolasiban 900 mg vs placebo groups in all three trials was performed.

MATERIALS AND METHODS: For the clinical trials, IVF patients (≤37 years and ≤ 1 previous failed cycle) were recruited from 60 fertility centers in 11 European countries between 2015 and 2019. In the clinical trials, a single dose of nolasiban or placebo was administered four hours before embryo transfer. Key clinical endpoints in the clinical trials were pregnancy test (14 days post-oocyte pick-up), clinical pregnancy (6 weeks post-ET), ongoing pregnancy (10 weeks post-ET), pregnancy loss, and live birth. Population pharmacokinetics of nolasiban were also assessed. The MoA study assessed the effect of single doses of 900 and 1800 mg in healthy female volunteers on measures of endometrial receptivity including uterine contractions, endometrial blood flow and endometrial gene expression.

RESULTS: A significant increase in ongoing pregnancy and live birth rates was observed in the 900 mg nolasiban group compared to placebo in the first Phase 3 trial but not confirmed in the second study. A meta-analysis of all the clinical trials showed an absolute increase of 5% (p=0.029) in ongoing pregnancy rate with nolasiban 900 mg versus placebo. There was a similar magnitude of effect with Day 3 compared to Day 5 ET (increases of 6.18% and 4.54%, respectively), although statistical significance was not achieved for either ET day when considered separately. Comparison of population PK results to pregnancy outcomes indicated a correlation between higher nolasiban exposures and pregnancy. In the MoA study, nolasiban showed effects suggesting an improvement in endometrial receptivity, including changes in gene expression associated with endometrial receptivity with the higher dose.

CONCLUSIONS: A single oral dose of 900 mg nolasiban administered 4 h before ET increased ongoing pregnancy rate by an absolute 5% (p=0.029) (i.e., a 15% relative increase) in a meta-analysis of 3 clinical trials. The overall clinical data, including pharmacokinetic modeling and evidence from the MoA study, support future evaluation of higher doses and/or alternate regimens.

SUPPORT: The trials were funded by ObsEva SA.

ASSOCIATION BETWEEN ESTRADIOL LEVELS AND OBSTETRIC OUTCOMES IN LETROZOLE-STIMULATED FROZEN EMBRYO TRANSFER CYCLES. Wendy Y. Zhang, BS,[1] Maya K. Ramachandran, BS,[1] Gayathree Murugappan, MD,[2] Lusine Aghajanova, MD PhD,[2] Ruth Bunker Lathi, MD,[2] [1]Stanford University School of Medicine, Stanford, CA; [2]Stanford University, Stanford, CA.

OBJECTIVE: Letrozole-stimulated frozen embryo transfer (LTZ-FET) cycles are increasingly utilized due to growing evidence of improved success rates in multiple populations, including patients with polycystic ovary syndrome, diminished ovarian reserve, tubal factor, or unexplained infertility. The degree of estrogen suppression is variable between patients, and the impact of low estradiol (E2) levels in the follicular phase is unknown. Thus, the goal of this study was to assess the impact of low estradiol on outcomes of LTZ- FET cycles.

DESIGN: Retrospective cohort

MATERIALS AND METHODS: We studied all LTZ-FET cycles at an academic center from 1/2018 to 8/2019 (n=220). 5 mg of letrozole was administered daily for 5 days from cycle day 3. Ovulation was triggered with HCG when the lead follicle was ≥18 mm and endometrial thickness (EMT) was >7 mm. FET was performed 7 days after trigger or 6 days after LH surge, and micronized progesterone was given vaginally twice daily 2 days after ovulation. Peak serum E2 levels were measured on the day of trigger, with low E2 defined as <10th percentile (E2<104.4 pg/mL). The primary outcomes including EMT, clinical pregnancy rate (presence of fetal cardiac activity), and LBR were compared using t- and chi-squared tests between low and normal E2 groups.

RESULTS: There were no differences in age, BMI, race, distribution of infertility diagnoses, gravidity, parity, number of embryos transferred, and use of PGT between groups. The mean E2 level for the normal E2 (control) group was 738.7±878.7 pg/mL compared to 77.6±19.3 in the low E2 group. Cycle characteristics, pregnancy rates, and biochemical miscarriage rates were similar between groups. However, the low E2 group had a significantly higher miscarriage rate and a significantly lower LBR.

	Controls n=186	Low estradiol n=34	P-value
Baseline characteristics			
Age (y)	36.1 ± 4.2	36.0 ± 3.6	0.98
BMI	24.0 ± 4.8	24.1 ± 6.8	0.92
Cycle characteristics day of trigger			
Peak estradiol (pg/mL)	738.7 ± 878.7	77.6 ± 19.3	0.0001
Progesterone (ng/mL)	0.57 ± 0.45	0.64 ± 0.46	0.41
LH (IU/L)	22.4 ± 21.0	22.1 ± 18.5	0.93
Endometrial thickness (mm)	8.6 ± 1.2	8.9 ± 1.4	0.19
# of follicles >14mm	1.6±0.9	1.4 ± 0.8	0.42
Clinical Outcomes			
Progesterone at first BHCG (ng/mL)	39.5 ± 15.1	41.5 ± 16.6	0.46
Pregnancy rate, n(%)	121 (65.1)	19 (55.9)	0.31
Biochemical miscarriage rate, n(%)	20 (10.8)	4 (11.8)	0.86
Miscarriage rate, n(%)	18 (14.9)	7 (36.8)	0.02
Live birth rate, n(%)	103 (55.4)	12 (35.3)	0.01

CONCLUSIONS: In LTZ-FET cycles, low E2 levels were associated with a significantly higher miscarriage rate and lower live birth rate. Our data suggest that E2 levels in the follicular phase may have an effect on cycle outcomes, but further studies are needed to confirm our findings and understand the mechanisms behind these differences.

ENDOMETRIAL COMPACTION DOES NOT PREDICT ONGOING PREGNANCY RATE IN PROGRAMMED SINGLE EUPLOID EMBRYO TRANSFER CYCLES. Carrie Riestenberg, MD,[1] Molly M. Quinn, MD,[1] Alin Lina Akopians, MD, PhD,[2] Hal Danzer, MD,[2] Mark Surrey, MD,[2] Shahin Ghadir, MD,[2] Lindsay Kroener, MD,[1] [1]University of California, Los Angeles, Los Angeles, CA; [2]Southern California Reproductive Center, Beverly Hills, CA.

OBJECTIVE: To evaluate whether endometrial compaction using sequential transvaginal ultrasound is associated with improved ongoing pregnancy rate in programmed single euploid FETs.

DESIGN: Retrospective observational study.

MATERIALS AND METHODS: All single euploid FET cycles between January and December 2018 were assessed for eligibility. Natural cycle and controlled ovarian stimulation FETs as well as gestational carrier cycles were excluded. Patients were also excluded if their endometrial thickness was <7 mm at the initiation of progesterone. All patients received the same exogenous hormones for endometrial preparation per clinic protocol. Endometrial thickness was measured with transvaginal ultrasound after an average of 9-10 days of estrogen. Progesterone in oil 50mg daily and endometrin 100 mg TID were started within two days of the final lining measurement if the endometrium was ≥7 mm and trilaminar in appearance. Patients returned the day prior to embryo transfer for reassessment of the endometrial lining using transvaginal ultrasound. All FETs were performed on the sixth day of progesterone. The primary outcome was ongoing pregnancy rate defined as the presence of fetal cardiac activity at 10 weeks. We grouped patients by percentage of endometrial compaction, defined as the difference in endometrial thickness at the end of the estrogen-only phase and the day before embryo transfer, divided by the thickness at the end of estrogen-only phase. Cycles in which the percent compaction was less than +/-5% were considered unchanged.

RESULTS: A total of 294 single euploid FETs were included in the analysis. Only 17.3% (51/294) of the cycles demonstrated ≥5% compaction, whereas 82.7% (243/294) either expanded or were unchanged. Of those without any compaction, 30.0% (73/243) had no change in compaction and 70.0% (170/243) expanded ≥5%. Ongoing pregnancy rate did not significantly differ between cycles with compaction, no change, or expansion (69.8% vs 57.5% vs 58.8%, p=0.94) (Table 1). When considering only those

TABLE 1. Ongoing pregnancy rate (any compaction vs no change vs any expansion)

	Any Compaction	No Change	Any Expansion	p-value[a]
Ongoing Pregnancy Rate	31/51 (69.8%)	42/73 (57.5%)	100/170 (58.8%)	0.94

[a]chi-squared

TABLE 2. Ongoing pregnancy rate by percent compaction

	No Change	5-9%	10-14%	≥15%	p-value[a]
Ongoing Pregnancy Rate	42/73 (57.5%)	12/17 (70.6%)	9/15 (60%)	10/19 (52.6%)	0.72

[a]chi-squared

cycles in which the endometrium compacted, no difference was seen in ongoing pregnancy rates at different levels of compaction (p=0.72) (Table 2).

CONCLUSIONS: Endometrial compaction is not associated with ongoing pregnancy rate in single euploid FETs in our cohort.

P-485 4:30 PM Monday, October 19, 2020

PREGNANCY AND BIRTH OUTCOMES ASSOCIATED WITH MATERNAL AGE AND EUPLOID EMBRYO GRADE AFTER NATURAL CYCLE FROZEN TRANSFER. Wendy Y. Zhang, BS,[1] Jasmyn K. Johal, MD, MS,[2] Brindha Bavan, MD,[3] Amin A. Milki, MD,[4] [1]Stanford University School of Medicine, Stanford, CA; [2]Stanford University, Dept of Obstetrics & Gynecology, Stanford, CA; [3]Stanford Fertility and Reproductive Medicine Center, Sunnyvale, CA; [4]Stanford Medicine Fertility and Reproductive Health Services, Sunnyvale, CA.

OBJECTIVE: As aging decreases female fertility due to diminished oocyte quality and increased aneuploidy risk, it similarly impacts IVF success via diminished embryo quality. However, data are lacking with regards to the effect of maternal age when euploid embryos of similar grade are used. Thus, we examine whether age – when aneuploidy and embryo quality are accounted for - still influences IVF outcomes.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: We studied all natural cycle frozen embryo transfers (NC-FET) with one euploid blastocyst from 2016 to 2019 (n=516 cycles). Blastocysts were graded from AA to DD based on their inner cell mass and trophectoderm morphology; CC or better embryos were biopsied. To minimize confounding by poor quality embryos, our study included only embryos of grade BB or better. We also performed a subanalysis stratifying by embryo grade. The outcomes studied were viable pregnancy (presence of fetal cardiac activity), miscarriage, live birth, preterm delivery, and birth weight. We compared three age groups: <35, 35-39, and ≥40. ANOVA and chi-squared tests were used for continuous and categorical variables, respectively.

RESULTS: Patients had similar baseline characteristics including BMI, race, smoking rate, and endometrial lining thickness. As expected, women age ≥40 had significantly lower antral follicle counts and AMH levels. Among women who transferred euploid embryos of similar grade, advanced maternal age (≥35) was still associated with significantly decreased rates of viable pregnancy (p=0.0002) and live birth (p=0.0008). However, once viable pregnancy was confirmed, there were no significant differences in miscarriage rate, preterm delivery rate, and mean birth weight. Upon stratification by embryo grade, this significant pattern persisted for embryo grade AA, with a similar trend for grades AB, BA, and BB.

CONCLUSIONS: Despite the use of euploid embryos of similar quality, advanced maternal age is still associated with significantly decreased rates of viable pregnancy and live birth. This remains true even if the best quality (AA) embryos are used. These findings may help further guide age-based counseling for women seeking IVF treatment.

Maternal Age Groups (y)	<35	35-39	≥40	P-value
Outcomes for all embryo grades				
	N=155	*N=248*	*N=113*	
Viable pregnancy n(%)	121 (78.1)	150 (60.5)	65 (57.5)	*0.0002*
Live birth n(%)	115 (74.2)	142 (57.3)	56 (49.6)	*0.0008*
Miscarriage n(%)	6 (3.9)	8 (3.2)	9 (7.9)	*0.1*
Preterm delivery n(%)	8 (7.0)	8 (5.6)	4 (7.1)	*0.8*
Birth weight (grams)	3258 ± 505	3321 ± 556	3337 ± 684	*0.3*
Outcomes for embryo grade AA				
	N=64	*N=92*	*N=30*	
Viable pregnancy	52 (81.3)	58 (63.0)	17 (56.7)	*0.01*
Live birth	50 (78.1)	55 (59.8)	13 (43.3)	*0.003*
Miscarriage	2 (3.8)	3 (3.3)	4 (13.3)	*0.06*
Birth weight	3244 ± 428	3251 ± 669	3336± 309	*0.3*

P-486 4:30 PM Monday, October 19, 2020

LIVE BIRTH RATE AND ORAL CONTRACEPTIVES PRETREATMENT IN IVF CYCLES: WHO TO CONSIDER FOR A FRESH EMBRYO TRANSFER?. Yao Lu, M.D.,[1] Steven R. Lindheim, M.D.,[2] Yun Sun, M.D.[1] [1]Center for Reproductive Medicine, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [2]Wright State University, Dayton, OH.

OBJECTIVE: Concern regarding the use of pretreatment of oral contraceptives (OC) in IVF cycles has been debated. We investigated for factors that may have been associated with live birth rate (LBR) in fresh embryo transfer cycles after OC pretreatment.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: From January 2014 to June 2017, all normo-ovulatory patients (defined as regular menstrual cycles between 21–35 days), aged 20–35 years and a basal FSH < 10IU/L who were undergoing their first autologous IVF or intra-cytoplasmic sperm injection (ICSI) cycle followed by fresh cleavage embryo transfer were reviewed. All patients who used gonadotropin releasing hormone (GnRH) antagonist (ant) or long GnRH-agonist (a) protocol for ovarian stimulation after OC pretreatment were included. Excluded were cycles those diagnosed with PCOS, uterine abnormalities, untreated hydrosalpinges and those undergoing preimplantation genetic testing (PGT).

RESULTS: 814 patients were included in the analysis. Multivariate logistic regression analysis demonstrated that GnRH-ant protocol was significantly associated with lowered LBR (adjusted OR 0.70, 95% CI 0.52-0.94), while endometrial thickness on day of hCG trigger was associated with increased LBR (adjusted OR 1.16, 95% CI 1.06-1.28). Despite patients' age, duration of infertility, BMI, primary/secondary infertility and basal FSH were all comparable between GnRH-a and GnRH-ant groups, the GnRH-ant group resulted in significantly lower LBR compared to the GnRH-a group (48.5% vs. 37.4%, p=0.002). Using ROC analysis and a cut-off endometrial thickness < and ≥9.5mm, those <9.5mm in the GnRH-ant group result in a significantly lower LBR than GnRH-a group (28.5% vs. 43.4%, p=0.004),

while no differences were noted with an endometrial thickness ≥9.5mm (49.6% vs.51.1%, p=0.78).

CONCLUSIONS: Live birth was significantly impacted in OC pre-treated GnRH-ant cycles with an endometrial thickness <9.5mm on day of hCG trigger. Cryopreservation of all embryos in these cycles when using GnRH-ant protocols should be considered.

FACTORS ASSOCIATED WITH IMPLANTATION OF EMBRYOS NOT ABLE TO BE BIOPSIED UNTIL DAY 7.

Devora Aharon, MD,[1] Carlos Hernandez-Nieto, MD,[2] Joseph A. Lee, BA,[2] Eric Flisser, MD,[2] Alan B. Copperman, MD,[1] Lucky Sekhon, MD,[2] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Recent studies have demonstrated that extended culture of blastocysts to day 7 leads to satisfactory pregnancy outcomes in patients with slow-growing embryos.[1,2] However, even when confirmed to be euploid by preimplantation genetic testing for aneuploidy (PGT-A), day 7 embryos have lower rates of implantation, clinical pregnancy, and live birth compared to day 5 or day 6 embryos.[1] Prior studies assessing factors associated with implantation of euploid embryos only assessed embryos biopsied on day 5 or 6.[3,4] The objective of this study was to identify patient, cycle, and embryo characteristics associated with successful implantation of euploid day 7 embryos by comparing day 7 embryos resulting in clinical pregnancy to those that did not.

DESIGN: Case control study.

MATERIALS AND METHODS: The study included single, euploid, vitrified-warmed day 7 embryo transfers (FET) from September 2016 through March 2020. We compared day 7 embryo transfer cycles resulting in clinical pregnancy (cases), defined as the presence of a gestational sac on ultrasound, to those where clinical pregnancy was not achieved (controls). PGT-A was performed using Next Generation Sequencing. Demographic and cycle characteristics were evaluated among the cohorts and included: age, oocyte age, BMI, AMH, endometrial thickness, use of PGT for single gene disorder (PGT-M), fresh vs. frozen oocytes, availability of supernumerary euploid day 5 and 6 embryos for transfer, and morphology grading for embryo expansion, inner cell mass, and trophectoderm (TE). Comparative statistics and adjusted logistic regression were used for analysis.

RESULTS: A total of 228 single euploid day 7 FETs were identified, of which 72 resulted in clinical pregnancy and 156 did not result in clinical pregnancy. The groups were similar in terms of age, oocyte age, BMI, AMH, endometrial thickness, use of PGT-M, presence of supernumerary day 5/6 embryos, and fresh vs. frozen oocytes. Embryos resulting in clinical pregnancy had a significantly higher proportion of ICM grade A (54.2% vs. 32.1%, p=0.001) and a significantly lower proportion of ICM grade C (12.5% vs. 26.9%, p=0.015). Expansion and TE grade were similar between the groups. On multivariate logistic regression, when controlling for age, oocyte age, AMH, BMI, endometrial thickness, PGT-M, fresh vs. frozen eggs, supernumerary D5/6 embryos, expansion, and TE grade, ICM grade A vs. C was significantly associated with increased odds of clinical pregnancy (adjusted OR 3.56, 95% CI 1.41-9.0, p=0.0071).

CONCLUSIONS: The subset of day 7 embryos that successfully implant have a more robust inner cell mass, as defined by Gardner's score of A vs. C, than those that do not. Our study indicates that the same morphologic criteria shown to predict reproductive competence of euploid day 5 and 6 embryos is associated with the success of day 7 embryos, despite the lower overall implantation rate of these slower-growing embryos. As emerging data demonstrate the feasibility of day 7 embryo transfer, this study can inform recommendations regarding selecting an embryo for transfer to assist patients in achieving their family building goals.

DETERMINING THE OPTIMAL FOLLICLE SIZE AT TRIGGER IN PATIENTS UNDERGOING OVARIAN STIMULATION WITH A CLOMIPHENE CITRATE PLUS GONADOTROPIN ANTAGONIST PROTOCOL FOR IN VITRO FERTILIZATION.

Nirali J. Shah, MD,[1] Phillip A. Romanski, MD,[2] Pietro Bortoletto, MD,[2] Zev Rosenwaks, M.D.,[2] Isaac Kligman, M.D.[2] [1]Weill Cornell Medicine, New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To investigate the optimal follicle size at the time of ovulatory trigger in clomiphene citrate plus gonadotropin/antagonist IVF protocols.

DESIGN: Retrospective cohort study at a single academic center. Patients who underwent their first IVF cycle with a clomiphene citrate plus gonadotropin/antagonist protocol at our center between 01/01/2013 and 3/31/2019 were included. Patients were stratified into two groups by the median size of the three largest follicles on the day of trigger: <20 mm (Group A) and ≥20 mm (Group B). Patients were excluded if they did not have at least 3 follicles >12 mm at the time of trigger.

MATERIALS AND METHODS: On cycle day 2, patients received 100 mg clomiphene citrate for 5 days, with gonadotropins starting on cycle day 5 and continuing until the night before trigger. Patients were triggered with either hCG alone or in combination with GnRH agonist. The timing of trigger administration was determined by the treating physician. The primary outcome was the number of mature oocytes retrieved; secondary outcomes were the number of oocytes retrieved and the number of zygotes. Poisson regression was used to estimate RR (95% CI) adjusted *a priori* for patient age for oocyte and zygote development outcomes. A subgroup analysis was performed for women in the upper quartile for age (≥41.7 years).

RESULTS: A total of 635 patients were included (399 patients in the <20 mm group and 236 patients in the ≥20 mm group). The median (IQR) of the three largest follicles was 18.5 mm (18-19) in Group A and 21 mm (20.2-22) in Group B. Among the entire cohort, the mean number of oocytes retrieved was significantly higher in Group B (9.9 ± 6.5; RR 1.08; 1.03-1.14) compared to Group A (9.2 ± 6.3). Otherwise, when Group B was compared to Group A, the number of mature oocytes (7.3 ± 4.8 vs. 7.0 ± 4.9; OR 1.04; 0.98-1.11) and the number of zygotes (5.2 ± 4.3 vs. 4.9 ± 4.0; OR 1.07; 0.99-1.15) were similar. In the subgroup analysis of patients in the upper quartile for age (≥41.7 years), Group B was observed to have statistically significantly more oocytes retrieved (8.1 ± 5.9 vs. 6.7 ± 4.5; OR 1.23; 1.10-1.38), more mature oocytes retrieved (6.0 ± 4.0 vs. 5.2 ± 3.4; OR 1.16; 1.02-1.33), and more zygotes (4.7 ± 3.5 vs. 3.6 ± 2.8; OR 1.32; 1.13-1.55).

CONCLUSIONS: In clomiphene citrate plus gonadotropin/antagonist IVF protocols, patients who were triggered at larger follicle sizes yielded more oocytes retrieved, but a similar number of mature oocytes and zygotes when compared to patients triggered at smaller follicle sizes. However, in older patients, waiting to administer the ovulatory trigger until the median of the three largest follicles was ≥20 mm yielded more mature oocytes and zygotes per cycle. Based on these findings, we conclude that the ideal time to administer the ovulatory trigger in clomiphene citrate-based IVF cycles is when the median of the three largest follicles is ≥20 mm, particularly in patients of advanced maternal age.

A SINGLE-CENTER RCT DATA ANALYSIS OF UROFOLLITROPIN PRECONDITIONING TO IMPROVE THE EFFICACY OF ICSI THREAPY IN MEN WITH MODERATE TO SEVERE OLIGOSPERMIA AND ASTHENOSPERMIA. Tingting Li, Doctor Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To evaluate the possibility of urofollitropin preconditing to improve the sperm quality of infertility patients in ICSI treatment cycle in male patients who were diagnosed with moderate to severe oligospermia and asthenospermia, as well as the effect of treatment on fertilization rate and embryo quality.

DESIGN: Prospective clinical controlled trial.

MATERIALS AND METHODS: By analyzing the data of the experimental group, which 24 patients were intramuscularly injected uFSH(urofollitropin) 150U every three days before the ICSI period for 12 consecutive weeks, whilst other 8 patients didn't injected as the blank control group and the ratio was 3 to 1, we compared the 2PN fertilization rate, the available embryo rate, the high-quality embryo rate and the blastocyst formation rate between the experimental group and the blank control group.

RESULTS: There was no differences in the basic conditions inside the experimental group and the blank control group, such as the age of the male and female. The 2PN fertilization rate between the two groups was83.47% vs 81.69%, and the available embryo rate and blastocyst formation rate were 66.83 % vs 74.40 %, 54.95 % vs 67.74%, respectively .

CONCLUSIONS: ontinuous use of uFSH 150U Q3D for 12 weeks before ICSI entry in patients with moderate to severe oligospermia and asthenospermia did not improve or increase the subsequent ICSI oosphere fertilization rate and embryo quality.

OBJECTIVE: Follicle recruitment occurs throughout the cycle and is not limited to the follicular phase. We aim to determine the rate of blastocyst formation in luteal phase stimulation cycles in older women with severe diminished ovarian reserve (DOR) using mild stimulation.

DESIGN: Retrospective study at a large fertility center with a university affiliation.

MATERIALS AND METHODS: Patients over 38 years old with severe diminished ovarian reserve undergoing ovarian stimulation cycles at a single fertility center during the calendar years 2018-2019 were reviewed. Luteal phase stimulation was defined as ovarian stimulation in patients who had already ovulated and had serum progesterone levels > 3.0 ng/mL. Mini stimulation per center protocol was administered without injectable medications and mainly consisted of clomid (50-100 mg) and letrozole (2.5-5 mg) administered orally. Oocyte maturation trigger was performed with Ovidrel (hCG). Mature oocyte (MII) yields, 2PN rate, and blastocyst formation rate per cycle were calculated and stratified by Society for Assisted Reproductive Technology (SART) age groups. Data are presented as mean +- sem.

RESULTS: Two hundred fifty-eight cycles were included in data collection with a total of 483 oocytes retrieved in the luteal phase. In all participants, age was 43.7 ± 0.12 years, body mass index was 23.7 ± 0.5 kg/m2, serum P4 levels were 15.9 ± 0.6 ng/mL, and the menstrual cycle day when oocyte retrieval was performed was 25.1 ± 0.6. The total number of oocytes collected was 1.9 ± 0.1, MII oocytes was 1.4 ± 0.2, 2 PN was 1.0 ± 0.1, and blastocysts cryopreserved was 0.8 ± 0.1. The fertilization rate was 58.59% with a blastocyst formation rate of 42.40%. The table shows detailed results according to SART age group.

CONCLUSIONS: Mild ovarian stimulation is effective in producing blastocysts in women with severe DOR. These data are important for this patient population where time is of essence and can support random start times for infertility treatment. Mild stimulation is also helpful for women who desire to avoid injectable hormonal medications.

DOWN REGULATION WITH LUTEAL GONADATROPIN-RELEASING HORMONE AGONIST THERAPY IN EUPLOID EMBRYO TRANSFERS DOES NOT IMPACT PREGNANCY RATES.

Keri Bergin, MD,[1] Isabelle Kate Levin, BA,[2] Dmitry Gounko, MA,[3] Joseph A. Lee, BA,[3] Beth McAvey, MD,[4] Alan B. Copperman, MD,[4] Tanmoy Mukherjee, MD,[4] [1]Albany Medical Center, Albany, NY; [2]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, NY; [3]Reproductive Medicine Associates of New York, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: Gonadotropin-releasing hormone (GnRH) agonists have been used during assisted reproductive technology (ART) treatment both for pituitary suppression and stimulation. Some studies have shown benefits to prolonged GnRH agonist therapy prior to IVF and/or embryo transfer.[1,2] It has been suggested that GnRH suppression of toxic peritoneal cytokines and potential direct effect on endometrial tissue could improve pregnancy rates with ART treatment, particularly in patients with endometriosis.[1] Currently, clinical opinion is divided about whether GnRH agonist therapy improves pregnancy rates when used for luteal down-regulation in a frozen euploid embryo transfer (FET) cycle.[2,3] The objective of this study is to evaluate the clinical utility of GnRH agonist down-regulation in single, euploid FET cycles.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A retrospective analysis was performed at a single fertility center, using data from patients who underwent a single, euploid FET cycle from 2012 to 2019. Patients were segregated into two cohorts: Group A: single, euploid FET with down-regulation using GnRH agonist; Group B: single, euploid FET without down-regulation using GnRH agonist. GnRH agonist was started in the mid-luteal phase and continued through the addition of estrogen and progesterone for endometrial lining preparation. The GnRH agonist was stopped prior to a single, euploid FET. Primary outcome included pregnancy rates among study cohorts.

RESULTS: Group A demonstrated a pregnancy rate of 72.92% in 96 single, euploid FET cycles with down-regulation using a GnRH agonist. Group B demonstrated a pregnancy rate of 73.27% in the 5,668 single, euploid FET cycles without a GnRH agonist. There was no difference in pregnancy rates between groups, X2 (2, N = 5764) = 0.0061, p = 0.94. A subgroup of patients (n=5) with endometriosis in the GnRH agonist down-regulation group achieved an 80% (4/5) pregnancy rate.

CONCLUSIONS: Single, euploid FET cycle pregnancy rates were not affected by the use of down-regulation with a GnRH agonist. The increased pregnancy rates found with prolonged GnRH agonist use in other studies was not seen with the short-term use for down-regulated FET cycles in this study. Future research should focus on molecular markers and gene transcription signatures to attempt to define whether there is an ideal population of patients who would benefit from GnRH agonist down-regulation prior to frozen embryo transfer.[2,3] Luteal GnRH agonist for ovarian suppression in FET cycles does not appear to be detrimental to pregnancy rates, and may play a role in personalized reproductive treatment.

DO DIFFERENT LH LEVELS ON GNRH ANALOG TRIGGER DAY AFFECT THE NUMBER OF CRYOPRESERVABLE BLASTOCYSTS?.

Yucel Sahin, MD, Semra Kahraman, MD Prof. Istanbul Memorial Hospital, Istanbul, Turkey.

OBJECTIVE: The objective of our study was to discover whether different LH levels on gonadotrophine relasing hormone agonist (GnRHa) trigger day affect the number of mature oocytes and blastocysts suitable for freezing.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Data were collected from Istanbul Memorial Hospital ART and Genetics Center. 2437 GnRHa trigger cycles were evaluated between 2011 and 2020. Cycles were analyzed in three groups according to serum LH levels on GnRHa day: Group A (n=1983) LH level $\geq$ 1 mIU/mL; Group B (n=314) LH level 0.5-1 mIU/mL; Group C (n=140) LH level $\leq$ 0.5 mIU/mL. The numbers and percentages of obtained oocytes (COC), mature (MII) oocytes and fertilized oocytes (with 2PN), the blastocyst/2PN ratio and the number of cryopreservable blastocysts number in the three LH groups were compared.

RESULTS: Baseline characteristic differences between the three groups, including mean age (31,37±5,06 vs. 31,68±5,10 vs. 30,56±4,75 group A, B, C respectively, p:0.92), mean AMH level (5,08±3,52 vs. 4,78±2,72 vs. 5,175±3,08, p:0.339) and mean BMI (25,17±4,89 vs. 24,69±4,91 vs. 24,99±4,1, p:0.537) were not significant. However, some cycle characteristics were significantly different between the groups. In group A, day 2 LH level (7,52±3,47 vs. 6,28±2,64 vs. 6,23±2,97, p:0.0001) and (2,86±2,1 vs. 1,69±1,25 vs. 1,15±0,81 p:0.001) were significantly higher than in group B and in group C. There were no significant differences between group B and group C.

Although, the number of oocytes retrieved was significantly higher in group C than in group A and B (19.09±8.95 vs. 20.5±8.26 vs. 23.54±11.73 group A to C respectively, p:0.003) , the percentage of mature oocyte was significantly lower in group C than in groups A and B (85.3%± 13.9 vs. 85.3%±12.3 vs. 81.5%±13.8, A to C respectively, p:0.002). Despite these results, there were no significant differences between the three groups according to percentage of fertilized oocyte (81.5%±16.8 vs. 81.65±13.4 vs. 79.5%±14.7, p:0.370), the percentage of blastocyst/2PN (54.4%±22.4 vs. 54.5%±20.1 vs. 50.5%±19.9 p:0.121) and mean number of cryopreservable blastocysts (6.98±4.26 vs. 7.51±4.05 vs. 7.18±4.07 p:0.128).

CONCLUSIONS: GnRHa ovulation trigger in a GnRH antagonist protocol significantly decreases the ovarian hyperstimulation syndrome (OHSS) risk. There is a lack of clear information in the literature regarding the effectiveness of GnRHa trigger in cases with low (<1mIU/mL) or very low (<0.5mIU/mL) LH levels. Low and very low LH levels on the GnRHa trigger day have no negative effect on the number of cryopreservable blastocysts. In cases with the risk of OHSS, GnRHa trigger can be used safely regardless of LH level on trigger day.

P-493 4:30 PM Monday, October 19, 2020

FROZEN-THAWED EMBRYO TRANSFERS ARE ASSOCIATED WITH A HIGHER RISK OF LARGE FOR GESTATIONAL AGE NEWBORNS.

Magdalena Decia, MD,[1] Dana Kimelman, MD MS-RSM,[1] Lucia Goyeneche, BC,[2] Jimena Alciaturi, MSc.,[1] Gabriel A. De la Fuente, MD,[1] [1]Centro de Esterilidad Montevideo, Montevideo, Uruguay; [2]Embryologist, Montevideo, Uruguay.

OBJECTIVE: Improvements in cryopreservation techniques associated with the possible impairment in endometrial receptivity due to the supraphysiologic hormonal levels observed during conventional controlled ovarian stimulation (COS) have increased the implementation of frozen-thawed embryo transfers (FET). Perinatal outcomes of fresh embryo transfers (ET) and FET have shown to be similar. However, several studies associate FET with a higher risk of large-for-gestational-age (LGA), thereby, increasing risk of adverse obstetric and neonatal outcomes. This study aims to assess whether FET is associated with a higher risk of large for gestational age newborns, compared with fresh ET in our population.

DESIGN: Retrospective, single center study performed from 2017 to 2019.

MATERIALS AND METHODS: A total of 561 patients who became pregnant after fresh and frozen embryo transfers. A first study group included all IVF cycles where fresh embryo transfer resulted in a singleton live birth (fresh group n=254). A second cohort included FET that led to a singleton live birth (FET group n= 307). All embryos were transferred at a blastocyst stage and vitrification was the only cryopreservation method. In all FET the endometrium was artificially prepared through the administration of exogenous estrogen and progesterone. Data was collected from telephone surveys. We compared the number of LGA newborns and weight differences in both groups. z-test was applied for statistical analysis. A p value <0.05 was considered significant.

RESULTS: The median gestational age in both groups was 38 weeks. The mean adjusted birth weight after FET group was higher by 109.26 g, than the fresh group (3269.32 g vs 3160.13 g respectively, p=0.285). The incidence of newborns that weighted $\geq$ p50 was significantly higher for FET group (142 vs 75 for FET and fresh respectively, p= 0.000048). Moreover, the incidence of LGA livebirths was significantly higher in the FET group (p=0.0226) (23 from the FET group vs 8 from fresh ET). No difference in female to male ratio for LGA newborns or preterm birth rate was identified between groups.

CONCLUSIONS: FET is associated with increased risk of LGA in our population. FET has become an important technique in IVF; however, whether it should be the first choice for ET requires further analysis. An individual approach should remain when deciding between fresh or frozen embryo transfers. Longer-term potential health effects remain to be evaluated.

P-494 4:30 PM Monday, October 19, 2020

OOCYTE MATURITY AS A PREDICTOR OF IVF OUTCOME. Michelle L. Krohn, D.O.,[1] Amy E. Sparks, PhD,[2] Bradley J. Van Voorhis, MD,[3] [1]Monument Health, Spearfish, SD; [2]University of Iowa Center for Advanced Reproductive Care, Iowa City, IA; [3]University of Iowa, Iowa City, IA.

OBJECTIVE: Oocyte maturity after retrieval during IVF can vary significantly and is important in fertilization and development of embryos. Our purpose was to determine if low oocyte maturity from a retrieval cycle is a predictor of poor outcomes from IVF. Secondary objectives were; to identify factors predictive of low oocyte maturity, to assess oocyte maturity across cycles, and to determine if oocyte maturity is affected by the length of ovarian follicular stimulation or the total dose of gonadotropins used.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A total of 1451 autologous IVF cycles from 1/2016- 7/2019 at our center were evaluated. Oocyte maturity was initially assessed upon retrieval (M1 + M2 oocytes/total oocytes). The final oocyte maturity assessment was made 5 hours post retrieval, prior to ICSI (oocytes inseminated at ICSI/total oocytes). As the maturity score at the time of retrieval was correlated with score at ICSI (Pearson's r=.848, $p \leq .001$), we used maturity at retrieval as our measure of maturity, allowing inclusion of all cycles. Maturity designation as suboptimal vs. optimal was derived from previously established classifications (1). Statistical tests utilized included Pearson's correlation, independent samples t-tests, and generalized estimating equations.

RESULTS: There was no correlation between female age at retrieval and oocyte maturity (Pearson's r= .131, $p \leq .001$). A diagnosis of polycystic ovarian syndrome (PCOS) was associated with a slightly reduced maturity (81.9% $\pm$ 14.6 vs. 85.5% $\pm$ 14.0, p=.002). There was no association with diminished ovarian reserve (defined as AFC< 10; DOR) and oocyte maturity (p=.172). Increasing oocyte maturity was associated with increased clinical pregnancy rates, age adjusted odds ratio (AOR) 2.5 (1.1-5.8). Oocyte maturity was not found to be associated with miscarriage rates. When cycle 1 was compared to cycle 2 in the same patient, there was a fair correlation between oocyte maturity scores (Pearson's r=.339, $p \leq .001$) with 44% of those classified as suboptimal maturity also classified as suboptimal maturity within their second cycle. In contrast, only 22% of cycles classified as optimal maturity in cycle 1 had suboptimal maturity if a second cycle was performed. There was no evidence of correlation between days of stimulation prior to the trigger shot or total gonadotropins used and maturity scores (Pearson's r=0.43, p=0.149).

CONCLUSIONS: There is no correlation between oocyte maturity and female age or diagnosis of DOR. The diagnosis of PCOS is associated with a slight but statistically significant reduced oocyte maturity at retrieval; however this is unlikely to be clinically significant given that these patients most often have an increased number of total oocytes retrieved. Low oocyte maturity was associated with decreased clinical pregnancy rates but did not impact miscarriage rates. Cycles complicated by low oocyte maturity can be repetitive, and maturity did not appear to correlate with the duration of ovarian stimulation or total gonadotropin dosage used.

P-495 4:30 PM Monday, October 19, 2020

EVALUATION OF DUAL TRIGGER EFFICACY FOR FINAL OOCYTE MATURATION IN HIGH COMPLEXITY ASSISTED REPRODUCTION TECHNIQUES: A SYSTEMATIC REVIEW AND META-ANALISYS. Luciana Carvalho Delamuta, MD, Alexandre LS. Lobel, MD, PhD, Pedro AA. Monteleone, MD, PhD, Jose Maria Soares, Jr., MD, PhD, Edmund Chada Baracat, MD, PhD University of São Paulo, São Paulo, Brazil.

OBJECTIVE: To compare the number of mature oocytes, number of total oocytes and clinical pregnancy rate in assisted reproductive techniques that used dual trigger (gonadotropin releasing hormone agonist + human chorionic gonadotropin) or human chorionic gonadotropin (hCG) alone for oocyte final maturation.

DESIGN: Systematic review an meta-analysis.

MATERIALS AND METHODS: A systematic review was conducted to compare the number of mature oocytes, number of total oocytes and clinical pregnancy rate in assisted reproductive techniques that used dual trigger or human chorionic gonadotropin alone. For this evaluation, randomized clinical trials (RCT) and retrospective cohort studies were included. We comprehensively searched PubMed, EMBASE and Cochrane Library with the last search made in December 2019. Bibliographies of relevant studies identified by the search strategy and relevant reviews/meta-analyses were also searched for identification of additional studies. The following MeSH terms (gonadotropin-releasing hormone, human chorionic gonadotropin, oocyte maturation, in vitro fertilization) and their combinations were searched. Inclusion and exclusion of the studies were completed according strict criteria. The methodological quality of RCT and retrospective cohorts was assessed using the Review Manager software and the modified Newcastle-Ottawa scale respectively. Data from the included studies were extracted to define whether dual trigger improves the number of total and mature oocytes retrieved and the clinical pregnancy rate. The meta-analysis was performed using *software* R 3.6.1 (R Core Team, 2019) and *meta* package (Schwazer, 2013).

RESULTS: A total of 18 studies were included (8 RCT and 10 retrospective cohorts) with a total of 2798 patients in the dual trigger group and 2649 patients in the hCG trigger group. In six of the studies the patients had a prior failure in an assisted reproductive treatment (ART) and in the other 12 studies it was the first treatment. For the pregnancy rate the relative risk (RR) was 1,24 [CI 95% 1,14 – 1,36], for the number of mature oocytes the mean difference (MD) was 1,41 [CI 95% 0,63 – 2,19], and for the number of total oocytes the MD was 1,07 [CI 95% 0,40 – 1,73]. A subgroup analysis separating RCT from retrospective cohorts showed no difference between the types of study for all the outcomes analyzed. Another subgroup analysis separating patients who had the first ART from patients who had prior failure showed pregnancy rate RR 1,31 [CI 95% 1,06 - 1,62] for "previous failure" and 1,23 [CI 95% 1,12 – 1,34] for "first treatment". For the number of mature oocytes MD was 3,15 [CI 95% 2,39 – 3,91] for "previous failure and 0,81 [CI 95% 0,20 – 1,42] for "first treatment". For the number of total oocytes MD was, respectively, 1,60 [CI 95% 0,60 – 2,60] and 0,93 [CI 95% 0,20-1,66].

CONCLUSIONS: We can conclude that dual trigger for final oocyte maturation results in higher pregnancy rate and higher number of total and mature oocytes when compared to hCG alone. Patients who had a previous ART failure seem to be the subgroup that benefits the most from dual trigger use.

THE IMPACT OF DOUBLE-STRANDED SPERM DNA BREAKS ON ICSI OUTCOME. Derek Keating, B.A., Alessandra Parrella, M.Sc., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: We sought to evaluate specific sperm DNA damage, double-stranded DNA breaks (dsDNA), and its effect on embryo development and implantation.

DESIGN: Over a year-long period, a prospective pilot study was carried out on sperm samples to evaluate the proportion of dsDNA on samples screened by terminal deoxynucleotidyl dUTP transferase nick-end labeling (TUNEL) to assess total DNA fragmentation. Once a correlation was established, we extrapolated dsDNA values retrospectively onto patients who had their ejaculates screened by TUNEL to evaluate clinical outcome.

MATERIALS AND METHODS: Samples from consenting couples were screened for dsDNA rates by neutral Comet assay using an in-house protocol; 200 spermatozoa were assessed per patient. These samples were also assessed by TUNEL using a commercially available kit, analyzing at least 500 spermatozoa per patient. ICSI was performed in the standard fashion.

RESULTS: The pilot study reported an average total DNA fragmentation of 11.3±6% by TUNEL and an average dsDNA of 2.2±3% by neutral Comet. The results showed a linear relationship between the overall SCF and dsDNA rates (R^2=0.96). This equation was applied to extrapolate the dsDNA levels from 573 normozoospermic men (volume of 2.6±1 mL, concentration of 42.3±33x10^6/mL, 43.1±10% motility, and 4.2±1% normal morphology) with an average SCF of 14.2±8%. Therefore, on the basis of this preliminary test, we established a dsDNA threshold of 3%.

A total of 417 couples (maternal age, 37.0±4 yrs; paternal age, 38.6±5 yrs) underwent 777 ICSI cycles and presented with dsDNA levels of 1.8±0.6%. These cycles had a 73.0% fertilization rate, a 12.7% (123/966) implantation rate, and a 23.2% (102/440) clinical pregnancy rate (CPR), of which 15 were lost (14.7%), leaving a 19.7% (87/440) ongoing/delivery rate.

There were 155 couples with dsDNA levels of 4.2±1%. These couples underwent 268 ICSI cycles with a comparable maternal age of 37.3±5 years, but with older male partners at 41.3±8 years of age (P<0.001). These cycles had a comparable fertilization rate of 71.0%, implantation rate of 11.4% (53/464), and clinical pregnancy rate of 24.3% (44/181). However, these couples were much more likely to lose their pregnancy at 29.5% (13/44; P = 0.03), leaving an ongoing/delivery rate of 17.1% (31/181).

CONCLUSIONS: These findings provide further evidence that dsDNA has an important role in the success of a pregnancy generated by ICSI. dsDNA damage has been linked to aneuploidy and consequent pregnancy loss. The use of an assay in a laboratory setting to screen exclusively for dsDNA would help to identify paternally linked aneuploidy that traditional screening would only report as total SCF.

PREDICTORS OF EMBRYO ANEUPLOIDY AND MOSAICISM: INSEMINATION METHOD, SPERM AND PATIENT CHARACTERISTICS. Gabriela M. Grant, MSc,[1] Jessica R. Walter, MD,[1] Helena I. Russell, MSc,[2] Dara S. Berger, PhD,[1] [1]University of Pennsylvania, Division of Reproductive Endocrinology and Infertility, Philadelphia, PA; [2]Eastern Virginia Medical School, Norfolk, VA.

OBJECTIVE: Intracytoplasmic sperm injection (ICSI) is often the insemination method used with pre-implantation genetic testing (PGT). We studied the effects of insemination method on aneuploidy and mosaicism rates in a clinical setting.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Embryos created during an IVF cycle and biopsied using next-generation sequencing between 1/1/2016 to 12/21/2019 were included in this study. Embryos were categorized by insemination method, ICSI versus conventional insemination. Age of the patient, infertility diagnosis, stimulation protocol, and biopsy results were examined. Semen analysis performed using Krueger strict criteria to determine morphology (normal morphology defined as $\geq$ 4). Univariate statistical analyses were performed using the student t-test and chi-square test. Multinomial logistic regression with cluster standard error was performed to identify determinants of a normal, abnormal or mosaic biopsy outcome. Euploidy was the base outcome and all results are explained in terms of aneuploidy and mosaicism.

RESULTS: A total of 3522 embryos were biopsied from 818 IVF cycles. 2667 embryos (75.7%) were fertilized by ICSI. Oocytes inseminated by ICSI were from younger patients (36.3 years compared to 38.0 years, p<0.001), with a significantly higher percentage originating from abnormal morphology (32.0 % compared to 13.7%, p<0.001). Couples with ICSI embryos were more likely to have a reported component of male factor infertility (23.7 versus 2.1%, p <0.001). Female diagnoses of ovulatory dysfunction, structural (uterine/tubal disease), and advanced maternal age were more common in the conventionally inseminated group. Among embryos biopsied, 1758 (53.3%) were aneuploid and 530 (16.1%) demonstrated mosaicism. There were higher rates of aneuploidy among ICSI inseminated embryos (55.2% versus 47.6%; p<0.001) and higher rates of mosaicism among conventionally inseminated embryos (20.5% versus 14.8%, p<0.001). ICSI insemination was found to be an independent risk factor for aneuploidy (RR 1.38 95% CI 1.07-1.77, p= 0.01), when adjusting for oocyte age and female infertility diagnosis. Female infertility diagnosis, specifically ovarian pathology (diminished ovarian reserve, ovulatory dysfunction, and endometriosis), not presence or severity of male infertility, demonstrated an increase in the relative risk of mosaicism. Sperm morphology did not influence the relative risk of a specific biopsy results.

CONCLUSIONS: The influence of laboratory techniques and patient characteristics on aneuploidy and mosaicism rates, are not well understood. While semen parameters and male factor infertility were not shown to affect biopsy results irrespective of insemination method, we demonstrate in this large study that aside from oocyte age, ICSI may adversely affect euploid rate when controlling for relevant confounders, but neither meaningfully seem to influence mosaicism. Future studies are needed to examine the potential relationship between infertility diagnosis, specifically of ovarian origin, and mosaicism rates.

P-498 4:30 PM Monday, October 19, 2020

MICROFLUIDIC SPERM SELECTION IS AN EFFECTIVE METHOD FOR IMPROVING EMBRYO DEVELOPMENTAL COMPETENCE IN IVF WITH OLDER PATIENTS. Rie Matsunaga, M.A., Kana Isobe, B.A., Megumi Miura, M.A, Yuki Kobayashi, B.A., Minako Kamihata, B.A., Hiroshi Makino, Ph.D., Kurumi Iwaki, Ph.D., Tomoko Maeda, Ph.D, Toshitaka Horiuchi, Ph.D., Masanori Ochi, Ph.D. OCHI YUME CLINIC NAGOYA, Nagoya, Japan.

OBJECTIVE: Sperm DNA fragmentation can reduce the rate of embryo development and also increase the rate of miscarriage. Various methods have been developed to select and collect sperm with good motility. However, the DNA fragmentation index (DFI) of the collected sperm differs among these methods. The microfluidic sperm selection chamber (ZyMōt™; DxNow) is a selection kit designed to collect low DFI sperm. Although a few reports have suggested a relationship between embryo quality and euploidy rate (assessed by preimplantation testing for aneuploidy after intracytoplasmic sperm injection), there has been little investigation of the efficacy of microfluidic sperm selection (MSS) in IVF. We studied whether MSS can improve the success rate of embryo development in IVF.

DESIGN: The study was conducted between June 2019 and December 2019. Patients were divided into two groups according to the sperm processing method used: DGS (114 patients, 326 oocytes), and MSS (113 patients, 356 oocytes). For both groups, IVF was performed using selected sperm.

MATERIALS AND METHODS: We compared the rates of fertilization, blastulation, and available blastocysts (defined as those with Gardner Grade better than 4BC); we also compared the rates of available blastocyst cycle, defined as the rate of cycles that yielded at least one available blastocyst. IVF was performed using sperm selected by MSS; as a control, 4×10^4 sperm/ml was used for IVF in the DGS group.

RESULTS: The fertilization rates using 4×, 6×, and 8×104 sperm/ml in the MSS group were 44.8%, 55.3%, and 62.4%, respectively; by comparison, the rate in the DGS (control) group was 66.6%. Rates of oocyte fertilization using sperm selected by MSS were significantly lower at 4× and 6×104 sperm/ml than for the DGS control. However, the rate of fertilization improved with increasing sperm concentration in the MSS group and was comparable to DGS at the 8×104 sperm/ml concentration. Embryo development was compared for oocytes from women of different age ranges: under 34 years (A), 35–39 years (B), 40–42 years (C), and over 43 years (D). Blastulation rates did not differ between the DGS and MSS groups in A (76.9% vs. 71.7%), B (65.2% vs. 80.5%), C (70.0% vs. 53.6%), and D (35.3% vs. 62.5%). The rates of available blastocysts and the blastocyst cycle rates for MSS were comparable to DGS in A (49.1% vs. 53.8% and 81.3% vs. 83.3%, respectively), B (53.7% vs. 34.8% and 80.0% vs. 61.9%, respectively), and C (39.3% vs. 36.7% and 50.0% vs. 64.3%, respectively). These rates were significantly higher for MSS than DGS in D (33.3% vs. 5.9% and 53.8% vs. 9.1%, respectively).

CONCLUSIONS: The present study indicates that MSS might enable improvement in the rates of embryo development after IVF of oocytes from women with an advanced maternal age. The use of MSS for sperm

selection resulted in the production of a higher frequency of good quality IVF-embryos with these older patients.

NEONATAL AND MATERNAL OUTCOMES IN SINGLETON LIVE BIRTHS (LB) FOLLOWING SINGLE EUPLOID FROZEN EMBRYO TRANSFER (FET): DOES TRANSFER PROTOCOL MATTER?.

Hilary S. Friedlander, MD,[1] Paxton E. Voigt, BA,[1] Jennifer K. Blakemore, MD,[2] James A. Grifo, MD, PhD,[2] [1]NYU Langone School of Medicine, New York, NY; [2]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: Two FET protocols commonly used for endometrial preparation are programmed (PRG) and natural (NAT). Despite an increasing focus on preimplantation genetic testing for aneuploidy (PGT-A)[1] prior to FET, there are scarce data on outcomes by protocol following transfer of a single euploid embryo. We sought to evaluate the neonatal and maternal outcomes by protocol after single euploid FET.

DESIGN: Retrospective cohort study of all patients with a singleton LB from a single euploid FET (by aCGH or Next Gen Sequencing) between 1/2017 - 12/2018 at our center.

MATERIALS AND METHODS: All patients with a singleton LB after single euploid FET in the study time period were reviewed. Patients with monozygotic twins or whose delivery information was not verified were excluded. Patients were grouped by protocol: PRG or NAT. PRG cycles were defined by treatment of oral E2 daily, followed by progesterone (P4); either 50-75mg intramuscular in oil or vaginal suppository. NAT cycles, with and without with letrozole, were defined by monitoring until a dominant follicle reached >18mm and ovulation was confirmed, followed by supplementation with vaginal P4 suppository. Primary outcomes were 1) preterm birth (PTB) defined as delivery on or before 36w6d and 2) birth weight (BW) and low birth weight (LBW) defined as <2500g. A secondary outcome was a composite complication rate defined by inclusion of any of the following: hypertensive (HTN) disorders of pregnancy, HELLP syndrome, intrauterine growth restriction, oligohydramnios, abnormal placentation or umbilical cord anomalies. Statistical analyses included a Kolmogorov-Smirnov, Mann-Whitney U, chi-squared, and logistic regression where appropriate, with $p<0.05$ considered significant.

RESULTS: 647 cycles were included: 491 PRG and 156 NAT. Mean patient age was 37.2 ± 4.4 years (range 21-59). 7% (n=45) were donor egg (DE) recipients but use of protocol was not different (8.2% PRG vs 3.3% NAT, p=0.05). In this cohort, 7 (1.1%) had HTN, 3 (0.5%) had diabetes, and 81 (12.6%) had depression/anxiety. Mean gestational age (GA) at birth was 39 ± 1.9 wks (range 24w1d-42w4d), and 7.9% had PTB. Mean BW was 3299.4 ± 567.3 grams (range 737.1-5017.9). Infants with LBW and macrosomia (≥ 4000g) occurred in 6.9% and 7.9% of deliveries respectively. There was no difference in patient age (37.5 v 37.0, p=0.91), GA at delivery (39w0d v 38w6d, p=0.96), and BW (3350g v 3283.5g, p=0.50), between PRG and NAT cycles. The PTB (8.8% vs 5.1%; p=0.17) and LBW (8.0% vs 3.3%; p=0.62) rates did not differ by protocol, independent of age, past medical history (PMH) and GA (PTB p=0.99, LBW p=0.13). The overall composite complication rate was 6.3%. PRG cycles had more complications compared to NAT (8.1% vs 0.6%; $p<0.01$) even when controlled for by age, PMH and GA ($p<0.01$). Excluding DE, the complication rate was 6.0%, still higher in PRG cycles (7.8% vs 0.7%, $p<0.01$).

CONCLUSIONS: There is no difference in PTB or LBW rates by cycle protocol after single euploid FET. However, PRG cycles had a higher rate of complications. Further investigation, with larger cohorts, is needed to understand the differences with individual complications.

CAN ERA BIOPSY RESULTS BE PREDICTED BY FET CYCLE PARAMETERS?.

Barry E. Perlman, DO,[1] Alexander Vlahos, MD,[2] Weiyi Xia, MS,[3] Sara S. Morelli, MD, PhD,[2] Jacquelyn Loughlin, MD,[4] Peter G. Mcgovern, MD,[5] [1]Rutgers University, Newark, NJ; [2]Rutgers New Jersey Medical School, Newark, NJ; [3]Rutgers School of Public Health, Piscataway, NJ; [4]Rutgers New Jersey Medical School, Newark, New Jersey, NJ; [5]University Reproductive Associates, NJ, Hasbrouck Heights, NJ.

OBJECTIVE: Successful implantation requires synchronous development of the embryo and endometrium. Euploid embryos fail to implant in about 1/3 of IVF cycles, which may be attributable to a non-receptive endometrium. The endometrial receptivity array (ERA) has emerged as a diagnostic tool to identify receptive endometrium and to guide timing of embryo transfer. While studies have shown the utility of ERA testing in a natural cycle, the impact of endometrial stimulation with exogenous estrogen (E) and progesterone (P) on ERA results are not well understood. The objective of this study was to investigate whether cycle parameters obtained during a programmed endometrial stimulation cycle can predict abnormal ERA results.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We reviewed the records of all women who underwent a mock frozen-thawed embryo transfer (FET) cycle and ERA testing (n= 88) at a university-affiliated IVF clinic from 2017-2019. All women received endometrial preparation with exogenous oral estradiol (E2). Exogenous P was administered once endometrial thickness reached ≥8 mm. Endometrial biopsy for ERA testing was performed on the sixth day of exogenous P. Study measures included patients' age, BMI, number of previous failed embryo transfers, maximum (max) serum P level, max P dose, max endometrial thickness (MET), duration of E exposure, max serum E2 level, and ERA result. Multivariable logistic regression models and resulting odds ratios (OR) with 95% confidence intervals (CI) were used to test for measure association, where stepwise AIC selection criteria was applied to determine the optimal model. All reported p-values are 2-sided and a p-value < 0.05 was considered statistically significant.

RESULTS: Mean (SD) age was 36.3 (4.2) years and median (Q1, Q3) BMI was 26.3 (22.0, 28.5) kg/m^2. Of the 88 ERA tests performed, 21 (23.9%) were receptive and 67 (76.1%) were non-receptive. A full multivariable model for predicting non-receptive ERA results showed that the total number of transfers prior to ERA (OR [95% CI]: 0.81 [0.5, 1.31], p=0.40), MET (OR 0.97 [0.74, 1.27], p=0.83), age (OR 0.98 [0.85, 1.12], p=0.83), and duration of E exposure (OR 1.05 [0.91, 1.21], p=0.51) were not significant factors. Based on the reduced, optimized multivariable model, the odds of having a non-receptive ERA result decreased by 0.54 per 25 mg increase of P dose (OR [95% CI]: 0.46 [0.24, 0.87], p=0.016), increased by 0.31 per 100 pg/ml increase in max E2 level (OR 1.31 [1.03, 1.68], p=0.030) and increased by 0.13 per unit increase in BMI (OR 1.13[1.01, 1.26], p=0.039), when also adjusting for max serum P, max dose of P, max serum E2 level, and BMI.

CONCLUSIONS: Our data suggests total number of transfers prior to ERA, MET, age and duration of E exposure do not predict ERA results. However, when modeled together, serum P level, P dose, serum E2 and BMI can be used to predict ERA results. Since implantation failure may be a result of a non-receptive endometrium in programmed FET cycles, studies with a larger sample size are needed to determine if cycle parameters can help providers determine who may benefit from ERA.

P-501 4:30 PM Monday, October 19, 2020

ELEVATED AMH NOT ASSOCIATED WITH PRETERM DELIVERY IN IVF PREGNANCIES.

Michael K. Simoni, MD,[1] Ashni Nadgauda, B.S.,[2] Nathanael C. Koelper, MPH,[3] Anuja Dokras, M.D., Ph.D.[4] [1]University of Pennsylvania, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA; [3]University of Pennsylavia, Philadelphia, PA; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

OBJECTIVE: Recent evidence of an association between AMH and preterm birth (PTB) after in vitro fertilization IVF suggests a physiologic effect of AMH on the uterus, particularly among women with polycystic ovary syndrome (PCOS). In order to confirm these preliminary findings and account for additional variables, we examined a large US dataset at an academic fertility center.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We included all autologous (IVF) cycles that resulted in a live, singleton birth from 2015-2019. AMH values were compared in women who had a spontaneous PTB after 20 weeks gestation to those who delivered at full term. We excluded women with uterine and other factors necessitating a preterm delivery (e.g. severe pre-eclampsia, vasa previa, chorioamnionitis). Pregnancies in which delivery information could not be confirmed were not included in the analysis. Chi-square or Fisher's exact tests and t-test or Wilcoxon rank-sum test were used where appropriate. Multivariable logistic regression was used to adjust for age,

body mass index (BMI) and IVF cycle type (fresh vs frozen embryo transfer). $P < 0.05$ was considered statistically significant.

RESULTS: In the 606 unique patients, the median AMH values among women who had a PTB (n=39) was 2.5 ng/mL IQR [1.4-5.3], compared to 2.7 ng/mL IQR [1.3-5.2] among those who had a term delivery (n=567) (p=0.92). Odds of PTB was not significantly different by AMH quartile after adjusting for age, bod and cycle type. Women with AMH in the 2nd, 3rd, and 4th AMH quartiles had an adjusted odds ratio (aOR) for PTB of 0.80 (95% confidence interval (CI): 0.32 – 2.01), 0.50 (95% CI 0.18 – 1.42) and 1.01 (95% CI 0.41 – 2.48), respectively, when compared to the lowest quartile. Among women with PCOS (n=90), there was no difference in odds of PTB (2nd quartile - aOR 1.73, 95% CI: 0.26 – 11.58; 3rd quartile - aOR 0.57, (95% CI 0.18 – 1.42), 4th quartile - aOR 1.03; 95% CI 0.12 – 8.64) compared to the lowest quartile. No differences were also seen when examining AMH quartiles and prevalence of PTB in fresh (n=183) and frozen cycles separately (n=423).

CONCLUSIONS: Our study shows that women with elevated AMH were not more likely to experience a spontaneous PTB after IVF than women with lower AMH values. Women with the diagnosis of PCOS were also not more likely to experience a PTB, however the sample size was limited. Larger cohort studies specifically in women with PCOS are needed to understand the relationship between AMH and preterm birth.

P-502 4:30 PM Monday, October 19, 2020

REPRODUCTIVE OUTCOMES BETWEEN FRESH AND FREEZE ONLY DEFERRED BLASTOCYST TRANSFERS. Fred V. Morgan-Ruiz, MD,[1] Julio C. Rosales, M.D.,[1] Patrizio Pasquale, MD, MBE, HCLD,[2] Pablo Diaz-Spindola, MD,[1] Edelmiro Garza-Padilla, M.D.[1] [1]IECH, Monterrey, NL, Mexico; [2]Yale Fertility Center, Orange, CT.

OBJECTIVE: To compare the reproductive outcomes in patients who undergo fresh transfer vs. freeze only delayed transfers.

DESIGN: Retrospective, cross sectional, comparative study.

MATERIALS AND METHODS: 721 patients who underwent IVF/ICSI at the IECH, Monterrey, México, from January 2014 to December 2019 were studied. Patients were divided into two groups: 228 patients (31.6%) had a freeze only deferred embryo transfer (TED) and 493 patients (68.4%) had fresh transfer (TEF). Both groups were classified into suboptimal, normal and high responders according to the number of eggs obtained. All transfers and cryopreservation were at blastocyst-stage. The variables analyzed were implantation, clinical pregnancy and live birth rates. All the clinical records of infertility patients requiring IVF/ICSI with an age range of 21-40 years were included. In both transfer groups, patients received the same treatment protocols for controlled ovarian stimulation. Oocytes were retrieved vaginally 35 to 36 hours after hCG administration and fertilized using either standard IVF or ICSI. In the TED group, blastocysts were cryopreserved by vitrification and rewarmed few hours before the transfer.

RESULTS: The average age for both groups was 32.93 ± 3.85 for TED and 33.95 ± 4.09 ($p<0.001$) for fresh transfers. Overall, there were significant differences in favor of TED in implantation rate (58.13% vs 29.89%, $p<0.05$; OR: 3.25 95% CI: 2.44-4.33), clinical pregnancy (50% vs 25.08%, $p<0.05$; OR: 2.98, 95% CI: 2.24-3.98) and live birth r (54.26% vs 31.01%, $p<0.05$; OR: 2.63, 95% CI: 1.98-3.50).However, when the results were compared according to the ovarian response, the freeze only deferred embryo transfer maintained superiority over the fresh transfers only in the high ovarian response subgroup. In the TEF group there were no significant differences among the subgroups.

CONCLUSIONS: Deferred frozen embryo transfers offer better reproductive results (implantation rate, clinical pregnancy and live birth) compared to the fresh transfer strategy particularly in patients with high ovarian response.

SUPPORT: None.

P-503 4:30 PM Monday, October 19, 2020

THE CLINICAL USE OF ENDOMETRIAL RECEPTIVITY ANALYSIS (ERA®) AND THE EFFECTS ON IMPLANTATION RATES IN WOMEN WITH PRIOR FAILED TRANSFERS. Grace Z. Lu, B.S., Carolyn Givens, M.D., Liyun Li, M.D. Pacific Fertility Center, San Francisco, CA.

OBJECTIVE: Endometrial receptivity is thought to be an important cause of implantation success or failure. ERA® (Endometrial Receptivity Analysis) analyzes the transcription profile of luteal phase endometrium (in a natural or programmed cycle) to determine its receptivity. ERA® results purport to allow physicians to personalize frozen embryo transfer (FET) protocols to transfer embryos during the "receptive" window, and thus increase implantation (IR) and pregnancy (PR) rates. In this study, we aimed to (1) evaluate the utilization of ERA® in a single large private ART practice, (2) for patients who had "non-receptive" ERA® results, determine if customized modifications of FET protocols according to ERA® results have led to changes in IR and PR in subsequent FETs.

DESIGN: A retrospective cohort analysis.

MATERIALS AND METHODS: We reviewed records of patients who had an ERA® between 2014 to 2019 at our IVF center. All ERA® cycles were programmed cycles with an average progesterone duration of 133 (98-168) hours before the endometrial biopsy. Patient demographics, previous FET data, ERA® results, and outcome of subsequent FETs were analyzed. Data analysis was performed using Excel and MedCalc.org and SciStat.com.

RESULTS: 173 patients completed an ERA®. The age was 39±4.781 years, with 82% of patients having had at least one prior FET (0-7). 8.6% had a chart diagnosis of uterine factor, 7.5% with endometriosis, 11% with adenomyosis, and 15% of patients had fibroids. The average peak endometrial thickness was 9.8±2.0 mm for the ERA® cycle and 9.9±2.1 mm during the first subsequent FET.

Of all ERA®s completed, 40% (N=69) patients were receptive, 43% (N=74) pre-receptive (recommended transfer 24 hrs later), 14.45% (N=25) early receptive (12 hrs later), 2.3% (N=4) late receptive (12 hrs earlier), and one patient was post-receptive. 10% completed a second ERA® due to an invalid biopsy sample, and only one patient completed three ERA®s.

Overall FET PR in this cohort of patients pre-ERA® was only 5% (16/320). The overall PR post-ERA® was 36% (63/171) with an odds ratio of 11.1 (95% CI 6.1-20.0). Pre-ERA® IR of autologous euploid embryos was 6.3% (11/176). The post-ERA® IR of autologous euploid embryos was 42% (47/112) with an odds ratio of 10.8 (95% CI 5.3-22.2).

For the non-receptive groups (both pre- and post-receptive), the pre-ERA® PR was 5.5% (10/180) and post-ERA® PR was 36% (35/97) with an odds ratio of 7.9 (95% CI 3.3-18.8). The pre-ERA® IR of autologous euploid embryos was 8.7% (9/104). The post-ERA® IR was 42% (24/56) with an odds ratio of 9.6 (95% CI 4.5-20.53). For the receptive groups, the pre-ERA® PR was 4.3% (6/140), and post-ERA® PR was 37% (28/74) with an odds ratio of 13.6 (95% CI 5.3-34.9). The receptive group had a pre-ERA® IR of autologous euploid embryos of 2.8% (2/71), and a post-ERA® IR of 41% (23/55) with an odds ratio of 24.8 (95% CI 5.5-111.6).

CONCLUSIONS: 60% of patients had non-receptive ERA®s. While non-receptive patients had increased implantation and pregnancy rates post-ERA®, similar improvements were also seen in receptive patients making it difficult to draw the conclusion that ERA® was clinically beneficial.

DOES INTRACYTOPLASMIC SPERM INJECTION (ICSI) PROVIDE ANY BENEFIT OVER IN VITRO FERTILIZATION (IVF) ON PREGNANCY OUTCOMES IN NON-MALE FACTOR INFERTILITY CYCLES UNDERGOING PRE-IMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A)?. Jessica N. Tozour, MD, PhD, Alyson Brady, MS, Meredith Akerman, MS, Alicia J. Arnott, BS, Linda Sung, MD, Rani Fritz, DO, PhD, NYU Winthrop Hospital, Mineola, NY.

OBJECTIVE: ICSI is currently the recommended fertilization method for cycles undergoing PGT-A [1]. To our knowledge there are no studies evaluating pregnancy outcomes of PGT-A transferred embryos inseminated by IVF versus ICSI. Our objective is to evaluate whether significant differences exist in pregnancy outcomes from PGT-A transferred embryos fertilized by IVF compared to ICSI.

DESIGN: Retrospective cohort study at a single academic institution.

MATERIALS AND METHODS: All frozen embryo transfers (FET) performed from 1/2016 to 2/2020 that underwent PGT-A from trophectoderm biopsy and tested by next generation sequencing were evaluated. Exclusion criteria included diagnosis of male factor infertility, embryos tested for pre-implantation genetic testing for monogenic disorders, structural rearrangements, or HLA-typing, cryopreserved oocytes, blastomere or polar body biopsy, in vitro maturation, rescue ICSI, and split IVF/ICSI cycles. Patient demographics, infertility diagnoses, cycle characteristics, and pregnancy

outcomes including not pregnant, biochemical pregnancy, miscarriage, ongoing pregnancy (OP), and live birth (LB) were collected. Primary outcome was OP/LB rates. Secondary outcomes included miscarriage and biochemical rates. Chi-square or Fisher's exact test, as appropriate, and Mann-Whiney test were used for categorical and continuous variables, respectively. Outcomes between both groups were compared using a repeated-measures mixed-effects logistic regression model, in which the rates were adjusted for confounding variables attained during the univariate screen. Results were considered statistically significant with a p-value <0.05.

RESULTS: A total of 317 FET's met criteria (IVF-150 [47.3%]; ICSI-167 [52.7%]). Significant difference between the IVF and ICSI cohort existed in age (35.8 y/o vs. 36.8 y/o, respectively, p=0.03), BMI (23.6 vs 25.1, respectively, p=0.005), and ethnicities. LB/OP rates and miscarriage/biochemical rates demonstrated no significant differences in IVF vs. ICSI inseminated groups (Table 1).

CONCLUSIONS: There were no significant differences in pregnancy outcomes in FET's between IVF and ICSI inseminated embryos that underwent PGT-A. The use of ICSI in non-male factor infertility cycles undergoing PGT-A does not provide an advantage for LB/OP rates over IVF.

TABLE 1.

	IVF (150)	ICSI (167)	p-value
Not pregnant	35.7%	37.3%	0.79
Biochemical	12.1%	14.8%	0.62
Miscarriage	11.4%	7.8%	0.43
Live birth	37.3%	35.0%	0.69
Biochemical/Miscarriage	23.6%	22.5%	0.85
Live birth/Ongoing	39.8%	38.3%	0.74

PERINATAL AND MATERNAL OUTCOMES AFTER FROZEN VERSUS FRESH EMBRYO TRANSFER CYCLES IN WOMEN OF ADVANCED MATERNAL AGE. Xinyi Zhang, PhD, Jichun Tan, PhD Shengjing Hospital of China Medical University, shenyang, China.

OBJECTIVE: The delay of childbearing age in women has become a worldwide issue in recent decades. The application of assisted reproductive technology in women of advanced maternal age (AMA) is increasing. There is still lacking evidence on the safety and outcomes of frozen embryo transfer (FET) compared with fresh embryo transfer (ET) in women of AMA. Therefore, the objective of the present study is to compare perinatal and maternal outcomes after autologous FET and fresh ET cycles in women of AMA.

DESIGN: This was a retrospective study of 1663 FET cycles and 3964 fresh ET cycles in four reproductive medical centers from 2009 to 2014. Women $\geq$35 years of age who had clinical pregnancies after autologous frozen or fresh ET were included.

MATERIALS AND METHODS: Main perinatal outcome measures included birth weight, gestational age, rates of macrosomia, low birth weight (LBW), very low birth weight and preterm birth. Maternal outcome measures included rates of hypertensive disorders of pregnancy, gestational diabetes mellitus and preterm premature rupture of the membranes.

RESULTS: Women who underwent FET had a higher risk of hypertensive disorders of pregnancy [1.1% vs. 0.4%, adjusted OR (95%CI): 2.76 (1.39-5.51); $p = 0.004$]. Singletons born after FET had significantly higher mean birth weight (3388.78 $\pm$ 538.47 vs. 3316.19 $\pm$ 549.08; $p = 0.001$). Furthermore, increased risk of macrosomia [13.5% vs. 10.4%, adjusted OR (95% CI): 1.35 (1.07-1.71); $p = 0.013$] and decreased risk of LBW [3.6% vs. 5.3%, adjusted OR (95%CI): 0.67 (0.45-1.00); $p = 0.048$] were found in singletons born after FET.

CONCLUSIONS: Perinatal risks of AMA patients are higher in FET than in fresh ET, including higher birth weight, risks of macrosomia in singleton births and hypertensive disorders of pregnancy.

P-506 4:30 PM Monday, October 19, 2020

HLA-G LEVELS IN FOLLICULAR FLUID ARE NOT ASSOCIATED WITH FOLLICULAR G-CSF CONCENTRATIONS IN WOMEN UNDERGOING IN VITRO FERTILIZATION. Dimitar Parvanov, PhD,[1] Rumiana Ganeva, MSc,[1] Milena Todorova, MSc,[1] Kristina Nikolova, MSc,[1] Magdalena Vasileva, MSc,[1] Ivaylo Rangelov, MSc,[1] Fabio Scarpellini, MD,[2] Georgi Stamenov, MD/PhD,[1] [1]Nadezhda Women's Health Hospital, Sofia, Bulgaria; [2]Center For Endocrinology And Reproduction, Rome, Italy.

OBJECTIVE: Recently, soluble human leukocyte antigen-G (sHLA-G) and granulocyte colony-stimulating factor (G-CSF) quantified in the follicular fluid have been proposed as non-invasive biomarkers of oocyte competence in both stimulated and natural IVF/ICSI cycles. sHLA-G, G-CSF and their receptors were described in various human fetal tissues and it was suggested that they play an important role in ovulation, oocyte maturation, embryo development and implantation. However, the possible association between these two molecules in the follicular fluid has not been studied yet.

The purpose of the present study was to determine whether the sHLA-G levels are associated with the G-CSF levels in follicular fluid of women undergoing in vitro fertilization.

DESIGN: This is a cohort study of 56 women undergoing stimulated cycles and in vitro fertilization between September 2019 and November 2019 at Nadezhda Women's Health Hospital.

MATERIALS AND METHODS: Follicular fluid from up to six clear follicular aspirates was collected during regular egg collection procedure of 56 patients. Samples were stored at -20°C until measurement. Follicular fluid levels of sHLA-G and G-CSF were evaluated by ELISA kits (Elabscience; E-EL-H1663 and RayBiotech; ELH-GCSF-1, respectively) according to the manufacturer's instructions. The absorption was measured on a microplate reader (Beckman Coulter DTX 880 Multimode detector) at 450 nm. Statistical analysis was performed using SPSS v.21 (IBM Corp., Armonk, NY, USA).

RESULTS: **s**HLA-G was detected in all 56 follicular fluid samples, with a median value of 47.52 IU/ml and a range of 13.85-63.06 IU/ml. Follicular fluid G-CSF was also detected in all samples and ranged between 3 and 116 pg/ml with a median of 16.23 pg/ml.

Measured sHLA-G levels did not show a significant correlation with G-CSF concentration in follicular fluid ($P = 0.63$).

CONCLUSIONS: This is the first report regarding the association between follicular fluid levels of sHLA-G and G-CSF. Although the increased secretion of both sHLA-G and G-CSF usually correlates with better oocyte quality and implantation success, our findings suggest that they are not related to each other.

EFFECT OF FOLLICLE SIZE AT TRIGGER IN GNRH ANTAGONIST PLUS LETROZOLE IVF CYCLES ON OOCYTE QUALITY OUTCOMES. Phillip A. Romanski, MD,[1] Nirali J. Shah, MD,[2] Pietro Bortoletto, MD,[1] Zev Rosenwaks, M.D.,[1] Glenn Schattman, MD,[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Weill Cornell Medicine, New York, NY.

OBJECTIVE: To assess the effect of follicle size at trigger in GnRH antagonist/letrozole IVF cycles on oocyte yield and fertilization rate.

DESIGN: We conducted a retrospective cohort study at an academic center. Patients who underwent their first IVF cycle with a GnRH antagonist/letrozole protocol at our center between 01/01/2012 and 12/31/2019 were included. Patients were stratified into two groups by the size of the second largest follicle on the day of trigger: $\leq$21 mm and >21 mm. Patients with fewer than three follicles >12 mm on the day of trigger (n=23) and patients on continuous letrozole protocols (n=334) were excluded.

MATERIALS AND METHODS: The primary outcome was the number of mature oocytes retrieved; secondary outcomes were the total number of oocytes retrieved and the number of fertilized oocytes. Poisson regression adjusted *a priori* for patient age and AMH level was used to estimate the risk ratio (RR) with a 95% confidence interval (CI) among the study groups. The antagonist/letrozole protocol used was 5mg letrozole daily for five days starting on cycle day two. Gonadotropins were then started on cycle day four

and continued until the night of trigger administration. The timing of trigger administration is determined by the treating physician. The trigger used was either hCG alone or GnRH agonist plus hCG (dual trigger).

RESULTS: A total of 278 GnRH antagonist/letrozole cycles resulting in an oocyte retrieval were included: 140 patients in the ≤21 mm group and 138 patients in the >21 mm group. The mean (mean ± standard deviation) number of oocytes retrieved was significantly lower in the ≤21 mm group (7.6 ± 5.9) compared to the >21 mm group (10.2 ± 5.8; RR 1.15 (95% CI 1.06-1.25)). The mean number of mature oocytes retrieved was significantly lower in the ≤21 mm group (5.4 ± 3.9) compared to the >21 mm group (7.0 ± 4.1; RR 1.12 (95% CI 1.02-1.24)). The mature oocyte rate observed was 73.8% in the ≤21 mm group and 70.7% in the >21 mm group. The mean number of fertilized oocytes in the ≤21 mm group was 3.8 ± 3.2, which was not statistically significant when compared to the >21 mm group (4.8 ± 3.8; RR 1.09 (95% CI 0.96-1.24)). The fertilization rate observed was 63.6% in the ≤21 mm group and 59.0% for the >21 mm group.

CONCLUSIONS: In ovarian stimulation protocols where letrozole is utilized, timing the trigger to when the second largest follicle is >21 mm yields a higher number of total and mature oocytes. Additionally, a mean of one additional zygote per cycle was observed in the >21 mm group. While this was not a statistically significant finding, it is a clinically meaningful outcome. Therefore, we conclude that the ideal time to administer the ovulatory trigger in cycles utilizing letrozole is when the second largest follicle is >21 mm. The optimal size identified in this study is larger than the optimal follicle size that has been identified in traditional GnRH antagonist protocols. We hypothesize that this may be due to alterations in cell signaling and oocyte development as a result of temporary aromatase inhibition and suppression of estradiol formation.

SUPPORT: None.

P-508 4:30 PM Monday, October 19, 2020

PROGESTERONE/ESTRADIOL RATIO HAS A BETTER PROGNOSTIC VALUE THAN PROGESTERONE ALONE IN THE PREDICTION OF PREGNANCY OUTCOMES IN INTRACYTOPLASMIC SPERM INJECTION (ICSI) CYCLES.

Reda S. Hussein, MD,[1] Ihab M. El-Nashar, MD,[1] Ahmed F. Amin, MD,[1] Yulian Zhao, Ph.D.,[2] Ahmed M. Abbas, MD,[1] Ahmed M. Abdelmagied, MD,[1] Osama S. Abdalmageed, MD,[1] Ahmed Youssef, MD,[1] Esraa Badran, MD,[1] Tarek Farghaly, MD,[1] Ahmed Ali Abdelaleem, MD,[1] Mostafa N. Ibrahim, MD,[1] Hisham A. Abou-Taleb, MD, PhD,[1] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN.

OBJECTIVE: To compare the predictive value of progesterone/estradiol ratio (P/E) ratio and absolute progesterone (P) level on the ovulation triggering day for pregnancy outcomes in fresh gonadotropin-releasing hormone (GnRH) antagonist intracytoplasmic sperm injection (ICSI) cycles.

DESIGN: A retrospective cohort study conducted in a university-affiliated IVF center between January 2017 and April 2019.

MATERIALS AND METHODS: The study included women who underwent their first- or second-ranked GnRH antagonist ICSI cycles with day-3 embryo transfer. P/E ratio was calculated as [P (ng/mL) × 1000]/E (pg/mL). Cut-off values of ≥1.5 ng/ml for high P (HP) and ≥0.55 for high P/E ratio were chosen based on literature [1]. A receiver operating curve (ROC) curve was performed to detect the predictability of serum P/E and P for the ongoing pregnancy rate. First, patients were divided according to either P level (low P< 1.5 ng/mL and high P≥ 1.5 ng/mL) or P/E ratio (low P/E< 0.55 and high P/E≥ 0.55). Patients were further divided into four subgroups [Group A: High P (HP) and high P/E ratio, group B: low P and low P/E ratio, group C: HP only, group D: high P/E only]. A multivariate regression analysis models were used to account for the effect of the cycle confounders on the likelihood of pregnancy.

RESULTS: A total of 402 ICSI cycles were analyzed. The area under the curve (AUC) was 0.67 and 0.59 for P/E and P, respectively. P/E showed a significant association with ongoing pregnancy (aOR: 0.409, 95% CI 0.222-0.753, p=0.004) while HP revealed no significant predictive value (aOR: 0.542, 95% CI 0.284-1.036, p=0.064) after the multivariate analysis.

CONCLUSIONS: P elevation may not present as an independent predictor for cycle outcomes. P/E ratio has a better prognostic value than P alone in predicting pregnancy outcomes of GnRH antagonist cycles.

FROZEN EMBRYO TRANSFER CYCLES MAY OFFER ADVANTAGE IN BOTH PREGNANCY SUCCESS AND REDUCING THE NUMBER OF PATIENTS DISCONTINUING CARE.

G David Ball, PhD,[1] Anne E. Martini, DO,[2] Stephanie Beall, MD, PhD,[3] Gilbert L. Mottla, MD,[4] Brooke Hayward, SM, MBA,[5] Mary C. Mahony, PhD, HCLD,[5] Allison B. Catherino, PhD,[5] [1]Seattle Reproductive Medicine Center, Seattle, WA; [2]National Institute of Child Health and Human Development, NIH, Bethesda, MD; [3]Shady Grove Fertility Center, Towson, MD; [4]Shady Grove Fertility Center, Annapolis, MD; [5]EMD Serono, Inc. (a business of Merck KGaA, Darmstadt, Germany), Rockland, MA.

OBJECTIVE: To evaluate pregnancy and discontinuation rates after a single oocyte retrieval, by type of transfer – fresh vs freeze-all – with subsequent frozen embryo transfer (FET).

DESIGN: Non-randomized, observational, retrospective cohort study.

MATERIALS AND METHODS: Electronic medical records of patients from a large US database of fertility clinics (IntegraMed America, Inc.) were analyzed. Patients included had a first treatment cycle in 2015–2017, with a single oocyte retrieval followed by fresh embryo transfer (ET; and subsequent FET, if frozen embryo(s) were available) or freeze-all cycle, with subsequent FET(s). Clinical pregnancy rate (CPR) was defined as clinical intrauterine gestation or later evidence of pregnancy. Patient discontinuation rate was determined by evaluating the proportion of patients with no further cycles after the last ET without a pregnancy.

RESULTS: Of 18,875 patients who had a single oocyte retrieval, 11,784 (62.4%) had a fresh ET (followed by 0–7 FETs) and 7091 (37.6%) had a freeze-all cycle (followed by 1–6 FETs). The overall proportion of cycles that underwent preimplantation genetic testing for aneuploidy was 1.9% for patients who initially had a fresh ET and 22.4% for freeze-all. CPR following a single fresh ET was 75.5%, compared with 82.9% for a single FET in freeze-all cycles, with the elective single ET (eSET) rate for the first fresh ET being 39.0% compared with 68.8% for first FET in freeze-all cycles with subsequent FETs. CPRs were >70% for ≤2 FETs following fresh ET or ≤3 FETs after freeze-all. Rates of eSET decreased with each subsequent transfer attempt and were consistently lower after fresh ET (1st FET 39.0% and 2nd FET 27.9%) than after first FET (2nd FET 60.3% and 3rd FET 43.7%). Patients who had a fresh ET and did not achieve a pregnancy had fewer surplus embryos after the first ET than patients who had their first FET after a freeze-all cycle (mean [standard deviation]: 0.75 [1.99] vs 3.20 [3.73], respectively). Patient discontinuation rate was higher for patients who had started with a fresh ET, with 23.9% discontinuing treatment without a pregnancy, compared with 19.2% who had undergone FET(s) after freeze-all. Among the 23.9% of patients who initially had a fresh ET and discontinued, most stopped after the fresh ET (19.2%) or 1 FET (3.7%); just 3.9% of patients had ≥2 FETs, even with surplus embryos available.

CONCLUSIONS: Elective cryopreservation of all embryos followed by FET resulted in higher CPRs and patient retention rates when compared with fresh ET followed by FET. Rates of eSET were also higher with a freeze-all approach, which minimizes the incidence of multiple pregnancies and associated risks, and reserves surplus embryos for later use without the need for additional retrievals.

SUPPORT: Study sponsored by EMD Serono, Inc., Rockland, MA, USA (a business of Merck KGaA, Darmstadt, Germany).

P-510 4:30 PM Monday, October 19, 2020

TIME FROM OOCYTE RETRIEVAL TO SINGLE EMBRYO TRANSFER IN THE NATURAL CYCLE DOES NOT AFFECT CYCLE OUTCOMES.

Pietro Bortoletto, MD,[1] Phillip A. Romanski, MD,[1] Brady I. Magaoay, BA,[1] Steven Spandorfer, MD,[2] [1]Weill Medical College of Cornell University, New York, NY; [2]Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine if time from oocyte retrieval to single frozen embryo transfer (FET) in the natural cycle affect reproductive or neonatal outcomes?

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: Reproductive (pregnancy & live birth rate) and neonatal outcomes (gestational age & weight) between first (n=222) vs. second menstrual cycle (n=354) after oocyte retrieval were compared. Rank-sum, Student's t-test, and Chi-square tests were performed as appropriate. A multivariable logistic regression was performed with adjustment for age, infertility diagnosis, ovulatory trigger type, and pre-implantation genetic testing. Statistical significance was denoted by $p<0.05$

RESULTS: A total of 576 women were analyzed, of which n=222 transferred an embryo during their first menstrual cycle after retrieval and n=354 in a subsequent cycle. Patient and cycle characteristics are provided in Table 1. Prior to adjustment for confounding, we found a significantly different pregnancy rate (72.5 vs. 64.4%, $p = 0.043$) and live birth rates (57.7 vs. 48.6%, $p = 0.034$) for natural cycle FET occurring in the first versus second menstrual cycle, respectively. In a multivariate analysis, performing a natural cycle FET of a single blastocyst in the second, compared to the first menstrual cycle did not statistically impact odds of live birth rate (OR: 0.76, 95% CI: 0.54-1.08). After adjustment for age, diagnosis, and ovulatory trigger type, only PGT testing was associated with significantly increased odds of live birth compared to no PGT testing (OR: 2.46, 95% CI: 1.72-3.52). There were no differences in mean singleton birth weight (3429 vs. 3333 grams, $p = 0.148$) or gestational age at time of delivery (39.0 vs. 38.7 weeks, $p = 0.076$) between both groups.

CONCLUSIONS: Performing a natural cycle FET of a single blastocyst in the second, compared to the first menstrual cycle following ovarian stimulation did not statistically impact odds of live birth. Furthermore, gestational age and birth weight were similar between groups. Patients and providers should feel comfortable selecting a timeline for FET that best suits their clinical and personal needs.

	First Menstrual Cycle N=222	Second Menstrual Cycle N=354
Age years mean (SD)	36.0 (3.7)	35.6 (4.0)
Parity median (IQR)	0 (0-1)	0 (0-1)
Infertility Diagnosis n(%)		
Diminished ovarian reserve	111 (50.0)	150 (42.4)
Male factor	49 (22.1)	105 (29.7)
Uterine factor	24 (10.8)	23 (6.5)

P-511 4:30 PM Monday, October 19, 2020

IN VITRO PERI-IMPLANTATION DEVELOPMENT OF GOOD QUALITY HUMAN EMBRYOS IS AFFECTED BY BLASTOCYST MORPHOLOGICAL GRADE AND MATERNAL AGE. Deirdre M. Logsdon, M.S., Rachel C. West, PhD, Rebecca Kile, MS, Courtney K. Grimm, MS, Mandy G. Katz-Jaffe, PhD, Sue McCormick, BS, Karen Maruniak, MLS, William B. Schoolcraft, MD, Rebecca L. Krisher, PhD, Ye Yuan, PhD, Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Peri-implantation development during in vitro extended culture may reflect a human blastocysts developmental potential following transfer. The objective of this study was to determine whether blastocyst morphology and maternal age impact peri-implantation developmental potential as determined by extended embryo culture.

DESIGN: Retrospective study.

MATERIALS AND METHODS: Over two years, 653 human blastocysts donated for research (WIRB study #1179872) underwent extended embryo culture for various research projects in our laboratory. Each embryo was assessed for attachment to fibronectin coated microslides on day (D) 2 and D 3 of culture. Where applicable, images were taken of embryos for outgrowth (OG) area measurements, spent media was saved for hCG quantification, and embryos were fixed with 4% paraformaldehyde to determine total (DAPI) and epiblast (POU5F1) cell numbers with fluorescent imaging using a spinning disk confocal microscope and Imaris software. Good quality blastocysts ($\geq$3BB) with the highest morphological grade (high) that typically yield live birth rates above 60 % were compared with those of lower morphological grade (low) that typically result in less than 55% live birth rate, based on our historical data. In addition, blastocysts from advanced maternal age (AMA; $\geq$ 36 years) and younger ($\leq$ 35 years) patients were compared. Measurements were analyzed using one-way ANOVA.

RESULTS: Embryos with high morphological grade had significantly larger OG areas than those with low morphological grade on D 3 (0.17 mm2 n=218 high; 0.12 mm2 n=74 low; $p \leq 0.05$) and D 7 (0.56 mm2 n=28 high; 0.23 mm2 n=11 low; $p \leq 0.05$) of extended culture. There were no significant differences in embryo attachment, total cell number, epiblast cell number or hCG production between these two groups. Embryos from AMA women had significantly lower attachment on D 3 of extended culture (91.3% $\pm$ 1.8% young, 84.5% $\pm$ 2.9% AMA; $p \leq 0.05$). In addition, significantly fewer embryos from AMA women contained POU5F1-positive epiblast cells (62.1% $\pm$ 6.0%, n=66 young; 44.6% $\pm$ 6.2% n= 65 AMA: $p \leq 0.05$), and AMA embryos with POU5F1 positive cells tended to have fewer epiblast cells by D 5 in extended culture (75.3 $\pm$ 11.5, n=24 young; 44.5 $\pm$ 8.1, n=17 AMA: $p \leq 0.06$). There were no significant differences in OG area on D 3, total cell number, or hCG production in extended culture.

CONCLUSIONS: Our data collected from 653 human embryos in extended culture provides valuable information about a time in development that cannot be observed in vivo. Better blastocyst morphology, which in our experience results in higher pregnancy rates after transfer, is also associated with improved extended culture outcomes suggesting that our system is a sensitive method to predict post transfer developmental potential. Advanced maternal age may contribute to decreased developmental potential of morphologically good quality blastocysts, which could result in implantation failure after transfer. Additional studies examining the impact of maternal BMI, stimulation protocol, infertility diagnosis, ovarian reserve, and embryo grade on developmental potential are underway.

P-512 4:30 PM Monday, October 19, 2020

USE OF ADJUVANT HUMAN GROWTH HORMONE DOES NOT IMPROVE BLASTOCYST EUPLOIDY RATES IN PATIENTS UNDERGOING IN VITRO FERTILIZATION. Holly Mehr, MD MSEd,[1] Zain Al-Safi, MD,[1] Carrie Riestenberg, MD,[1] Victoria Lee, BS,[1] Rong Guo, MS,[1] Kathleen Brennan, MD,[1] Lindsay Kroener, MD,[1] UCLA.[1]University of California, Los Angeles, Los Angeles, CA.

OBJECTIVE: To determine if the use of adjuvant human growth hormone (hGH) during in vitro fertilization (IVF) improves euploid rates in patients age <35, 35-38, and $\geq$39.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All patients who underwent autologous IVF with preimplantation genetic testing for aneuploidy at a single academic center between 1/2016 and 12/2019 were screened for inclusion. Patients who received adjuvant hGH 2.32mg/40iu daily from the first day of stimulation until day of trigger were compared to those who were not treated with hGH. Baseline patient characteristics and cycle outcomes were compared between groups. Summary statistics for cycle outcomes were stratified by age at the time of oocyte retrieval (< 35, 35-38, and $\geq$39 yo). Mixed model analysis was performed to examine hGH effect on euploid rate after controlling for possible confounders.

RESULTS: A total of 280 patients underwent 405 IVF cycles during the study period. The hGH and control groups had a comparable percent of cycles resulting in no embryos for biopsy (10% vs 7.6%, p=0.39). The remaining 367 IVF cycles from 258 patients had at least one embryo for biopsy and were analyzed. Compared to the control group, the hGH group had a lower AFC in patients $\geq$ 39 yo (12.7 vs 17.2, p=0.031), a higher FSH dose in patients $\geq$ 39 yo (3509 vs 5182, p=0.007), and more prior IVF cycles in patients <35 yo (0.7 vs 0.16, p <0.0001) and 35-38 yo (0.65 vs 0.17, p=0.006). Baseline characteristics were otherwise similar between groups. Patients $\geq$ 39 yo treated with hGH had fewer embryos to biopsy (3.6 vs 4.9, p=0.043). For all other outcomes, including euploid rate, there was no significant difference between groups prior to adjustment (Table 1). In the multiple mixed model analysis adjusting for age, BMI, prior IVF cycles, AFC, and FSH dose there was no significant effect of hGH on euploid rate (p=0.604).

TABLE 1. Unadjusted IVF outcomes; Mean (SD)

	Age < 35 (n=119)			Age 35-38 (n=102)			Age ≥ 39 (n=146)		
	No hGH (n=63)	hGH (n=56)	p-value	No hGH (n=38)	hGH (n=66)	p-value	No hGH (n=33)	hGH (n=113)	p-value
Oocytes retrieved	19.3 (8.1)	18.8 (10.1)	0.352	19.1 (9.0)	15.7 (7.4)	0.143	17.0 (9.1)	13.6 (7.9)	0.147
Embryos biopsied	6.2 (3.9)	6.0 (3.3)	0.725	6.1 (3.7)	5.5 (3.4)	0.745	4.9 (3.6)	3.6 (2.4)	**0.043**
Euploid embryos	3.8 (2.5)	3.1 (2.1)	0.388	3.0 (2.3)	2.1 (2.0)	0.266	1.2 (1.1)	0.9 (1.2)	0.555
Euploid rate (%)	59 (25)	55 (27)	0.366	4.9 (2.8)	3.9 (24)	0.083	25 (24)	23 (27)	0.750

CONCLUSIONS: Use of adjuvant hGH in IVF did not result in a significant improvement in embryo euploid rates for women of any age group. Our study may have failed to identify and adjust for unmeasured confounders that would lead a physician to offer hGH. Further randomized studies are warranted to determine if there is a unique population who may benefit from adjuvant hGH.

P-513 4:30 PM Monday, October 19, 2020

CLINICAL CHARACTERISTICS SHOULD NOT BE OVERLOOKED WHEN SELECTING EMBRYOS CULTURED IN A TIME-LAPSE INCUBATOR SYSTEM. Amanda Souza Setti, MSc,[1] Daniela Paes de Almeida Ferreira Braga, PhD,[1] Ana Caroline Silva Soares, DVM, PhD,[2] Patricia Guilherme, MSc,[2] Assumpto Iaconelli, Jr., MD,[1] Edson Borges, Jr., PhD.[1] [1]Fertility Medical Group / Sapientiae Institute, Sao Paulo, Brazil; [2]Fertility Medical Group, Sao Paulo, Brazil.

OBJECTIVE: Single embryo transfers (SETs) has become indispensable to maximize live birth rates while avoiding multiple pregnancies. The development of a non-invasive embryo implantation predictor has become crucial for reproductive medicine. Time-lapse imaging systems (TLS) allow for the mapping of morphological changes or events with the exact time-point of occurrence. Analysis of implantation-related morphokinetic characteristics has facilitated the development of algorithms for implantation prediction. The main drawback of most studies is that each embryo is treated as an individual, and clinical and stimulation–related confounding factors are ignored. The aim of this study was to investigate the influence of morphokinetic events and patients and cycles characteristics on embryo implantation.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: This study included 175 embryos cultured in a TLS incubator deriving from ICSI cycles with single day 5 embryo transfers, between Jan-2019 and Dec-2019. The effect of morphokinetic events and patients and cycles characteristics on embryo implantation was evaluated by multiple regression models. Recorded kinetic markers were: pronuclei appearance (tPNa), timing to pronuclei fading (tPNf), timing to two (t2), three (t3), four (t4), five (t5), six (t6), seven (t7), and eight cells (t8), and timing to blastulation (tB). Durations of the second (t3-t2) and third (t5-t3) cell cycles (cc2 and cc3, respectively) and timing to complete synchronous divisions s1 (t2-tPNf), s2 (t4-t3), and s3 (t8-t5) were also calculated. Maternal age, number of follicles, number of retrieved oocytes, number of mature oocytes, and oocyte yield, as well as the presence of endometriosis, male and ovarian factors of infertility were also added to the model. To cross-validate the results, variables which significantly affected embryo implantation were included in a stepwise discriminant analysis for the prediction of grouping variable implantation outcome, defined as positive or negative. Cut-off points for the selected variables were established halfway between averages in both implantation groups.

RESULTS: Multiple regression results showed that female age (OR: 0.813, p=0.041), total dose of FSH (OR: 0.998, p=0.003), longer t8 (OR: 0.938, p=0.040) and s3 (OR: 0.922, p=0.029), and the presence of endometriosis (OR: 0.311, p<0.001) negatively influenced the chance of embryo implantation, while the number of follicles (OR: 1.947, p=0.018) and mature oocytes (OR: 1.133, p=0.001) had a positive influence. The discriminant function correctly classified 77.8% of original cases, best predicting negative implantation (98.8%). Established cut-off points for positive implantation were 37.1 years-old for female age, 2701.2 IU for total dose of FSH, 10.1 follicles, 5.4 MII oocytes, 56.6 hours for t8 and 7.8 hours for s3.

CONCLUSIONS: Our evidences underline the importance of patients individual characteristic for the development of any algorithm for embryo implantation. Ignoring the impact of confounder's factors, as the embryo origin, may weaken the model and its predictive value.

ENDOMETRIAL MIRNOME ESTABLISHMENT DURING THE IMPLANTATION WINDOW UNDER HORMONE REPLACEMENT THERAPY FOR FROZEN EMBRYO TRANSFER CAN PREDICT SUCCESSFUL PREGNANCY. Samir Hamamah, MD, PhD,[1] Chloé Baron, PhD, student,[2] Anna Gala, MD,[2] Alice Ferrieres-Hoa, MD,[2] Sophie Brouillet, PharmD, PhD,[2] Frida Entezami, MD,[3] Delphine Haouzi, PhD.[2] [1]Arnaud de Villeneuve Hospital, CHU Montpellier, Montpellier, France; [2]Inserm U1203, CHU Montpellier, St-Eloi Hospital, Montpellier, France; [3]American Hospital of Paris, Neuilly sur Seine, France.

OBJECTIVE: Can endometrial miRNAs profile during the implantation window under the same HRT for frozen embryo replacement cycle, predict successful implantation?

DESIGN: Endometrial biopsies (n=12) were collected during the implantation window from RIF patients (mean ± SD, age: 36.7 ± 6.4 years) under hormone replacement therapy (HRT) for frozen embryo transfer. RNAs were extracted to perform the miRNA expression profile. Then, miRNA expression was analyzed according to following pregnancy outcome: implantation achieved (n=6) or implantation failure (n=6). Successful implantation was defined as both a positive b-hCG and clinical pregnancy and implantation failure as a negative b-hCG.

MATERIALS AND METHODS: Endometrial biopsies were performed during a mock HRT cycle from RIF patients, according to the definition by Polanski *et al.* (RBMonline 2014). Then, miRNA expression profile between the two groups, successful *vs.* implantation failure after frozen embryo replacement was evaluated with the *Affymetrix® miRNA 4.1 Array Strips.* The significant analysis of microarrays (SAM) were used to identify *miRNAs* that were differentially expressed between groups.

RESULTS: *SAM analyses according to a pregnancy successful or implantation failure identified 188, 157, and 163 miRNAs using the ANOVA,* Student's *t-test, and Wilcoxon test, respectively with a fold change (FC) >2 and* false discovery rate (FDR) <5%. *The 136 miRNAs identified according the three statistical analyses were overexpressed in endometrium associated with implantation failure. Supervised hierarchical clustering of these 136 miRNAs showed a good segregation of endometrium samples from patients with and without a successful implantation.* Using the Ingenuity software, we first aimed to identify the potential target genes of these microRNAs. We identified 41 miRNAs that are putative regulators of 13663 genes attached to numerous biological functions including the leukocyte extravasation signaling, the regulation of the epithelial-mesenchymal transition pathway, the epithelial adherent junction signaling and the growth hormone signaling that play a crucial in implantation and maintain of pregnancy. The top-five miRNAs over-expressed in endometrium from patients with implantation failure were miR-1 (x7, FDR<0.0001), miR-2 (x6.3, FDR<0.0001), miR-3 (x4.9, FDR<0.0001), miR-4 (x4.3, FDR<0.0001), miR-5 (x4.2, FDR=0.004). The miR-2 was validated by RT-qPCR in an independent cohort of 23 patients opening new perspectives in the development of a non-invasive test to predict pregnancy outcome (p = 0.002).

CONCLUSIONS: miRNAs profile of endometrial tissues during the implantation window preceding frozen embryo transfer cycle can predict the pregnancy outcome. These data are crucial leading potentially to the

development of a prognostic tool of the attempt, opening news perspectives in the patient care management.

DOES ENDOMETRIAL COMPACTION ON THE DAY OF FROZEN BLASTOCYST TRANSFER IMPROVE THE OUTCOME OF FROZEN-THAWED CYCLES? INTERIM ANALYSIS.

Eman A. Elgindy, MD, PhD,[1] Amany Abdelghany, MD,[2] Hoda Sibai, MD,[2] Dalia O. El-Haieg, MD,[1] Magdy I. Mostafa, MD.[3] [1]Professor Obstetrics and Gynecology, The University of Zagazig, Zagazig, Egypt; [2]Associate professor Obstetrics and Gynecology, The University of Zagazig, Zagazig, Egypt; [3]professor Obstetrics and Gynecology, Cairo University, Cairo, Egypt.

OBJECTIVE: To assess whether the occurrence of endometrial compaction (decreased thickness) on the day of frozen blastocyst transfer has a role in optimizing pregnancy outcome in frozen-thawed cycles. Further, to investigate possible interrelationship between the occurrence of compaction and progesterone (P) blood level on the day of transfer.

DESIGN: Observational cohort study.

MATERIALS AND METHODS: According to sample size calculation, 220 patients undergoing good quality frozen blastocyst transfer (GFBT) are to be included. Interim analysis of 120 patients is done. All patients received estradiol valerate (6mg daily) and 100 mg of intramuscular (IM) progesterone (P). Endometrial thickness was measured by transvaginal ultrasound at the end of the estrogen phase and on the day of embryo transfer. Progesterone level was measured on the day of GFBT.

RESULTS: Endometrial compaction occurred in 63 (52.5%) of 120 cases. The ongoing pregnancy rate (OPR) was higher in the endometrial compaction group in comparison to those without compaction (62.5% versus 47.1% respectively); however, it did not reach statistical significance (P= 0.11). Furthermore, the endometrial compaction group had a comparable P level on the day of ET (37.96±16.4 ng/ml to those without compaction (38.3±10.7 ng/ml), where the difference was not statistically significant (P= 0.94).

CONCLUSIONS: Although there was an increase in the OPR in the endometrium compaction group, it is not yet statistically significant in the cases observed so far. In addition, the P level on the day of ET was not found to be different in the compaction group. The validity of these findings will be determined through the observation of the remaining cases.

CLINICAL OUTCOMES AFTER SINGLE VERSUS DOUBLE EMBRYO TRANSFERS IN WOMEN WITH ADENOMYOSIS: A RETROSPECTIVE STUDY.

Jiayi Guo, Master The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: The single blastocysts embryo transfers policy is an effective strategy known to minimize the risk of multiple pregnancy for non--adenomyosis women. However, little is known about its applicability to women with adenomyosis. The purpose of this study is to compare pregnancy outcomes between single blastocysts embryo transfers (SBT), double blastocysts embryo transfers (DBT), single cleavage-stage embryo transfers (SET) and double cleavage-stage embryo transfers (DET) in the frozen - thawed embryo transfer cycles among adenomyosis patients.

DESIGN: This retrospective study was conducted in all frozen-thawed autologous embryo transfer cycles conducted between 2014 and 2019 in Reproductive Centre of Six Affiliated Hospital of Sun Yat-sen University. A total of 393 frozen-thawed autologous blastocyst or cleavage-stage embryo transfer cycles performed in adenomyosis patients were enrolled. Differences in baseline characteristics between the four groups were assessed. The major clinical outcomes were implantation rate (IR), clinical pregnancy rate (CPR), miscarriage rate (MR), multiple pregnancy rate (MPR) and live birth rate (LBR).

MATERIALS AND METHODS: Among the adenomyosis women, 203 single blastocysts transfers (SBT), 75 double blastocysts transfers (DBT), 13 single cleavage-stage embryo transfers (SET) and 102 double cleavage-stage embryo transfers (DET) were performed.

RESULTS: The SBT and DBT groups achieved higher IR (47.78%, 39.33%, vs 38.46%, 26.96%, $P<0.05$) , CPR (39.90%, 49.33%, vs 7.70%, 33.33%, $P<0.05$), LBR (28.72%, 38.57%, vs 7.69%, 21.88%, $P=0.040$) and lower MR (27.84%, 21.43%, vs 80.00%, 49.90%, $P<0.05$) than the SET and DET groups. But the SBT and DBT groups achieved similar CPR and LBR. The SBT and SET groups achieved lower MPR(0%, 0%, vs 28.57%, 10.20%, $P<0.001$) than the DBT and DET group.

CONCLUSIONS: When performing frozen-thawed embryo transfer cycles among adenomyosis patients, the SBT group has similar IR, CPR, MR, LBR but lower MPR compared to the DBT group. Therefore, SBT might be offered as standard practice.

CORRELATION BETWEEN ENDOMETRIAL THICKNESS AND PROBABILITY OF LIVE BIRTH IN FROZEN BLASTOCYST TRANSFER CYCLES WITH AND WITHOUT PRE-IMPLANTATION GENETIC TESTING.

Rachel Grimes Sprague, MD,[1] Samad Jahandideh, PhD,[2] Kate Devine, MD,[2] Anthony N. Imudia, MD,[1] [1]Department of Obstetrics and Gynecology, Morsani College of Medicine, University of South Florida, Tampa, FL; [2]Shady Grove Fertility, Washington D.C., DC.

OBJECTIVE: 1) To detect if a correlation exists between endometrial thickness and probability of live birth in PGT-A tested and untested frozen embryo transfer (FET) cycles and 2) To determine optimal endometrial thickness to achieve live birth in PGT-A tested and untested FET cycles.

DESIGN: Retrospective study.

MATERIALS AND METHODS: All FET cycles in 2018 at the Rockville office of Shady Grove Fertility were included. All cycles were autologous elective single-embryo transfer. The generalized estimating equation (GEE) model was used to associate last endometrial thickness measured prior to transfer and the probability of live birth from PGT-A tested and untested FET cycles when controlled for age and body mass index (BMI). Subgroup analysis was performed based on endometrial thickness (<8mm, 8-12mm, and >12mm) with a two-sided chi-square test performed on live birth observations.

RESULTS: A total of 742 PGT-A tested and 689 untested FET cycles were analyzed. The endometrial thickness and probability of live birth showed a positive correlation in PGT-A tested (adjusted odds ratio [aOR] 1.01, 95% CI 0.95-1.08) and a negative correlation in PGT-A untested cycles (aOR 0.99, 95% CI 0.94-1.05); however, these did not reach statistical significance ($p>0.05$). Regression analysis detected a correlation between age and probability of live birth for PGT-A untested, but not PGT-A tested cycles (aOR 0.95, 95% CI 0.91-0.98, $p<0.001$). Sub-analysis did not detect a statistically significant association between endometrial thickness groups of <8mm, 8-12mm, or >12mm and probability of live birth in either PGT-A tested or untested cycles ($p>0.05$).

	Mean (SD)	Adjusted OR (95% CI)	Adjusted p-value
PGT-A Tested (n=742 cycles)			
Endometrial Thickness	9.63 (2.21)	1.01 (0.95-1.08)	0.74
Age	36.20 (3.54)	0.99 (0.95-1.03)	0.68
BMI	25.70 (5.00)	1.00 (0.97-1.03)	0.97
PGT-A Untested (n=689 cycles)			
Endometrial Thickness	9.90 (2.52)	0.99 (0.94-1.05)	0.92
Age	34.20 (4.15)	0.95 (0.91-0.98)	<0.001*
BMI	26.10 (5.64)	0.99 (0.97-1.02)	0.73

CONCLUSIONS: These results did not detect a difference in the probability of live birth with either combined or categorized (<8mm, 8-12mm, or >12mm) endometrial thickness in both PGT-A tested and untested cycles suggesting lack of optimal endometrial thickness to achieve live birth.

P-518 4:30 PM Monday, October 19, 2020

THE IMPACT OF MODE OF DELIVERY ON SUBSEQUENT SINGLE EMBRYO TRANSFER CYCLES IN INFERTILE PATIENTS. Zachary Walker, MD,[1] Emily K. Osman, MD,[2] Ashley W. Tiegs, MD,[2] Julia G. Kim, MD, MPH,[2] Brent M. Hanson, MD,[2] Nola S. Herlihy, MD,[2] Amber M. Klimczak, MD,[2] Emre Seli, M.D.,[2] Richard Thomas Scott, Jr., MD,[2] [1]University of Alabama at Birmingham, Birmingham, AL; [2]IVI-RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: To determine (1) if live birth rates vary between infertile women with a prior cesarean section (CS) versus those with a prior vaginal delivery (VD) and (2) to assess if differences exist in endometrial thickness in frozen thawed embryo transfer (ET) cycles according to previous mode of delivery.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All infertile women that received in vitro fertilization (IVF) treatment resulting in a live birth and returning for a subsequent ET at a single, large infertility center from January 2006 until September 2019 were included. Women with a previous live birth at time of initial presentation for infertility evaluation, use of donor oocyte, gestational carrier, prior uterine surgery, those with intrauterine fluid present during the ET stimulation cycle, double or multiple ET and pregnancies with multiple gestation were excluded. Logistic regression was performed to assess if differences existed in the live birth rates between women with a prior CS versus VD. Differences in mean peak endometrial thickness before and after delivery were analyzed using linear regression with mixed effects modeling. Embryo ploidy, body mass index (BMI), type of uterine stimulation and smoking status were controlled for in all analyses.

RESULTS: In total, 2,026 subsequent ETs of 1,410 patients were analyzed; 687 with prior CS and 723 with prior VD. Of these frozen-thawed ET cycles, 1,678 were synthetic, 301 were natural, and 47 were stimulated. The mean difference in peak endometrial thickness between the ET cycle which resulted in the first live birth and subsequent ET cycles did not differ by the mode of delivery (0.11 ± 2.1 mm VD vs. 0.30 ± 2.0 mm CS, $p=0.53$). Patients with a prior CS had a lower live birth rate (59.1%) with the first ET cycle after initial delivery compared to women with prior VD (67.6%, $p<0.01$; OR 0.69, 95% confidence interval 0.53-0.90).

CONCLUSIONS: Although differences in endometrial thickness did not vary between ET cycles according to the mode of delivery, infertile patients with a prior CS have lower live birth rates in comparison to those that have had a previous vaginal delivery. This may be attributable to the presence of structural uterine abnormalities after CS, such as an isthmocele or mucocele, which could lead to alterations in the endometrium and decreased live birth rates. Further investigation is needed to assess the relationship between uterine abnormalities that may be present after CS and decreased live birth rates in infertile patients. Women with a previous CS should be counseled on these potential implications in future transfer cycles.

LIVE DELIVERED PREGNANCY RATES ACCORDING TO AGE AND EMBRYO CLEAVAGE RATES IN WOMEN WITH DIMINISHED OOCYTE RESERVE (DOR) HAVING ONLY A SINGLE EMBRYO TO TRANSFER ON DAY 3. Jerome H. Check, M.D., Ph.D.,[1] Donna Summers, M.S.,[2] Carrie K. Wilson, B.A.,[2] Jung Choe, M.D.,[1] Laura X. Zalles, MD,[3] [1]Cooper Medical School of Rowan University, Camden, NJ; [2]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ; [3]Cooper University Hospital, Camden, NJ.

OBJECTIVE: To determine the confounding effect of age and blastomere number on pregnancy outcome in women whose oocyte reserve was so low that only one embryo cleaved to at least 4 cells on day 3.

DESIGN: Prospective observational comparison study.

MATERIALS AND METHODS: Women were identified who have diminished oocyte reserve (DOR) based on a day 3 serum follicle stimulating hormone (FSH) level >12 mIU/mL who were undergoing in vitro fertilization-embryo transfer (IVF-ET). They agreed to have an ET on day 3 even if there was only 1 embryo to transfer as long as it cleaved to at least 4 cells. For those having only 1 embryo to transfer, the pregnancy outcome was sub-analyzed according to 2 age groups $\leq$35 and 36-39 and according to blastomere number (<6 cells vs. $\geq$6 cells). All patients were treated with a very mild FSH stimulation protocol depending on baseline FSH ranging from completely natural, to a small boost of 75 IU FSH starting in the late luteal phase, to as much as 150 IU FSH from day 3. Cetrorelix or ganirelix was used in most cycles as was human chorionic gonadotropins.

RESULTS: Clinical and live delivered pregnancy rates according to 2 age groups and 2 blastomere number groups is seen in the table below.

	Age $\leq$35		Age 36-39	
Cell stages	$\leq$5 cells	$\geq$6 cells	$\leq$5 cells	$\geq$6 cells
# transfers	14	48	43	113
% clinical preg./transfer	14.3%	31.3%	14.0%	15.9%
% delivered	14.3%	25.0%	7.0%	13.3%

CONCLUSIONS: The results show that for women $\leq$39 years old with such DOR that only one embryo cleaved to day 3, and even if the number of blastomeres is only 4 or 5 cells, live delivered pregnancies are possible. If the trend would continue it would seem that for younger women $\leq$35 years old, an embryo cleaving to at least 6 cells has about twice the chance of producing a live baby following single embryo transfer. This seems to be the case also for women age 36-39. The data show that for women with such DOR that only one embryo cleaves to at least 4 blastomere by day 3, the majority will at least attain a 6-cell embryo (76.4%, 48/62 for women $\leq$35 and 72.4%, 113/156 for women 36-39). Thus, a woman aged $\leq$35 with severe DOR leading to only 1 cleaved embryo to transfer on day 3, has a 22.4% of having a live baby vs. 11.5%, 18/156 in women age 36-39. There does not seem to be any advantage to the patient to freeze the embryo and perform multiple retrieval cycles to get one transfer with several embryos (as is the policy in some IVF centers) or to let the embryo cleave to the blastocyst stage with or without pre-implantation testing for aneuploidy as is performed in some other IVF centers.

SUPPORT: None.

LIVE BIRTH RATES ARE COMPARABLE BETWEEN MODIFIED NATURAL AND PROGRAMMED FROZEN EMBRYO TRANSFER CYCLES. Elizabeth L. Wolfe, MD,[1] Denis A. Vaughan, MD,[2] Daniel W. Duvall, Jr., BA,[3] Denny Sakkas, PhD,[3] Thomas L. Toth, MD,[2] [1]Maine Medical Center, Portland, ME; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Boston IVF, Waltham, MA.

OBJECTIVE: The increasing utilization of frozen embryo transfer (FET) has intensified the need to assess outcomes and refine protocols. Currently, the use of natural, modified natural or programmed FET cycles varies both regionally and internationally. The aim of this study was to compare live birth rates (LBR) between commonly used modified natural and programmed FET protocol regimens.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All FET cycles between January 2014 and December 2017 at a university-affiliated IVF center were reviewed. Modified natural cycles relied on either an hCG trigger or an endogenous LH surge, with supplemental vaginal progesterone (P4). FET was performed 7 days after hCG trigger or 6 days after LH surge with P4 supplementation starting 3 days before FET. Programmed FET cycle protocols included endometrial preparation with oral and/or transdermal estrogen until a satisfactory endometrial thickness was achieved and the use of either vaginal P4, intramuscular (IM), or a combination, with FET after approximately 108-112 hours of P4 exposure. The primary outcome was LBR. Only those aged <38 years, with a single blastocyst transfer, <3 prior miscarriages, <3 prior FETs, and <3 prior IVF cycles were included in this analysis. Chi-squared test was used to compare outcomes.

RESULTS: 703 modified natural and 2131 programmed FET cycles were included, resulting in 1326 total live births (LBR 47%). The mean age was similar in both groups (33 years). Similar numbers of cycles had embryos transferred that were deemed euploid by PGT (23% of modified natural cycles and 24% of programmed cycles). There was a higher clinical pregnancy rate amongst modified natural cycles (423/703, 60%) compared to all programmed cycles (1161/2131, 54%, P=.012). A significantly higher LBR was noted in modified natural cycles compared to all programmed cycles (Table 1). When a sub-analysis was performed comparing modified natural to programmed cycles in which IM P4 was used (alone or in combination with vaginal) no significant difference in LBR was noted.

CONCLUSIONS: Live birth rates are comparable in modified natural FET cycles and programmed hormone replacement cycles with IM P4. Further efforts are needed to standardize and optimize FET protocols. Based on this study, shared decision making between patient and provider is encouraged when selecting FET protocols. Emerging information regarding maternal and perinatal outcomes may influence clinical decision making in the future.

TABLE 1. FET cycle outcomes

Category	Cycles	Live Births	P value*
Modified Natural	703	366 (51%)	-
Programmed (All)	2131	960 (45%)	0.01
Programmed (IM)	791	407 (55%)	0.81

*Live births compared to modified natural cycles

P-521 4:30 PM Monday, October 19, 2020

ASSOCIATION BETWEEN DAY OF TROPHECTODERM BIOPSY AND OUTCOMES OF EUPLOID EMBRYO TRANSFERS. Catherine Gordon, MD, Andrea Lanes, PhD, Ann M. Thomas, PhD, Catherine Racowsky, PhD Brigham and Women's Hospital, Boston, MA.

OBJECTIVE: To compare clinical outcomes following transfer of euploid blastocysts biopsied on day 5 with those of embryos deemed unsuitable for biopsy on day 5 and that were biopsied on day 6.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Warmed NGS-tested euploid single embryo transfers from autologous IVF cycles performed at our center from 10/2015 to 2/2020 were included. Implantation rates (IR) and ongoing pregnancy rates (OPR) beyond 12 weeks gestation were assessed. Transfers were grouped by blastocyst quality (good, fair and poor) and then stratified by day of biopsy. Relative risks (RR) and 95% confidence intervals (CI) were calculated within each blastocyst quality class using log-binomial regression adjusting for age. GEE modeling was used to account for patients contributing multiple cycles.

RESULTS: 237 transfers from 191 patients were analyzed. See table below.

Both the IR and OPR were increased for embryos biopsied on day 5 compared to those biopsied on day 6 when combining all transfers regardless of blastocyst quality (72.4% vs. 63.0%; 62.3% vs. 53.2%). However, these differences were not significant. When stratified by biopsy day and blastocyst quality, a similar trend was noted for good and poor quality embryos. Fair quality Day 5 embryos and good quality Day 6 embryos had equivalent IR and OPR (RR 0.97 95%CI 0.78, 1.20; RR 0.94 95%CI 0.75, 1.17). The IR of poor quality day 5 blastocysts was significantly increased compared with that of poor quality day 6 blastocysts (72.7% vs. 36.0%; RR 0.69 95%CI 0.53, 0.88).

CONCLUSIONS: Although statistically not significant, the approximate 10% increase in IR and OPR between embryos biopsied on day 5 vs. day 6 is clinically significant and is useful for patient counseling. When the choice is available, a euploid embryo that was biopsied on day 5 should be transferred over one biopsied on day 6, regardless of blastocyst quality.

DO ANDROGENS MAKE STRAIGHT A STUDENTS?: EXPLORING THE LINK BETWEEN HYPERANDROGENISM AND BLASTOCYST GRADE. Nepheli Raptis, B.A., M.A.,[1] Hanna Mandell, M.A.,[1] Lauren Grimm, M.A.,[1] Emma Radley, M.A.,[1] Christy Oso, B.A.,[1] Zoran J. Pavlovic, M.D.,[2] Jessi Anderson, MPH,[1] Roohi Jeelani, MD,[1] Angeline Beltsos, MD[1] [1]Vios Fertility Institute, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.

OBJECTIVE: To determine whether hyperandrogenic-presenting PCOS patients produce blastocysts of different quality compared to classically-presenting PCOS patients.

DESIGN: While polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders of reproductive-age women, researchers have recently established a hyperandrogenic subgroup of PCOS patients who specifically present with the clinical symptoms of adult acne and hair growth. In order to optimally diagnose and treat this subgroup, the clinical implications must be better understood. Previous research determined that endocrine disorders underlying PCOS threaten follicular and oocyte development. Furthermore, hyperandrogenic PCOS patients were found to have a lower blastocyst utilization rate compared to classical PCOS patients, which we hypothesized could be accounted for by a potential difference in blastocyst quality score between these PCOS subgroups.

MATERIALS AND METHODS: Retrospective chart review at a private multi-site infertility center. Patients who underwent in-vitro fertilization (IVF) cycles between April 2017 and September 2019 and who had PCOS were included. A serum anti-mullerian hormone (AMH) level of $>$ 5ng/mL was used as a surrogate marker for PCOS. Hyperandrogenic PCOS and classical PCOS subgroups were defined based on the presence or absence of self-reported adult acne and hair growth. Baseline characteristics were evaluated, and blast quality score (BQS) and pregnancy outcomes were analyzed. BQS was calculated according to the Gardner and Schoolcraft criteria. Two sample t-tests and chi square analysis were used to analyze the data using SPSS (SPSS Inc., Chicago, IL, USA).

RESULTS: A total of 109 IVF cycles were identified as having a cycle resulting in at least 1 blastocyst stage embryo. Baseline characteristics, including age, BMI, and AMH were similar between the two groups. Fifty-three of these cycles were those who presented with hyperandrogenic PCOS, while 56 were those with classical PCOS. There is no statistical difference (p=.59) between the average BQS for the non-hyperandrogenic PCOS group (15.881) compared to the hyperandrogenic group (16.464). Differences in pregnancy outcomes between both groups were also similar (p=0.70).

CONCLUSIONS: While hyperandrogenic PCOS patients may experience a decrease in utilizable embryos following an IVF cycle compared to their classical PCOS counterparts, these results support that this difference may not be caused by a difference in blastocyst quality. Given these results, physicians may counsel their hyperandrogenic PCOS patients to complete more IVF cycles to produce utilizable, high quality embryos in consideration of their patients' family planning objectives. Further research investigating other potential factors that could account for this

P-523 4:30 PM Monday, October 19, 2020

EFFECT OF CERVICAL MICROBIOME ON CLINICAL PREGNANCY RATE OF WOMEN UNDERGOING IN VITRO FERTILIZATION.

Xinyao Hao, bachelor degree, Pingping Li, PhD, Jichun Tan, PhD Shengjing Hospital of China Medical University, shenyang, China.

1. OBJECTIVE: To investigate if cervical microbiome influences the in vitro fertilization (IVF) outcome.

2. DESIGN: A nested case-control study involving 100 IVF patients.

3. MATERIALS AND METHODS: This study included 100 IVF patients transplanted with two cleavage stage embryos. Divided into 4 groups according to clinical pregnancy outcome and transplantation cycle. Two samples of cervical secretions were collected before all patients underwent embryo transfer. The variable regions 3 and 4 (V3-V4) of the 16S ribosomal ribonuclease acid gene were amplified by polymerase chain reaction and analyzed by Illumina MiSeq sequencing to compare the diversity of the four groups of microbiome.

4. RESULTS: In the fresh cycle, the alpha diversity of the clinical pregnancy group(n=25) was significantly lower than that of the non-pregnancy group(n=26)(P=0.0078), and there were statistical differences between the pregnancy group and non-pregnancy group in the beta diversity (P=0.004). During the thawing cycle, the alpha diversity of the clinical pregnancy group(n=27) was also lower than that of the non-pregnancy group(n=22), but it was not significant, and the two groups were not statistically significant in the beta diversity analysis. For cervical microbiome of fresh cycle patients, we obtained five main different strains by differential analysis, namely Lactobacillus, Akkermansia, Desulfovibrio, Atopobium, and Gardnerella. Among them, Lactobacillus was negatively correlated with other differential strains, and positively correlated with serum E_2 levels. Regression analysis of fresh cycle data showed that the composition of the cervical microbiome on the transplantation day would affect the clinical pregnancy rate of IVF(P=0.030).

5. CONCLUSIONS: The composition of the cervical microbiome can affect the outcome of patients undergoing IVF treatment. The next step should be to clarify the mechanism of non- Lactobacillus -dominated microbiome affecting embryo implantation.

P-524 4:30 PM Monday, October 19, 2020

PREDICTORS OF ENDOMETRIAL COMPACTION PRIOR TO THAWED BLASTOCYST TRANSFER.

Carrie E. Bedient, MD,[1] Angela H. Liu, MD,[2] Melody A. Rasouli, MD, MBA,[2] Ankita Raman, MD,[3] Leah A. Kaye, MD,[1] Forest C. Garner, MS,[1] Bruce S. Shapiro, M.D., Ph.D., H.C.L.D.[1] [1]Fertility Center of Las Vegas, Las Vegas, NV; [2]University of Nevada, Las Vegas, Las Vegas, NV; [3]University of Nevada, Las Vegas, School of Medicine, Las Vegas, NV.

OBJECTIVE: Recent reports of a correlation between changes in endometrial thickness after progesterone (P4) exposure and success rates after thawed embryo transfer suggest a potential relationship with endometrial receptivity. We have found in our center that the change in endometrial thickness after progesterone exposure was correlated with pregnancy and ongoing pregnancy rates, so that those with less expansion (or with compaction) had greater ongoing pregnancy rates than those with more endometrial expansion after progesterone exposure. This study attempts to find factors that are predictive of the change in endometrial thickness.

DESIGN: IRB-approved retrospective cohort study of single vitrified-warmed blastocyst transfers at a private fertility center.

MATERIALS AND METHODS: There were 232 autologous vitrified-warmed single-blastocyst transfers following transvaginal ultrasonographic (TVU) measurement of endometrial thickness on the day of progesterone start and 5 days later, on the day of transfer. Vitrified-warmed blastocysts were transferred on the 6th day of P4 injection (100 mg/day) in cycles of artificial endometrial preparation with exogenous estradiol. Linear regression was used to identify factors that are predictive of the percent change in endometrial thickness from the day of P4 start until 5 days later on the day of planned transfer. Potential predictive factors included patient age, weight, BMI, endometrial thickness on the day of P4 start, and endometrial growth from baseline (E2 start) until P4 start. Also available were serum E2 levels measured before, on the day of, and 2 days after P4 start. P4 levels were also measured 2 days after P4 start and on the day of transfer. Additionally, the E2/P4 ratio measured 2 days after P4 start was available. $P<0.05$ was considered significant.

RESULTS: Only the endometrial growth from baseline to P4 initiation was a significant predictor of the change in endometrial thickness after P4 start ($P<0.001$). A greater degree of growth from baseline until P4 initiation was associated with less expansion (or greater compaction) between P4 initiation and FET.

CONCLUSIONS: These results suggest that endometria that responded most vigorously to exogenous E2 (more growth) are those most likely to have compaction (or less expansion), while those with less vigorous response to E2 (less growth) are those most likely to have greater endometrial expansion after P4 start. Whether this is an inherent property of those endometria, perhaps through biological variation, or is something that can be clinically manipulated is yet to be determined.

DONOR SPERM CANNOT IMPROVE ART OUTCOMES IN WOMEN WITH LOW OVARIAN RESERVE.

Tingting Li Doctor,[1] Panyu Chen Master.[2] [1]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the efficiency of assisted reproductive technology in patients with low ovarian reserve who choose sperm donor or husband sperm in vitro fertilization-embryo transfer (IVF-ET).

DESIGN: A retrospective analysis.

MATERIALS AND METHODS: A retrospective analysis was carried out on patients with ovarian reserve decline who underwent IVF-ET assisted pregnancy in the Reproductive Center of the Sixth Affiliated Hospital from January 2014 to May 2019. AMH $<$ 1.1 ng/ml and antral follicle count (AFC) $<$ 6 were selected. All the patients divided into 3 groups according to sperm source and sperm quality: Group 1 was IVF group for donor sperm, 73 cycles. SPSS statistical software was used to match the tendentiousness score with the control group, and group 2 was ICSI for 64 cycles due to less severe male infertility. Group 3: husband sperm IVF group, 73 cycles.

RESULTS: There was no significant difference in age, BMI, AMH, basal FSH, AFC, other general data among the three groups.Compared with group 3, group 1 and group 2 had higher non-oocyte cycles, 13 and 10 cycles respectively. The probability of available embryos among the three groups were 64.38%, 57.81%, 76.71% respectively, with no statistical difference. The clinical pregnancy rates in the three groups were 31.03%, 37.5% and 40.91%, respectively, with no significant difference. The miscarriage rate in group 2 increased significantly (50%). As the number of cases was relatively small, there was no significant difference after analysis (P=0.233).

Group	1 (n=73)	2 (n=64)	3 (n=73)	F/X2	P
Age(y)	38.88±5.66	37.09±5.05	36.77±4.93	0.068	0.934
BMI	22.08±2.61	22.41±2.74	22.57±3.35	0.511	0.600
Basal FSH	10.28±5.61	9.33±4.11	9.04±3.64	1.485	0.229
AMH(ng/ml)	0.51±0.28	0.65±0.26	0.79±0.25	1.069	0.303

Number of eggs obtained	2.58±1.90	2.63±1.73	2.73±1.64	1.759	0.165
Number of no eggs obtained cycles	13	10	1		
Ratio of available embryo cycles (%)	64.38 (47/73)	57.81 (37/64)	76.71 (56/73)	5.206	0.074
2PN fertilization rate(%)	67.55(127/188)	60.12(101/168)	59.56(162/272)	3.402	0.183
Available embryo rate(%)	79.53(101/127)	81.19(82/101)	79.63(129/162)	0.121	0.941
D3 high quality embryo rate(%)	77.23(78/101)	78.05(64/82)	81.40(105/129)	0.681	0.711
Clinical pregnancy rate (%)	31.03 (9/29)	37.5 (6/16)	40.91 (9/22)	0.556	0.757
Embryo implantation rate (%)	21.74 (10/46)	20.69 (6/29)	32.35 (11/34)	1.535	0.464
Miscarriage rate (%)	11.11 (1/9)	50 (3/6)	11.11 (1/9)	3.455[a]	0.233[a]
Live birth rate (%)	20.69 (6/29)	18.75 (3/16)	31.82 (7/22)	1.157	0.618

CONCLUSIONS: Assisted reproductive technology for patients with low ovarian reserve can not increase pregnancy rate by donor sperm.

P-526 4:30 PM Monday, October 19, 2020

DOES TRIGGER DAY PROGESTERONE AFFECT THE OUTCOME OF SUBSEQUENT FROZEN EMBRYO TRANSFER?. Ji Yeon Han, Fellow,[1] Soo Jin Han, MD,[1] Se Jin Kim, Fellow,[1] Hye Kyeong Kim, Fellow,[1] Sung Woo Kim, Professor,[1] Hoon Kim, Professor,[1] Seung Yup Ku, Professor,[1] Chang Suk Suh, Professor,[1] Seok Hyun Kim, MD. PhD.[2] [1]Seoul National University Hospital, Seoul, Korea, Republic of (South); [2]Seoul National University College of Medicine, Seoul, Korea, Republic of (South).

OBJECTIVE: To investigate the effect of progesterone level measured at trigger day on subsequent frozen embryo transfer cycle.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The medical records of 123 women who underwent in vitro fertilization (IVF) without fresh embryo transfer were reviewed. Patients were divided in two groups, women with elevated progesterone (EP, $\geq$1.5ng/mL) on trigger day (n=26) and women with other reasons of elective cryopreservation (n=97), such as usage of letrozole, risk of ovarian hyperstimulation syndrome, and poor endometrium condition, etc. The outcome of first frozen embryo transfer was investigated. Mann-Whitney test and Fisher's exact test were used for statistical analysis.

RESULTS: Age, BMI, AMH, basal FSH, and initial antral follicle count (AFC) were similar between two groups. Stimulation days were significantly longer in EP group (10.23 vs. 8.73, p=0.004), and total gonadotropin dose was also higher in EP group (3181.73 vs. 2235.05, p=0.002). The outcomes of COS, such as fertilization rate, and the number of oocytes retrieved, mature oocyte, good embryo, and blastocyst, did not differ between two groups. Clinical pregnancy rate was higher in EP group, but it did not achieve statistical significance (34.6% vs. 17.7%, p=0.062). Miscarriage rate was similar in both groups (EP: 33.3% vs. control: 35.3%, p=0.372).

CONCLUSIONS: Baseline characteristics did not differ according to progesterone level of trigger day, except stimulation days and total gonadotropin doses. Additionally, the outcome of next frozen embryo transfer cycle was similar, regardless of progesterone level on trigger day.

SUPPORT: No external funding was used for this study. None of the authors has any potential conflict of interest.

P-527 4:30 PM Monday, October 19, 2020

DOES GONADOTROPIN DOSAGE AFFECT THE RATE OF ANEUPLOIDY?. Michelle Volovsky, MBBS (Hons),[1] Richard Grazi, M.D.[2] [1]Maimonides Medical Center, New York, NY; [2]University of Washington, Seattle, WA.

OBJECTIVE: Our aim was to investigate whether increased gonadotropin doses during ovarian stimulation affects the rate of aneuploidy in subsequently produced embryos.

DESIGN: This is a retrospective cohort analysis performed using data from a single outpatient assisted reproductive technology (ART) facility.

MATERIALS AND METHODS: A standardized data set spanning 2016-2019 was analysed. This was comprised of 308 cycles in which gonadotropins in the form of follicle stimulating hormone or human menopausal gonadotropin were administered during ovarian stimulation, with pre-implantation genetic testing for aneuploidy being performed on all subsequently produced high-grade blastocysts. The main outcome assessed was the rate of aneuploidy among the tested embryos. Using a logistic regression model controlling for anti-mullerian hormone (AMH) and age, this rate was compared to the total dose of gonadotropins administered. Factors such as prior pregnancy, body mass index (BMI), intracytoplasmic sperm injection, cause of infertility, stimulation protocol, days of gonadotropin administration and type of ovulation trigger were evaluated and found not to affect the aneuploidy rates and hence were not included in the final logistic regression model. A secondary analysis was performed after separating total units of gonadotropin dose administered (Gn) into three groups [low (Gn $<$2000IU), moderate (Gn 2000-3000IU) and high (Gn $>$3000IU)] in order to assess whether a certain dose threshold would produce a statistically significant change in aneuploidy.

RESULTS: In the initial analysis we observed no statistically significant difference in aneuploidy rates with increasing gonadotropin doses when controlling for age and AMH. The secondary analysis, however, demonstrated a statistically significant decrease in the odds of aneuploidy in the moderate dose group by 0.73 ($p < 0.05$), when compared to the low dose group. There was no statistically significant difference between the moderate and high dose groups.

CONCLUSIONS: Previous reports have suggested that high gonadotropin dosing during ART cycles might have an adverse impact on the rate of aneuploidy. Our data suggests that lowering the dosage of gonadotropins might in fact raise the aneuploidy rate, independent of age, ovarian reserve (as measured by AMH), BMI and cause of infertility. The gonadotropin dosage in ART cycles should be appropriate for the patient's age and ovarian reserve, with the goal of safely maximizing the number of blastocysts, as lower doses do not appear to improve the chromosomal integrity of resultant embryos.

THE INFLUENCE OF OOCYTE MATURATION RATE ON EMBRYO DEVELOPMENT AND PREGNANCY OUTCOMES IN ICSI CYCLES. Tingting Li*, Doctor,[1] Yi Zhou, master,[1] Cong Fang, PHD, MD,[2] [1]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: The aim of this study was to investigate the influence of oocyte maturation rate on embryo development and pregnancy outcomes in intracytoplasmic sperm injection(ICSI) cycles in different age groups.

DESIGN: A retrospective study.

MATERIALS AND METHODS: This was a retrospective study analyzing date from 5442 ICSI cycles in a single reproductive center between January 2015 and December 2019. According to the oocyte maturation rate(OMR),

patients were divided into 3 groups: Group A, OMR ≤ 30%; Group B, 30% < OMR ≤ 60%; Group C, OMR > 60%. Fertilization rate, embryo development and pregnancy outcomes were compared among groups stratified by 40 age cut-point.

RESULTS: The average number of mature oocytes is higher in patients aged < 40 years than patients aged ≥ 40 years(9.70±5.20 vs 6.58±3.42 , P < 0.001), but no significant difference was found in the OMR different age groups. In patients aged < 40 years, the two pronucleus (2PN) fertilization rate is highest in Group C(P < 0.001). The cleavage rate, rate of transferable embryos, rate of good-quality embryos, implantation rate and clinical pregnancy rate were higher with increasing OMR(Group A < Group B < Group C , P < 0.05). The live birth rate is significantly lower in Group A compared with Group B and C(respectively 9.1% vs 40.5% ; 9.1% vs 44.8% , P < 0.05) and is similar in Group B and C. In patients aged ≥ 40 years, though the number of transferable embryos and good-quality embryos is higher with increasing OMR(Group A < Group B < Group C , P < 0.001), no significant difference was found in embryo development and pregnancy outcomes.

CONCLUSIONS: In patients aged < 40 years, increasing OMR is associated with better embryo development and pregnancy outcomes in ICSI cycles. The embryo development competency and pregnancy outcomes significantly decrease when the OMR ≤ 30%.

P-529 4:30 PM Monday, October 19, 2020

THE TROPHECTODERM BIOPSY EXPERIENCE DOES NOT AFFECT PGT OUTCOME. Tuong V. D. Pham, B.S.,[1] Randall Dunn, M.D.,[1] Subodh Chauhan, M.D.,[1] Leah Schenk, M.D.,[1] Rakesh Mangal, M.D.,[1] Audie Co, B.S.,[1] Melissa Pinasco, M.S.,[1] Wan-Song A. Wun, PhD,[2] Aspire Fertility,[1]Aspire Fertility, Houston, TX; [2]Harvest Fertility, Arcadia, TX.

OBJECTIVE: The PGT at the blastocyst stage looks to be a trend worldwide. Trophectoderm biopsy is the first step in performing PGT. There are reports (Aoyama and Kato, 2019; Capalbo et al, 2015; Munne et al, 2017) concerning the technique and the experience of the biopsy practitioner. How newly trained biopsy practitioner affect the outcome of PGT is examined in this study.

DESIGN: Retrospective study.

MATERIALS AND METHODS: All trophectoderm biopsy cases during 2016-2018 are included in this study. A total of 4897 blastocysts had trophectoderm biopsy. An experienced embryologist has performed 4284 biopsies. The newly trained embryologist performed 613 biopsies. There were 20.3% biopsies on day 5, 70% on day 6, and 9.6% on day 7. The trophectoderm biopsy uses the suction approach (no pre-assisted hatching). A Saturn V laser was used to cut the trophectoderm samples to take about 4-6 trophectoderm cells. All biopsies on day 5 and day 6 are at the expanded or hatching stage. A small number of biopsies are done at blastocyst stage on day 7.

This is a retrospective study. Chi-square tests used for statistical analysis.

RESULTS:

CONCLUSIONS: The results show there are no significant difference on the euploid rate, LLM, or NR with an experienced biopsy practitioner and a newly trained biopsy practitioner. This result is similar to the Capalbo et al (2015) observation. The ploidy state seems already inherently determined and the experience of the biopsy practitioner does not have a significant affect on the euploid status. It is interesting finding to see the experienced embryologist had a significantly higher HLM which may be due to selection bias or inherent in a retrospective analysis. Good quality and easy cases are usually targeted to be handled by the new biopsy practitioner in this setting.

P-530 4:30 PM Monday, October 19, 2020

ESTABLISH A NOMOGRAM MODEL TO PREDICT LIVE BIRTH RATE OF PCOS PATIENTS AFTER IVF/ICSI TREATMENT. Xing Yang, Ph.D., Linzhi Gao, Master degree, Lina Wei, Ph.D. The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: The clinical outcome after in vitro fertilization (IVF) or intracytoplasmic sperm injection (ICSI) treatment is diverse in infertility patients with polycystic ovary syndrome (PCOS). The aim of this study was to develop a nomogram model based on patients' characteristics to predict the live birth rate of PCOS patients after IVF/ICSI treatment.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All women in a public university hospital who attempted to conceive by IVF/ICSI for PCOS infertility from January 2014 to October 2018 were included. PCOS was diagnosed according to the Rotterdam criteria. A nomogram was built from a training cohort of 178 consecutive patients and tested on an independent validation cohort of 81 patients. Multivariable logistic regression was used to generate coefficients for each variable and the constant in the equation. The nomogram was constructed to be a graphic representation of the prediction model with the R software. Backward stepwise selection was performed to determine independent covariates.

RESULTS: No significant difference was observed in the patients' characteristics between the two cohorts. 79 patients (44.69%) achieve live birth in the training cohort. According to univariable logistic regression analysis, live birth was significantly correlated with total serum cholesterol (TC) ($p = 0.005$), BMI ($p=0.010$) and basal FSH ($p=0.080$). In multivariable analysis of the training cohort, live birth was significantly correlated with TC > 6.11 ng/ml (odds ratio [OR] 0.209; 95% CI 0.069–0.548; $p=0.003$), BMI > 23.9 (OR 0.478; 95% CI 0.250–0.900; $p=0.023$) and basal FSH (OR 1.291; 95% CI 0.990–1.705; $p = 0.064$). Higher TC, BMI and FSH were associated with a decreased live birth rate. Age and Day of Transfer were not statistically related to the live birth rate but were included in the predictive model due to their clinical relevance. Their inclusion improved the overall quality of the model as well (as measured by the Akaike information criterion).Therefore, this predictive model built on the basis of BMI, TC, basal FSH, Day of Transfer and age showed good calibration and discriminatory abilities, with an area under the curve (AUC) of 0.708 (95% CI 0.632–0.785) for the training cohort. The nomogram showed satisfactory goodness-of-fit and discrimination abilities in the independent validation cohort, with an AUC of 0.686 (95% CI 0.556–0.815).

CONCLUSIONS: Our simple evidence-based nomogram presents graphically risk factors and prognostic models for IVF/ICSI outcomes in patients with PCOS, which can offer useful guidance to clinicians and patients for individual adjuvant therapy.

P-531 4:30 PM Monday, October 19, 2020

OPTIMAL REPRODUCTIVE OUTCOMES OBTAINED FROM VASECTOMIZED MALES UNDERGOING TESE (TESTICULAR SPERM EXTRACTION) AND INTRACYTOPLASMIC SPERM INJECTION WITH OWN OR DONATED OOCYTES. Irene Hervas, MSc,[1] Nicolas Garrido, PhD,[2] Lorena Valls, M.D,[3] Rocio Rivera-Egea, PhD,[4] Maria Gil Julia, MSc, MRes,[1] Jose Maria Martinez-Jabaloyas, M.D,[4] [1]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [2]IVI Foundation

- IIS La Fe Biomedical Research Institut, Valencia, Spain; [3]Hospital Clínico de Valencia, Valencia, Spain; [4]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: Vasectomy is a permanent contraceptive method in males aiming birth control. Studies have shown that 3.4–7.4% regret their decision and request either sterilization reversal or in vitro fertilization treatment. Literature is scarce, series limited, main outcomes reported insufficient and often female contribution to reproductive success neglected. The aim of this study is to better address clinical outcomes of intracytoplasmic sperm injection (ICSI) cycles with testicular sperm after vasectomy in the largest series published so far.

DESIGN: Unicentric retrospective study.

MATERIALS AND METHODS: Data from vasectomized patients who underwent testicular sperm extraction followed by ICSI (TESE-ICSI) were obtained. Main outcome measures included implantation (IR), biochemical (BPR), clinical (CPR), and ongoing pregnancy (OPR) and delivery with live birth (LBR) rates per embryo transfer (ET), per controlled ovarian stimulation (COS) and couple. Proportions were compared with Chi-square tests, while survival curves were constructed with the Kaplan Meier method to estimate cumulative live birth rate (CLBR) per number of embryos consecutively replaced until the first newborn or abandoning.

RESULTS: A total of 513 TESE-ICSI cycles were evaluated, including 390 couples using their own (OE) and 123 donors' eggs (DE), in 497 and 215 embryo transfers respectively. Mean time since vasectomy and male age were 11.7 (CI95% 11.1-12.3) and 39.5 years (CI95% 38.7-40.3) in OE cycles, while in DE were 13.3 (CI95% 12.0-14.5) and 54.8 years old (CI95% 53.1-56.2). When using own's eggs, IR was 29.7% (CI95% 26.2-33.2), BPR 51.4% (CI95% 47.0-55.8), CPR 42.3% (CI95% 37.9-46.7) and OPR 35.0% (CI95% 30.8-39.2). The livebirth rate was 33.9% (CI95% 29.7-38.1) per ET, 23.0% (CI95% 19.8-26.2) per COS and 43.1% (CI95% 38.2-48.0) per couple. On the other hand, considering the 215 ET from donated oocytes ICSI cycles, IR was 33.6% (CI95% 28.1-39.0), BPR 54.2% (CI95% 47.5-60.9), and a CPR and OPR of 45.8% (CI95% 39.1-52.5) and 36.0% (CI95% 29.6-42.4) respectively. The LBR was 34.1% (CI95% 27.8-40.4) per transfer, 44.8% (CI95% 37.2-52.4) per COS and 59.3% (CI95% 50.6-68.0) per couple. Cumulative LBR were 33.6% (CI95% 27.9-39.3) with OE and 39.4% (CI95% 30.6-48.2) with DE when two embryos were transferred, 56.7% (CI95% 49.8-63.6) and 66.0% (CI95% 55.6-76.4) with four embryos replaced, and 75.6% (CI95% 68.2-83.1) *versus* 72.1% (CI95% 60.5-83.7) with seven embryos transferred, respectively. When up to nine embryos were transferred, the cumulative live birth rate was 85.9% (CI95% 79.0-92.8) in own oocytes cycles and 89.5% (CI95% 77.5-101.5) in donated oocytes treatments.

CONCLUSIONS: Clinical outcomes post-vasectomy results show reasonably high success rates, in both, autologous or donated oocytes, as estimated per ET, COS, couple and the cumulative livebirth rates depending on the number of consecutive embryos transferred using the largest series so far, to aid doctors and patients in the decision making process.

P-532 4:30 PM Monday, October 19, 2020

FOLLITROPIN ALFA (OVALEAP®) COMPARED WITH FOLLITROPIN BETA (PUREGON®) IN WOMEN UNDERGOING A FIRST GNRH ANTAGONIST CYCLE FOR ICSI: A RETROSPECTIVE COHORT STUDY. Lien Van den Haute, Specialist degree, Panagiotis Drakopoulos, MD, PhD, Greta Verheyen, PhD, Michel De Vos, MD, Herman Tournaye, MD, PhD, Christophe Blockeel, MD, PhD, University Hospital Brussel, Brussels, Belgium.

OBJECTIVE: Based on published evidence, ovarian stimulation (OS) for IVF/ICSI with follitropin alfa (Gonal-F®) and follitropin beta (Puregon®) is equally efficient .

Although pharmacokinetic studies of Ovaleap®(follitropin alfa, Theramex), a biosimilar to Gonal-F, showed dose-proportional and bioequivalent results compared to the reference follitropin alfa product (Gonal-F®), the efficacy of Ovaleap® and Puregon® has not previously been compared.

The objective of this study was to determine whether cumulative live birth rates (CLBR) after Ovaleap® and Puregon® are similar when used for OS with ICSI in a first-rank GnRH antagonist protocol.

DESIGN: Retrospective single centre cohort study including infertile patients undergoing their first ICSI cycle at a tertiary referral Centre between July 2016 and July 2019.

MATERIALS AND METHODS: In total, 894 patients were included. Of those, 358 patients had used follitropin alpha (Ovaleap®) and 536 patients had received follitropin beta group (Puregon®). The primary outcome was CLBR defined as the delivery of a live born (>24 weeks of gestation) after a fresh or a subsequent frozen–thawed embryo transfer (ET) using solely embryos derived from one OS cycle. Secondary outcomes were gonadotrophin consumption, duration of stimulation, oocyte yield, fertilization rate, number of cryopreserved embryos and live birth rate (LBR).

RESULTS: Patient age was similar in both groups (32.5 ± 4.6y vs 32.9 ± 4.8y, p= 0.1), while AMH was also comparable (2.9 ± 1.9 vs 3 ± 2, p= 0.31)

The cause of infertility was comparable in both groups (p= 0.92).

There was no difference in OS starting dose (171 ± 31.6 IU in the Ovaleap® group vs 173 ± 30 IU in the Puregon® group, p= 0.28), but the duration of stimulation was slightly higher in the Ovaleap ® group (10.6

Oocyte yield was similar (11.3 ± 7.7 vs 11.8 ± 6.6 oocytes, p= 0.06). Fertilization rate (defined as fertilized oocytes/mature oocytes*100) after Ovaleap® (74.7 ± 24.2%) and Puregon® (72.1 ± 23.7%) was significantly different (p= 0.03). The number of cryopreserved embryos was similar in both groups (2.7 ± 2.8 with Ovaleap® and 2.6 ± 2.6 with Puregon®, p= 0,86).

Live birth rate after fresh ET (93/358 (26.0%) vs 142/535 (26.5%), p= 0.85) and CLBR (185/358 (51.7%) vs 249/535 (46.5%), p= 0.13) were not significantly different.

Multivariate regression analysis allowing adjustment for relevant confounders revealed that the type of gonadotropin was not associated with CLBR.

CONCLUSIONS: This retrospective study shows no significant difference in CLBR between Ovaleap® and Puregon® in patients undergoing a first GnRH antagonist ICSI cycle.

P-533 4:30 PM Monday, October 19, 2020

RELATIONSHIP BETWEEN NUMBER OF OOCYTES RETRIEVED AND EMBRYO EUPLOIDY RATE. Jonathan D. Buerger, MD,[1] Jitesh Datla, MS,[2] Shahab Minassian, MD,[3] Michael J. Glassner, MD,[3] John J. Orris, DO,[3] Nicolle Clements, PhD,[2] Alyssa Sheffy, BS,[3] Sharon H. Anderson, PhD,[3] [1]Tower Health Reading Hospital, West Reading, PA; [2]Saint Joseph's University, Philadelphia, PA; [3]Main Line Fertility Center, Bryn Mawr, PA.

OBJECTIVE: Controlled ovarian stimulation (COS) protocols for in vitro fertilization (IVF) cycles for preimplantation genetic testing for aneuploidy (PGT-A) are optimized to obtain the highest number of high-quality, competent embryos while minimizing the chance of ovarian hyperstimulation syndrome. The objective of this study is to determine if higher number of oocytes retrieved affects rate of euploidy in the embryos.

DESIGN: Retrospective, cohort study of data from a private fertility center between 2017-2019.

MATERIALS AND METHODS: Data from 902 patients undergoing COS for IVF-PGT-A was analyzed. Interactive real-time graphing software Tableau was used to plot number of oocytes retrieved (independent variable) and embryo euploidy rate (dependent variable). Three multiple linear regression models were used to evaluate the relationship between number of oocytes retrieved and euploidy rate, where euploidy rate was analyzed per number of biopsied blastocysts, per number of oocytes retrieved, and per number of fertilized oocytes. The independent variables were patient age, anti-Mullerian hormone (AMH) level, PGT-A testing lab, and number of oocytes retrieved. Statistical significance was set at $p<0.05$.

RESULTS: The number of oocytes retrieved ranged from one to 63. A negative trend was observed between the number of oocytes retrieved and embryo euploidy rate when the interactive Tableau graphing software was used for visual analytics, especially when more than 25 oocytes were retrieved. After regression analysis, patient age was the only variable found to have a statistically significant negative effect ($p<0.0001$) on euploidy rate in all three regression models. Number of oocytes retrieved was not found to have a statistically significant effect on euploidy rate when analyzed per number of biopsied blastocysts (p=0.5356), per number of oocytes retrieved (p=0.1025), and per number of fertilized oocytes (p=0.7241). AMH and PGT lab were not found to have a statistically significant effect on euploidy rate in any of the three regression models. Regression models showed negative parameter estimate (-0.000929) for number of oocytes retrieved.

CONCLUSIONS: There was a statistically significant effect found in the regression analyses between patient age and embryo euploidy rate, which is already known. A negative trend in euploidy rate was observed in the Tableau visual analytics graphs, especially when number of oocytes retrieved was greater than 25. There is some evidence to suggest that higher number of oocytes retrieved may negatively impact the number of euploid embryos per number of oocytes retrieved based on the visual analytic graphs, p-value approaching significance, and the negative parameter estimate in the regression

models. Further research on the effect of high egg yields on embryo euploidy rates is needed.

P-534 4:30 PM Monday, October 19, 2020

PREDICTING THE NUMBER OF BIOPSY QUALITY BLASTOCYSTS BASED ON OOCYTES RETRIEVED. Catherine Gordon, MD, Andrea Lanes, PhD, Kimberly W. Keefe, MD, Catherine Racowsky, PhD, Brigham and Women's Hospital, Boston, MA.

OBJECTIVE: To determine the rate of attrition from oocytes retrieved to biopsy-quality blastocysts formed to aid in patient counseling regarding the decision to proceed with preimplantation genetic testing for aneuploidy (PGT-A).

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Autologous IVF PGT-A cycles performed at our center from 4/2015 to 12/2018 resulting in at least one biopsy-quality blastocyst on either day 5 or 6 were included. Number of oocytes, mature oocytes (MII), zygotes (2PN), blastocysts, and biopsy-quality blastocysts were assessed. Data were stratified by age and adjusted for AMH and BMI. Relative risks (RR) and 95% confidence intervals were calculated using Poisson regression. GEE modeling was used to account for patients contributing more than one cycle.

RESULTS: 886 cycles from 687 patients were analyzed (See table).

	Age					Total
	<35	35-37	38-40	41-42	>42	
# Oocytes	23.16 ±12.46	19.73 ±11.44	15.00 ±9.38	14.84 ±9.79	12.58 ±7.55	18.85 ±11.26
# MIIs	17.63 ±10.07	15.62 ±9.65	11.53 ±7.45	11.45 ±8.13	9.51 ±5.43	14.54 ± 9.40
# 2PNs	14.35 ±8.57	12.54 ±7.99	8.8 ±6.19	9.07 ±6.7	6.67 ±5.02	11.56 ±7.96
# Blastocysts (%)*	10.33 ±6.61 (44.6)	8.26 ±6.02 (41.9)	5.21 ±4.52 (34.7)	5.38 ±4.52 (36.3)	3.27 ±2.97 (26.0)	7.66 ±6.11 (40.6)
# Biopsy quality blastocysts (%)*	6.85 ±5.07 (29.6)	5.67 ±4.26 (28.7)	3.71 ±3.19 (24.7)	3.18 ±2.84 (21.4)	1.73 ±1.40 (13.8)	5.23 ±4.46 (27.7)

Data expressed as mean ±SD. * % of oocytes

Values for all assessed variables decreased with increasing patient age. As age increased the proportion of oocytes that formed blastocysts ($p<0.01$; trend) and biopsiable blastocysts ($p<0.01$; trend) decreased, especially comparing the 41-42y and >42y groups (blastocysts: 36.3% vs 26.0%; $p<0.01$; biopsiable blastocysts: 21.4% vs 13.8%; $p=0.01$). Adjusting for AMH and BMI revealed no significant change in either number of blastocysts or biopsiable blastocysts for 35-37y vs <35y women (RR 0.95, 95%CI 0.87-1.03 and RR 0.94, 95%CI 0.84-1.06, respectively). However, the number of blastocysts was significantly lower in each group of women over 37y compared to <35y (38-40y RR 0.80 95%CI 0.73-0.88; 41-42y RR 0.82 95%CI 0.73-0.92; >42y RR 0.57 95%CI 0.45-0.71). The age-related decline was even more pronounced for biopsiable blastocysts in the adjusted analysis (38-40y RR 0.79 95%CI 0.70-0.91; 41-42y RR 0.66 95%CI 0.56-0.79; >42y RR 0.42 95%CI 0.31-0.59).

CONCLUSIONS: Blastocyst conversion and the number of biopsy quality blastocysts is inversely correlated with age. After adjusting for AMH and BMI, this trend remained significant for patients aged 38y and older. Women over the age of 37y should be counseled on the high rate of blastocyst attrition with advancing age.

P-535 4:30 PM Monday, October 19, 2020

DOES THE ADDITION OF VAGINAL ESTROGEN IN FROZEN EMBRYO TRANSFER CYCLES WITH LOW SERUM ESTRADIOL LEVELS BUT ADEQUATE ENDOMETRIAL LINING IMPROVE CYCLE OUTCOMES?. Joshua C. Combs, MD,[1] Karrie A. Walker, DO,[1] Peter G. Lindner, MD,[1] Micah J. Hill, DO,[1] Alan H. DeCherney, MD,[2] Mae W. Healy, DO,[1] [1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

OBJECTIVE: To determine, in the setting of an adequate endometrial thickness (≥8mm) prior to progesterone start, if the addition of vaginal estrogen for patients with a serum estradiol level of < 200 pg/mL altered clinical outcomes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All vitrified blastocyst embryo transfers from September 2016 to December 2018 were included. All patients received oral estrace for endometrial preparation followed by embryo transfer on day 6 of progesterone in oil. Only patients with an adequate endometrial thickness of ≥8mm noted on day 14 to 16 were included. Vaginal estrogen (estrace 1mg daily) was added by some providers if the patient's serum estradiol level was <200 pg/mL on that day. Cycles with an endometrial thickness measuring <8mm, and natural cycle frozen blastocyst transfers were excluded from this study. Chi-squared analysis was performed to evaluate for statistical significance between the two cohorts in respect to biochemical pregnancy loss, clinical miscarriage rates, clinical pregnancy rates, and live birth rates.

RESULTS: 164 patient-cycles met inclusion criteria; 85 with vaginal estrogen added, 79 with no vaginal estrogen added. There was no difference

	n	Biochemical Pregnancy Loss	Clinical Miscarriage Rate	Clinical Pregnancy Rate	Live Birth Rate
Vaginal Estrogen Added	85	12(14%)	5(9%)	54(64%)	48(56%)
No Vaginal Estrogen Added	79	7(9%)	10(19%)	52(66%)	41(52%)
p Value		0.49	0.32	0.99	0.84

in biochemical pregnancy loss, clinical miscarriage rates, and clinical pregnancy rates between the two groups (Table 1). Live birth rate was similar between the two groups (56% versus 52%, p=0.84) (Table 1).

CONCLUSIONS: In a vitrified blastocyst embryo transfer cycle, treating estradiol levels < 200 pg/mL with additional vaginal estrogen, in the setting of an adequate endometrial thickness of ≥8mm, does not improve biochemical pregnancy loss, clinical miscarriage rates, clinical pregnancy rates or live birth rates.

SUPPORT: None.

P-536 4:30 PM Monday, October 19, 2020

THIN ENDOMETRIAL LINING DURING FROZEN EMBRYO CYCLES- A CASE-CONTROL STUDY OF RISK FACTORS AND NATURAL HISTORY.

Emily A. Jacobs, MD,[1] Bradley J. Van Voorhis, MD,[1] Karen M. Summers, MPH CHES,[1] Amy E. Sparks, PhD,[2] [1]University of Iowa, Iowa City, IA; [2]University of Iowa Center for Advanced Reproductive Care, Iowa City, IA.

OBJECTIVE: To identify predictors of thin endometrial lining in the first frozen embryo transfer cycles and to characterize the natural history of this condition over subsequent cycles.

DESIGN: Retrospective case-control study

MATERIALS AND METHODS: Cases were patients who had a standard hormonal endometrial preparation cycle (Estrace 6 mg/day in divided doses for a minimum of 12 days) and had their first frozen blastocyst embryo transfer (FET) delayed or cancelled due to thin endometrium (<6 mm) between the years of 2012 and 2018. Controls were the next two consecutive patients undergoing a standard hormonal preparation who did not have a thin endometrium (≥ 6 mm) and proceeded with their first FET. Medical charts were reviewed and demographic data and pertinent medical history was extracted. Multivariable logistic regression was performed to determine predictors of inadequate endometrium in FET cycles. Types of interventions utilized and subsequent endometrial thickness in additional cycles were recorded and the cumulative delivery rate from the initial attempt at FET onwards was calculated and compared with Fishers exact test and Kaplan-Meier survival analysis.

RESULTS: **Risk factors-** This study included 29 cases and 58 controls. Multiple logistic regression analysis of factors related to thin endometrium indicated thinner fresh cycle endometrium and lower body weight were associated with thin endometrial lining in FET cycles. Specifically, for each additional 5 kilograms of weight, the odds of having an endometrial lining under 6 mm decreased by 0.845 (95% CI: 0.717-0.995), and for every 1 mm increase in endometrial thickness in the fresh cycle, women were 0.659 times less likely to have a thin endometrium in the subsequent FET (95% CI: 0.521-0.835). **Natural History-** The mean endometrium during first FET was 4.9 ± 1.1 mm in cases versus 9.5 ± 2.6 mm in controls (p-value <0.001). During first FET, 18/29 cases had their estrogen dose extended. Subsequently, 10/18 were able to achieve an adequate endometrium (mean 7.14 ± 1.5 mm) and had a FET with a live birth rate of 40%. A second FET occurred in 21 cases and 20 controls. The mean endometrium during second FET was 6.2 ± 1.3 mm in cases versus 9.3 ± 2.6 mm in controls (p-value <0.001). Endometrial thickness for cases undergoing a second FET did not differ clinically based on intervention utilized (6.5 ± 1.1 mm with the addition of vaginal estrogen vs. 5.7 ± 2.2 mm with intramuscular estrogen vs. 6.6 ± 0.8 mm with low dose gonadotropin stimulation). There was no statistically significant difference in cumulative live birth rate between cases and controls (55% vs 72% respectively, p-value 0.148), however cases underwent more cycles to achieve live birth (mean number of cycles 3.0 vs 2.1 in control group, p-value 0.013).

CONCLUSIONS: This study shows that prognosis after a diagnosis of thin endometrium is favorable. Lower weight and thinner fresh cycle lining are predictors of thin endometrium in FET cycles. Most importantly, women with a diagnosis of thin endometrium have similar live birth rates as those with adequate endometrium, although their time to achieve live birth is slightly longer.

P-537 4:30 PM Monday, October 19, 2020

EFFECT OF BED REST FOLLOWING SINGLE EUPLOID BLASTOCYST TRANSFER ON PREGNANCY OUTCOMES.

Nancy L. Bossert, PhD,[1] April E. Batcheller, MD,[1] William B. Schoolcraft, MD,[2] Hannah Van Der Geest, BS,[1] Jason E. Swain, PhD, HCLD,[3] [1]CCRM Minneapolis, Edina, MN; [2]CCRM Colorado, Lone Tree, CO; [3]CCRM IVF Network, Lone Tree, CO.

OBJECTIVE: Recommending bed rest following embryo transfer was a common practice in ART. More recent publications suggest no positive impact of bed rest and even a possible detriment. Prior studies examined short time periods prior to ambulation and did not utilize a strong model to control for embryo stage or quality. The objective of this study was to examine whether extended bed rest following frozen embryo transfer using a single euploid blastocyst had any impact on subsequent pregnancy rates.

DESIGN: Retrospective data analysis

MATERIALS AND METHODS: Standard laboratory practice entailed 30-60 minutes of bed rest following embryo transfer in the procedure room, with extended bed rest the test of the day once leaving the office. This practice was stopped for 2 months and patients were permitted to ambulate immediately with no bed rest recommendation. Outcomes from frozen embryo transfers using a single euploid blastocyst with no bedrest were compared to the same type of frozen embryo transfers from the preceding 6 months with bed rest, as well as to the same 2 month time period 1 year prior with bed rest. All frozen embryo transfers utilized a single blastocyst of at least 3BB quality. No laboratory culture procedures or transfer procedures were changed during this time and examination of the 2 control time periods with bed rest were selected to try to control for other possible variables. Groups were compared using ANOVA and pairwise comparisons.

RESULTS: No significant differences were apparentl in the examined patient demographics (female age, male age, uterine lining thickness). No significant differences in clinical outcomes were apparent between patients who utilized the bedrest paradigm following single euploid blastocyst transfer compared to those who had no bedrest.

	No Bed Rest	Bed Rest – 1 yr prior	Bed Rest- Prior 6 Months
Not preg	(14/86) 16.3%	(8/50) 16.0%	(25/144) 17.4%
+ hCG	(72/86) 83.7%	(42/50) 84.0%	(119/144) 82.6%
Biochemical	(14/72) 19.4%	(5/42) 11.9%	(18/119) 15.1%
Clinical Preg	(58/72) 80.6%	(37/42) 88.1%	(101/119) 84.9%
Avg. Female Age	35.2	36.1	35.9
Avg. Male Age	37.3	37.2	37.8
Avg. uterine lining	9.88	10.5	9.85

CONCLUSIONS: Stopping the practice of extended bedrest following transfer of a frozen/thawed single, high quality euploid blastocyst had no statistically significant impact on the clinical outcomes measured in this study. This has implications for clinical workflow related to embryo transfer procedures.

P-538 4:30 PM Monday, October 19, 2020

DO INSULIN-LIKE GROWTH FACTOR (IGF-1) LEVELS IN INFERTILITY PATIENTS AFFECT IVF OUTCOMES?.

Norbert Gleicher, MD,[1] Sarah K. Darmon, PhD,[2] David F. Albertini, PhD, MS,[3] Emanuela Molinari, PhD,[2] Pasquale Patrizio, M.D.,[4] David H. Barad, MD, MS,[2] [1]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY; [2]Center for Human Reproduction, New York, NY; [3]Bedford Research Foundation, Boston, MA; [4]Yale Fertility Center, New Haven, CT.

OBJECTIVE: Since IGF-1 serves as a major effector of growth hormone (GH)-stimulated somatic growth, to determine whether peripheral IGF-1 levels in infertile women prior to IVF cycle start are predictive of IVF outcomes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We here report on 978 consecutive patients undergoing 1033 IVF cycles at our center between 2018-2020 who, indiscriminately, had peripheral IGF-1 level determinations at time of initial presentation as part of an initial work-up. IGF-1 was tested immunochemiluminometric by commercial assay (LabCorp, Burlington, NC), with normal range for all ages defined as 78-270ng/mL. Patients on human growth hormone (HGH) supplementation and repeat cycles were excluded from the study. Ultimately, 302 (29.2%) fresh non-donor cycles qualified as final study population. Based on IGF-1 levels, these women were divided into 3 subgroups representing lower 25thpercentile (Group A, <132ng/mL, n=64),

25th-75thpercentile (B, 132-202ng/mL, n=164) and upper 25thpercentile (C, >202ng/mL, n=74). Study endpoints were cycle cancellations, oocytes retrieved, embryos transferred, pregnancies and live births after adjustments for age.

RESULTS: IGF-1 distribution was Gaussian. Patients in the lowest IGF-1 quartile (Group A)) were significantly older (43.0 ±4.8 years) than those in mid-range (Group B, 41.3 ±4.9 years) and highest quartile Group C (40.7 ±5.6 years; P=0.019). IGF-1 levels were age dependent. Linear regression revealed that IGF-1 levels decreased with increasing age 2.2 ±0.65 ng/mL per year (P=0.0007). Though not statistically different, trends of ovarian reserve parameters were the best in B (FSH 17.3 ± 17.8 vs. A, 24.8 ±35.3 and C, 18.1 ± 20.6 mIU/mL; P=0.085; AMH 1.4 ± 3.3 vs. A, 0.7 ±1.2 and C, 1.0 ± 1.6; P=0.200). Cycle cancellations were statistically the lowest in C (11.6%), the highest in A (25.0%) and in mid-range in B (13.5%; P=0.042). Oocytes, transferred embryos, pregnancy and live birth rates did not differ significantly, though oocyte numbers trended the highest in B (5.2 ± 5.4 years) vs. 3.6 ± 5.4 (A) and 4.5 ± 5.0 (C). Adjusting statistical assessments for age, the difference of cancelled cycles remained significant (P=0.021), while all other outcome, likely because of too small patient numbers, remained non-significant.

CONCLUSIONS: This study hints at best effects on outcomes of baseline IGF-1 on IVF at mid-range of 132-202 ng/mL, representing lowest cycle cancellations. The study, thus, warrants further exploration of HGH supplementation in women with low IGF-1 levels, usually mostly older patients. Cautious interpretation of here presented results is, however, advised since they in general reflect patients of very advanced ages. Low pregnancy and live birth rates in such patients, moreover, likely, prevented adequate power to inform on pregnancy and live birth rates.

P-539 4:30 PM Monday, October 19, 2020

COMPARING IVF OUTCOMES AND PROVIDER ASSESSMENT OF PATIENT TOLERANCE DURING OOCYTE RETRIEVAL PROCEDURES USING CONSCIOUS SEDATION VERSUS MONITORED ANESTHESIA CARE.

Nischelle Kalakota, MD,[1] Andrea Starostanko, M.D.,[2] Abhinav Hasija, BS, MS,[3] Kurt Peterson, DO,[4] Suruchi Thakore, MD,[5] [1]UC Medical Center, Cincinnati, OH; [2]University of Cincinnati Center for Reproductive Health, West Chester Township, OH; [3]The Ohio State University- Fisher College of Business, Columbus, OH; [4]University of Cincinnati, Cincinnati, OH; [5]University of Cincinnati Medical Center, West Chester, OH.

OBJECTIVE: As in vitro fertilization becomes more widely utilized to treat infertility, oocyte retrieval has become one of the most common minor surgical procedures. With adequate pain control, complete patient immobilization can be achieved, thus improving provider ease.[1] No previous studies have investigated the differences in IVF outcomes, provider ease and patient tolerance for conscious sedation (CS) with midazolam and fentanyl versus monitored anesthesia care (MAC) with propofol.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: A questionnaire was used to document providers' opinions regarding ease of procedure, patient movement and discomfort during oocyte retrievals at the UC Center for Reproductive Health (CRH). The surveys were utilized for a quality improvement project during the transition from CS to MAC from January 2018 to May 2019. After obtaining IRB approval, data was collected regarding the patient's reported level of pain and nausea post procedure, cycle information, oocyte retrieval outcomes and pregnancy rates. Provider assessments and IVF outcomes were compared between the two groups (CS vs MAC). Statistical analysis was performed using multivariate linear and logistic regression using R software, with $p<0.05$ considered significant.

RESULTS: A total of 101 patients were included in the study. Anesthesia during oocyte retrieval was conducted with either CS (n=48) or MAC (n=53). Patient demographics regarding medical diagnosis, cycle information, BMI and age were similar in both anesthesia groups. No statistical difference was found in the number of oocytes retrieved when comparing anesthesia type (p=0.06) or provider score regarding procedure difficulty (p=0.13). A higher BMI predicted increased procedure difficulty amongst both anesthesia types (p=0.001). However, this trend was mitigated in higher BMI patients when using MAC versus CS (p=0.053). Patient reported postoperative pain and nausea were also similar between the types of anesthesia (p=0.54 and p=0.72, respectively). Lastly, no difference in pregnancy outcome was found between anesthesia groups (p=0.63).

CONCLUSIONS: No differences were found between CS and MAC during oocyte retrieval regarding provider ease, patient tolerance or IVF outcomes. Although many fertility clinics have adopted MAC, CS appears to be a suitable alternative for those without readily available anesthesia providers and may be a more cost-effective option. However, consideration should be given to using MAC in higher BMI patients.

PREDICTIVE FACTORS OF AT LEAST ONE EUPLOID EMBRYO ON CUMULATIVE LIVE BIRTH RATES IN PATIENTS 40 YEARS AND OLDER UNDERGOING PRE-IMPLANTATION GENETIC TESTING FOR ANEUPLOIDY.

Benjamin Yoones Zaghi, M.D.,[1] Baruch Abittan, M.D.,[2] Gabriel San Roman, II, MS,[3] Gabriel San Roman, MD,[4] [1]Northwell Health Southside Hospital, Bay Shore, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [4]North Shore University Hospital, Manhasset, NY.

OBJECTIVE: In vitro fertilization (IVF) is the recommended first-line treatment of infertility for patients aged 40 and older. However, patients often have a rapidly-declining ovarian reserve and exponentially increasing rate of aneuploidy embryos. We set out to investigate whether the embryonic ploidy outcome of a patient's first cycle is predictive of her cumulative live birth rate (CLBR) from IVF, and if markers of ovarian reserve can aid in that prediction.

DESIGN: Retrospective cohort study of IVF with preimplantation genetic testing for aneuploidy (PGT-A) at an academic fertility center from 2015-2019.

MATERIALS AND METHODS: 298 women age 40 to 45 undergoing their first autologous IVF cycle with PGT-A were included. Anti-mullerian hormone (AMH) and follicle-stimulating hormone (FSH) levels were measured prior to ovarian stimulation. The cycle protocol was individualized to each patient by their respective physician. PGT-A was performed by one laboratory on trophectoderm biopsies from expanded blastocysts. The study patients' cumulative live birth rate (CLBR) was defined as the probability of a live birth from all cycles (first, and subsequent) during the study period. Descriptive statistics, Mann-Whitney U, and tests were computed; $p<0.05$ was considered significant.

RESULTS: Of the 298 women undergoing IVF-PGT-A, 47% resulted in at least one euploid embryo. Younger age and higher AMH levels were associated with at least one euploid embryo ($p<0.001$ and $p<0.001$, respectively). FSH levels did not have a statistically significant effect on producing an euploid embryo ($p = 0.337$). The CLBR was significantly higher in patients who had at least one euploid embryo compared to patients who did not have any euploid embryos (39.3% vs 5.1%, $p<0.001$).

	No Euploid Embryos	At Least One	p
N	158	140	-
Age	41.84	40.84	< 0.001
AMH	1.88	2.78	< 0.001
FSH	8.22	7.77	0.337
CLBR	5.1%	39.3%	< 0.001

CONCLUSIONS: While IVF is the recommended treatment for patients aged 40 and above, the ability to produce at least one euploid embryo in a patient's first cycle is a good prognostic indicator of ability to achieve live birth through autologous IVF.

P-541 4:30 PM Monday, October 19, 2020

OPTIMIZING FROZEN EMBRYO TRANSFER (FET) SUCCESS: IMPROVED SUCCESS IN NATURAL CYCLES WITH THE USE OF HCG TRIGGER DESPITE SIMILAR OVERALL OUTCOMES WITH GONADOTROPIN STIMULATED, NATURAL, AND PROGRAMMED CYCLES. Rhea Chattopadhyay, MD, Rachel S. Weinerman, MD, James H. Liu, M.D., Rebecca Flyckt, MD, Sung Tae Kim, PhD, HCLD, University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH.

OBJECTIVE: To evaluate reproductive outcomes in FET cycles following hormonally programmed cycles vs alternate regimens of gonadotropin stimulated cycles or natural or letrozole-induced cycles. Within natural and letrozole cycles, pregnancy rates with and without hCG trigger to induce ovulation were compared.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All programmed, natural cycle, letrozole, and gonadotropin stimulated FETs from a single academic center from 2017 – 2020 were evaluated. Programmed cycles consisted of oral micronized estradiol 2 mg TID starting day 1 of menses followed by intramuscular progesterone. Gonadotropin stimulated cycles consisted of ovulation induction with FSH and/or hMG starting on Day 1-5 of menses followed by hCG injection ("trigger"), with vaginal or intramuscular progesterone in the luteal phase. Natural cycles involved no medication in the follicular phase, whereas letrozole cycles consisted of letrozole 5 mg cycle day 3-7. For both natural and letrozole cycles, transfer was timed either to the patient's own ovulation as measured by serum LH and progesterone or by ovulation induced by hCG trigger. Vaginal progesterone was used for luteal support. For the primary analysis, natural and letrozole cycles were included together in the natural group. One way- ANOVA was performed to compare baseline variables between cohorts. Chi-square was used to compare pregnancy outcome variables. Fisher's Exact test was used to compare two groups when appropriate due to sample size. A p value <0.05 was considered significant.

RESULTS: A total of 784 FETs were included: 728 programmed FETs, 24 natural cycle FETs, and 32 gonadotropin stimulated FETs. No statistical difference was found between all 3 cohorts based on age, BMI, endometrial thickness, or number of embryos transferred. Clinical pregnancy rates (CPR) or implantation rates (IPR) did not differ between programmed, natural/letrozole cycles, or gonadotropin stimulated FETs (54.3% vs 41.7% vs 59.4%, p=0.4) (46.3% vs 42.3% vs 48.8%, p= 0.9) respectively. Live birth/ongoing pregnancy rates were also not different (43.3% vs 41.7% vs 56.3%, p=0.3). Additionally, miscarriage rates did not differ between groups (10.3% vs 0% vs 3.1% p = 0.1). A subset analysis of natural cycle FETs showed no difference in letrozole induction versus spontaneous ovulation CPR (40% vs 42.9%, p=0.99), however natural/letrozole cycles with hCG trigger were associated with an increase in CPR (75% vs 25%, p=0.032).

CONCLUSIONS: Our center utilizes stimulated FET cycles as an alternative for patients who do not achieve appropriate endometrial growth with traditional programmed FET. Our findings suggest stimulated FET cycles can be a successful alternative for patients whose lining is not appropriate in a programmed FET cycle. We use letrozole or natural cycle FETs in patients for whom a programmed or stimulated FET is not appropriate, with similar success rates. However, our study suggests use of an hCG trigger may improve outcomes in natural or letrozole cycles.

P-542 4:30 PM Monday, October 19, 2020

LESSONS LEARNED FROM A 10 YEARS CRYOEMBRYO VITRIFICATION PROGRAM: THE AGE OF THE OOCYTE MATTERS. Carmen Vidal, M.D., Ph.D.,[1] Juan Giles, M.D., Ph.D.,[2] Guillermo Mollá Robles, M S,[3] Ma José de los Santos, PhD,[1] Jose Remohi, MD PhD,[1] Ana Cobo, PhD,[1] [1]IVIRMA Valencia, Valencia, Spain; [2]IVI-RMA Valencia, Valencia, Spain; [3]IVI Foundation, Health Research Institute La FE, Valencia, Spain.

OBJECTIVE: Embryo vitrification has been a breakthrough in assisted reproduction (ART), allowing higher cost-effectiveness of ART cycles by offering a higher number of embryos to be transferred per cycle, given the high survival rate of these embryos. The best-Known prognostic factor for success in fresh ART cycles is the oocyte's age (OA). Our objective is to analyze the influence of OA in the outcome of cryotransferences (CTs) conducted with vitrified embryos.

DESIGN: Retrospective cohort study in a university- affiliated infertility center.

MATERIALS AND METHODS: Ongoing pregnancy rate (OPR) and live birth rate from n= 9246 women undergoing 14442 CTs from January 2007 and December 2017 (6199 from egg donation, 8243 from own oocytes) involving 22263 Emb vitrified, was analyzed depending on the OA. $\chi 2$ test was used for pregnancy rates comparisons. A logistic regression was performed with live birth rate as the response variable and the OA, adjusting for patient age and BMI as well as for the type of CTs, and special analysis was performed considering only OA less than 36 and considering the origin of the eggs. Data are presented as means or proportions (95% confidence intervals).

RESULTS: Total mean OA the day of fertilization of the embryos was 30.78 y (30.69-30.87), from donated CTs OA was 25,90 (25.79-26.01), own oocytes CTs OA 34,45 (34.37-34.52), and mean receiver's age 38.03 y, embryo survival 97,29 %(97.13-97.46), 1.84 embryos warmed (1.81-1.85), 1.54 embryos transferred (1.53-1.55). Biochemical pregnancies, clinical pregnancy, and OPR/warming cycle were 54,29 %(53.47-55.10), 44.55%(43.74-45.37), and 35.09 %(34.31-35.88).

According to the model, for each year-increase in the OA, the odds of achieving a live birth rate (LBR) decrease by 1.83 % (OR 0.981.95 % CI 0.97-0.99, p< 0.001). In the younger group (until OA 35 y), the change from donated to own oocytes was found to have a statistically significant effect (OR 0.85 CI 95 %; 0.78-0.06, p=0-01), diminishing the odds of having an OPR by 14%.

CONCLUSIONS: OA is a key prognostic factor in the outcome of vitrification CTs program. OA yields a clear annual negative impact on OPR. In younger OA group, the fact that they come from egg donors and not from own oocytes equally affects the results. Increasing the number of embryos transferred should be taken in consideration for elder women according to these data.

SUPPORT: none.

P-543 4:30 PM Monday, October 19, 2020

TROPHECTODERM MORPHOLOGY IN EUPLOID EMBRYOS IS RELATED TO INFERTILITY DIAGNOSIS AND PREGNANCY OUTCOME AFTER TRANSFER. Nicole D. Ulrich, MD,[1] Ashley Hesson, MD, PhD,[2] Anne Waldo, MS,[3] Erin Inman, M.D.,[2] Micaela J. Stevenson, BS,[4] Molly B. Moravek, MD, MPH,[3] Samantha B. Schon, MD, MTR,[1] Min Xu, Ph.D,[3] [1]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI; [2]University of Michigan, Obstetrics and Gynecology, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI; [4]University of Michigan Medical School, Ann Arbor, MI.

OBJECTIVE: A number of studies have shown that both day 3 and day 5 embryo morphology correlates with ongoing pregnancy rate and live birth rate. However, in the era of single euploid embryo transfer, few studies are available regarding effect of inner cell mass (ICM) and trophectoderm (TE) morphology on pregnancy outcomes after euploid transfer. We aimed to evaluate pregnancy outcomes, including live birth, as they relate to embryo characteristics and morphology.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: We reviewed all single euploid embryos transfers in an academic fertility clinic by retrospective chart review from January 1, 2016 through August 31, 2018. Blastocyst morphology was evaluated by Gardner grading system. PGT-A was performed using a next generation sequencing platform. Variables assessed included blastocyst expansion level (EL), ICM grade, TE grade, patient age at retrieval, number of oocytes retrieved, infertility diagnosis, pregnancy (serum hCG), ongoing pregnancy (fetal cardiac activity) and pregnancy outcome. Logistic and linear mixed models with random intercepts to account for within-patient correlation were used to evaluate association between predictors and outcomes. All models were adjusted for age at retrieval and BMI.

RESULTS: We evaluated embryo morphology in 341 single euploid embryo transfers including EL 3-6 (9 embryos were EL 3, 14 EL 4, 285 EL 5, 32 EL 6), ICM grade (136 A and 205 B), and TE grade (94 A, 222 B, 25 C). Pregnancy rate (positive serum hCG/total transfers) was only correlated with TE grade and was significantly lower in TE grade C (40%) transfers when compared to A and B (67%, 73%); (p=0.003, OR 0.3; 0.1-0.6). There was no difference in pregnancy rate between blastocysts frozen on day 5 vs 6. However, after a positive HCG, transfer of day 6 blastocyst was negatively associated with ongoing pregnancy (p=0.02; OR 0.3; CI 0.2-0.7). TE grade, ICM grade, and EL of blastocyst were not predictive of ongoing pregnancy after positive HCG. When TE grade C embryos resulted in pregnancy, subsequent live births were similar at 60% compared to grades

A and B (71%, 62%). Of 12 spontaneous abortions in our cohort, there were none in the TE grade C group; unsuccessful pregnancies in this group were all classified as biochemical. The mean proportion of TE grade C embryos compared to total embryos created per fresh cycle was 17.4%. Unexplained infertility diagnosis was an independent predictor for a higher proportion TE grade C embryos per fresh cycle (p=0.02). There was no correlation between number of oocytes retrieved and proportion of TE grade C embryos.

CONCLUSIONS: Euploid embryos with poor TE morphology occur more often in unexplained infertility. While pregnancy rate and initial HCG level is lower in embryos with poor TE morphology, ongoing pregnancy rates are similar, and live births occur. Setting appropriate expectations is key when counseling patients prior to single euploid embryo transfer. It is important that we understand subtle differences in expected outcomes based on embryo characteristics and morphology.

P-544 4:30 PM Monday, October 19, 2020

CLEAVAGE STAGE OR BLASTOCYST STAGE - WHAT IS THE OPTIMAL STAGE OF FROZEN EMBRYO TRANSFER IN PATIENTS WITH PREDICTED POOR OVARIAN RESPONSE AFTER UNDERGOING IN VITRO FERTILIZATION WITH MILD OR MINIMAL STIMULATION?.

Kimberly Yau, MD,[■] Josette C. Dawkins, MD,[2] David Prokai, MD,[3] Orhan Bukulmez, MD,[2] Zexu Jiao, MD/PhD,[2] [1]UT Southwestern Medical Center, Dallas, TX; [2]UT Southwestern, Dallas, TX; [3]■■■.

OBJECTIVE: To determine outcomes between cleavage versus blastocyst stage frozen embryo transfers (FET) in women with predicted poor ovarian response (POR) after mild/minimal stimulation

DESIGN: Retrospective cohort analysis.

MATERIALS AND METHODS: Women with predicted POR by the Bologna criteria underwent mild/minimal stimulation in vitro fertilization treatment with oocyte retrieval and frozen embryo accumulation, followed by FET at a single academic center from 2012 to 2018. Only first and second FET cycles were assessed. Patients with both blastocyst and cleavage stage transfer across cycles were excluded. 420 FET cycles were reviewed; 88 cycles met inclusion criteria. Statistical analysis was performed using independent t test and χ^2 test as appropriate. $P < 0.05$ was considered statistically significant.

RESULTS: While there was no difference in AMH, the basal FSH was significantly higher, the mean age was significantly older, and the duration of infertility was significantly shorter in the cleavage compared to the blastocyst stage FET group. There was no difference in number of embryos transferred; however, more oocytes were retrieved per stimulation in the blastocyst FET group. There was a 60% live birth rate (LBR) after preimplantation genetic testing (PGT) in the blastocyst FET group, but sample size was small (n=5). Clinical pregnancy rate (CPR) and LBR were higher after blastocyst compared to cleavage stage FET, but differences were not statistically significant. There were no differences in birth weight. Birth defects were not reported in either group.

Table 1

	All cycles	Cleavage stage	Blastocyst stage	*P* value
Age (y)	39.1±3.6	40.6±2.9	38.0±3.7	<0.05 *
BMI (kg/m^2)	26.8±5.0	27.6±5.5	26.1±4.6	NS
AMH (ng/mL)	0.7±0.4	0.7±0.6	0.6±0.3	NS
Basal FSH (IU/mL)	13.2±8.7	17.3±10.8	10.2±4.9	<0.05 *
Gravidity	1.1±1.3	1.0±1.3	1.2±1.3	NS
Months of infertility	41.3±32.8	33.2±15.6	47.1±40.1	<0.05 *
# Oocytes retrieved	3.2±1.7	2.8±1.5	3.6±1.9	<0.05 *
# Embryos transferred	1.7±0.6	1.6±0.5	1.7±0.6	NS
Cycle 1 (n)	67	26	41	
CPR (%)	49.3	34.6	58.5	NS
LBR (%)	41.8	26.9	51.2	NS
Cycle 2 (n)	21	11	10	
CPR (%)	47.6	36.4	60.0	NS
LBR (%)	19.0	9.1	30.0	NS
Birth weight (g)	3351.9±596.5	3537.2±295.8	3283.7±668.4	NS

CONCLUSIONS: There is paucity of data regarding optimal day of FET in POR patients after mild/minimal stimulation due to difficulty in randomization. Counseling should be guided by the patient's age, number of oocytes retrieved, cumulative number of embryos obtained, and other clinical parameters. Although PGT is associated with higher LBR in patients >35, there has been no proven benefit in POR patients. Mild/minimal stimulation remains a useful tool for patients with predicted POR who undertake FET, with acceptable LBR regardless of the stage of embryo transfer.

P-545 4:30 PM Monday, October 19, 2020

EVALUATING THE EFFECTS OF OOCYTE COHORT SIZE AND MATURITY IN ANTAGONIST IVF CYCLES ON FERTILIZATION, CLEAVAGE, BLASTULATION, AND HIGH-QUALITY EMBRYO FORMATION.

Jenna M. Rehmer, MD,[1] Elliott G. Richards, MD,[1] Nina Desai, Ph.D., HCLD,[2] [1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Beachwood, OH.

OBJECTIVE: Study aim was to determine whether number of oocytes retrieved and oocyte maturity rate following antagonist protocol IVF cycle affected the following outcomes: fertilization, cleavage, blastulation, and high-quality blastocyst formation rates.

DESIGN: Single center, retrospective study involving 240 infertile women undergoing a total of 261 completed oocyte retrievals in 2018.

MATERIALS AND METHODS: Based upon prior literature we divided our patients into 3 cohorts, grouped by number of oocytes retrieved: Group 1 with <10 oocytes, Group 2 with 10-15 oocytes, and Group 3 with >15 oocytes. Various predictive factors of high-quality blastocyst formation have been reported. For this study we collected the following data variables: age, BMI, baseline AMH level, TSH, total FSH stimulation dose, use of HCG during stimulation, trigger drug used, estrogen level on day of ovulation trigger, number and size of follicles, number of oocytes retrieved, number of mature oocytes, fertilization rate, cleavage rate, blastulation rate, and rate of high-quality blastocysts. For fertilization and cleavage rates, the denominator was total oocytes retrieved. For blastulation and high-quality blastocyst rates, the denominator was total fertilized. Utilizing total fertilized as our dominator eliminated poor fertilization secondary to lower oocyte maturity as a confounder. Kruskal-Wallis test was used to compare the median rate of variables.

RESULTS: Significant differences between the groups with relation to age at retrieval, baseline AMH, estrogen level day of retrieval, total FSH stimulation dose, and trigger drug administered. These differences were anticipated and reflect known variances in IVF stimulation across the ovarian reserve spectrum.

With regards to cohort maturity, group 3 had significantly less mature oocytes, median rate of 74% mature, compared to group 2 with median rate of 81% of oocytes being mature. When comparing fertilization rate, cleavage rate, and blastulation rate there was no difference between the three groups.

There was significant difference in formation of high-quality blastocyst between group 1 and group 3 with a median rate of 63% and 53% respectively. Group 2 formed high-quality blastocyst 62% of the time, similar to Group 1. However, this was not statistically different from Group 3, likely due to population size.

CONCLUSIONS: Cohorts with >15 oocytes have reduced oocyte maturity. This marker for reduced cytoplasmic maturity is manifesting in a 9-10% lower median rate of high-quality blastocyst formation. Interestingly, the fertilization rate, cleavage rate, and blastulation rate are unaltered in these oocytes. However, additional studies on the implantation potential, ongoing pregnancy rates, and live birth rates is needed to understand if reduced cytoplasmic maturity has additional downstream effects aside from high-quality blastocyst formation. Additionally, our data offer reassurance to women who have lower than average oocyte cohort recruitment. While total oocyte yield is suboptimal, the rate of high-quality blastocyst formation remains high with a median rate of 63%.

BIRTH OUTCOMES FROM ACUPUNCTURE ADDED TO FROZEN EMBRYO TRANSFER (FET) OF AUTOLOGOUS EMBRYOS WITHOUT GENETIC SCREENING: A RETROSPECTIVE COHORT STUDY. Lee Hullender Rubin, DAOM,[1] Carmelo S. Sgarlata, M.D.,[2] Morgan Hogue, MAcOM,[2] Lisa Pate, MAcOM,[2] Elizabeth Richards, MAcOM,[2] Lisa K. Tongel, MAcOM,[2] Hong Jin, DAOM, MD(PRC),[3] [1]Osher Center for Integrative Medicine University of California San Francisco, San Francisco, CA; [2]ORM Fertility, Portland, OR; [3]Oregon College of Oriental Medicine, Portland, OR.

OBJECTIVE: For patients who underwent Frozen Embryo Cycles (FET) of autologous embryos without any genetic screening, our objective was to assess birth outcomes between patients with no known additional therapies compared with the addition of two distinct acupuncture approaches varying in dose (2 sessions or ≥3 sessions) and treatment (standardized or individualized).

DESIGN: Retrospective cohort study of patient charts from a single, private clinic and matched charts from affiliated acupuncturists' clinics.

MATERIALS AND METHODS: The fertility clinic contracted with six acupuncture associates to perform day of embryo transfer acupuncture (ET Acu) onsite. Charts were reviewed of women who completed an FET cycle of autologous embryos with no genetic screening and with or without ET Acu between July 2016 and December 2018. The acupuncturists also extracted data from charts from their community clinics of shared fertility clinic patients who added acupuncture prior to embryo transfer (ET). Data was matched by name and ET date then merged with the fertility clinic database for analysis. Cycles with gestational carriers, donor eggs, no transfer, or embryos with chromosomal screening were excluded. Patient groups were categorized as 1) usual care for women who completed FET alone (UC group); 2) UC and ET Acu of two standardized acupuncture sessions before and after ET (ET Acu group); and 3) UC, ET Acu and acupuncture therapy received in the community prior to ET that included Traditional Chinese Medicine therapies such as diet and lifestyle modifications, warming therapy, or if appropriate, Chinese herbal therapy (TCM group). Comparability between groups was assessed by age and number of embryos transferred. Differences in means were assessed using one-way analysis of variance and proportions by Chi-square analysis. Main outcome measure was live birth.

RESULTS: We identified 275 FET cycles with 181 in UC, 33 in ET Acu, and 61 in TCM. Mean age was not comparable between groups: 35.8 ± 4.6 in UC, 37.6 ± 4.9 in ET Acu, and 37.3 ± 6.0 in TCM (*p=0.04*). The UC, ET Acu and TCM groups were comparable on mean number of embryos transferred (1.48 ± 0.5, 1.42 ± 0.5, and 1.49 ± 0.5, respectively, *p=0.82)*. The proportion of live births by group was 50.5% in UC, 33.3% in ET Acu, and 59.0% in TCM. The association in the proportion of live births between UC and ET Acu groups trended towards significance (*p=0.07*), but there was no difference between UC and TCM (*p=0.25*). However, TCM was associated with more live births when compared with ET Acu (*p=0.02*). Miscarriage rates were 12.5% in UC, 12.1% in ET Acu, and 6.6% in TCM, and no associations were observed with this outcome (UC vs ET Acu *p=0.95*, UC vs TCM *p=0.20*, TCM vs ET Acu *p=0.36)*.

CONCLUSIONS: Three or more acupuncture sessions were associated with more FET live births compared with two sessions in women with unscreened embryos, but not FET alone. These observations are limited by small group numbers of women who differed from those who did FET alone. Future investigations should assess individualized acupuncture in a prospective, randomized trial to determine the appropriate dose of acupuncture needed to support FET.

SUPPORT: No financial support to disclose.

ELECTIVE DOUBLE EUPLOID EMBRYO TRANSFER IN ADVANCED MATERNAL AGE COUPLES – IS THERE A BENEFICIAL ROLE?. Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Vijay Kumar Sharanappa, Sr., MBBS, MD, MCE,[2] Sarvani Bellala, II, M.S. Biomedical Genetics (Spl. in GC) B.S.(BC, BT & HG),[1] Durga Gedela Rao, Sr., MRCOG,[1] Sandeep Karunakaran, Sr., MS, PGDHM, PGDMLE,[1] [1]Oasis fertility, Hyderabad, India; [2]Oasis Fertility, Hyderabad , Telangana, India.

OBJECTIVE: Is there a beneficial role for elective euploid double embryo transfer(e-DET) in Advanced Maternal Age (AMA) couples to optimize reproductive outcomes?

DESIGN: This retrospective case series study was done from May 2014 to May 2019 at a Private Teaching Fertility Clinic. A total of 51 AMA (Age ≥ 37 years) in our study group and 181 young (Age < 37 years) patients in control group underwent Intracytoplasmic Sperm Injection(ICSI), Trophectoderm(TE) biopsy and Next Generation Sequencing(NGS). Patients who at least had two euploid embryo were considered in this study. Based on the number of embryos transferred in Frozen Embryo Transfer cycle (FET) patients were divided into eSET group and eDET group.

MATERIALS AND METHODS: All In-Vitro Fertilization (IVF) patients who underwent Pre-Implantation Genetic Testing for Aneuploidy (PGT-A) were divided into 2 groups depending on number of embryo/s transferred. Decision on the number of embryos for FET was taken by the couples after discussion with the clinicians about the risks and benefits. A written consent was obtained for the same. Reproductive outcomes of the study group were compared with control group.

Group 1 (eSET) – AMA (n = 32) Vs Young (n = 147)

Group 2 (eDET) – AMA (n = 19) Vs Young (n = 34)

Following reproductive outcomes were compared - Implantation Rate (IR), Clinical Pregnancy Rate (CPR), Miscarriage Rate (MR), Multiple Pregnancy Rate (MPR), Live Birth Rate (LBR)

RESULTS: Mean of the Reproductive outcomes with eSET in Study Vs Control group were as follows:

CPR – 65.63% Vs 65.99% (**P = 0.96**)
IR – 68.75% Vs 67% (**P = 0.84**)
MR – 15.63% Vs 10.88% (**P = 0.45**)
MPR – 0% Vs 0.68% (**P = 0.64**)
LBR – 50% Vs 55.10% (**P = 0.60**)

Mean of the Reproductive outcomes with eDET were as follows:

CPR – 78.95% Vs 82.35% (**P = 0.76**)
IR – 47.36% Vs 53% (**P = 0.57**)
MR – 21.05% Vs 14.71% (**P = 0.57**)
MPR – 15.78% Vs 2.94% (**P = 0.09**)
LBR – 57.89% Vs 67.65% (**P = 0.48**)

When considering Euploid embryos for transfer, AMA women or younger women had comparable reproductive outcomes with eSET or eDET.

In spite of transferring two euploid embryos the IR was still lower in eDET group (when compared with eSET) and there was no statistical significance with LBR. Higher multiple pregnancies in AMA group poses higher risk for maternal morbidity and mortality.

AMA women with euploid embryos should be counselled for eSET as there is no added benefit with eDET.

CONCLUSIONS: Transferring two euploid embryos in advanced maternal age women doesn't optimize reproductive outcomes. Even in AMA women eSET policy is recommended.

IS THERE A CORRELATION BETWEEN ENDOMETRIAL THICKNESS AND IVF OUTCOMES?. Magdalena Decia, MD, Dana Kimelman, MD MS-RSM, Lucia Abulafia, MD, Gabriel A. De la Fuente, MD Centro de Esterilidad Montevideo, Montevideo, Uruguay.

OBJECTIVE: Endometrial thickness (ET) has been traditionally used as predictor of reproductive outcomes in fresh and frozen-thawed embryo transfer (FET) cycles in patients undergoing in-vitro fertilization (IVF). Multiple studies have been conducted to evaluate endometrial thickness as an independent predictor of outcomes. Findings have shown conflicting results. Given the discrepancies in the literature, the aim of this study is to evaluate the relationship between endometrial thickness and IVF outcomes with different endometrial preparation protocols. We hypothesized there is an optimal endometrial thickness value to predict pregnancy.

DESIGN: Retrospective, single center study performed from January 2017 to march 2019.

MATERIALS AND METHODS: Autologous and egg donor FET and fresh egg donor ET cycles were included. Both natural and artificial endometrial preparation protocols were used. Women with known intrauterine anomalies, ectopic and biochemical pregnancies were excluded. For the purpose of the analysis, patients were categorized into 3 groups: autologous FET (n=141), egg donor fresh embryo transfers (n=142 patients), egg donor FET (n=99). Data was obtained from medical records. Endometrial thickness (defined as the distance between the echogenic interfaces of the myometrium) was measured the day progesterone supplementation was initiated (5-6 days before ET). The impact of endometrial thickness on pregnancy (hCG $>$ 20 IU/L), live birth and pregnancy loss rates were analyzed. All analyses were conducted using jupyter-notebooks, with python 3.6 as the main tool for the development of descriptive statistics. A p value $<$0.05 was considered significant. Cutoff values of endometrial thickness were proposed every 1mm, from 5 mm to 11 mm. An optimal endometrial thickness value was proposed as a predictor of pregnancy.

RESULTS: A total of 382 patients were included. Mean age was 38.6 $\pm$ 5.4. The overall pregnancy rate was 49,74%, miscarriage rate 19,47% and live-birth rate 39,5%. The mean endometrial thickness was 8.5 mm (SD: 1.95). The optimal cutoff value for the total n was 8.0 mm (p=0.013). For fresh and frozen egg donor cycles endometrial thickness cutoff was $\geq$8.5mm (p=0.036 and p=0.002 respectively). In autologous oocyte FET there was no significant difference in pregnancy (p=0.22), miscarriage or live-birth rates. Our data does not show a cutoff value to predict miscarriage or live birth. When submitted to a multivariate logistic regression analysis in which demographic variables where included (i.e age, number of oocytes retrieved, MII oocytes, number of fertilized oocytes, number of blastocysts available), endometrial thickness no longer remained as an independent predictor of pregnancy rates (p=0.43).

CONCLUSIONS: Our results show pregnancy rates increase when endometrial thickness is $\geq$8.5mm in egg donor cycles. This finding no longer remains significant after controlling for potentially relevant confounders, this finding may be due to the small sample. Further research is needed to elucidate if endometrial thickness is a critical predictor of pregnancy rates and live birth.

P-550 4:30 PM Monday, October 19, 2020

MICROFLUIDIC SPERM SORTING VS. DENSITY GRADIENT: A PRELIMINARY ANALYSIS EXAMINING EMBRYO GRADE AND PREGNANCY OUTCOMES IN IVF-ICSI CYCLES USING VARYING SPERM SELECTION METHODS. Zoran J. Pavlovic, M.D.,[1] Megan R. Sax, MD,[2] Alex Tawa, B.S.,[3] Lauren Grimm, M.A.,[4] Nepheli I. Raptis, B.A., M.A.,[4] Jessi Anderson, MPH,[4] Emma Radley, M.A.,[4] Hanna Mandell, M.A.,[4] Christy Oso, B.A.,[4] Angeline Beltsos, MD,[4] Roohi Jeelani, MD,[4] [1]Rush University Medical Center, Chicago, IL; [2]University of Cincinnati and Cincinnati Children's Medical Center, Cincinnati, OH; [3]Midwestern University Chicago College of Osteopathic Medicine, Downers Grove, IL; [4]Vios Fertility Institute, Chicago, IL.

OBJECTIVE: To determine differences in embryo quality and clinical pregnancy rates in cycles using microfluidic sperm sorting as compared to cycles using density gradient centrifugation.

DESIGN: Male factor infertility is estimated to be the sole cause of infertility in nearly 20% of couples. In the presence of normal semen parameters, male infertility may be overlooked. DNA fragmentation tests have been recently utilized to allow for a more comprehensive analysis of male factor infertility for ongoing unexplained infertility and to evaluate sperm quality. Microfluidic sperm sorting methods may allow for selection of healthy sperm, including those with less DNA fragmentation and reactive oxygen species. This is a promising area of investigation to improve pregnancy rates and clinical outcomes for couples undergoing assisted reproductive technologies (ART).

MATERIALS AND METHODS: A retrospective cohort analysis was performed on patients who underwent density gradient IVF-ICSI cycles followed by microfluidic sperm sorting IVF-ICSI cycles. Baseline characteristics included paternal and maternal age, BMI, primary infertility diagnosis and semen analysis. The primary outcome was embryo grade using the Gardner scale that was organized into high (3-6 AB or AA), medium (2-6 BB or BA) and low grade (any embryo with an Expansion Grade of 1 as well as 2-6 BC, CB or CC) groups. The secondary outcome measured was clinical pregnancy rate. Results were analyzed by chi-square test of association.

RESULTS: Patients that underwent both density gradient and microfluidic sperm sorting IVF-ICSI cycles were identified. Within this patient population, 373 and 376 MII oocytes underwent ICSI with microfluidic and density gradient selected sperm, respectively. 73.5% (274/373) of microfluidic IVF-ICSI embryos and 74.2% (279/376) of density gradient IVF-ICSI embryos developed to day 4 of incubation before being classified as either arrested/morula or receiving a grade. All embryos that did not incubate past day 3 were excluded from analysis. There was no significant difference in the quantity of embryos that developed beyond a day 4 morula/arrested classification and achieved blastocyst status between the two groups. Similarly, there was no significant difference between the two groups in terms of the number of embryos that were cryopreserved (34.3% vs. 30.0%), transferred (4.7% vs. 5.0%) or discarded (65.7% vs. 70.0%), respectively. When comparing embryo quality there was no significant difference between the number of blastocysts rated as high (29.4% vs. 25.2%), medium (36% vs. 29.5%) or low

(34.6% vs. 45.3%) quality between the two groups. Finally, out of the embryos that were transferred, only 23% (3/13) in the microfluidic group and 7.1% (1/14) in the density gradient group achieved a clinical pregnancy which was not a statistically significant difference.

CONCLUSIONS: There is no significant difference in embryo quality or clinical pregnancy rate between microfluidic sperm sorting IVF-ICSI vs. density gradient selected IVF-ICSI cycles. Both methods are promising options to improve clinical outcomes for patients undergoing ART.

THE EFFECT OF MODIFIABLE RISK FACTORS ON IMPLANTATION SUCCESS FOLLOWING IN-VITRO FERTILIZATION: A RETROSPECTIVE COHORT.

Emily E. Lenk, MD,[1] James W. Akin, Jr. MD,[2] [1]University of Kentucky, Lexington, KY; [2]Bluegrass Fertility Center, Lexington, KY.

OBJECTIVE: The objective of this study was to examine how modifiable factors, specifically Body Mass Index (BMI) and smoking status, impact the ability to generate a serum detectable pregnancy following in-vitro fertilization (IVF) treatment.

DESIGN: This is a retrospective cohort study over nine years of IVF data from a fertility clinic in Lexington, KY.

MATERIALS AND METHODS: Over 1200 patients with age range 24-44years old and BMI range 17-47 were analyzed over 9 years. They were divided into current smoker and current non-smoker. Both fresh and frozen embryos were used, and the number transferred in each cycle was 1-3 embryos. Pregnancy was defined as a positive serum beta human chorionic gonadotropin (hCG) greater than 5mIU/mL at 2 weeks after egg retrieval. Those who used egg donors, had Ovarian hyper-stimulation syndrome, or lacked data on the factors of interest were excluded. A logistic regression model, including BMI, smoking status, and age as potential explanatory variables was used with p-value of less than 0.05 considered significant. All analyses were completed in SAS 9.4

RESULTS: As expected, there was an effect of age on pregnancy success as defined by a positive beta hCG and was included in the final data. However, the results show no significant impact of BMI or smoking status on pregnancy success following IVF. The results are summarized in the table below:

Factor	Test Statistic (Degrees of Freedom), p-value	Odds Ratio Estimates, with 95% confidence interval
BMI	$X^2(1) = 0.00$, (p= 0.9530)	1.000 (0.981, 1.020)
Smoking	$X^2(1) = 1.39$, (p= 0.2384)	1.296 (0.842, 1.992)
Age	$X^2(1) = 25.02$, (p= <0.0001)	0.938 (0.915, 0.962)

CONCLUSIONS: There are numerous factors that influence the fertility potential for a woman. Many of these are out of their control including; ovarian reserve, tubal factor, uterine factor, and male factor. However, there are also modifiable lifestyle factors that have been previously shown to impact fertility, including Body Mass Index and smoking status. The fact that both elevated BMI and smoking has resulted in altered follicular fluid contents with increased leptin and cotinine levels respectively, suggests that this could also impact the molecular ability of the oocyt to function and implant. However, because no significant difference was found between BMI nor smoking status on the resulting early pregnancies following IVF, this suggests that these modifiable lifestyle factors may have greatest impact on maintaining a pregnancy, but not necessarily as important for actual implantation and establishment of a pregnancy.

P-552 4:30 PM Monday, October 19, 2020

A MODIFIED PROGESTIN PRIMED OVARIAN STIMULATION PROTOCOL FOR PREDICTED POOR RESPONDERS IN IVF/ICSI.

He Cai, M.D., Li Tian, M.D., Ting Wang, M.D., Juanzi Shi, M.D., Ph.D. Northwest Women's and Children's Hospital, XI'AN, China.

OBJECTIVE: A novel modified progestin primed ovarian stimulation (mPPOS) protocol (administrating medroxyprogesterone acetate (MPA) in the late follicular phase) has been described to adequately prevent premature ovulation and yield comparable number of retrieved and vitrified oocytes in oocyte donor cycle. The aim of the study was to test the hypothesis that a low-cost regimen of mPPOS is similarly effective or only slightly worse than GnRH-antagonist regimen in predicted poor ovarian responders.

DESIGN: A prospective cohort study associated with a cost-effectiveness analysis.

MATERIALS AND METHODS: Infertile women with less than 10 antral follicles undergoing planned freeze-all cycles were recruited. Ovarian stimulation was started with 150-225IU of gonadotropin on the second day of cycle. Each eligible patient could choose whether to undergo either a single cycle of the mPPOS or GnRH antagonist regimen. MPA (10 mg) or GnRH antagonist (0.25 mg) (mPPOS group/GnRH antagonist group) was given daily when the leading follicle reached 14 mm and continued until the day of ovulation trigger. Viable embryos were cryopreserved for later frozen-thawed embryo transfer in both groups. Multiple linear regressions analysis was performed to search for a correlation between individual characteristics and the number of retrieved oocyte. Primary outcome was the number of oocytes retrieved. Secondary outcomes included the incidence of premature LH surge, duration of stimulation, total gonadotropin use, embryological laboratory outcomes and direct medical costs.

RESULTS: We included 53 eligble women who had stimulation cycle performed with either a mPPOS (n=26) or an antagonist (n=27). The number of oocytes retrieved and viable embryos were similar between two groups (5.0±4.0 vs 4.8±3.6; 2.9±2.7 vs 2.4±2.1; P>0.05). No significant differences were observed in the duration of stimulation and total gonadotropin consumption. No premature LH surge occurred in either group. Only female age ($p = 0.001$) was associated with the number of retrieved oocytes in the multiple regression model. In the cost-effectiveness analysis, the mPPOS protocol was strongly dominant over the antagonist protocol.

CONCLUSIONS: Progestin used later is feasible and effective in ovarian stimulation for predicted poor ovarian responders without intent to fresh embryo transfer. Current GnRH antagonist and mPPOS protocols were associated with similar results but the economic analysis was in favor of latter one. There was no statistically significant difference might be due to the sampling size. Large randomised controlled trials are needed to further confirm.

P-553 4:30 PM Monday, October 19, 2020

ROLE OF BLASTOCYST MORPHOLOGY IN PREDICTING CLINICAL OUTCOMES IN SINGLE FROZEN BLASTOCYST TRANSFERS. Gaurav Majumdar, MCE, PhD, Sonal Sehgal, MBBS, MD, Sir Ganga Ram Hospital, New Delhi, India.

OBJECTIVE: To assess the value of individual blastocyst morphological parameters in predicting clinical outcomes in single frozen blastocyst transfers.

DESIGN: A retrospective cohort study in which, 1046 frozen embryo transfers (FETs), performed between June 2015 and June 2019, were analyzed.

MATERIALS AND METHODS: Only autologous, single, frozen blastocyst transfers with female age $\leq$ 38 years were included in the analysis. Those FET cycles were excluded in which, either, partially damaged blastocysts or blastocysts that failed to show any re-expansion post warming, were transferred. All frozen thawed blastocysts included in the analysis were originally graded prior to vitrification, on day 5 or 6 of culture, on the basis of morphology and individual scores were assigned to each blastocyst in terms of degree of expansion, inner cell mass (ICM) and trophectoderm (TE) cells using the Gardner and Schoolcraft scoring system. Multi-collinearity test and logistic regression analysis was used to study the relationship between blastocyst morphology and FET cycle outcomes.

RESULTS: Univariate analysis showed that there is very little correlation between blastocyst morphology and the likelihood of implantation or that of a pregnancy loss, subsequently. Multivariate analysis showed that implantation rates were highest when a blastocyst with the following combination, having degree of expansion = 5, ICM = A and TE = A, was transferred. For all other combinations, little or no association was observed with both, implantation rates and pregnancy loss rates. Outcome prediction using logistic regression showed that grade 5 hatching blastocyst was the only statistically significant variable in predicting implantation. Prediction accuracy of 55.1% and 33.8% was observed for implantation and pregnancy loss, respectively.

CONCLUSIONS: Our data shows that none of the parameters used to assess morphology were predictive of implantation for frozen blastocysts. The pregnancy loss rates were also found to be same irrespective of morphology or degree of expansion. Prediction accuracy of 33% for pregnancy loss showed that blastocyst morphology in no way governed the clinical likelihood of a pregnancy loss.

P-554 4:30 PM Monday, October 19, 2020

PLATELET RICH PLASMA (PRP) CAN IMPROVE PREGNANCY OUTCOME IN PATIENTS WITH RECURRENT IMPLANTATION FAILURE (RIF) AND THIN ENDOMETRIAL LINING. Janelle M. Jackman, MBBS,[1] Shelena Ali-Bynom, M.D., M.P.H,[2] Alex Amberg, M.D.,[2] John Zhang, MD, PhD,[3] Lana Lipkin, M.D.,[3] Meir Olcha, M.D.,[3] Zaher Merhi, MD, HCLD,[3] [1]New Hope Fertility Center, New York, NY; [2]The Brooklyn Hospital Center, Brooklyn, NY; [3]SUNY Downstate University and New Hope Fertility Center, New York, NY.

OBJECTIVE: Autologous PRP has recently had a considerable attention as a new modality in assisted reproductive technology. PRP contains many chemicals such as growth factors, cytokines, chemokines, adhesive proteins, and integral membrane proteins that contribute to cell growth and proliferation. This study aimed to report the efficacy of autologous intrauterine PRP on clinical pregnancy rate (CPR) in patients with history of recurrent implantation failure and in women with persistently thin endometrial lining thickness (EMT) following frozen single embryo transfer (ET)

DESIGN: Retrospective data analysis at a large fertility center with university-based affiliation.

MATERIALS AND METHODS: Women (n=16) with recurrent implantation failure (3 or more failed ET) or with more than two cancelled ET cycles due to thin EMT (<7 mm) were included. Women with any known endometrial problem such as Asherman's syndrome, congenital uterine anomalies or any known causes of implantation failure were excluded from the study. The PRP (0.5- 1 mL) was prepared from the patient's own peripheral blood using centrifugation techniques and infused by catheter inside the uterus 2-3 days prior to the ET. Vaginal progesterone was used for luteal phase support. CPR was calculated following the PRP infusion with clinical pregnancy defined as the presence of a fetal heartbeat at 6-7 weeks of gestation. Data are expressed as mean $\pm$ sem. Chi-square test was performed for comparison of CPR before and after PRP infusion.

RESULTS: The 16 patients who met the inclusion criteria had CPR of 0% in the cycle treatment before PRP intrauterine infusion. The age of all the participants was 41.8 $\pm$ 1.3 years. 13 patients had ET at the blastocyst stage and 3 patients had ET at the cleavage stage of embryo development. The EMT on the day vaginal progesterone was started ranged from 5-10 mm (7.3 $\pm$ 0.4 mm). Of the 16 patients, 31.2% had positive serum b-HCG levels; 80% of which had an ongoing clinical pregnancy ($p<0.05$ compared to CPR before PRP) and 20% had an early spontaneous miscarriage or a chemical pregnancy.

CONCLUSIONS: These preliminary data suggest that PRP intrauterine infusion can improve pregnancy outcome in women with recurrent implantation failure or persistently thin EMT. Larger randomized clinical trials are needed to confirm our findings and further basic science research is needed to determine the exact mechanism by which PRP improves endometrial receptivity.

P-555 4:30 PM Monday, October 19, 2020

ASSOCIATION BETWEEN AGE AND ESTRADIOL/ PROGESTERONE INDEX WITH GOOD QUALITY BLASTOCYSTS. Marianna Pérez-Vargas, M.D.,[1] Jose I. Obeso Montoya, PhD,[1] Roberto Santos, M.D.,[1] Patrizio Pasquale, MD, MBE, HCLD,[2] Arnoldo Gonzalez, M.D.,[3] Salomon Alvarado, MD,[1] Edelmiro Garza-Padilla, M.D.[1] [1]IECH, Monterrey, NL, Mexico; [2]Yale Fertility Center, Orange, CT; [3]RESIDENTE SEGUNDO AÑO, MONTERRY, NL, Mexico.

OBJECTIVE: To determine if female age and the estradiol/progesterone index measured on the day of hCG administration is a predictive factor for blastocyst quality.

DESIGN: A retrospective, cross-sectional, and descriptive study.

MATERIALS AND METHODS: Patients attending our private fertility clinic between January 2018 and December 2019 were included and factors as female age (up to 39 years old), AMH, number of MII oocytes, fertilization rate, number and quality of blastocyst-stage embryos (using the Istanbul Consensus scoring system) were evaluated. Male factor and women with diminished ovarian reserve were excluded. The estradiol/progesterone index was determined on the day of hCG administration by calculating the progesterone value multiplied by one thousand and dividing the estradiol value over the progesterone result. The analysis used a multivariable regression model and receiver operator curve to evaluate the association between the clinical parameters.

RESULTS: Seventy-four cycles and 181 blastocyst-stage embryos were evaluated. The proportion of the cases were 39 ICSI (53%), 17 IVF (23%), and both 18 (24%). The factors associated with the presence of two or more optimal embryos in the sample were patient age under 35 years (ROC = 0.6243), estradiol over 1895 ng/dL (ROC = 0.6511), and an estradiol / progesterone index greater than 5.4 (ROC = 0.6194). Including the variables mentioned above, using a multivariate logistic regression model (ROC = 0.7107, SPE 79.31%, SEN 63.93%) it was possible to predict those patients that would have at least two good quality embryos. AMH after the logistic regression model had a non-relevant, low positive correlation.

CONCLUSIONS: Patient's age, the estradiol, as well as the estradiol/progesterone index, measured on the day of hCG administration, can provide a valid indicator to predict blastocyst development and embryo quality. To validate this model a prospective study is currently planned.

GNRH ANTAGONIST AND LETROZOLE CO-TREATMENT IN NORMAL OVARIAN RESERVE PATIENTS. Tingting Li, Doctor Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the clinical value of letrozole in IVF-ET for normal ovarian reserve patients who were treated using GnRH antagonist protocol.

DESIGN: A retrospective study.

MATERIALS AND METHODS: Patients underwent firs or second IVF-ET cycle, with age between 22-38 years old, AMH between 1.1-3.6ng/ml, FSH<10U/L, AFC>6, were involved. The 867 cycles were analyzed. All the cycles were divided into 2 groups based on whether use letrozole 5 mg qd*5 in GnRH antagonist protocol: cycles with letrozole (Group A, n=462), cycles without letrozole (Group B, n=405). We compared the basic status of patients and clinical outcomes of the 2 groups.

RESULTS: There were no significantly differences found in age, BMI, AMH, and basal FSH between 2 groups, Group A had significantly lower Gn doses, E_2 levels on trigger day, numbers oocytes retrieved, higher rate of LH increase and progesterone advance. Most importantly, Group A had significantly lower rate of oocyte maturation, 2PN fertilization, high quality embryo, clinical pregnancy. But positive aspects is that Group A had lower OHSS incidence rate (1.93% vs 4.44%).

CONCLUSIONS: Combination of letrozole in antagonist protocal for patients with normal ovarian reserve may have adverse effects on pregnancy rate, oocyte maturation and fertilization. Positive effects are to reduce Gn usage and OHSS incidence.

P-557 4:30 PM Monday, October 19, 2020

LOW LUTEAL SERUM PROGESTERONE LEVELS ARE ASSOCIATED WITH LOWER ONGOING PREGNANCY AND LIVE BIRTH RATES IN ART: SYSTEMATIC REVIEW AND META-ANALYSES. Noemie Ranisavljevic, M.D., Ph.D.,[1] Stephanie Huberlant, M.D., Ph.D.,[2] Marie Montagut, M.D.,[3] Pierre Marie Alonzo, PharmD,[4] Bernadette M. Darné, MD,[5] Solene Languille, PHD,[5] Tal Anahory, M.D., Ph.D.,[1] Isabelle Cedrin-Durnerin, M.D.[6] [1]CHU and University of Montpellier, Montpellier, France; [2]University hospital of Nimes, Nimes, France; [3]Clinique La Croix du Sud, Quint-Fonsegrives, France; [4]Gedeon Richter France, Paris, France; [5]Monitoring Force, Maisons Laffitte, France; [6]Jean Verdier Hospital, bondy, France.

OBJECTIVE: To determine whether ongoing pregnancy (OP), live birth (LB) and miscarriage rates are associated with luteal serum progesterone levels according to the number of corpus lutea (CL): none (artificial cycle for frozen-thawed embryo transfer (FET)), one or few (ovulation induction, intra-uterine insemination, natural cycle for FET) or several (fresh embryo transfer).

DESIGN: Systematic review and meta-analysis prospectively registered (PROSPERO CRD42019139019).

MATERIALS AND METHODS: A systematic review was performed using the following key words: 'ART', 'IVF', 'ICSI', 'IIU', 'ovulation induction/stimulation', 'embryo transfer', 'progesterone', 'follicular phase', 'live birth', 'pregnancy'. Searches were conducted on MEDLINE, EMBASE and the Cochrane Library, from 1990 up to 2019. This study was restricted to published research articles that reported serum progesterone level determined during luteal phase and clinical outcomes (OP or LB). Two independent reviewers carried out study selection, quality assessment using the adapted Newcastle-Ottawa Quality Assessment Scales, bias assessment using ROBIN-1 tools and data extraction according to Cochrane methods. Original author was contacted if required to complete information/data. Using Review Manager 5, independent random-effect meta-analyses were performed according to the number of CL.

RESULTS: Overall 2,366 non-duplicate records were identified, of which 20 relevant studies were available for quantitative analysis. In artificial cycles with no CL (n=7 studies), OP and LB rates were significantly decreased when progesterone level is low compared to optimal progesterone level (risk ratio [RR] 0.63; 95% Confidence interval [CI] 0.49-0.81 and 0.61; 95% CI 0.43-0.86, respectively). The RR for miscarriages was 1.62 (95% CI 1.06-2.47). Only two studies were related to cycles with one or few CL, hence meta-analysis was not conducted. In cycles with several CL, RR of OP and LB rates could not be evaluated neither (n=2 studies). However, in cycles with several CL, mean progesterone levels were displayed in OP and no OP groups (n=5 studies) and in LB and no

	Group A (n=462)	Group B(n=405)	*P* values
Age (year)	35.010 ± 5.168	34.610 ± 2.980	0.710
BMI	23.128 ± 3.166	22.997 ± 3.085	0.082
Basal FSH (U/L)	6.764 ± 1.461	6.685 ± 1.284	0.553
AMH (ng/ml)	3.757 ± 3.608	3.807 ± 0.539	0.241
Gn days	8.640 ± 1.672	8.820 ± 1.623	0.164
Gn doses	1735.673 ± 607.855	1880.786 ± 615.408	<0.001
Em thickness (mm)	9.988 ± 2.187	11.041 ± 2.114	<0.001
E2 on HCG day (pg/ml)	738.061 ± 478.824	2196.872 ± 1065.920	<0.001
LH on HCG day (U/L)	4.517 ± 3.502	3.130 ± 2.354	<0.001
P4 on HCG day (ng/ml)	0.625 ± 0.322	0.671 ± 0.322	0.094
No. retrieved oocytes	8.250 ± 4.125	10.470 ± 4.386	<0.001
progesterone advance rate on trigger day (≥1.5pg/ml)%	11.69 (54/462)	7.16 (29/405)	0.024
LH increased rate on trigger day (>10U/L)%	9.96 (46/462)	3.95 (16/405)	0.001
oocyte maturation rate (ICSI)%	64.30 (913/1420)	73.64 (1084/1472)	0.000
2PN fertilization rate (%)	52.63 (2004/3808)	59.23 (2657/4486)	0.000
available embryo rate (%)	76.40 (1531/2004)	77.00 (2046/2657)	0.627
high quality embryo rate (%)	78.12 (1196/1531)	81.48 (1667/2046)	0.013
embryo transplant ratio (%)	38.74 (179/462)	44.69 (181/405)	0.076
Clinical pregnancy rate (%)	35.75 (64/179)	46.96 (85/181)	0.031
Miscarried rate (%)	16.13 (10/62)	19.75 (16/81)	0.578
ectopic pregnancy rate (%)	3.13 (2/64)	4.71 (4/85)	0.627
incidence of moderate and severe OHSS	1.95 (9/462)	4.44 (18/405)	0.035

LB groups (n=3 studies). Means of progesterone level were significantly lower in no OP and no LB groups than in OP and LB groups [difference in means 68.8 (95% CI 45.6-92.0) and 272.4 (95% CI 10.8-533.9), ng/ml, respectively].

CONCLUSIONS: Low luteal progesterone concentrations are related to lower OP and LB rates in cycles with absence of CL or iatrogenically induced luteal phase defect suggesting that standard luteal support might not be effective for optimizing outcomes in ART. These results support the requirement of luteal serum progesterone level monitoring in order to individualize progesterone administration.

P-558 4:30 PM Monday, October 19, 2020

THE EFFECT OF GROWTH HORMONE ON CLINICAL OUTCOMES OF POOR OVARIAN RESPONDER UNDERGOING IN VITRO FERTILIZATION/INTRACYTOPLASMIC SPERM INJECTION TREATMENT: A RETROSPECTIVE STUDY BASED ON POSEIDON CRITERIA. Xing Yang, Ph.D.,[1] Mei-hong Cai Master,[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Guangzhou First People's Hospital, School of Medicine, South China University of Technology, Guangzhou, China.

OBJECTIVE: Poor ovarian responder (POR) had been dramatically increased among patients require assisted reproductive technology. The effect of growth hormone (GH) adjuvant in POR had been widely discussed. The novel POSEIDON criteria could better differentiate patients with minor heterogeneity[1]. The aim of this retrospective analysis is to explore whether GH treatment is beneficial for POR patients undertaken in vitro fertilization/intracytoplasmic sperm injection (IVF/ICSI) treatment.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: POR meet the POSEIDON criteria were recruited and stratified into the 4 subgroups according to ovarian reserve and patients age [1]. Patients in each subgroup were further divided into GH adjuvant group (GH+ group) and the counterpart without GH pretreatment (GH- group). One-to-one case-control matching was performed to adjust essential confounding factors between GH+ group and GH- group in two layers, normal ovarian reserve and poor oavarian reserve. Conventional ovarian stimulation protocols were applied for IVF/ICSI treatment. The demographic data, cycle characteristic and clinical outcomes between GH+ group and GH- group in each subgroup were compared separately.

RESULTS: A total of 1104 patients were included in this study, among which 428 with normal ovarian reserve and 676 with poor ovarian reserve. GH adjuvant showed a beneficial effect on the ovarian response and live birth rate in poor ovarian reserve subgroups (PG3 and PG4). The further stratification revealed that in the PG4, the number of good-quality embryos were significantly increased in the GH+ group than in the GH- group (1.58±1.71 vs. 1.25±1.55, P =0.032), the miscarriage rate (6.7% vs. 13.8%, P=0.173) and live birth rate (29.89% vs. 17.65%, P =0.028) were also greatly improved, these effects failed to been detected in patients with normal ovarian reserve(PG1,PG2) or in poor ovarian responder younger than 35 (PG3).

CONCLUSIONS: In conclusion, GH pretreatment is beneficial for promoting ovarian response and live birth rate, further decreasing miscarriage rate in poor ovarian reserve patients older than 35 (PG4).

IMPROVEMENT OF PREGNANCY OUTCOME BY TARGETING A CUSTOMIZED TIMING OF FROZEN EMBRYO TRANSFER IN PATIENTS FOR DONOR EGG RECIPIENTS. Delphine Haouzi, PhD,[1] Frida Entezami, MD,[2] Charlotte Mauries, MD,[1] Alice Ferrieres-Hoa, MD,[1] Anna Gala, MD,[3] Emmanuelle Vintejoux, MD,[3] Cecile Brunet, MD,[3] Claire Vincens, MD,[4] Sophie Bringer-Deutsch, MD,[3] Sophie Brouillet, PharmD, PhD,[3] Samir Hamamah, MD, PhD,[3] [1]Inserm U1203, CHU Montpellier, St-Eloi Hospital, Montpellier, France; [2]American Hospital of Paris, Neuilly sur Seine, France; [3]Arnaud de Villeneuve Hospital, CHU Montpellier, Montpellier, France; [4]ART-PGD department, Arnaud de Villeneuve Hospital, CHU Montpellier, Montpellier, France.

OBJECTIVE: The aim of this study was to optimize pregnancy outcome using customized embryo transfer according to the evaluation of endometrial receptivity of patients included in eggs donation program.

DESIGN: Endometrial biopsies are performed during the implantation windows 5-9 days after progesterone administration under hormone replacement therapy. Then, the transfer strategy consists in performing cET of blastocysts according the endometrium receptivity day identified using the Win-Test. Therefore, frozen day 2/3 embryos were transferred 72/48 hours before this specific receptivity day, respectively. When the endometrial sample was defined as non-receptive, a second evaluation was performed later, according to transcriptomic result.

MATERIALS AND METHODS: 45 patients in eggs-donation program due to an advanced age (n=36) or premature ovarian failure (n=9) were included. RNAs from biopsies were extracted and the Win-Test gene expression was assessed by qRT-PCR. Positive pregnancy test was defined as at least two consecutive positive b-hCG serum concentration. Clinical pregnancy, implantation rate and live birth rate were recorded after cET according to the transcriptomic results.

RESULTS: Analyses of endometrial receptivity status (n=108 biopsies) in patients in oocyte donation program (age mean ± SD: 41.2 ± 3.8 years) revealed a strong inter-patient variability of the moment of the opening of the receptivity window within the implantation window. Majority of patients (84%) present a delay of their receptivity window compared to the classical timing for blastocyst transfer (16% at Pg+5/Pg+6). This delay was mainly between 1 (40%) to 2 days (33%), or more (11%). Then, a cET can to be perform during a subsequent cycle according the endometrium receptivity day and in the respect of the synchronization of the fœto-maternal dialogue. Using this strategy, the positive b-hCG and clinical pregnancy rate per patient were 73.3% and 60%, respectively. The implantation and live birth rates after cET were 50% and 48.9%, respectively.

CONCLUSIONS: This finding demonstrated that customized embryo transfer according to the specific cycle day where endometrium is receptive improves both implantation rate and live birth rate in patients in oocyte donation program.

SUPPORT: This work was partially supported by a grant from the Gedeon Richter Pharmaceutical Company.

ESTABLISHING THE FOLLITROPIN DELTA DOSE PROVIDING COMPARABLE OVARIAN RESPONSE AS 150 IU/DAY FOLLITROPIN ALFA FOR CONTROLLED OVARIAN STIMULATION. Joan-Carles Arce, MD, PhD, Per Larsson, PhD, Ferring Pharmaceuticals, Copenhagen, Denmark.

OBJECTIVE: To determine the daily follitropin delta dose (μg) providing similar ovarian response as 150 IU/day follitropin alfa.

DESIGN: Post-hoc analysis of ovarian response in 1,591 IVF/ICSI patients undergoing controlled ovarian stimulation in two randomized, assessor-blind, controlled, multi-center trials in the development program for follitropin delta (NCT01426386; NCT01956110). Ovarian response was evaluated in terms of number of oocytes retrieved as well as number of follicles by size and hormone response.

MATERIALS AND METHODS: The phase 2 dose-response trial included 265 IVF/ICSI patients who were randomized to receive a daily dose in the range 5.2-12.1 μg of follitropin delta (Rekovelle, Ferring Pharmaceuticals) or 150 IU (11 μg) of follitropin alfa (Gonal-F, Merck Serono) with no dose adjustments of either follitropin during stimulation. The phase 3 efficacy trial included 1,326 IVF/ICSI patients who were randomized to an individualized follitropin delta dose (determined for each woman based on her serum AMH level and body weight) that was fixed throughout stimulation or to a starting dose of 150 IU (11 μg) follitropin alfa for the first five days followed by potential dose adjustments as per the investigator's judgement. Dose-response relationships for follitropin delta dose and ovarian response parameters were approximated by log-linear functions. For the phase 3 trial, follitropin delta was compared to follitropin alfa by stratifying follitropin alfa patients

according to the dose they would have received if randomized to follitropin delta. Analyses were made for these patient populations: all, AMH $\geq$15 pmol/L, no dose changes, and AMH $\geq$15 pmol/L and no dose changes.

RESULTS: Mean follitropin delta doses of 10.0 [95% CI 7.9; 12.8] μg and 10.3 [95% CI 9.7; 10.8] μg yielded the same number of oocytes retrieved as 150 IU follitropin alfa for all patients in the phase 2 and 3 trials, respectively. When analyzing patients with normal/high ovarian reserve (based on serum AMH $\geq$15 pmol/L) and with no dose changes during stimulation, the same number of oocytes retrieved was obtained with 150 IU follitropin alfa and mean doses of follitropin delta of 9.7 [95% CI 7.5; 12.4] μg in the phase 2 trial and 9.3 [95% CI 8.6; 10.1] μg in the phase 3 trial. Evaluation of additional ovarian response parameters besides number of oocytes retrieved provided consistent findings. Mean follitropin delta doses in the range 9.4-10.1 μg were estimated to correspond to 150 IU follitropin alfa in terms of number of follicles $\geq$10 mm, $\geq$12 mm and $\geq$17 mm at end of stimulation, across all analysis populations in the phase 3 trial. Further, for serum estradiol, progesterone and inhibin A at end of stimulation, mean follitropin delta doses in the range 9.4-10.6 μg were estimated to correspond to 150 IU follitropin alfa.

CONCLUSIONS: In IVF/ICSI patients, a daily follitropin delta dose of 10 μg provides a similar ovarian response as 150 IU/day follitropin alfa. The establishment of this equivalence factor will facilitate the use of follitropin delta in both dosing algorithms and conventional dosing and will also ease patient transition between protocols.

IN-UTERO ANDROGEN EXPOSURE CHANGES NEONATAL OVARIAN GENE EXPRESSION IN A LEAN PCOS MOUSE MODEL. Jamie Merkison, MD, Chellakkan Selvanesan Blesson, PhD. Baylor College of Medicine, Houston, TX.

OBJECTIVE: To investigate the role of prenatal androgen exposure on the neonatal ovary by analyzing gene expression and mitochondrial structure.

DESIGN: Prospective cohort study investigating the role of androgens in fetal ovarian development by analyzing gene expression in neonatal ovary exposed to dihydrotestosterone (DHT).

MATERIALS AND METHODS: Pregnant mice were treated with DHT (250μg/day) or vehicle (sesame oil) on days 16 -18 of gestation. Ovaries from pups were micro-dissected at birth (day 0) and RNA and protein were sent for RNA sequencing, bioinformatics, and qPCR. Relevant genes were further studied via Western blot analysis. *t*-tests and one-way ANOVA were used to analyze the differences when appropriate.$P < 0.05$ was considered statistically significant.

RESULTS: The neonatal ovaries of DHT treated group had 287 upregulated and 95 downregulated genes compared to untreated group.Upregulated genes were associated with infertility, abnormal follicle development and altered hormonal signaling.Top 20 up and downregulated genes were validated with qPCR – 26 were differentially expressed. These 26 genes were found to be related to mitochondrial dysfunction, oocyte maturation, ovarian cell cycle regulation, and PCOS. Of the 26 genes, 8 had been previously described to be related to reproduction physiology. From those genes that have been previously described within the literature, 3 genes showed a statistically significant difference in the amount of protein expressed on Western blot analysis.

CONCLUSIONS: Prenatal androgen exposure altered transcriptional pathways in ovarian gene expression, with resulting differences in the amount of protein produced in affected mice. Data suggests that PCOS development occurs prior to birth with alterations in gene expression evident during the neonatal period.

P-562 4:30 PM Monday, October 19, 2020

CUMULUS CELL TRANSCRIPTOMIC PROFILES OF OOCYTES THAT RESULT IN WHOLE CHROMOSOME 21 MONOSOMY AND TRISOMY ARE SIGNIFICANTLY DIFFERENT. Ashley W. Tiegs, MD,[1] Shiny Titus, PhD,[2] Sameet Mehta, PhD,[3] Rolando Garcia-Milian, MLS, AHIP,[3] Emre Seli, M.D.,[2] Richard Thomas Scott, Jr., MD[2] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]IVI RMA New Jersey, Basking Ridge, NJ; [3]Yale School of Medicine, New Haven, CT.

OBJECTIVE: To determine if the transcriptomic profile of cumulus cells (CCs) from oocytes that resulted in embryos diagnosed to be whole chromosome aneuploid for chromosome 21 by preimplantation genetic testing for aneuploidy (PGT-A) differs from that of CCs of oocytes that resulted in euploid embryos.

DESIGN: Prospective experimental study.

MATERIALS AND METHODS: Cumulus cells from individualized oocytes were obtained prospectively from consenting patients undergoing in vitro fertilization/intracytoplasmic sperm injection (IVF/ICSI) with PGT-A (August 2018 - December 2019). Embryos were individually cultured to enable accurate correlation with trophectoderm PGT-A results. The CC transcriptomic profiles from 22 non-sibling embryos were evaluated and compared: 7 monosomy 21, 8 trisomy 21, and 7 euploid. RNA sequencing was followed by ingenuity pathway analysis (IPA) for assessment of overrepresented pathways in differentially expressed genes in trisomy 21 and monosomy 21 as compared to euploid embryos. Real-time polymerase chain reaction (PCR) was then performed to confirm differential gene expression as specifically indicated by the IPA results.

RESULTS: RNA sequencing revealed significant differences in CC gene expression between PGT-A euploid and whole chromosome 21 aneuploid embryos. Specifically, a total of 3122 genes in CCs associated with monosomy 21 and 19 genes in CCs associated with trisomy 21 embryos were differentially expressed as compared to CCs associated with PGT-A euploid embryos. Thirteen of these genes were differentially expressed in both monosomy and trisomy 21 aneuploid as compared to euploid embryos, including disheveled segment polarity protein 2 (DVL2), cellular communication network factor 1 (CCN1/CYR61) and serum response factor (SRF). Such genes have been previously implicated in embryo developmental competence. Additionally, IPA analysis revealed cell-to-cell contact functioning to be significantly altered in CCs associated with both monosomy and trisomy 21 embryos as compared to CCs associated with PGT-A euploid embryos.

CONCLUSIONS: Significantly altered expression of several genes implicated in embryo development was identified upon comparison of CC transcriptomic profiles of embryos with whole chromosome aneuploidy for chromosome 21 (monosomy and trisomy) versus euploid embryos. As a proof-of-concept study, these findings encourage further investigation of CC gene expression analysis for the development of biomarkers evaluating oocyte quality for patients undergoing fertility preservation of oocytes.

NATURAL COMPOUND METHYL JASMONATE SHOWS PROMISING ANTI-FIBROID EFFECTS IN HUMAN UTERINE FIBROIDS VIA INHIBITION OF EZH2 MEDIATED WNT/B-CATENIN SIGNALING PATHWAY ACTIVATION. Mohamed Ali, B.Pharm, MSc,[1] Ayman Al-Hendy, MD, PhD,[2] Qiwei Yang, PhD[1] [1]University of Illinois at chicago, Chicago, IL; [2]University of Illinois at Chicago, Chicago, IL.

OBJECTIVE: Uterine Fibroids (UFs) are the most common benign tumors in women of reproductive age with subsequent significant quality of life and economic negative impact. EZH2 and Wnt/β-catenin are linked to many diseases pathogenesis including UF. Current treatment options are primarily surgical and no FDA approved medical treatment is available so far. Natural compounds may be beneficial for UFs patients as a safe non-hormonal therapeutic option. Methyl Jasmonate (MJ) is a natural compound isolated from jasmine with a potent anti-EZH2 activity. In this study, we determine the effect of MJ on UFs.

DESIGN: Laboratory research studies using Human uterine leiomyoma (HuLM) and normal uterine smooth muscle cells (UTSM).

MATERIALS AND METHODS: HuLM and UTSM cells were treated with (0.1mM-3mM) of MJ and cell proliferation was assessed by MTT assay after 24 and 72 hr. Protein and RNA levels of several markers were measured in MJ treated or untreated HuLM, including ECM markers collagen type1(-COLL1A) and Fibronectin (FN), proliferation markers Cyclin D1 (CCND1) and (PCNA), tumor related marker (P21, EZH2 and β-catenin) and apoptotic markers {Bax, Cytochrome-c and cleaved caspase 3}. EZH2 overexpression or inhibition was achieved using EZH2-expressing adenovirus or chemical EZH2-inhibitor (DZNep) respectively in HuLM, and protein expression of EZH2, β-catenin and PCNA were measured as well as alterations of gene expression in WNT signaling pathway using 84-gene Prime-PCR array with subsequent confirmation of 9 genes using qRT-PCR. Unpaired student t test was used for statistical significance. ($P< 0.05$) is considered significant.

RESULTS: EZH2 overexpression significantly increased nuclear translocation of β-catenin and PCNA with subsequent many Wnt ligands gene expression increase (PITX2, WISP1, WNT5A, WNT5B and WNT9A), while EZH2 inhibition blocked Wnt/ β-catenin signaling activation where aforementioned genes were significantly decreased as well as PCNA, CyclinD1 and PITX2 protein expression compared to untreated HuLM ($P<0.05$). MJ showed a potent anti-proliferative effect on HuLM cells in a concentration and time dependent manner ($P<0.05$). Interestingly, dose range (0.1-0.5 mM) showed selective growth-inhibitory effect on HuLM not normal UTSM cells. MJ treatment at 0.5 mM for 24 hr. significantly decreased both protein and RNA levels of EZH2, β-catenin, COLL1A, FN, CCND1, PCNA, WISP1 and PITX2, while increased protein levels of p21, Bax, Cytochrome-c and cleaved caspase-3 compared to untreated HuLM ($P<0.05$). MJ treated cells exhibited downregulation in RNA expression of 35 genes including *CTNNB1*, *CCND1*, *Wnt3*, *Wnt5A*, *Wnt5B* and upregulation in expression of 36 genes including Wnt antagonist genes *WIF1*, *PRICKlE1* and DKK1 compared to control.

CONCLUSIONS: Our studies provide a novel link between EZH2 and Wnt/β-catenin signaling pathway in UFs. MJ exhibited a promising anti-fibrotic effect via inhibition of this link. MJ might offer a promising therapeutic option as safe non-hormonal long term and cost-effective treatment against UFs with favorable clinical utility especially for women seeking future fertility.

PLASMINOGEN DOES NOT IMPROVE BLASTOCYST HATCHING IN VITRO, BUT MAY IMPROVE BLASTOCYST QUALITY. Heidi J. Engelhorn, MS,[1] William B. Schoolcraft, MD,[2] Rebecca L. Krisher, PhD[1] [1]CCRM Colorado, Lone Tree, CO; [2]CCRM Fertility Network, Lone Tree, CO.

OBJECTIVE: The aim of this study was to determine if the addition of transferrin-selenium-ethanolamine (TSX) and/or plasminogen to mouse embryo culture medium would increase the incidence of blastocyst hatching and cell number. TSX is a commonly used cell culture supplement. Transferrin regulates iron uptake, selenium is a precursor for proteins acting as antioxidants, and ethanolamine supports cell membrane function. Plasminogen is a precursor to the protease plasmin that degrades fibrin and is thought to be a component of blastocyst hatching mechanisms in vivo.

DESIGN: Research study.

MATERIALS AND METHODS: A sequential culture medium was used to prepare four treatments: control, TSX, plasminogen and TSX+plasminogen, which were added exclusively to the final culture step. Mature mouse (CF1, 4 wks) oocytes were collected following PMSG and hCG stimulation, fertilized in vitro, and 2PN embryos selected for culture and randomly allocated to treatments. Blastocyst development and hatching were assessed on days 4 (96 hr) and 5 (112 hr). Forty day 5 hatching and hatched blastocysts per treatment were fixed in 4% paraformaldehyde and stained to determine TE (CDX2) and ICM (SOX2) cell number. Five biological replicates were performed (120-123 embryos/treatment). Data was analyzed by two-tailed t test with a p value for significance of <0.05.

RESULTS: There were no significant differences in blastocyst development on day 4 or blastocyst hatching on day 5. No differences in the number of hatching sites or thickness of the zona pellucida were noted between treatments. Inclusion of plasminogen significantly decreased blastocyst trophectoderm cell number (122 ± 6.1) compared to control (139.4 ± 5.2), TSX (145 ± 4.6) and TSX+plasminogen (147.2 ± 5.9), as well as total cell number (plasminogen, 138.1 ± 6.6; control, 156 ± 5.6; TSX, 162.7 ± 5.1; plasminogen+TSX, 162.3 ± 6.5). However, ICM cell number was not affected by treatment (control, 16.6 ± 0.8; plasminogen, 16.1 ± 0.9; TSX, 17.7 ± 0.9; plasminogen+TSX, 15.1 ± 1.1). As a result, blastocysts cultured with plasminogen had a higher percentage of ICM cells (11.8%) compared to TSX+plasminogen (9.3%), but did not differ from control (10.7%) or TSX (10.9%).

CONCLUSIONS: Although plasminogen is suspected to play a role in blastocyst hatching in vivo, the addition of plasminogen to culture medium did not improve in vitro hatching of mouse blastocysts. Plasminogen may improve in vitro blastocyst quality, as suggested by an increase in the percentage of ICM cells. The combination of TSX and plasminogen provided no overall benefit to embryo development, and may actually be detrimental as the percentage of ICM cells was reduced.

P-566 4:30 PM Monday, October 19, 2020

A REDUCED NUTRIENT CULTURE ENVIRONMENT IMPROVES BOVINE BLASTOCYST DEVELOPMENT AND ALTERS MITOCHONDRIAL METABOLISM AS ELUCIDATED BY SINGLE CELL RNA SEQUENCING. Benjamin B. Goheen, BS,[1] Sandeep K. Rajput, PhD,[1] Deirdre M. Logsdon, MS,[1] Ye Yuan, PhD,[1] Zongliang Jiang, Ph.D,[2] William B. Schoolcraft, MD,[1] Rebecca L. Krisher, PhD[3] [1]Colorado Center for Reproductive Medicine, Lone Tree, CO; [2]Louisiana State University, Baton Rouge, LA; [3]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: To characterize developmental and transcriptomic differences between in vitro embryos produced in standard culture medium (IVC) with those produced using a culture medium with 75% reduced nutrients (25% of the carbohydrates and amino acids of control medium; IVRN).

DESIGN: Prospective Research Study.

MATERIALS AND METHODS: Bovine embryos were cultured to the blastocyst stage and bisected. The portion of the embryo containing both ICM and TE was dissociated using Accumax (Innovative Cell Technologies) into single cells. Single cell RNA sequencing libraries were prepared using the Smart-Seq v2 approach and sequenced with Illumina HiSeq platform. In total, we sequenced 215 single cells and obtained an average of approximately 10 million 150bp paired-end reads per sample. The resulting data underwent pre-processing, alignment, and feature selection before being analyzed for differential gene expression using limma-voom and pathway analysis using Ingenuity Pathway Analysis (Qiagen).

RESULTS: IVRN embryos had improved blastocyst development (49.8% of total oocytes; n=649) compared to control (31.6% of total oocytes, n=637). RNA-seq results revealed upregulation of IGF-1 (z-score: 1.667, p-value: 6.13E-04), AKT (z-score: 1.291, p-value: 3.76E-03), and insulin receptor signaling (z-score: 1.069, p-value: 2.25E-02) pathways involved in glucose transport, suggesting an increase in glucose uptake by IVRN embryos. Increased AMPK signaling (z-score: 2.2524, p-value: 4.98E-05) and expression of CPT1A, CPT1B & CPT2 genes in IVRN blastocyst indicate reliance on fatty acid oxidation (FAO) for ATP production under reduced nutrient conditions. Upregulation of PDK1 and PDK2 enzymes (inhibit PDH/conversion of glycolytic pyruvate to acetyl-coA and entry into the TCA cycle) and increased expression of glutaminase (GLS) in IVRN blastocyst suggests that glucose is diverted into another pathway such as lactate production or the PPP, but that the TCA cycle remains active not only via FAO but also via glutaminolysis. Collectively, these results suggest that

embryos cultured under reduced nutrient conditions switch to a Warburg-like metabolism to maintain energy homeostasis. Supporting this conclusion, ERK/MAPK signaling was upregulated in IVRN blastocysts (z-score: 1.147, p-value: 2.51E-03), suggesting that growth and proliferation are upregulated similar to cancer cells, which also employ Warburg metabolism. IVRN embryos also had elevated levels of mtDNA compared to control (IVRN = 1951.25122.42, IVC= 1530.7357.36, p = 0.003.

CONCLUSIONS: The metabolic strategy adopted by IVRN embryos appears to support increased blastocyst development and quality in vitro, although the ultimate viability of these embryos after transfer has not been evaluated. This study provides novel insight into embryo metabolic strategies that support blastocyst development, as well as potential approaches to manipulate metabolism to improve both the quantity and quality of embryos produced in vitro.

P-567 4:30 PM Monday, October 19, 2020

THE ROLE OF TRYPTOPHAN 2,3-DIOXYGENASE IN HUMAN UTERINE LEIOMYOMA HARBORING MED12 MUTATION. Anne P. Hutchinson, M.D.,[1] Ping Yin, M.D., PhD,[2] John S. Coon V, M.S.,[2] Ilona Neale, BA (expected 2020),[2] Serdar E. Bulun, MD[3] [1]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]250 E Superior, Chicago, IL.

OBJECTIVE: Uterine leiomyomas (fibroids) represent the most common reproductive-age benign tumor in women. Two distinct subtypes, which carry a Mediator complex subunit 12 (MED12) mutation (mut-MED12) or with high mobility group AT-hook 2 (HMGA2) overexpression (ov-HMGA2), comprise 85% of all leiomyomas. A universal feature of all leiomyomas is responsiveness to estrogen and progesterone, which function by activating their cognate nuclear receptors ERα and PR, respectively, to increase their binding to regulatory regions of target genes and control their transcription and function. Using leiomyomas carrying mutant MED12 (G44D), wild type MED12, and over expression of HMGA2, and their corresponding adjacent normal myometrial tissues, we performed RNA-seq and ChIP-seq against PR, ERα, and MED12. Integrative analyses of these data identified that the tryptophan (Trp) 2,3-dioxygenase (*TDO2*) gene expression was significantly upregulated in mutant MED12 leiomyoma. TDO2 protein catalyzes the oxidation of L-Trp to N-formyl-L-kynurenine (Kyn), as the first and rate-limiting step of Kyn production, which plays important roles in tumorigenesis in general. It has been reported that Trp was significantly downregulated in mutant MED12 leiomyoma; however, the underlying mechanism remains unclear and the role of this pathway in leiomyoma tumorigenesis has not been explored. The aim of the present study was to determine the expression levels TDO2 and the other two enzymes that catalyze the same enzymatic step: indoleamine-2,3-dioxygenease 1 (IDO1) and IDO2 in different subtypes of leiomyoma.

DESIGN: Laboratory Study.

MATERIALS AND METHODS: Mutation screening was performed for MED12 exons 1 and 2 and the intronic flanking regions using Sanger sequencing in 48 leiomyoma and matched myometrial tissues (n=24 subjects). Quantitative real-time polymerase chain reaction (qRT-PCRs) was performed in order to estimate the expression of TDO2, IDO1, and IDO2 in leiomyoma samples with or without MED12 gene mutations.

RESULTS: MED12 mutations were detected in 18 (75%) leiomyoma samples, including 6 tissues harboring G44D (131G>A) mutation (the most frequently observed mutation in leiomyomas). TDO2 expression was significantly higher in mutant MED12 leiomyomas not only in comparison with all myometrial samples ($p<0.0001$), but also in comparison with leiomyomas without a MED12 mutation ($p<0.05$). The expression of IDO2 was undetectable using qRT-PCR in all tissues, and the expression of IDO1 was low and not significantly different between leiomyoma and myometrium, suggesting that TDO2 is the key enzyme responsible for Trp metabolism in leiomyoma carrying MED12 mutation.

CONCLUSIONS: We demonstrated that TDO2 expression was dysregulated in leiomyomas carrying MED12 mutation. Therefore, it may serve as a good therapeutic target and provide new insight into understanding the molecular mechanisms responsible for the pathogenesis of the MED12 mutation-specific leiomyoma subtype.

P-568 4:30 PM Monday, October 19, 2020

USING MIRROR COPIES OF PARENTAL GENOMES TO GENERATE DEVELOPMENTALLY COMPETENT EMBRYOS. Philip Xie, B.S., Aysha Trout, B.A., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To create identical copies of parental genomes to generate developmentally competent zygotes.

DESIGN: Mirror copies of parental genomes were created for the male genome by injecting an individual spermatozoon into an enucleated oocyte. For the female genome, parthenogenetic activation was performed. Both constructs were allowed to reach the first embryonic cleavage. A single male pseudo-blastomere was fused with a female counterpart to reconstitute a diploid zygote. The reconstructed zygotes were cultured in a time-lapse incubator up to full preimplantation development compared to zygotes generated by piezo-actuated ICSI that served as a control.

MATERIALS AND METHODS: To generate male pseudo-blastomeres, MII oocytes from superovulated B6D2F1 mice were treated by cytochalasin B, enucleated, injected by a sperm head from the same strain, and allowed to cleave to the 2-cell stage. Female counterparts were generated by exposing unmanipulated oocytes to 10 mM calcium ionophore and allowed to reach the first division. DNA polymerase inhibitor was supplied to culture medium immediately after the first division to synchronize cell cycles before zygote reconstruction. Biparental zygote reconstruction was performed by Sendai virus–mediated fusion of a male pseudo-blastomere with a female counterpart. Reconstructed zygotes were cultured and monitored up to 96h and compared to control ICSI conceptuses.

RESULTS: Enucleation of 60 MII oocytes generated 57 ooplasts; 43 survived subsequent injection (74%), and each developed a single pronucleus. After culturing for 16h, 40 androgenetic embryos reached the 2-cell stage (93%). For the female counterparts, 50 out of 55 MII oocytes (87%) were successfully activated and cleaved. Forty zygote reconstructions were performed, yielding 36 reconstructed biparental zygotes (90%). An additional 35 zygotes were generated by ICSI and served as controls. The control and experimental zygotes were observed in a time-lapse system and maintained up to 96h. Early development of control and experimental conceptuses into 2-cell (86% vs 78%) and 4-cell embryos (80 vs 69%) was comparable. Morula compaction in the control and experimental groups was 77% and 50%, respectively ($P < 0.01$), and further development into blastocysts was 77% and 44%, respectively ($P < 0.01$). The experimental group displayed morphokinetic abnormalities during cleavage and higher instances of fragmentation.

CONCLUSIONS: It is feasible to use mirror copies of parental genomes to generate zygotes, albeit at a lower rate of preimplantation development as compared to zygotes generated by ICSI. This experiment sheds light on the process of syngamy, and the technique has potential for use in genomic editing as well as in screening for inheritable heterozygous genetic disorders.

P-569 4:30 PM Monday, October 19, 2020

HYPOXIA INDUCES TROPHOBLAST MIGRATION AND INVASION GENE PATHWAYS A SUBSET OF WHICH ARE REDUCED IN PREECLAMPSIA CVS. Barry E. Perlman, DO,[1] Audrey Merriam, MD, MS,[2] Alexander Lemenze, PhD,[1] Salma Begum, PhD,[3] Qingshi Zhao, PhD,[1] Carrie J. Shawber, PhD,[4] Nataki C. Douglas, MD, PhD[1] [1]Rutgers New Jersey Medical School, Newark, NJ; [2]Yale University, New Haven, NJ; [3]Rutgers-New Jersey Medical School, Newark, NJ; [4]Columbia University College of Physicians and Surgeons, New York, NY.

OBJECTIVE: At the start of pregnancy, trophoblasts (TBs) migrate and invade into the decidua and remodel the spiral arteries in physiologic hypoxic conditions (1-3% O_2). Persistent hypoxia secondary to a defect in remodeling of the maternal arteries is proposed to lead to a failure to increase oxygen tension, leading to poor placental perfusion and pregnancy complications, such as preeclampsia (PE). The objectives of this study are to determine how exposure to hypoxia impacts gene expression and cellular motility of first trimester TBs, and to assess if expression of migration-associated genes is

dysregulated in 2nd trimester chorionic villous samples (CVS) from PE pregnancies relative to CVS from healthy pregnancies.

DESIGN: Laboratory *in vitro* studies using the first-trimester TB cell line, HTR-8/SVneo (HTR-8). RNA-sequencing (RNA-seq) of HTR-8 cells and CVS.

MATERIALS AND METHODS: HTR-8 cells were exposed to hypoxia (2.5% O_2) or normoxia (21% O_2) for 6hrs and RNA-seq was performed. Significant differentially expressed genes (SDEGs) and upregulated Gene Ontology (GO) cellular pathways were identified. To determine if gene expression changes were associated with changes in cellular response, transwell assays were performed to assess HTR-8 cell migration and invasion after exposure to 2.5% O_2 or 21% O_2 for 6hrs and 24hrs. For transwell migration assays (n=6), number of migrated cells through culture inserts were counted. For invasion assays (n=6), number of cells that invaded into Matrigel and collagen I matrices were counted. Means were compared using unpaired t tests and statistical significance was defined as $p < 0.05$. To determine if changes in gene expression induced by exposure of HTR-8 to 2.5% O_2 were present in 2nd trimester CVS from PE pregnancies relative to healthy pregnancies, CVS were collected and analyzed under an IRB approved protocol. RNA-seq of CVS from PE (n=2) and healthy (n=4) pregnancies was performed and DEGs were identified.

RESULTS: GO analysis showed that exposure of HTR-8 to 2.5% O_2 for 6hrs upregulated cellular migration pathways. SDEGs included genes involved in TB migration and invasion (*MMP9, TIMP1,* and *PAPPA)*, as well as genes involved in tumor migration and invasion (*ACTA2, MFAP4, SNAI2, SLCO4A1, GDF15, KLF5, ZBTB20,* and *ZNF703*). HTR-8 cell migration and invasion, through both collagen I and Matrigel matrices, was significantly increased after exposure to 2.5% O_2 for 24hrs but not 6hrs. Analysis of RNA-seq data from CVS of PE and healthy pregnancies identified 17 significant DEGs, 4 of which (*FAT2, SPON2, RASGRF2*, and *SCLO4A1*) were decreased in CVS from PE pregnancies and are involved in cellular migration and invasion.

CONCLUSIONS: Exposure of 1st trimester TBs to physiologic hypoxic conditions induces expression of genes associated with cellular migration and invasion and increases 1st trimester TB migration and invasion *in vitro*. Decreased expression of migration and invasion genes in CVS from PE pregnancies may impair TB migration and invasion in the 2nd trimester of pregnancy, resulting in inadequate spiral artery transformation and prolonged hypoxia, preceding the development of PE.

P-570 4:30 PM Monday, October 19, 2020

IN VITRO MATURED OOCYTES DERIVED FROM THREE DIMENSIONAL CULTURE (3-D) OF PRE-ANTRAL FOLLICLES IN A HYALURONAN BIO-MATRIX ARE FUNCTIONALLY COMPETENT.

Maribeth Spangler, MS,[1] Arsela Gishto, MS,[1] Alyssa Brown, MS,[1] Nina Desai, Ph.D., HCLD[2] [1]Cleveland Clinic, Beachwood, OH; [2]Cleveland Clinic, Beachwood, OH.

OBJECTIVE: In vitro culture systems that preserve 3-D follicle architecture and oocyte-granulosa cell interaction may be the key to in vitro oocyte maturation (IVM). Hyaluronan is one component of natural extracellular matrices that provide support to cells in vivo. This report describes the application of hyaluronan for 3-D in vitro follicle culture and the production of developmentally competent metaphase II oocytes.

DESIGN: Pre-antral follicle culture in vitro.

MATERIALS AND METHODS: Ovaries of 14- 16 day old B6D2F1 mouse pups were treated with collagenase. Released pre-antral follicles with 2-3 layers of granulosa cell were collected. The hyaluronan hydrogel (HA) was prepared by mixing 25 μl of the HA gel (3 mg/ml) with 1 μl of 0.03% hydrogen peroxide to initiate cross-linking. Microdrops of HA gel (5-7 μl) were placed in individual wells and rapidly seeded with 4 follicles before gelling was completed. Culture medium (100 μl) was added to each well and the dish was overlaid with oil. Follicle culture was performed in $\propto$-MEM supplemented with 5% FBS, 100 mIU/ml FSH, 10 mIU/ml LH and ITS. Dishes were incubated at 37°C with 6% CO2. Final maturation was triggered with hCG (1.5 IU/ml) and EGF (5 ng/ml) after 12 days of growth. Follicles were monitored daily. Mature oocytes were inseminated with epididymal sperm. Fertilization was assessed the following morning based on presence of 2 pronuclei or cleavage to 2-cell. Outcome parameters monitored were estradiol levels, follicle morphology and survival throughout the in vitro culture interval (IVC), germinal vesicle breakdown (GVBD), oocyte maturation to metaphase II stage, fertilization and development to blastocyst. Cell number in blastocysts was determined by Hoechst staining

RESULTS: Pre-antral follicles measured 121.9 $\pm$ 40.9 μM with oocyte diameters of 61.1$\pm$ 4.1 μM at time of seeding. Mean oocyte diameter, measured after maturation was 90.2 $\pm$ 8.0 μM. IVM data from three experiments were pooled. A total of 402 pre-antral follicles were embedded in HA gel. Antrums were observed in 55% of follicles by day 8. Post-hCG trigger 314 oocyte-cumulus complexes ovulated from the cultured follicles and 84% (264/314) underwent GVBD. The maturation rate to MII was 72.6%. (228/314). The fertilization rate was 82.5% (188/228). The subsequent blastulation rate with IVM oocytes was 46.3% (87/188). Blastocysts were cryopreserved for future transfer experiments to determine their ability to produce live offspring. Seven blastocysts were subsequently thawed and stained with Hoechst to determine cell number. Mean cell number was 55 $\pm$ 7.5.

CONCLUSIONS: HA was an excellent biomaterial for 3-D culture, allowing follicle growth, antrum formation and ovulation of oocyte-cumulus complexes upon hCG trigger. This matrix was easy to use, its rigidity could be adjusted and its transparent nature allowed optimal visualization. Functional competence of HA- matured oocytes was evidenced by their ability to fertilize and continue development to the blastocyst stage. Live birth data are needed to further validate this 3-D culture system. Testing of HA with follicles from larger animal models is warranted.

P-572 4:30 PM Monday, October 19, 2020

CORONAVIRUS DISEASE (COVID-19): TRANSCRIPTOMIC AND PROTEOMIC INVESTIGATION OF CELLS OF THE MALE AND FEMALE REPRODUCTIVE SYSTEMS TO EVALUATE SARS-COV-2 INFECTION RISK.

Kate E. Stanley, B.A.,[1] Elizabeth Thomas, B.A.,[1] Megan Leaver, M.Sc.,[1] Dagan Wells, Ph.D.[2] [1]Nuffield Department of Women's and Reproductive Health, Oxford, United Kingdom; [2]Juno Genetics, Oxford, United Kingdom.

OBJECTIVE: To identify cell types in male and female reproductive systems at risk of SARS-CoV-2 infection based on expression of viral host entry proteins.

DESIGN: Transcriptomic and proteomic analysis.

MATERIALS AND METHODS: Publicly available single cell RNA sequencing (scRNAseq) data in human testis and non-human primate ovary was analyzed, as well as bulk RNA and proteomic data in human testis and ovary. Additionally, novel RNA sequencing data from 18 samples of human cumulus cells was generated. Tissue- and cell-type specific risk of viral infection was predicted based on the co-expression of host receptor angiotensin-converting enzyme 2 (*ACE2*) and transmembrane serine protease 2 (*TMPRSS2*) which are required for viral binding and cleavage, respectively. Expression of receptor basigin (*BSG*) and cysteine protease cathepsins L (*CTSL*) were also assessed as they are hypothesized to facilitate viral entry.

RESULTS: Based on scRNAseq data in non-human primate ovarian tissue, *ACE2* and *TMPRSS2* co-localize in a sub-population of oocytes in antral follicles (62% of cells, Pearson correlation=0.37), but to a lesser extent in less mature oocytes (Pearson correlation=0.13-.21) and not at all in ovarian somatic cells. While *ACE2* transcripts were detected in human cumulus cells (mean 24.03 transcripts per million), *TMPRSS2* expression was absent in 15/18 samples and low in the others (0.13 TPM). Consistent with these findings, bulk RNA and protein data showed *ACE2* expression in ovarian tissue, but no *TMPRSS2* expression. In testicular cells, including sperm, co-expression of *ACE2* and *TMPRSS2* was not detected (Pearson correlation=-0.01). Bulk RNA and protein data revealed *ACE2* but no *TMPRSS2* expression. *BSG* was more broadly expressed in testis than *ACE2* and was co-expressed with *CSTL* in early (78.7%) and late (90.8%) primary spermatocytes.

CONCLUSIONS: Given that known COVID-19 symptoms are associated with tissues co-expressing *ACE2* and *TMPRSS2* (e.g. lung, heart, kidney, gut), it is conceivable that reproductive function could be effected if constituent cells co-express these genes. Based on these results, testicular cells including sperm are not at risk of *ACE2-TMPRSS2*-mediated viral entry, however low levels of SARS-Cov-2 in human semen have been reported and may suggest alternative routes of entry. The cells predicted to have the greatest susceptibility to infection are antral oocytes which are either ovulated or atrophy within several days of appearance each cycle and are therefore unlikely to have sustained impact on female fertility if infected. Moreover, the lack of *ACE2-TMPRSS2* expression in cumulus cells may act as a barrier to infection. Therefore, procedures in which cumulus cell-enclosed oocytes are collected and fertilized outside the female reproductive tract (e.g. IVF) may not pose a risk. IVF success rates decline with increasing female age and it is therefore imperative that patients are allowed to access fertility treatments if safe to do so. The results presented here are indicative, but ovarian pathology data from women of reproductive age with COVID-19 at time of death is needed for definitive confirmation.

P-573 4:30 PM Monday, October 19, 2020

SEPT12 EXPRESSION IN HUMAN TROPHECTODERM CELLS: INSIGHT INTO EMBRYONIC ARREST.

Christine Briton-Jones, PhD, HCLD,[1] Lucky Sekhon, MD,[1] Kimaada Allette, BS,[2] Ethan Ellis, BS,[2] Ying-Chih Wang, MS,[2] Joseph A. Lee, BA,[1] Melissa L. Smith, PhD,[2] Eric Schadt, PhD,[2] Robert P. Sebra, PhD,[2] Alan B. Copperman, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: *SEPT12*, a member of the Septin gene family, has expression restricted to the testis and is critical for normal spermatogenesis. Septin genes code for polymerizing guanosine triphosphate (GTP) binding proteins whose homologs have been conserved throughout evolution from yeast to humans (1). Roles assigned to Septin genes include cell division, cytoskeletal organization, and membrane-remodeling events including the epithelial-mesenchymal transition in metastatic cancers (2). A study that investigated azoospermia and teratozoospermia in a mouse knockout model demonstrated oocytes fertilized via ICSI with sperm targeted *SEPT12* antisense alleles resulted in embryo arrest by the morula stage (3). The application of RNA sequencing to elucidate the expression profile of *SEPT12* in human preimplantation embryos may unlock insights into the transcriptional events of early embryogenesis.

DESIGN: Prospective cohort study on human, donated embryos.

MATERIALS AND METHODS: The study included patients who donated fresh embryos at the blastocyst stage during an IVF cycle between January, 2016 and June, 2016. Embryos were biopsied, and approximately 2-4 cells were removed for preimplantation genetic testing for aneuploidy (PGT-A) by next generation sequencing (NGS) using the ReproSeq assay to assess copy number variants (CNVs). The remaining cells of the embryo were designated for RNA Sequencing. Read counts per gene were summed across embryo cohorts and normalized using the median of ratios. Differential gene expression between embryo cohorts was calculated using DESeq2, in order to estimate variance-mean dependence and evaluate differential gene expression using a negative binomial distribution. A likelihood ratio test was used to account for heterogeneity due to patient, batch, and ploidy and growth status (arrested/ongoing). The adjusted threshold for significance was $p<0.05$.

RESULTS: 43 blastocysts underwent PGT-A assessment and RNA sequencing. 36 showed expression of *SEPT12*, 6 of the 7 blastocysts that failed to show *SEPT12* expression had poor trophectoderm morphology grade. The expression of *SEPT12* was further examined in 15 embryos, 9 were enriched (>90%) for trophectoderm cells (TE) and 6 enriched (>80%) for inner cell mass cells (ICM). *SEPT12* expression was significantly higher in TE cells than ICM cells, where $P<0.0001$.

CONCLUSIONS: Septins were first discovered nearly fifty years ago however their function remains poorly understood (4). The importance of this gene family has been indicated by the conservation of the functional domains throughout evolution. *SEPT12* has been shown to be critically important in spermatogenesis. This study is the first to characterize *SEPT12* expression in the human embryo. Our data supports the findings that wild type *SEPT12* expression was preferentially associated with blastocyst formation compared to arrest at the morula stage for embryos that contained the antisense *SEPT12* allele (3). Our current studies are focused on characterizing *SEPT12* expression in cleavage and morula stage human embryos to further elucidate this gene's role in early embryogenesis.

DIFFERENCES IN METABOLIC SIGNATURES BETWEEN THE INNER CELL MASS AND THE TROPHECTODERM IN DISCARDED HUMAN BLASTOCYSTS. Marta Venturas, M.Sc.,[1] Jaimin S. Shah, M.D.,[2] Tim H. Sanchez, Ph.D.,[3] Will Conway, Bs in Physics and Biology,[1] Denny Sakkas, PhD,[4] Dan Needleman, Ph.D.[1] [1]Harvard University, Cambridge, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [3]None; [4]Boston IVF, Waltham, MA.

OBJECTIVE: To determine whether non-invasive metabolic imaging can detect differences in metabolic profiles between the inner cell mass (ICM) and the trophectoderm (TE) of discarded human blastocysts.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: We used 192 morphologically normal human vitrified blastocysts from 126 patients (mean age 35.5 ±4.75 years) that were discarded and donated for research under an approved institutional review board protocol. These embryos were warmed, cultured for 2h and imaged, to analyze their metabolic signatures. Metabolic function was assessed using Fluorescence Lifetime Imaging Microscopy (FLIM). FLIM enables non-invasive imaging of the autofluorescent endogenous molecules, NADH and FAD+, essential coenzymes for cellular respiration and glycolysis. FLIM yields quantitative information on metabolite concentrations from fluorescence intensity and on enzyme engagement from fluorescence lifetimes. A single measurement provides 9 metabolic parameters (4 for NADH, 4 for FAD and Redox Ratio) which was used to separately analyze the metabolic signatures of the ICM and TE from each embryo. Metabolic parameters from the ICM were compared to those of the TE using paired t-test analyses while a sub analysis of embryo day (5 or 6) was performed using multilevel models.

RESULTS: Our data showed statistically significant variations in all metabolic parameters between the ICM and the TE from discarded human blastocysts. Both NADH and FAD+ intensities, that correlate with the concentration of these coenzymes, were significantly different between the ICM and the TE ($p<0.0001$). Furthermore, the lifetimes of these molecules and the fraction engaged with enzyme were significantly different between the ICM and the TE ($p<0.0001$). These findings are in line with previous evidence in mouse blastocysts showing that the ICM of mouse embryos have a relatively quiescent metabolism compared with that of the TE. Additionally, metabolic signatures from the ICM and the TE correlated with blastocyst day. When comparing day 5 and day 6 embryos, distinct metabolic signatures were visualized in the ICM (6/9 FLIM parameters, $p<0.002$) and also in the TE (6/9 FLIM parameters, $p<0.001$).

CONCLUSIONS: Non-invasive metabolic imaging can detect significant metabolic variations between the ICM and TE of discarded human blastocysts, suggesting different metabolic demands specific to the ICM and TE. Further studies on human embryo samples are planned which will investigate possible correlations between metabolic signatures of both the ICM and the TE with embryo morphology and pregnancy outcomes.

SUPPORT: Supported by the Blavatnik Biomedical Accelerator Grant at Harvard University. Becker and Hickl GmbH, and Boston Electronics sponsored research with the loaning of equipment for FLIM.

P-575 4:30 PM Monday, October 19, 2020

CIRCULATING MIRNAS AS A NON-INVASIVE DIAGNOSTIC TOOL TO PREDICT IMPLANTATION FAILURE. Chloé Baron, PhD student,[1] Delphine Haouzi, PhD,[1] Frida Entezami, MD,[1] Sophie Brouillet, PharmD, PhD,[1] Samir Hamamah, MD, PhD[2] [1]Inserm U1203, CHU Montpellier, St-Eloi Hospital, Montpellier, France; [2]Arnaud de Villeneuve Hospital, CHU Montpellier, Montpellier, France.

OBJECTIVE: Do circulating miRNAs profile during the implantation window under the same hormone replacement therapy (HRT) treatment for frozen embryo replacement cycle,predict successful pregnancy?

DESIGN: Serum (n=14) were collected during the implantation window from repeated implantation failure (RIF) patients (mean ± SD, age: 38.6 ± 5.0 years) under HRT treatment for subsequent frozen embryo transfer. RNAs were extracted to perform the miRNA expression profile. Then, miRNA expression was analyzed according to the following pregnancy outcome: successful implantation (n=7) or implantation failure (n=7). Successful implantation was defined as both positive b-hCG and clinical pregnancy and implantation failure as negative b-hCG.

MATERIALS AND METHODS: Serum were obtained during a mock HRT treatment cycle from 14 RIF patients. Then, miRNA expression profile between groups, successful *vs*. implantation failure after frozen embryo replacement was evaluated by Next Generation Sequencing using the HTG EdgeSeq miRNA Whole Transcriptome Assay (Illumina, Firalis). miRNA sequencing data were normalized using the method recommended by HTG molecular diagnostic. Then, statistical analysis and receiver operating characteristic (ROC) analysis were applied to miRNA sequencing data.

RESULTS: We identified 44 miRNAs differentially expressed between groups with a fold change > 2 and a p-value < 0.05. All miRNAs were overexpressed in serum from patients with successful implantation. Supervised hierarchical clustering of these 44miRNAs showed a good segregation of serum samples from patients with and without a successful implantation. Related to these 44 miRNAs, we note four of them which are members of the let-7 family [miR-1 (x2.4, $p = 0.017$, AUC $= 0.88$), miR-2 (x2.2, $p = 0.004$, AUC $= 0.94$), miR-3 (x2.1, $p = 0.001$, AUC $= 0.90$), miR-4 (x2.1, $p = 0.001$, AUC $= 0.98$)].The microRNA target filter function from Ingenuity software predicted that 1375 mRNAs were targeted by the let-7 family that are involved in cell invasion, proliferation, growth and survival via integrin subunit beta 3 (*ITGB3*), vimentin (*VIM*), B-cell CLL/lymphoma 2 like 1 (*BCL2L1*) that play a central role in endometrial receptivity acquisition and implantation process. These results might have potential clinical applications to develop a non-invasive diagnostic tool to predict successful implantation, to avoid endometrium biopsy and consequently, to increase IVF/ICSI success.

CONCLUSIONS: We identified a miRNA signature in serum during the implantation window that can predict successful implantation. This information is crucial and can lead to the development a prognostic tool of the attempt, opening new perspectives in the patient care management. Further investigations with a larger number of patients are in progress to validate theses results.

DISRUPTION OF NRF2- MEDIATED STRESS RESPONSE AND DNA REPAIR PATHWAYS ARE ASSOCIATED WITH LIMITED DEVELOPMENTAL POTENTIAL OF TRISOMY EMBRYOS. Jason C. Parks, BS, Mary E. Haywood, PhD, Blair R. McCallie, BS, Sue McCormick, BS, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD. Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Embryonic chromosomal trisomy is recognized as a leading cause of reproductive failure and pregnancy loss in human reproduction. Interestingly, specific trisomy's have differing implantation potential and only a handful of trisomies (chromosome 13, 18, 21, X and Y) will even develop past the first trimester. The aim of this study was to investigate the association between the embryonic transcriptome and a range of embryonic trisomy with differing implantation potentials.

DESIGN: Research study.

MATERIALS AND METHODS: Surplus, frozen blastocysts (n = 55) were donated to research with IRB and patient consent. Blastocysts underwent micromanipulation to isolate trophectoderm (TE) cells for transcriptome analysis. In addition to euploid blastocysts (n=17), the following trisomies were identified based on differing implantation potential: trisomy 7 (n=11) and trisomy 11 (n=5) that are most likely to result in implantation failure, as well as trisomy 15 (n=11) and trisomy 22 (n=11) which are able to implant but will always result in miscarriage. Individual TE total RNA (n = 25) was isolated for sequencing on the NovaSEQ 6000 (Illumina). Reads were aligned to hg38 using GSNAP and only reads mapping to non-trisomy chromosomes were included in downstream analysis (genes on chromosomes 7, 11, 15, and 22 were excluded in all samples). Differential gene expression was analyzed with edgeR and limma (FDR<5%), and interpreted using Ingenuity Pathway Analysis (Qiagen). Validation was performed on additional individual TE samples (n = 30; 6 per group) with gene expression confirmed using Real-Time PCR (ViiA 7 Real-Time PCR System; $P<0.05$).

RESULTS: An interplay of several biological processes were evident in all trisomy embryo groups compared to euploid, regardless of the specific chromosome involved in the meiotic error, with a total of 389 differentially expressed genes ($P<0.05$). There was no enrichment for chromosome type or cytoband. Pathway analysis identified a globally inhibited NRF2-mediated stress response including validation of the two central players in the pathway, NRF2 and KEAP1 ($P<0.001$) and 8 significantly decreased NRF2 targets

(regulating key antioxidant and metabolic genes; P<0.05). CLPTM1L, also a target of NRF2, was validated showing increased expression that may result in activation of apoptosis (P<0.05). DNA damage response was also significantly associated with embryonic trisomy (P<0.05). Specific validated genes included confirmation of significant increased expression of BRCA2, PALB2 and ATR, all genes that are essential for DNA damage repair pathways (P<0.0001).

CONCLUSIONS: This in-depth molecular characterization of embryonic trisomy concluded that regardless of the individual triploid chromosome, a globally compromised transcriptome was apparent. Significant disruption to the NRF2- mediated stress response and DNA repair pathways were specifically evident in all trisomy embryos, which explains why the vast majority of trisomy conceptions will have limited potential and perish during the early stages of development.

AGE-EFFECT ON THE FATTY ACID AND LIPIDOMIC PROFILE OF THE FOLLICULAR FLUID DURING IN-VITRO FERTILIZATION CYCLES.

Gustavo N. Cecchino, M.D.,[1] Mariona Jové, Ph.D.,[2] Reinald Pamplona, Ph.D.,[2] Juan A. Garcia-Velasco, MD, PhD,[3] Eduardo Rial, PhD[4] [1]IVIRMA Madrid, Madrid, Spain; [2]Universitat de Lleida, Lleida, Spain; [3]IVI Madrid, Rey Juan Carlos University, Madrid, Spain; [4]Centro de Investigaciones Biológicas Margarita Salas - CSIC, Madrid, Spain.

OBJECTIVE: Compelling evidence suggests that the metabolic profile and lipidomic composition of the human follicular fluid (FF) may play a role in reproductive outcomes. However, there are gaps in current knowledge regarding the follicular environment of aging, which is the main factor affecting female reproductive capacity. Thus, we aimed to evaluate if there is any variability in the fatty acid and lipidomic composition of the FF between oocyte donors and infertile patients with advanced age.

DESIGN: Prospective observational case-control and experimental study.

MATERIALS AND METHODS: Non-targeted lipidomic and fatty acid analysis of the FF from two groups: 17 oocyte donors aged < 35 years *versus* 17 infertile women aged ≥ 38 years that underwent controlled ovarian stimulation with an antagonist protocol between September and October 2018. Women with diseases that could potentially impair ovarian function were excluded. Pooled follicular aspirate from each patient was centrifuged at 800g for 20 min to isolate FF from cells. The supernatant was sterile-filtered using a 0.22 mm pore size membrane filter and stored at -80oC. Lipids were extracted according to the method of Bligh and Dyer, subjected to liquid chromatography-mass-spectrometry and analysed using MassHunter Qualitative Analysis software. Fatty acid groups were analysed as methyl ester derivates by gas chromatography and compared with authentic standards.

RESULTS: We detected 4431 molecular species in the FF. Only those found in at least 70% of samples of the quality-control and presenting a low variability were selected, which resulted in 159 lipid species. Multivariate analysis failed to demonstrate statistically significant differences in the lipidomic profile between groups. Principal component analysis (PCA) and hierarchical clustering revealed that the lipidome does not seem to be an important feature defining the reproductive age. Similarly, partial least square-discriminant analysis (PLS-DA) was applied to identify molecules that could explain variability within samples. Despite the good clusterization between groups, permutation test and cross-validation showed that the model was overfitted. Univariate statistics revealed two lipid species which were substantially increased in the older group. Those were the ones with the highest weight explaining the variability in the PLS-DA model. Unfortunately, only one of them could be identified, the sphinganine. Finally, we analyzed the fatty acid composition of samples, but no differences were found regarding saturated fatty acids, unsaturated fatty acids, monounsaturated fatty acids, and polyunsaturated fatty acids n-3 and n-6 series. Likewise, the double bond index and the peroxidability index were similar between groups.

CONCLUSIONS: The sphinganine was the only lipid specie showing higher concentrations in FF from older patients. Since the sphinganine is a precursor of ceramide, it could be associated with increased apoptotic metabolism and, ultimately, depletion of ovarian reserve and function as women age. Further molecular studies should confirm our findings.

P-578 4:30 PM Monday, October 19, 2020

MITOCHONDRIAL STRESS RESPONSE GENE CLPP IS NOT REQUIRED FOR GRANULOSA CELL FUNCTION.

Ecem Esencan, M.D.,[1] Gizem Imamoglu, MD,[1] Mauro Cozzolino, MD,[2] Emre Seli, M.D.[1] [1]Yale School of Medicine, New Haven, CT; [2]IVIRMA Foundation, Valencia, Spain.

OBJECTIVE: Mitochondrial unfolded protein response (mtUPR) is a highly conserved mechanism by which cells can maintain their homeostasis in the presence of cellular or metabolic stress. CLPP (caseinolytic peptidase P) plays a key role in this process by promoting degradation of unfolded mitochondrial proteins. We have previously shown that global deletion of *Clpp* in mice results in female infertility and accelerated follicular depletion. However, it is not known whether the infertility phenotype observed in mice with global deletion of *Clpp* results from an impact on oocytes, granulosa cells, or both. In this study, we investigated whether CLPP is required for granulosa cell function.

DESIGN: Experimental study.

MATERIALS AND METHODS: $Clpp^{flox/flox}$ mice were generated and crossbred with *Cyp19a1-Cre* mice in order to generate mice with granulosa cell specific *Clpp* deletion ($Clpp^{-/-}$). Mature (8-week old) $Clpp^{-/-}$ female mice were compared to same age wild type (WT) mice. To assess fertility, $Clpp^{-/-}$ (n=8) were mated with adult WT males with proven fertility for 12 weeks and compared to WT female mice (n=8). To analyze folliculogenesis, serial ovarian sections were obtained and stained with hematoxylin and eosin. Primordial, primary, secondary, early antral and antral stage follicles were counted and numbers were compared between $Clpp^{-/-}$ and WT mice. Mice were injected with of PMSG (5IU) or PMSG and HCG (5IU) to assess generation of germinal vesicle and MII stage oocyte, respectively. ANOVA, student's t-test, and Chi Square analysis were used for statistical analysis as appropriate.

RESULTS: Fertility of mature $Clpp^{-/-}$ female mice was similar to WT females; they produced similar number of pups per litter (9.0±1.0 vs 7.32±0.58, p=0.067). Folliculogenesis was not affect by loss of CLPP in granulosa cells as $Clpp^{-/-}$ and WT mice had similar numbers of primordial (317.80±119.90 vs 278.20±13.08, p=0.69), primary (147.80±88.74 vs 135.30±31.47, p=0.87), secondary (71.0±26.16 vs 83.50±3.54, p=0.57), early antral (54.75±12.37 vs 46.25±13.08, p=0.57), and antral follicles (3.0±2.12 vs 1.75±0.35, p=0.5). Number of GV (32.67±2.52 vs 40.67±6.11, p=0.10) and MII (19.0±8.19 vs 22±2.65, p=0.59) oocytes collected from $Clpp^{-/-}$ and WT female mice were also similar.

CONCLUSIONS: Fertility in female mice is not affected by granulosa cell-specific mtUPR disruption through CLPP deletion even though mtUPR and CLPP have been shown to be required for female fertility and oogenesis. Our findings suggest that oocyte but not granulosa cells require CLPP-mediated mtUPR.

P-579 4:30 PM Monday, October 19, 2020

SUPPLEMENTATION OF CULTURE MEDIUM WITH MELATONIN IMPROVES BLASTOCYST DEVELOPMENT AND REVERSES GLUCOSE INTOLERANCE IN IVF MICE.

Yanping Jia, student, Wenqiang Liu, Research associate, Dandan Bai, student, Kunming Li, professor, Miaoxin Chen, PhD Center for Reproductive Medicine, Shanghai First Maternity and Infant Hospital,Tongji University, Shanghai, China.

OBJECTIVE: This study aimed to determine if the adverse effects of IVF on blastocyst and offspring could be reversed by supplementation of culture medium with melatonin in mice.

DESIGN: A cross-sectional mouse model was utilized, wherein blastocysts were generated by natural mating (control group) or IVF with or without melatonin (10^{-6}M) (mIVF and IVF group respectively) in clinical grade fertilization and culture media. Blastocysts were transferred to pseudo-pregnant ICR females. Cell lineage allocation was assessed for 30-40 blastocysts from each group. Body weight, glucose tolerance, energy expenditure, hepatic gene expression was measured in 6-10 mice from each group.

MATERIALS AND METHODS: C57BL/6 female mice and DBA2 male mice were used to generate blastocysts by natural mating (control group) or IVF with or without melatonin (10^{-6}M) (mIVF and IVF group respectively) in clinical grade fertilization and culture media. Blastocysts were transferred to pseudo-pregnant recipients. Embryo development was recorded for IVF groups. Cell numbers of inner cell mass (SOX2) or trophectoderm (Cdx2+) were determined by immunohistochemistry. Males were weaned at 3 weeks

of age onto a chow diet or a high-fat diet (60% fat) for 8 weeks. Glucose tolerance was assessed by an intraperitoneal glucose tolerance test (2g/Kg). Energy metabolism was examined in metabolic cages. Hepatic gene expression was measured by RNA-Seq and validated by real-time quantitative PCR.

RESULTS: Blastocyst rates were similar in the two IVF groups. Reduced inner cell mass, trophectoderm and total cell number were observed in IVF blastocysts, compared with the control group ($P<0.05$). IVF pups had significantly lower birth weight and body weight before weaning, but exhibited increased body weight and liver weight at 11 weeks of age compared with controls ($P<0.05$), independently of diet. IVF mice were glucose intolerant shown as an increased glucose area under the curve, and had decreased energy expenditure as well as a large number of differentially expressed genes related to metabolic pathways in the liver tissue compared with the control group ($P<0.05$), independently of diet. The mIVF group showed intermediate cell numbers in blastocysts, body weight, liver weight and differentially expressed hepatic genes compared with the IVF group and control group, and normalized glucose tolerance and energy expenditure compared with the IVF group ($P<0.05$), independently of diet. Importantly, there was no significant difference in glucose tolerance and energy expenditure between the mIVF group and the control group.

CONCLUSIONS: The data suggests that supplementation of culture medium with melatonin improved IVF blastocyst differentiation, reduced excessive weight gain after birth and normalized glucose intolerance in adult male offspring of IVF mice.

SUPPORT: The study was funded by two grants from the National Natural Science Foundation of China (81671468, 81871213).

P-580 4:30 PM Monday, October 19, 2020

BREAKDOWN OF FOLLICLE-OOCYTE COMMUNICATION CONTRIBUTES TO AGE-RELATED INFERTILITY: DISRUPTED *TGFB1* SIGNALING IMPAIRS ACQUISITION OF OOCYTE COMPETENCE. Jennifer E. Russ, BS, Mary E. Haywood, PhD, Blair R. McCallie, BS, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Ovarian aging precedes that of any other mammalian organ, and resultant attenuated oocyte quality and quantity are key limiting factors in female fertility. Our aim is to elucidate the impact of ovarian aging on folliculogenesis and oocyte development as it pertains to reduced female reproductive potential.

DESIGN: Longitudinal research study.

MATERIALS AND METHODS: Outbred female mice were naturally aged to represent young (3-4 months old; Young) and advanced reproductive age (12-15 months old; Aged) populations. Total RNA was isolated from individual follicles (n=6 per age group) and oocytes (n=12 per age group). Sequence libraries were prepared using the NEBNext Single Cell/Low Input RNA library prep kit and sequenced on the Illumina NovaSEQ6000. Differentially expressed genes (DEGs) were generated using edgeR and evaluated by Ingenuity Pathway Analysis (IPA)(Qiagen). Sequencing was validated by RT-qPCR on additional follicles (Applied Biosystems) (n=6 per age group).

RESULTS: A globally decreased transcriptome was observed for the Aged females. In the follicles, 24,373 transcripts were identified, which included 7,388 DEGs in the Aged females (2,921 increased and 4,461 decreased in expression; $p<0.01$). Single-cell RNA sequencing of oocytes identified 12,986 transcripts and 226 DEGs in Aged oocytes (64 increased and 162 decreased in expression; $p<0.05$). Unsupervised hierarchical clustering of DEGs cleanly separated follicles and oocytes according to female age. IPA revealed significant decreased expression of EIF2 Signaling, Cell Cycle Control of Chromosomal Replication, Estrogen-mediated S-phase Entry and G2/M DNA Damage Checkpoint Regulation in Aged follicles ($p<0.0001$), indicating severe impairment of DNA replication, protein translation, cell division and proliferation. In the oocyte, transforming growth factor beta 1 (*Tgfb1*) was identified as the most significant upstream regulator and predicted to be inhibited in Aged oocytes ($p<0.0001$). *Tgfb1* signaling maintains meiotic arrest within the oocyte, and its disruption results in premature meiotic resumption. *Tgfb1* is initially secreted from the follicle as an inactive precursor molecule unable to interact with cellular receptors until activated. We observed increased *Tgfb1* expression in the follicle accompanied by inhibited *Tgfb1* signaling in the oocyte, suggesting that activation of latent *Tgfb1* is prevented in the Aged follicle. Conversion of *Tgfb1* to its biologically active form occurs through various tissue-specific mechanisms, and our data implicates Thrombospondin-1 (*Thbs1*). *Thbs1* is a known activator of *Tgfb1* and exhibited significantly decreased expression in Aged follicles ($p<0.005$).

CONCLUSIONS: Insufficient expression of *Thbs1* required for *Tgfb1* activation could lead to aberrant *Tgfb1* follicle-oocyte signaling resulting in premature meiotic resumption and oocyte incompetence. Collectively, these results provide insight to the molecular mechanisms of ovarian aging and suggest that disrupted intercellular communication between follicle and oocyte contributes to the fertility decline with age.

P-581 4:30 PM Monday, October 19, 2020

OVARIAN TISSUE FROM DECEASED DONORS MAINTAINS NORMAL FOLLICLE VIABILITY DESPITE PROLONGED COLD ISCHEMIA. Yuting Fan, MD, PhD,[1] Colleen L. Flanagan, MSE,[1] Margraret Brunette, MS,[1] Andrea Jones, PhD,[1] Sherman Silber, MD,[2] Ariella Shikanov, PhD[1] [1]University of Michigan, Ann Arbor, MI; [2]Infertility Center of St. Louis, St. Louis, MO.

OBJECTIVE: To evaluate the number and quality of ovarian follicles that can be isolated from young deceased human donors before and after cryopreservation.

DESIGN: Fresh ovaries were obtained from 5 deceased donors aged 18-26 years from the International Institute for the Advancement of Medicine (IIAM) between 1/10/19 and 12/20/19.

MATERIALS AND METHODS: The characteristics of the donors, average cold ischemic time during transportation, volume of the ovaries and follicle density were analyzed. Ovarian cortex tissues were dissected from ovaries and ovarian tissue cryopreservation (OTC) was performed using slow freezing. Follicle morphology and classification were assessed with hematoxylin-eosin staining. DNA fragmentation of follicles and stroma was detected with TUNEL staining. Preantral follicles were enzymatically isolated from fresh and cryopreserved/thawed ovarian tissue. Follicle viability was determined using LIVE/DEAD staining.

RESULTS: Histologically, the mean follicle density in the 5 donors was 1781 ± 2249 follicles/mm^3 (mean $\pm$ SD), ranging from 14-4704 follicles/mm^3. Follicle density negatively correlated with age ($r = -0.943$, $P < 0.05$). A total of 2803 follicles from fresh and 1608 follicles from cryopreserved tissues were classified and analyzed. The average percent of morphologically normal follicles in cryopreserved/thawed and fresh group was 95.88% and 95.67% respectively, while there was no significant difference between the two groups ($P > 0.05$). Analysis of the data obtained from histologic slides stained with the TUNEL assay indicated no significant differences in DNA damage in the follicles and the stroma cells after cryopreservation compared to fresh tissue ($P > 0.05$). Morphologically normal preantral follicles were enzymatically isolated from both fresh and cryopreserved tissue with $88.51 \pm 5.93\%$ (mean $\pm$ SD) of the isolated follicles confirmed viable ($n = 443/490$).

CONCLUSIONS: The quantity and quality of follicles isolated from fresh and cryopreserved ovarian tissue of deceased donors were not affected by ischemia during transport of the organs from the hospital to the laboratory. Follicles at different developmental stages tolerated the cryopreservation process and maintained a high survival rate. The ample source of human ovarian tissues obtained from deceased donors may be applied to promoting research and future clinical applications.

P-582 4:30 PM Monday, October 19, 2020

UNIQUE SUBCELLULAR CO-LOCALIZATION OF FMR1 WITH FIBRILLARIN AND AMH IN GRANULOSA CELLS SUGGESTS NOVEL ROLES IN LOCALIZED REGULATION OF CELL CYCLE PROGRESSION. Jianjun Hu, MD,[1] Min Yang, PHD,[2] Lin Zhang, MD,[1] David F. Albertini, PhD, MS,[1] Emanuela Molinari, PhD,[1] David H. Barad, MD, MS,[1] Norbert Gleicher, MD[3] [1]Center for Human Reproduction, New York, NY; [2]Rockefeller University, New York, NY; [3]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY.

OBJECTIVE: To explore where and how FMR1 protein, as an RNA-binding protein, plays at subcellular level in granulosa cells multiple roles in regulating ovarian reserve and follicle recruitment.

DESIGN: Experimental human research.

MATERIALS AND METHODS: Granulosa and cumulus cells were in IVF cycles isolated from follicular fluids after oocyte collection and

cumulus-oocyte-complex identification. Primary and selectively cultured granulosa cells were stained after whole mount fixation or chromatin spread for subcellular localization analysis. To characterize the structural nature of unique localization patterns inside the nucleus and the peri-nuclear region, double staining of FMR1-Fibrillarian (nucleolus marker), FMR1-CREST (centromere marker), FMR1-gamma-tubulin (centrosome marker), FMR1-AMH (anti-Müllerian hormone), and AMH-gamma-tubulin, were performed, respectively. Phosphorylated FMR1 (pS1194) antibody was used to verify the novel findings of FMR1 antibody. Puromycin treatment followed by immunostaining was applied to determine whether FMR1, fibrillarin and/or AMH were enriched in active puromycin incorporation sites, suggesting relatively active protein translation regions. Matched secondary antibodies were used as controls for staining background. GAPDH and TOM20 antibodies were used as controls for antibody specificity.

RESULTS: Unique subcellular localization patterns of FMR1 in granulosa cells were observed by nuclear spread and whole mount preparation followed by immunostaining. Interestingly, FMR1 was enriched in the nucleolus as confirmed by double staining of FMR1-Fibirllarian (nucleolar marker). Unexpectedly, FMR1 protein was enriched in centromere (CREST as the marker) in metaphase, but not in any non-metaphase. Strikingly, FMR1 was found in centrosomes (gamma-tubulin as the marker) in both metaphase and non-metaphase. More strikingly, we found that: (i) AMH, previously reported diminished in large antral follicles, was relatively enriched in centrosomes; (ii) Double staining of FMR1-Fibrillarin, FMR1-gamma-tubulin, AMH-Fibrillarin, AMH-gamma-tubulin verified that FMR1, Fibrillarin and AMH were all co-localized in centrosomes in non-metaphase. Puromycin incorporation showed that FMR1, phospho-FMR1 (pS1194), Fibrillarin and AMH were co-enriched with puromycin signals in the nucleolus and centrosomes in many of the stained cells. As controls, GAPDH and TOM20 did not show similar patterns.

CONCLUSIONS: In granulosa cells, FMR1 and its phosphorylated form FMR1(pS1194) localized to the nucleolus and centrosomes in non-metaphase, and to both centromeres and centrosomes in metaphase. FMR1 and AMH were, thus, unexpectedly found co-enriched in centrosomes in non-metaphase, unexpectedly revealing that FMR1 might play roles in regulating nucleolar assembly and disassembly, spindle formation and/or stability as well as chromosome segregation in cell cycles. Further studies identifying FMR1 targets, and characterizations of inter-talk or inter-regulation between FMR1 and AMH are underway.

SUPPORT: Intramural funds from The Center for Human Reproduction and Foundation for Reproductive Medicine.

P-583 4:30 PM Monday, October 19, 2020

ASSOCIATION BETWEEN THE PERCENTAGE OF P16-POSITIVE SENESCENT CELLS AND THE EXPRESSION OF ESTROGEN AND PROGESTERONE RECEPTORS IN HUMAN ENDOMETRIUM DURING THE MID-LUTEAL PHASE. Dimitar Parvanov, PhD, Rumiana Ganeva, MSc, Nina Vidolova, MSc, Georgi Stamenov, MD/PhD. Nadezhda Women's Health Hospital, Sofia, Bulgaria.

OBJECTIVE: Progesterone and estrogen secretion and the expression of their receptors are strongly connected with the cyclic changes in endometrium and its receptivity. We previously reported that the frequency of occurrence of p16-positive senescent cells in human endometrium appear to be also associated with endometrial receptivity and successful embryo implantation. The objective of this study was to analyze the relationship between the percentage of senescent cells and estrogen and progesterone receptors expression in human endometrium during the mid-luteal phase of the menstrual cycle.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: This study includes 383 women who had an endometrial biopsy during the mid-lutheal phase (7 days after LH surge) of the natural cycles. Tissue sections were stained immunohistochemically for ER, PR and p16 using the following monoclonal antibodies: progesterone receptor (PR) (NCL-PGR-312, Leica Microsystems), 1:100 dilution; estrogen receptor (ER) (NCL-L-ER-6F11, Leica Microsystems), 1:100 dilution; p16 ^{ink4a} antibody (MAD-000690QD–7, Master Diagnostica), ready-to-use. The percentage of positively stained p16 cells and the levels of ER/PR expression were evaluated by Image-J software (NIH, Maryland, USA) in multiple endometrial sections. Statistical analysis was performed by Spearman's correlation test using SPSS v.21 (*IBM* Corp., Armonk, NY, USA).

RESULTS: No correlation was found between the frequencies of occurrence of senescent p16-positive stromal, luminal and glandular epithelial cells and PR ($p>0.05$). In contrast, the glandular expression of ER showed low, but a significant correlation with the percentage of p16+ glandular epithelial cells ($R=0.34$; $p=0.03$).

CONCLUSIONS: In conclusion, we found that the increased cell senescence in endometrial glands during the mid-luteal phase is associated with increased expression of glandular ER in the mid-luteal phase of the cycle. These results suggest an estrogen related change of endometrial senescent cells during the period of embryo implantation.

P-584 4:30 PM Monday, October 19, 2020

EARLY EMBRYO INITIATED UTERINE RECEPTIVITY REGULATED BY LOCAL APOPTOTIC CASPASE-3 MEDIATED PROSTAGLANDIN ACTION. Sicily E. Garvin, MD, MSBS,[1] Chandrashekhara Kyathanahalli, PhD,[2] Jeyasuria Pancharatnam, PhD,[2] Jennifer Condon, PhD[2] [1]Wayne State University, Detroit, MI; [2]Wayne State University School of Medicine, Detroit, MI.

OBJECTIVE: We observed a twenty-fold increase in caspase-3 activation in pregnant the mouse uterus on day 1 post coitus (1dpc) which rapidly declined on 2dpc to barely detectable levels. The function of caspase-3 at this early gestational time-point in pregnancy has not been determined. We have previously determined that elevated levels of apoptotic caspase-3 at term regulate uterine prostaglandin synthesis through the cleavage and activation of phospholipase-A2 (iPLA2). Therefore, the primary objective of this current study was to determine if elevated caspase-3 on 1dpc also regulates prostaglandin synthesis very early in pregnancy, which others have demonstrated to play a leuteoprotective role, thereby enhancing uterine receptivity. Our secondary objective was to determine if the conceptus was the trigger for this very early pregnancy surge in uterine caspase-3.

DESIGN: Prospective laboratory animal study using pregnant mouse models.

MATERIALS AND METHODS: Utilizing an inbred strain of non-pregnant mice, the following mouse models were created. Unilaterally ligated and bilaterally ligated mouse models were generated with non-pregnant mice that underwent surgical ligation of uterine horn/horns just proximal to the oviduct. Mice which did not undergo surgical uterine horn ligation, served as controls. All mice were time mated, sacrificed and uteri collected from pregnant control mice on day 1-19 dpc, unilateral and bilateral and control pregnant mouse models on day 1, 3 and 6 of gestation and non-pregnant mice at estrous and diestrous ($n=3$ for each). Uteri were examined for apoptotic indices, including caspase-3 activation and TUNEL staining. Immunohistochemical analysis was performed to identify the site of apoptotic caspase-3 activation. Cytoplasmic and nuclear extracts were prepared and examined for caspase-3 activation, PARP cleavage and the appearance of cleaved iPLA2 by western blot analysis, PDI and NCOA3 served as our loading controls.

RESULTS: Apoptotic caspase-3 and iPLA2 cleavage were isolated to the uterine endometrial compartment in control mice and both uterine horns of unilaterally ligated model solely on 1dpc. Apoptotic caspase-3 and cleaved iPLA2 were absent in the bilaterally ligated uterine horn model on all days examined.

CONCLUSIONS: Our data supports, a novel link for apoptotic endometrial casepase-3 in promoting prostaglandin mediated uterine receptivity in early pregnancy. The absence of apoptotic caspase-3 and iPLA2 cleavage in the bilaterally ligated uterine horn supports that the early conceptus and not coitus acts as the trigger for endometrial caspase-3 in very early pregnancy. We therefore propose that the conceptus releases systemic signals as evidenced by caspase-3 activation and cleaved iPLA2 in both horns of the control and unilateral pregnant model on 1dpc, acting to increase prostaglandin E2 levels thereby supporting corpus luteal progesterone production and endometrial receptivity in very early pregnancy.

P-585 4:30 PM Monday, October 19, 2020

INTERFERON-STIMULATED GENE 15 ENHANCEMENT OF TROPHOBLAST INVASION IS REGULATED BY INCREASED FILAMENTOUS-ACTIN FORMATION AND β1 INTEGRIN EXPRESSION AND DECREASED β4 INTEGRIN LEVELS. Ali E. Wells, MD, A. S. L. I. Ozmen, PhD, Xiaofang Guo, MD, Ozlem Guzeloglu-Kayisli, PhD, Charles J. Lockwood, MD, MHCM, Umit A. Kayisli, PhD. Department of Obstetrics and Gynecology, Morsani College of Medicine, University of South Florida, Tampa, FL.

OBJECTIVE: During early placentation, cytotrophoblasts differentiate to an invasive phenotype associated with increased β1 integrin and decreased β4 integrin expression. We previously showed significantly decreased interferon-stimulated gene 15 (ISG15) expression in interstitial extravillous trophoblasts (EVTs) in the decidua basalis of pre-eclamptic *vs.* gestational-age-matched control specimens. We also showed that silencing ISG15 inhibits trophoblast migration/invasion in an HTR8 cell line (EVT cells). We hypothesize that ISG15 regulates trophoblast invasion by switching integrin types and regulating filamentous- (F-) actin formation. Thus, this study investigates expression of integrin-β4 as a non-invasive hemi-desmosome receptor, and integrin-β1, an extracellular matrix receptor of invasive trophoblasts and F-actin levels as an indicator of focal adhesion and migration in ISG15-silenced HTR8 cells.

DESIGN: Laboratory research, designed to study role of ISG15 in regulation of β1and β4 integrin and F-actin formation in trophoblast cultures**.**

MATERIALS AND METHODS: HTR8/SVNeo cell cultures were grown to confluence and were transfected with either scrambled (control) or ISG15 siRNAs according to the manufacturer's protocols. qRT-PCR analysis was used to amplify the target genes: human β1 integrin (*ITGB1)*, human β4 integrin *ITGB4,* and housekeeping gene human *ACTB*. Phalloidin-conjugated F-actin immunofluorescence staining was performed to compare F-actin formation in ISG15-siRNA versus control-siRNA transfected HTR8 cell cultures. Results were analyzed via *t-test* where $P<0.05$ was considered significant.

RESULTS: We initially confirmed that ISG15 siRNA treatment reduced levels of ISG15 mRNA and protein expression in HRT8 cells analyzed by qPCR and immunoblot analyses. qRT-PCR analysis revealed that ISG15 siRNA silencing led to a significant decrease in *ITGB1* mRNA expression (1.00± 0.00 *vs*. 0.42± 0.11 *P=0.007*, n=3) and a significant increase in *ITGB4* mRNA expression (1.01± 0.01 *vs*. 1.73± 0.15 *P=0.009*, n=3) compared to control siRNA treated group. Moreover, immunofluorescence staining revealed ISG15 silencing in HTR8 cells resulted in reduced F-actin formation compared to controls.

CONCLUSIONS: These results indicate that ISG15 stimulates trophoblast differentiation toward an invasive phenotype and that silencing of ISG15 in trophoblast cultures upregulates β4 integrin and inhibits β1 integrins and F-actin formations, thereby contributing to reduced trophoblast invasion.

P-586 4:30 PM Monday, October 19, 2020

PHTHALATES AND HYPEROSMOTIC STRESS FORCE LOSS OF GROWTH AND PROGRESSION PAST G1 PHASE IN FUCCI EMBRYONIC STEM CELLS. Elizabeth E. Puscheck, MD, MS, MBA,[1] Mohammed Abdulkareem Abdulhasan, Ph.D.,[2] Steven J. Korzeniewski, Ph.D.,[3] Katherine Gurdziel, Ph.D.,[4] Douglas Ruden, Ph.D.,[4] Daniel Rappolee, Ph.D.[3] [1]InVia Fertility, Hoffman Estates, IL; [2]Reproductive Stress 3M, Inc., Grosse Pointe Farms, MI; [3]Wayne State University School of Medicine, Detroit, MI; [4]Wayne State University, Detroit, MI.

OBJECTIVE: Determine whether various stresses including positive control hyperosmotic sorbitol, hormonal cortisol, PFOA (Perfluorooctanoic acid) and phthalates slow growth and suppress cell cycle progression measured by FUCCI (Fluorescence Ubiquitination Cell Cycle Indicator) embryonic stem cells (ESC) to test for effects on growth and stemness/differentiation balance.

DESIGN: Experimental

MATERIALS AND METHODS: FUCCI- ESC were tested for confluence/growth and cell cycle commitment by IncuCyte Zoom by bulk or single cell (sc) RNAseq after 72 hr exposures to 0-300 mM hyperosmotic sorbitol or 1 nM-100uM PFOA (with stemness-maintaining Leukemia Inhibitory Factor, LIF) to quantify stress-forced differentiation. Controls for normal stemness were LIF+ and normal differentiation were LIF-. RNA was isolated by RNAeasy lysis or 10XGenomics Dropseq, RNA quality was checked by Agilent TapeStation, cDNA was synthesized using Lexogen's QuantSeq library kit, and barcoded, multiplexed and sequenced by Illumina NovaSeq 6000. Data were demultiplexed by CASAVA software and FC expression was compared between conditions. In triplicate experiments, significant fold change (FC) genes ($FC\geq 2$; $FDR\leq 0.05$, $P<0.05$) identified affected genes. Validating studies including qPCR.

RESULTS: Hyperosmotic sorbitol and PFOA caused dose-dependent decrease in growth measured by confluence and decreased fraction of fluorescent green cells moving from G1 into cell cycle S-M phase. IC50 for PFOA at approximately 1 uM is consistent with several in vitro and in vivo assays. Significant increases in cell checkpoint gene transcripts in hyperosmotic stressed ESC compared with normally differentiating ESC by p-Value and FDR were observed for TRP53 (2.1fold), Cdkn1c/p57KIP2 (4.1fold), and decreased Cdk5r2 (3.2fold) were observed, although decreases in Cdkn2a/p16/INK4A (3.5 fold) was observed. Like trophoblast stem cells, media change at 24 hr is insufficient to maintain stem cells in asynchronous, rapid growth. After 24 hr media change, there was an immediate 6-10 fold surge in cells entering S-M phase and there were nil S-M phase cells in the last 12 hr after media change. Media change every 12 hr decreased the FUCCI green peaks post-media change.

CONCLUSIONS: FUCCI ESC are useful to perform Quality Control (QC) during high throughput screening and validate cell number, handling and reported PFOA and hyperosmotic induced decreases in cell cycle and cell accumulation. FUCCI ESC showed that media change should be done more frequently and can be used to assess ESC used for high throughput screening for environmental toxicants.

TRANSFER OF DIPLOID SOMATIC CELLS INTO ENUCLEATED OOCYTES TO INDUCE MEIOSIS-LIKE HAPLOIDIZATION. Aysha Trout, B.A., Philip Xie, B.S., Robert Setton, M.D., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: We compared haploidization rates and preimplantation development of embryos generated by somatic cell nuclear transfer using three sources of somatic cells: *cumulus oophorus*, fibroblasts, or mouse embryonic stem cells (mESCs).

DESIGN: Metaphase II (MII) enucleated oocytes isolated from B6D2F1 mice were fused with *cumulus* cells (CCs), fibroblasts, or mESCs. The resulting constructs, identifiable by meiotic-like spindle development, were injected with mouse spermatozoa by piezo-ICSI. A series of unmanipulated oocytes were piezo-ICSI inseminated and served as controls. Successful haploidization by extrusion of a pseudo polar body, the appearance of biparental pronuclei, and full preimplantation development were compared between the experimental and control groups. Whole genome karyotype analysis was performed on the resulting blastocysts.

MATERIALS AND METHODS: MII oocytes were enucleated in the presence of cytochalasin B by extracting the spindle complex and first polar body under Oosight™ visualization. A single CC, fibroblast, or mESC was fused with the ooplast of enucleated oocytes using Sendai virus. After $\geq$2 hours, successful somatic cell fusion and meiotic-like spindle development were assessed. Piezo-actuated sperm injection was executed on the experimental and unmanipulated oocyte controls. Fertilization and preimplantation development were monitored by time-lapse imaging. DNA *seq* was used to assess the karyotype of the resulting blastocysts.

RESULTS: After enucleation of 535 MII oocytes, haploidization by spindle development was verified at a significantly higher rate for those transferred with CCs (56%, $P<$ 0.00001) compared to those with fibroblasts (30%) or mESCs (32%). After injection, the controls had an 86% survival rate, while oocytes reconstituted with CCs, fibroblasts, or mESCs survived at rates of 54%, 53%, and 57%, respectively ($P<0.001$). The control group fertilized at a rate of 74%, while oocytes reconstituted using CCs fertilized at a rate of 52%, fibroblasts at 35%, and mESCs at 55% ($P<0.001$). Finally, 81% of fertilized oocyte controls developed to blastocysts, while only 21% of oocytes reconstituted with CCs, 20% of fibroblasts, and 5% of mESCs reached the blastocyst stage ($P<$ 0.00001). Moreover, experimental conceptuses had morphokinetic developmental characteristics to the blastocyst stage comparable to the controls, as assessed by time-lapse imaging. Preliminary results of 4-8 cells taken from 9 CC-derived blastocysts and 1 mESC-derived blastocyst, sequenced at an independent laboratory, show that 5 CC blastocysts and the 1 mESC blastocyst were euploid.

CONCLUSIONS: While these results indicate that the chances of fertilization and blastocyst development among the different somatic cell sources are lower than the controls, they were still achievable and had comparable morphokinetic characteristics. CCs also appear to be more easily reprogrammed, as shown by a significantly greater rate of haploidization. Once optimized and reproduced in humans, this technique may generate genotyped female gametes to alleviate age-related infertility.

P-588 4:30 PM Monday, October 19, 2020

DEFECTIVE MITOPHAGY IN EGGS FROM WOMEN OF ADVANCED MATERNAL AGE. Shaihla A. Khan, PhD,[1] Deirdre M. Logsdon, MS,[2] Heidi J. Engelhorn, MS,[2] Sue McCormick, BS,[3] William B. Schoolcraft, MD,[3] Rebecca L. Krisher, PhD[2] [1]Post-Doctoral Research Associate, Lone Tree, CO; [2]CCRM Colorado, Lone Tree, CO; [3]Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Both oocyte number and quality decrease as women age; however, the mechanisms underlying these changes remain unclear. Oocyte mitochondrial metabolism is critical for oocyte and subsequent embryo quality. This aim of this study was to investigate the mechanisms involved in the loss of mitochondrial quality and health in oocytes from women of advanced maternal age (AMA).

DESIGN: Research Study.

MATERIALS AND METHODS: Expression of proteins involved in mitochondrial upregulated protein response (UPR^{mt}) and mitophagy was investigated in *in vitro* matured metaphase II (MII) oocytes collected from 10 young (< 32 years old) and 10 AMA (>38 years old) patients. Specific proteins were detected using Jess Simple Western, a modified western blot analysis that allows protein detection from samples containing as little as 300 ng total protein. One MII oocyte per replicate was used to detect Heat Shock Protein 60 (HSP60), Lon Peptidase 1, mitochondrial (LONP1); phosphorylated Parkin (p-Parkin), total Parkin (Parkin), PTEN induced kinase 1 (PINK1) and p62. Total protein concentration in each sample was used to normalize proteins of interest. All protein expression was represented relative to young oocytes, which were set to a value of 1 for comparison. Data is expressed as mean ± SEM of 6-10 independent replicates for each protein. Results were analyzed for significance using Students t- test in GraphPad Prism 6.0.

RESULTS: AMA oocytes had significantly less total (mean= 0.25± 0.1) and phosphorylated (mean= Parkin compared to young oocytes ($p \leq 0.05$). Although not significant, we also observed decreased PINK1 protein in AMA MII oocytes (mean= 0.3± 0.12, p=0.14). There were no significant differences in HSP60, LONP1 and p62 expression between young and AMA MII oocytes.

CONCLUSIONS: We have shown for the first time that Parkin mediated mitophagy is significantly decreased in MII oocytes from AMA women. There was no significant difference in UPR^{mt} between young and AMA MII oocytes, indicating that eggs may not induce this pathway to regulate mitochondrial quality. Functional mitochondria are important to provide energy for cellular processes during maturation, fertilization and embryonic development. In addition, inefficient mitochondria will contribute to elevated ROS. Therefore, mitochondrial quality control is critical for the oocyte, and if compromised may result in decreased developmental competence. We have demonstrated that compromised mitophagy may be responsible, at least in part, for the poor oocyte quality observed in oocytes from AMA women.

P-589 4:30 PM Monday, October 19, 2020

TRANSCRIPTOMIC EVIDENCE OF SEXUAL DIMORPHISM IN EARLY HUMAN BLASTOCYSTS. Christine Briton-Jones, PhD, HCLD,[1] Erkan Buyuk, MD,[2] Sydney Chang, MD,[2] Joseph A. Lee, BA,[1] Sam Steffan, BA Sc.,[3] Amit U. Sinha, PhD,[3] Alan B. Copperman, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Basepair Inc, New York, NY.

OBJECTIVE: Although it is widely accepted that there are differences in early growth, development, and implantation between male and female embryos, few studies have yet to fully circumvent study design obstacles when evaluating the transcriptome of the human embryo (1). The objective of this study was to compare and contrast the transcriptome patterns of sibling male and female euploid blastocysts.

DESIGN: Prospective cohort study on human embryos.

MATERIALS AND METHODS: After receiving IRB consent, eleven sibling embryos were donated for research by an infertile couple. The embryos underwent embryo biopsy for preimplantation genetic testing for aneuploidy (PGT-A) by next generation sequencing (NGS) and vitrification. The blastocysts were thawed and underwent RNA Sequencing. Read counts per gene were summed across embryo cohorts and normalized using the median of ratios. Differential gene expression between embryo cohorts was calculated using DESeq2, in order to estimate variance-mean dependence and evaluate differential gene expression using a negative binomial distribution. A likelihood ratio test was used to account for heterogeneity due to batch. The adjusted threshold for significance was $p<0.05$.

RESULTS: Of the 11 euploid blastocysts, differential gene expression was compared between 5 male and 6 female embryos. 21,417 genes were identified, 357 were up-regulated and 538 were down-regulated in male blastocysts. Of the 10 genes showing the lowest P value for significantly different expression levels between male and female blastocysts, 8 were located on the Y chromosome and 2 on the X. 7 of the 8 Y chromosome genes have paralog genes located on the X chromosome. The majority of the genes showing significantly different expression levels were located on the sex chromosomes, however there were a number located on autosomes. One example is the gene GCK located on chromosome 7. It showed a 7.97 Fold (log2) lower expression in male blastocysts, where $P<0.0003$. 1658 different molecular pathways were active in the two cohorts, while the ranking of the most active pathways was different between males and females, none showed statistical differences. Putative roles for these genes have been described in other tissues and include protein synthesis, cell proliferation, metabolism and cell differentiation.

CONCLUSIONS: At a period in development when there are no obvious morphological or functional differences between males and females, 895 of the 21,417 (4%) of the active genes identified were expressed at significantly different levels in males compared to females. Many of the functions ascribed to the genes showing different levels of expression are related to processes in cellular proliferation and differentiation in adult stem cells and cancers. Most of the genes located on the sex chromosomes have homologous genes on the opposite sex chromosome, thereby correcting for a gene imbalance. Understanding transcriptomic events associated with mammalian sexual dimorphism may provide insights into the etiology of embryo morphokinetics, implantation, and maybe even later behavior patterning.

X INACTIVE SPECIFIC TRANSCRIPT (*XIST*) AND ANTISENSE *TSIX* EXPRESSION IN SIBLING EUPLOID HUMAN BLASTOCYSTS: INSIGHTS INTO HUMAN X CHROMOSOME INACTIVATION. Christine Briton-Jones, PhD, HCLD,[1] Alan B. Copperman, MD,[2] Sydney Chang, MD,[2] Joseph A. Lee, BA,[1] Sam Steffan, BA Sc.,[3] Amit U. Sinha, PhD,[3] Erkan Buyuk, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Basepair Inc, New York, NY.

OBJECTIVE: Within a mouse model, X chromosome inactivation has been shown to be tightly regulated in early embryo development (4 cell stage), and remains so throughout adulthood (1). The RNA of two non-coding genes (*Xist* and *Tsix*) coats the X chromosomes within the cell nucleus (2). Mouse *Xist* is expressed by the inactive paternal X, yet, future activity of the X chromosome is protected from *Xist* inactivation by antisense RNA *Tsix* (2). While the human homologs of *Xist* and *Tsix* have been described, their roles in human X chromosome inactivation remains misunderstood. Only studies utilizing human embryonic stem cells and / or placental tissue have attempted to elucidate the roles of *XIST* and *TSIX* in the human embryo. The objective of this study was to compare *XIST* and *TSIX* gene expression in sibling euploid male and female human blastocysts.

DESIGN: Prospective cohort study on human embryos for research.

MATERIALS AND METHODS: After receiving IRB consent, eleven sibling embryos were donated for research by an infertile couple. These embryos had previously undergone embryo biopsy, with approximately 2-4 cells removed for preimplantation genetic testing for aneuploidy (PGT-A) by next generation sequencing (NGS) prior to vitrification. The embryos were derived from an anonymous oocyte donor and the sperm from the couple's male partner. After standard warming procedures, the blastocysts underwent RNA Sequencing. Read counts per gene were summed across embryo cohorts and normalized using the median of ratios. Differential gene expression between embryo cohorts was calculated using DESeq2, in order to estimate variance-mean dependence and evaluate differential gene expression using a negative binomial distribution. A likelihood ratio test was used to account for heterogeneity due to batch. The adjusted threshold for significance was $p<0.05$.

RESULTS: 11 euploid blastocysts, 5 male and 6 female were analyzed. The two embryo cohorts compared were male versus female. Both *XIST* and *TSIX* were expressed in all blastocysts. Male blastocysts showed significantly lower expression of *XIST* than females, -3.36 fold change where p=0.0003. *TSIX* was expressed at significantly lower levels in males compared to female blastocysts, -3.30 fold change where p=0.0005.

CONCLUSIONS: The inherent variability in human embryos makes studying the molecular processes of X inactivation difficult. The strongest feature of this study is the known ploidy status of the sibling embryos derived from a young, healthy oocyte donor. Unlike studies using a mouse model, ours demonstrated expression of both the *XIST* and *TSIX* genes within the human male blastocysts. Our finding suggests the *XIST* and *TSIX* genes are co-expressed allowing expression of both in male blastocysts. Again, we diverge from studies utilizing a mouse model, wherein the *Xist* gene is expressed only from the inactive X and the *Tsix* gene from the active X chromosome only seen in mouse female embryos. Our study shows that *XIST* and *TSIX* are active in both male and female human blastocysts. The expression of both genes in male embryos indicates the roles that these genes play may be different in the human than the mouse.

ATOSIBAN AND BARUSIBAN IMPROVED IMPAIRED ENDOMETRIAL BLOOD FLOW IN PREGNANT RABBITS.

Joan-Carles Arce, MD, PhD,[1] Luciano Cunego, MS,[2] Paolo Perfetti, Dr,[2] Stéphane P. Milano, PhD,[3] Torsten M. Reinheimer, PhD, Prof[1] [1]Ferring Pharmaceuticals A/S, Copenhagen, Denmark; [2]Aptuit An Evotec Company, Verona, Italy; [3]Double Strand Consulting Company, Saint Nizier d'Azergues, France.

OBJECTIVE: Despite considerable success in generating human blastocytes with artificial reproductive technologies, embryo implantation remains a challenge for unclear reasons. Excessive uterine movements may cause implantation failure while atosiban (ATO), a mixed vasopressin (VP) V_{1A}/oxytocin (OT) receptor antagonist, is used off-label to normalize uterine movements. In addition to inflammation or iatrogenic factors, poor perfusion can contribute to low implantation rates. It is hypothesized that elevating the uterine blood perfusion may increase the quality of the uterine mucosa and thus implantation success. The objective was to quantify whether ATO or barusiban (BAR), a selective OT antagonist, can improve endometrial blood perfusion in a rabbit model of early pregnancy.

DESIGN: In early pregnant rabbits (GD8–10), the endometrial blood flow (EBF) was monitored by laser Doppler flowmetry under propofol anesthesia. Following uterotomy, a laser probe was placed on the luminal site of the endometrium at a blastocyst. Mean arterial pressure (MAP), heart rate (HR) and femoral blood flow (FBF) were monitored. Vehicle or drugs were administered cumulatively via the right jugular vein.

MATERIALS AND METHODS: Five doses of 10-min duration of 2.22–1390 ng/kg/min OT, 634 pg–407 ng/kg/min VP, 4–40,000 ng/kg/min ATO or 0.4–4000 ng/kg/min BAR or vehicle were tested on EBF and cardiovascular parameters (N=6/group). In the ATO, BAR and vehicle groups, an IV bolus of 4170 ng OT was administered at the end of the infusion to test the antagonistic action of ATO and BAR.

RESULTS: EBF at the highest OT infusion dose was markedly reduced by 77% relative to vehicle, and in the VP group by 62% (both $P<0.01$) with similar potency. By contrast, no changes were apparent after infusion of vehicle, ATO or BAR. Similarly to EBF, a decrease in FBF was observed with VP (or OT), whereas administration of vehicle, ATO or BAR did not result in any change. The administration of an OT bolus to the vehicle group resulted in a decrease of EBF. No such decrease was observed following ATO or BAR pretreatment, indicating that the OT-induced EBF reduction by the bolus was antagonized by either ATO or BAR. Both OT and VP induced a large increase in MAP by 93% and 57%, respectively ($P<0.001$) with similar potency. MAP did not display any change in the vehicle, ATO or BAR groups. The OT bolus induced a small increase in MAP in the vehicle, ATO and BAR groups and was not blocked. No relevant changes in HR was observed in the vehicle, OT, VP, ATO or BAR groups.

CONCLUSIONS: ATO or BAR infusions did not influence baseline EBF in the early pregnant rabbit. Indeed, pre-treatment with ATO or BAR prevented OT-induced EBF reduction. This complicated model allowed only a small number of animals. Additionally, it was not possible to elucidate the relative importance of the OT receptor versus the V_{1A} receptor, because no differences were found between the agonists or between the antagonists despite their differences in receptor activity. The study suggests a benefit of OT or VP receptor antagonism in terms of recovery of OT-compromised EBF and thus potentially increases embryo implantation success.

LOSS OF MIR-29A IMPAIRS PROLIFERATION AND DECIDUALIZATION OF ENDOMETRIAL STROMAL CELLS VIA ENHANCING THE INTERACTION OF TET3 AND COL1A1 DURING PATHOPHYSIOLOGY OF EARLY PREGNANCY LOSS.

Aixia Liu, PH.D., Dimin Wang, M.D., Mengmeng Jin, M.D., Ying Zhou, B.S., Laidi Xie, B.S. School of Medicine, Zhejiang University, Hangzhou, China.

OBJECTIVE: MiR-29a plays an important role in differentiation and proliferation of various uterine cells through regulating downstream target genes. However, whether miR-29a affects proliferation and decidualization of endometrial stromal cells (ESCs), and involves implantation and maintenance of early pregnancy remain unknown.

DESIGN: The expression and significance of miR-29a and TET3 were explored in endometrial or decidual tissues. Isolated primary ESCs were decidualized and exposed to miR-29a antagomir *in vitro*.

MATERIALS AND METHODS: This study protocol was approved by the Ethical Committee of the Women's Hospital. The endometrial tissues collected from patients in proliferative phase (10 cases) or secretory phase (15 cases), and the decidual tissues from patients with early pregnancy loss (EPL) (23 cases) and normal early pregnancy (22 cases) were used to determine the differential expression patterns of miR-29a and TET3. The primary ESCs were isolated from human uterine tissues and used to constructe the *in vitro* decidualized cell model. The miR-29a antagomir, CCK-8, quantitative PCR, western blot, RNA pull-down, immunofluorescence assays and bioinformatics analysis were used to investigate the relationship among miR-29a, TET3 and Col1A1 and their function on the proliferation and decidualization of ESCs.

RESULTS: The increased expression of miR-29a and the decreased expression of TET3 were found in the endometrial tissues of secretory phase compared with the endometrial tissues of proliferative phase. However, the expression of miR-29a was significantly reduced and the protein expression of TET3 was enhanced in the endometrial tissues of EPL in comparison to the normal early pregnancy. To study the significance of the ectopic expression levels of miR-29a and its potential relationship with TET3, miR-29a was inhibited by miR-29a antagomir in decidualized ESCs *in vitro*. Subsequently, we found inhibition of miR-29a significantly suppressed the Human ESCs viability. Moreover, the expression levels of decidualized biomarkers PRL and IGFBP1 were remarkably reduced, and the Col1A1, which involved in TET3 methylation, were downregulated following inhibition of miR-29a. Furthermore, after decidualization of ESCs, TET3 expression levels were decreased significantly, while inhibition of miR-29a promoted a significant increase in TET3 expression levels. Meanwhile, TET3 was predicted to be targeted by miR-29a by bioinformatics analysis. Most importantly, we found the binding capacity of TET3 and Col1A1 was decreased after ESCs decidualization. Interestingly, inhibition of miR-29a was revealed to enhance the interaction of TET3 and Col1A1 in the ESCs. In addition, loss of TET3 reversed the inhibitory effect of miR-29a antagomir on the proliferative activity in decidualized ESCs, as well as the protein expression levels of PRL and IGFBP1.

CONCLUSIONS: Loss of miR-29a suppressed proliferation and decidualization through enhancing the interaction of TET3 and Col1A1 in ESCs, which uncovers the important role of miR-29a/TET3/ Col1A1 in the regulation of decidualization and embryo implantation.

HYPERBARIC OXYGEN PRECONDITIONING OF OVARIAN TISSUE BEFORE CRYOPRESERVATION MODULATE GENES INVOLVED IN FOLLICLE ACTIVATION AND ANTI-APOPTOTIC PATHWAYS.

Anders Kjellberg, MD, DESA, EDIC, PhD student,[1] Christina Diakaki, Master student,[2] Xia Hao, PhD student,[2] Amandine Anastácio, PhD, PostDoc,[2] Kenny A. Rodriguez-Wallberg, MD, PhD, Associate Professor[3] [1]Karolinska Institutet, Stockholm, Sweden; [2]Laboratory of Translational Fertility Preservation, Karolinska Institutet, Stockholm, Sweden; [3]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden.

OBJECTIVE: Our overall hypothesis is that pre-conditioning with **hyperbaric oxygen** (HBO) can promote **survival** by improving **hypoxia tolerance** and modulation of genes in **anti-apoptotic** pathways.

DESIGN: Controlled experimental study, parallel arms.

MATERIALS AND METHODS: Ovaries (n=6) from B6CBA/F1 postnatal day-4 mice, were harvested and randomly assigned to either **pre-conditioning** ex vivo with **hyperbaric oxygen** in HBO chamber at 2.5 ATA for 30 minutes or control (30 minutes in room air). Both groups were kept in cryopreservation buffer on ice. **Cryopreservation** through slow freezing. RNA including miRNA was extracted using miRNeasy Mini Kit (Qiagen). RNA concentration was checked with NanoDrop™ 2000C; integrity and Quality Control were confirmed with Agilent Tapestation 2200®. **Gene expression** and **microRNA interactions**, 3 pooled samples from each group were analyzed using *Affymetrix Clariom D MTA 1.0 and microRNA 4.0 arrays, (performed by BEA core facility service at KI/Huddinge)*. Data analysis was performed using TAC 4.0 software, filter criteria: Fold change > 2 or <-2. The study was approved by the ethics review board for animal experiments in Sweden.

RESULTS: Out of 65956 genes identified in the analysis, 633 genes passed filter criteria, 379 were upregulated and 254 downregulated. Analysis of the 20 most altered genes in the Affymetrix array indicated genes involved in follicle activation. **Gremlin1** was highly downregulated (-6.8-fold change) suggesting that a preconditioning effect was obtained. A number of genes that stimulate growth and differentiation, such as immediate early genes **Fos** (-45.3-fold), **Fosb** (-44.7-fold) and **JunB** (-12.5-fold) were downregulated. Aromatase, encoded by **cyp191a** (-12.4-fold) was also downregulated. The most differently expressed microRNA was miR-714 (-10.89), associated with Fosb.

CONCLUSIONS: **Pre-conditioning** of ovarian tissue from mice with **hyperbaric oxygen** *ex vivo* induced changes in gene expression that are associated with **primordial follicle activation**, **oocyte maturation**, **hypoxia tolerance** and **apoptosis**. MiR-714 may be a useful biomarker for Fosb gene expression that warrant further investigation. The model seems promising for future studies with the **aim** to **improve survival** of **ovarian tissue** post **re-transplantation**. The data suggest a pre-conditioning effect but needs to be confirmed using methods to evaluate functionality of follicle development and maturation.

SUPPORT: The research was funded by grants from The Swedish Cancer Society, The Swedish Childhood Cancer Foundation, The Cancer Research Funds of Radiumhemmet, the Stockholm County Council and Karolinska Institutet (to KRW) and Gösta Franekels foundation (AK).Â We also would like to thank the core facility at Novum, BEA, Bioinformatics and Expression Analysis, which is supported by the board of research at the Karolinska Institute and the research committee at the Karolinska hospital.

ASSESSMENT OF MITOCHONDRIAL DNA METHYLATION IN HUMAN BLASTOCYSTS.

Xin Tao, Ph.D,[1] Yiping Zhan, Ph.D,[2] Richard Thomas Scott, Jr., MD,[3] Emre Seli, M.D.[4] [1]Foundation for Embryonic Competence, Basking Ridge, NJ; [2]The Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA Global, Basking Ridge, NJ; [4]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Methylation of cytosine residues is a well-characterized epigenetic regulatory mechanism for nuclear genomic DNA (gDNA), affecting gene expression and cellular differentiation. Recent evidence suggests that methylation also occurs in mitochondrial DNA (mtDNA) and plays a role in mtDNA gene expression and replication. In addition, animal studies show that mtDNA methylation is not restricted to CG sites but also occurs at CHG and CHH sites, and may play help regulate programming during gametogenesis. In this study, we characterized mtDNA methylation in human blastocyst stage embryos, and investigated whether mtDNA methylation is affected by euploidy status and maternal age.

DESIGN: Experimental study.

MATERIALS AND METHODS: Two trophoectoderm (TE) biopsies from each of the previously diagnosed euploid (n=10) and aneuploid (n=20) embryos were analyzed using Whole Genome Bisulfite Sequencing (WGBS). Bisulfite conversion was performed using EZ DNA Methylation-Direct Kit (Zymo). Methylome sequencing libraries were constructed using TruSeq DNA Methylation Library Prep (Illumina) with 18 cycles of amplification. Sequencing was performed on Illumina HiSeq 2500 with paired-end 150 bp reads, and sequencing reads were aligned to human mtDNA reference using Bismark software. Duplicates were removed, unconverted reads were filtered, and cytosine methylation at single base resolution was determined. Statistical analysis was carried out using a linear model to assess the relationship of mtDNA methylation levels with ploidy status, maternal age (range 29.5 to 41.1), and time of blastulation (day 5 [n=16] vs. day 6 [n=14]).

RESULTS: Analysis revealed that an average of 1.5% of CpG sites in mtDNA were methylated in TE samples, which was significantly lower than methylation level of gDNA (20-30%; $p<0.0001$). CHH and CHG site methylation were found to be consistent in mtDNA and gDNA (CHH:1%, CHG:1.5%). There was no difference in mtDNA CpG, CHH, or CHG site methylation ratio between aneuploid and euploid embryos. Mitochondrial DNA CpG, CHH, or CHG site methylation levels were not correlated with maternal age. When blastocysts cryopreserved on day 6 were compared to those that were cryopreserved on day 5, mtDNA methylation levels of CpG, CHH, or CHG sites were not different.

CONCLUSIONS: Our findings suggest that mtDNA methylation of TE biopsies from human blastocysts is not associated with ploidy status, embryo growth characteristics, or maternal age. Therefore, it is unlikely that mtDNA methylation status can be used to develop a diagnostic test predictive of embryo viability for women undergoing infertility treatment with IVF.

P-595 4:30 PM Monday, October 19, 2020

MIRNA-92A SUPPRESSES ANDROGEN-PRODUCING STEROIDOGENIC GENES EXPRESSION IN H295R, A HUMAN PCOS IN-VITRO THECA-LIKE CELL MODEL.

Sahar Esfandyari, DVM. The University of Illinois College of Medicine, Chicago, IL.

OBJECTIVE: Polycystic ovary syndrome (PCOS) is a heterogeneous disorder, which affects up to 10% of reproductive-age women. The main characteristics are anovulation, hyperandrogenism and presence of polycystic enlarged ovary in reproductive age women. The underlying molecular mechanisms are not still clear. Previous study demonstrated that Mesenchymal stem cells secretes a variety of growth factors, cytokines, and miRNAs (including miRNA-92a) both free and in exosomes. Women with PCOS showed downregulation of miRNA-92a and high gene expression of main androgen-producing steroidogenic pathway genes CYP17A1, CYP11A1 and DENND1A in ovarian theca cells. In this study, we evaluated the effects of miRNA-92a mimic on steroidogenic gene expression using Human adreno-carcinoma cell line (H295R cells) an in-vitro PCOS cell model.

DESIGN: We hypothesize that H295R cells transfected with miRNA-92a mimic will exhibit a decrease in the gene expression of androgen biosynthesis genes in that PCOS cell model.

MATERIALS AND METHODS: The human adreno-carcinoma (H295R) cell line were seeded on 24-well plates at a density of 1×10^6 cells per well and cultured for 24 hours. Cells were transfected with different concentrations 30, 60, 90 pM of mirVana has- miR-92a-3p mimic or negative control-1 mimic using manufacturer protocol. After 24 hours of transfection, H295R cells were trypsinized and collected for analysis. The expression of CYP17A1, CYP11A1, and DENND1A genes were quantified at mRNA level by real-time PCR while DENND1A expression at protein level by western blot. Student t-test was used for statistical analysis and $p<0.05$ is considered as significant.

RESULTS: Human 295R cells transfected with 30pM of miRNA-92a-3p mimic showed significantly decrease CYP17A1, CYP11A1 and DENND1A gene expression ($p<0.05$) at RNA level and at protein level for DENND1A.V2 gene ($p<0.05$).

CONCLUSIONS: The miRNA-92a-3p mimic induced a significant suppression in androgen-producing steroidogenic pathway genes in a human PCOS cell model. Mesenchymal stem cell therapy may be a viable novel treatment option for PCOS patients.

ENHANCEMENT OF HUMAN GRANULOSA CELLS SELF-RESCUE BY MITOCHONDRIAL TRANSFER VIA TUNNELING NANOTUBES. Chia-Jung Li, Ph.D, Kuan-Hao Tsui, M.D; Ph.D. Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan.

OBJECTIVE: The intercellular transfer of mitochondria through tunneling nanotubes (TNTs) is a novel means of cell-to-cell communication between granulosa cells.

DESIGN: Experimental laboratory study.

MATERIALS AND METHODS: We established a co-culture system for human young GCs (P5) and aged GCs (P50) and found that tunneling nanotubes (TNTs) formed between them. Most of the TNTs initiated from young towards aged GCs. Disruption of TNTs using nocodazole abolished increased proliferation of young GCs initiated by contacts with aged GCs. Using specific fluorescent markers, we identified exchange of mitochondria via TNTs.

RESULTS: Young mitochondria were transferred towards the aged cells via TNTs, and the restoration of mitochondrial fusion between the young and old mitochondria occurred. We also observed that the young GCs exhibited mitochondria highly transfer and increased TNTs connections and lengths in co-cultured with aged GCs. Further morphological and molecular analyses indicated that the transfer of functional mitochondria reduced mitochondrial fission protein Drp1 expression in the aged cells. The transfer of young mitochondria was associated with a significant rescue of impairment of mitochondrial bioenergetics function in aged GCs.

CONCLUSIONS: Our data suggest that TNTs between young and aged GCs facilitate mitochondria transfer and therefore alter the properties, including the proliferation potential, of aged GCs.

EXPOSURE OF HUMAN BLASTOCYSTS TO SPECIFIC GROWTH FACTORS BASED ON RECEPTOR PRESENCE IMPROVES EPIBLAST FORMATION IN EXTENDED EMBRYO CULTURE. Deirdre M. Logsdon, MS, Sandeep K. Rajput, PhD, Courtney K. Grimm, MS, William B. Schoolcraft, MD, Ye Yuan, PhD, Rebecca L. Krisher, PhD Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Embryos are exposed to multiple growth factors during preimplantation development in vivo. However, inclusion of a variety of growth factors in embryo culture medium has resulted in disparate results between studies and across species, making it difficult to ascertain the potential efficacy of growth factors to improve human embryo culture. Our objective was to identify the presence or absence of specific growth factor receptors in human blastocysts using western blot analysis, and then to determine the effect of exposing embryos to the growth factors for which receptors are present on embryo development and viability.

DESIGN: Research Study

MATERIALS AND METHODS: Western blots were conducted using the Protein-Simple Jess system, with detection of each putative growth factor receptor assessed in a pool of two human blastocysts as well as a positive control (human granulosa cells). Due to the paucity of human zygotes that are available for such research, we used vitrified human blastocysts donated for research, exposing blastocysts to growth factors for 48 hrs prior to placement into an extended embryo culture system (WIRB study # 1179872). After warming, day (D) 5 human blastocysts (n=35) were cultured in the presence (GF) or absence (control) of selected growth factors. After 48 hrs (D7), the zona pellucidae were removed prior to placing blastocysts on fibronectin coated 8 well chambered microslides for extended culture. Embryo outgrowth area was measured on D10, D11, and D12, at which time embryos were fixed and stained with DAPI and antibodies against F-actin and the pluripotency marker POU5F1 to determine the number of epiblast cells and total cells using 3D spinning disk confocal microscopy. Data was analyzed using t-test.

RESULTS: Of the eleven growth factor receptors analyzed, six were found to be present in human blastocysts. Receptors that were not detected included EGFR, ACVR1, ACVR2, IGF1R, and TGFβR2. There were no differences in embryo outgrowth area on D10, D11, or D12 (control, 0.206 ± 0.053 mm2; GF, 0.234 ± 0.046 mm2). More embryos cultured with chosen growth factors formed an epiblast (control, 35.7%; GF, 84.6%; p=0.03). However, there were no differences in the number of epiblast cells as an average of all embryos (control, 27.8 ± 15.4; GF, 38.8 ± 9.4) or as an average of only those embryos with epiblast cells (control, n=5, 77.8 ± 34.3; GF, n=11, 45.9 ± 9.6). There was also no difference in total cell number (control, 344.1 ± 116.0; GF, 413.4 ± 116.8) in the D12 embryo outgrowths.

CONCLUSIONS: In summary, inclusion of growth factors in embryo culture medium at the blastocyst stage, chosen based upon receptor presence, increased the ability of the embryos to form an epiblast suggesting that the presence of these growth factors increased embryo viability. Future work will examine the effect of these growth factors during preimplantation embryo culture on blastocyst development and quality prior to embryo transfer.

SIMULATED LONG-TERM EFFECTS OF RELUGOLIX COMBINATION THERAPY ON BONE MINERAL DENSITY AT THE LUMBAR SPINE AS PREDICTED BY A VALIDATED SEMI-MECHANISTIC EXPOSURE-RESPONSE MODEL. Anthe S. Zandvliet, PhD, PharmD,[1] Aziz Ouerdani, PharmD, PhD,[1] Tien-Yi Lee, PhD,[2] Elizabeth M. Migoya, Pharm D,[2] Juan Camilo Arjona Ferreira, MD,[2] Rik de Greef, MSc[1] [1]Certara, Oss, Netherlands; [2]Myovant Sciences Inc., Brisbane, CA.

OBJECTIVE: To address potential concerns of bone mineral density (BMD) loss associated with an endogenous estradiol (E2) suppression by relugolix, an oral, non-peptide gonadotropin-releasing hormone (GnRH) receptor antagonist, a semi-mechanistic, exposure-response model of BMD based on circulating E2 concentrations was developed and validated to predict maintenance of BMD during long-term (> 1 year) treatment with relugolix combination therapy (Rel-CT; relugolix 40 mg / E2 1 mg / norethindrone acetate 0.5 mg), upon which the E2 concentrations during treatment reflect the combined effect of exogenous E2 administration and relugolix-mediated endogenous E2 suppression.

DESIGN: E2 and BMD data from relugolix monotherapy (Phase 2) and Rel-CT (Phase 3) studies in women with uterine fibroids or endometriosis were used to develop the E2 – BMD model.

MATERIALS AND METHODS: The relationship between the % change from baseline in BMD at the lumbar spine based on circulating E2 concentrations over time during relugolix monotherapy or Rel-CT was described by a modified model originally proposed by Riggs et al (CPT Pharmacometrics & Systems Pharmacology, 2012) for approved GnRH receptor modulators. Data from a Phase 3 extension for up to 1-year treatment was used to validate the model-predicted BMD changes. Model-based simulations were performed to extrapolate expected BMD changes with Rel-CT for up to 2 years.

RESULTS: The model well described the BMD percent change from baseline during treatments with relugolix monotherapy up to 6 months or Rel-CT up to 1 year, with the 95% CI of the model-predicted quartiles for BMD change consistent with the corresponding values observed in the Phase 2 and Phase 3 studies and the Phase 3 extension. The model also predicted the plateau achieved in the BMD change upon E2 administration (concurrently with or initiated following 12 weeks of administration of relugolix alone) to be maintained for at least 2 years of Rel-CT treatment. Model-predicted BMD change over a 2-year treatment period was smaller than the clinical relevance bound of -2.2%, with the median (95% CI) of the predicted BMD loss from baseline over 2 years of 1.0% (0.3%, 1.9%) for Rel-CT. Of the women who received Rel-CT in the Phase 3 studies, 87.7% had E2 concentrations $\geq$ 20 pg/mL, an E2 concentration threshold proposed by Riggs et al to prevent the GnRH-modulator-associated BMD loss from baseline of greater than 2.2%.

CONCLUSIONS: A validated semi-mechanistic exposure-response model accurately described BMD change in the lumbar spine over time in women with uterine fibroids or endometriosis upon treatment with relugolix monotherapy (Phase 2) or Rel-CT (Phase 3), enabling prediction of Rel-CT to maintain BMD with long-term treatment for at least 2 years.

THE REPRODUCTIVE SUBJECTS REGISTRY AND SAMPLE REPOSITORY (RSRSR): ESTABLISHING A BIOREPOSITORY FOR THE STUDY OF REPRODUCTIVE HEALTH. Nicholas S. Raja, MD,[1] Samantha B. Schon, MD, MTR,[2] Min Xu, Ph.D,[1] Kun Yang, MD,[2] Jayne Reynolds, BA,[2] Heather G. Cameron, MPH,[2] Erica E. Marsh, MD, MSCI, FACOG[1] [1]University of Michigan, Ann Arbor, MI; [2]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI.

OBJECTIVE: Biorepositories are an invaluable resource for conducting population-wide studies into the pathophysiology of complex disease. Despite their utility in translational research, there are very few reports of biobanks dedicated to the fields of reproductive health and infertility. Here we describe our experience establishing a reproductive biorepository and specifically discuss the collection of samples from subjects undergoing in vitro fertilization (IVF) and gynecologic procedures.

DESIGN: Prospective enrollment and collection of biological specimens and clinical information.

MATERIALS AND METHODS: The Reproductive Subjects Registry and Sample Repository (RSRSR) was established in 2017. Collection of samples began in 2018. Consenting individuals presenting for care at the University of Michigan were asked to complete a comprehensive questionnaire collecting demographic information, medical history, and focused gynecologic and fertility history. Patients consented to donate biological samples that would otherwise be discarded after treatment. IVF materials collected include blood, urine, follicular fluid, granulosa cells, cumulus cells, and immature and unfertilized oocytes. Surgical specimens include benign endometrium, myometrium, fallopian tube, ovarian tissue, and cervix. All samples are processed using vitrification, flash freezing, paraffin embedding, or placed in RNAlater© and aliquoted for storage.

RESULTS: There are currently 1169 female patients enrolled in RSRSR. The average age of female participants at the time of enrollment is 42.9 years (range 18.5-80.6 years). The mean BMI is 29.4 (range 15.1-68.9). Participants are predominately Caucasian (80.5%) and Non-Hispanic (89.7%). They are also highly educated, with >65% reporting a Bachelor's degree or higher and >46% reporting an annual household income of >$100,000. 21.4% of female participants reported a history of infertility, and a range of gynecologic disorders were also reported including menorrhagia (21.5%), metrorrhagia (15.1%), fibroids (21.5%), polycystic ovarian syndrome (13.5%), and endometriosis (9.9%). IVF specimens collected to date include 98 unique cycle samples of follicular fluid, granulosa cells, immature oocytes, and cumulus cells. Surgical samples are available from 146 unique patients with aliquots of benign endometrium, myometrium, fallopian tube, ovarian tissue, and cervix.

CONCLUSIONS: Herein, we report our success establishing a reproductive biorepository and subject registry. Additionally, we have created a streamlined process for collection of samples from women undergoing IVF. The collection of these unique biological samples linked with clinical information allows for a comprehensive investigation of women undergoing IVF and gynecologic surgery. Furthermore, these samples are processed and stored using a variety of methods, facilitating multiple downstream analyses. As one of the few existing biorepositories centered on reproductive health and infertility, RSRSR offers tremendous potential for innovative and translational research in reproductive medicine.

NITRIC OXIDE SYNTHASE AND AGE RELATED INFERTILITY: THE ROLE OF ARGINASE II. Charalampos Chatzicharalampous, MD, PhD, David Bai, BS, Sana Khan, MD, Robert Morris, MD, Husam M. Abu-Soud, PhD Wayne State University, C.S. Mott Center for Human Growth and Development, Detroit, MI.

OBJECTIVE: Low L-Arginine (L-Arg) may lead to alteration in nitric oxide synthase (NOS) activity shifting from nitric oxide (NO) synthesis to $O_2^{\bullet-}$ generation, a process known as NOS uncoupling. Arginase II, a critical enzyme in the urea cycle, can modulate the availability of L-Arg for NOS, regulating NO release in many types of cells. Based on the relationship between L-Arg and NO modulation, we sought to determine the relationship between differing NO profiles in young and old mouse oocytes and their expression of the arginase gene (ARG1) as well as developmental effects such as fertilization and embryonic development.

DESIGN: This is an experimental case-control study.

MATERIALS AND METHODS: B6D2F1 mice were divided into young (6-10 week) and old (48-60 week) groups. An NO-selective electrode was used for direct NO measurements in ovaries, oviducts, and oocytes. A subset of ocytes were also further exposed to 50 μM Nitro-L-arginine methyl ester (L-NAME), an NOS inhibitor for 20-30 minutes. NO levels in each of those groups were measured using ICSI. *ARG1* expression was assessed in ovarian tissue of young versus old mice with real-time PCR. Ornithine, the final product of arginase II, and L-Arg were also measured in oocytes from young (n=100) versus old mouse (n=100) ovaries via high-performance liquid chromatography (HPLC).

RESULTS: NO levels in the ovaries of young mice were 20 $\pm$ 1.5 nmol. There was a marked reduction, ~60%, in old mouse NO, with similar results among oocytes, ovaries and oviducts. *ARG1* expression was upregulated (threefold) in old versus young mice. Ornithine was significantly increased (fivefold) in old versus young oocytes, while L-Arg levels, in contrast, were markedly decreased (0.25 +/- 0.02 nmol/ml) in old compared to young oocytes (0.50 +/- 0.01 nmol/ml).

CONCLUSIONS: The upregulation of *ARG1*, and therefore increased arginase II activity, in older animals was correlated with higher levels of ornithine, decreased L-Arg, and decreased NO. Therefore, our results suggest that increased activity of arginase II may be an important modulator of NOS activity and thus NO bioavailability in aged animals.

INFLAMMATORY MACROPHAGES DERIVED EXOSOMAL MIR-222 PROMOTED THECA CELL STEROIDOGENESIS BY MODULATING MYLIP EXPRESSION. Xing Yang, Ph.D., Linzhi Gao, Master degree, Lina Wei, Ph.D. The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To explore the role of M1 macrophages (M1M) in the linkage between low-grade inflammation and ovarian dysfunction in obesity.

DESIGN: In vitro experimental laboratory study.

MATERIALS AND METHODS: Raw264.7 macrophage was treated with lipopolysaccharide (LPS) to establish a model of M1M. Exosome (Exo) secreted by macrophage was isolated by ultracentrifugation and identified by transmission electron microscopy (TEM), western blot, and flow nanoanalyzer. The primary murine ovary theca cell (TC) was co-incubated with PKH67 fluorescence-labeled Exo to detect whether Exo secreted by macrophage could be uptaken by TC. The expression of CYP11A1 and CYP17A1 were analyzed by qPCR and western blot. Medium testosterone and progesterone level were analyzed. High-throughput sequencing was performed to analyze the expression of exosomal miRNA (miRNA-seq). In order to select key differential exosomal miRNA, the GSE97652 (species: mouse) was downloaded from the GEO DataBases. The data set contains 7 replications in both experimental group and control group. The experimental group is obese mouse adipose tissue macrophage (ATM)-derived Exo, and the control group is control mouse ATM -derived Exo. The overlap between miRNA-seq and GSE97652 differentially expressed miRNA was analyzed according to the Fold change $> 2, p < 0.01$ standard, which determined miR-222 and MYLIP for subsequent experiments. Next, gain-of-function experiments were performed to examine their role in TC steroidogenesis function with the involvement of the cholesterol metabolism pathway.

RESULTS: TEM, Flow NanoAnalyzer and western blot analysis confirmed the successful extraction of Exo. After co-cultured TC with PKH67-labeled Exo, green fluorescence could be detected in TC which demonstrated that TC was able to ingest Exo secreted by the macrophage. M1M increased the expression of CYP11A1 and the production of progesterone in TC which is dependent upon M1-Exo. The result of miRNA-seq showed that there were 30 upregulated miRNA and 112 down-regulated miRNA in M1M derived Exo compared with control Exo according to the standard of Fold change $> 2 (p < 0.05)$. A total of two differentially expressed miRNA, namely miR-222 and miR-155, were selected from the venn diagram of miRNA-seq and GSE97652. QPCR verified that miR-222 in both M1M derived Exo and M1M derived Exo treated TC were significantly upregulated. Subsequently, we predicted the target gene of miR-222 through five different databases. MYLIP, with the highest target score was selected, which has been identified as a key factor promoting LDLR degradation. M1M derived Exo was verified to display a high expression level of

miR-222, and M1M derived Exo mediated TC steroidogenesis depended miR-222. The overexpression of miR-222 resulted in the down-regulation of MYLIP expression and up-regulation of LDLR expression, followed by increased cholesterol influx, CYP11A1 overexpression and progesterone overproduction.

CONCLUSIONS: M1M derived Exo can be ingested by TC. M1M promote TC CYP11A1 overexpression and progesterone overproduction through Exo by delivering miR-222 into TC.

P-602 4:30 PM Monday, October 19, 2020

SIMILAR TO RETINOIC ACID, HYPEROSMOTIC STRESS INDUCES EXPRESSION OF A 2-CELL LIKE SUBSET OF PLURIPOTENT STEM CELLS WHILE ALSO INDUCING A SUBSET OF DIFFERENTIATED 1ST LINEAGE CELLS. Elizabeth E. Puscheck, MD, MS, MBA,[1] Sudipta Dutta, Ph.D.,[2] Mohammed Abdulkareem Abdulhasan, Ph.D.,[3] Katherine Gurdziel, Ph.D.,[2] Steven J. Korzeniewski, Ph.D.,[4] Douglas Ruden, Ph.D.,[2] Daniel Rappolee, Ph.D.[4] [1]InVia Fertility, Hoffman Estates, IL; [2]Wayne State University, Detroit, MI; [3]Reproductive Stress 3M, Inc., Grosse Pointe Farms, MI; [4]Wayne State University School of Medicine, Detroit, MI.

OBJECTIVE: Determine whether various stresses change the expression in embryonic stem cells and their differentiated lineages of a large set of viral receptors and susceptibility genes.

DESIGN: Experimental.

MATERIALS AND METHODS: Rex-1 promoter- ESC were tested by bulk or single cell (sc) RNAseq after 72 hr exposures to 0-300 mM hyperosmotic sorbitol (with stemness-maintaining Leukemia Inhibitory Factor, LIF) to quantify stress-forced differentiation. Controls for normal stemness were LIF+ and normal differentiation were LIF-. RNA was isolated by RNAeasy lysis or 10XGenomics Dropseq, RNA quality was checked by Agilent TapeStation, cDNA was synthesized using Lexogen's QuantSeq library kit, and barcoded, multiplexed and sequenced by Illumina NovaSeq 6000. Data were demultiplexed by CASAVA software and FC expression was compared between conditions. In triplicate experiments, significant fold change (FC) genes ($FC \geq 2$; $FDR \leq 0.05$, $P<0.05$) identified affected pathways. Proliferation or death were assayed by Hoechst staining or Trypan blue staining, respectively. Validating studies including qPCR.

RESULTS: Stress caused expression of 15/17 Warburg anabolic pathway genes and decrease of aerobic glycolysis pathway was highly significant by P value and FDR for 9 genes. Compared with two previous studies 14/21 genes during early XEN and15/18 genes of late ESC XEN during normal differentiation by LIF removal, were upregulated by stress despite LIF presence. But simultaneously with loss of stemness metabolism and gain of several first lineage markers, several markers of the 2-cell like state were significantly and highly; B020031M17Rik and GM8994 by bulk RNAseq analysis. These two genes were amongst 6 others identified by tSNE analysis of scRNAseq that approximately 3% of ESCs were induced into a 2-cell like state previously reported to be induced by retinoic acid as a reversible subpopulation of first lineage XEN cells that revert to 2-cell like stemness.

CONCLUSIONS: Taken together the data suggest that stress induces distinctly different events, an approximate 23% increase in Rex1-GFP-ESCs with stemness loss, and a similar 24% increase in intermediate bright PDGFRA-GFP+ gain indicating XEN, but that bulk RNAseq corroborates XEN subpopulation increase. Morever, like retinoic acid induction of XEN, scRNAseq suggests that stress-forced XEN also induce a small subpopulation of 2-cell like revertants that may reversibly form pluripotent stem cells.

THE HUMAN ENDOGENOUS RETROVIRUS ERVW-1 REGULATES TROPHOBLAST STEM CELL PROLIFERATION. Rachel C. West, PhD, William B. Schoolcraft, MD, Rebecca L. Krisher, PhD, Ye Yuan, PhD Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: The human endogenous retrovirus ERVW-1 drives differentiation of cytotrophoblast into syncytiotrophoblast, the fetal portion of the placenta responsible for secretion of hormones and nutrient exchange. ERVW-1 also presents in cytotrophoblast cells; however, its role in maintaining this undifferentiated population of cells is poorly understood. The objective of this study was to examine the role of ERVW-1 in the maintenance of proliferation of human trophoblast stem cells (TSC). We hypothesized that ERVW-1 regulates undifferentiated trophoblast cell proliferation during placental development.

DESIGN: Prospective research study.

MATERIALS AND METHODS: To assess the role of *ERVW-1*, we used the CT27 line of TSC first described by Okae et al. in 2018. TSC were treated with lentivirus containing either shRNA designed to knockdown *ERVW-1* (KD) or a scramble control (SC). To select successfully transduced cells, we treated wild type (WT), SC, and KD cells with 2 μg/mL puromycin. After 48 hours, all wild type cells treated with puromycin were dead. We continued puromycin selection for 5 additional days to ensure successful selection. After puromycin selection, RNA was isolated from WT, SC, and KD cells. First strand complementary DNA was synthesized using the BioRad iScript Reverse Transcriptase kit and real-time quantitative PCR (RT-qPCR) was performed to confirm knockdown of *ERVW-1*. After confirmation of knockdown, WT, SC, and KD cells were plated at a concentration of 5,000 cells/well of a 12-well tissue-culture treated plate. Cells were collected after 24, 36, 48, and 72 hours and counted to assess cell doubling time (n= 4 replicates). Finally, to assess trophoblast cell proliferation and health, we used RNA to determine gene expression of placental growth factor (*PGF)* in all 3 cell types using RT-qPCR (n= 3 replicates).

RESULTS: Knockdown cells had significantly reduced expression of *ERVW-1* mRNA compared to SC (73.5% reduction, $p<0.05$) and WT cells (80.9% reduction, $p<0.05$). *ERVW-1* knockdown cells had an average doubling time of 26 ± 1.74 hours compared to the 15.43 ± 0.46 and 16.18 ± 0.6 hour doubling time of the SC and WT cells, respectively. These data show that *ERVW-1* KD cells have a significantly ($p<0.005$) longer cell doubling time compared to WT and SC cells. There was no difference in cell proliferation between WT and SC cells. Additionally, mRNA levels of *PGF* were significantly decreased in the KD cells compared to SC control cells ($p=0.05$). As PGF is known to increase trophoblast cell proliferation and reduce apoptosis, these data further suggest that decreased expression of *ERVW-1* causes altered cell proliferation in TSC.

CONCLUSIONS: *ERVW-1* is important in maintaining cell proliferation in undifferentiated TSC. The decreased expression of *PGF* is also interesting as PGF is known to regulate cell proliferation as well as trophoblast vascularization. As reduced *ERVW-1* and *PGF* has been implicated in placental pathologies including preeclampsia, these data provide context for the role of *ERVW-1* in placental cell function outside of its classically understood role in regulating placental cell fusion.

P-604 4:30 PM Monday, October 19, 2020

HYALURONIDASE INHIBITS MIDKINE IN CUMULUS CELLS DURING OOCYTE DENUDATION. Mine Ergüven Assoc.Prof. Dr.,[1] Tülay İrez Prof. Dr.[2] [1]İstanbul Aydın University, Faculty of Medicine, İstanbul, Turkey; [2]İstanbul Yeniyüzyıl University, Faculty of Medicine, İstanbul, Turkey.

OBJECTIVE: Hyaluronidases are applied to break hyaluronic acid found in high levels in the cumulus-oocyte complex at the oocyte denudation for in vitro fertilization (IVF). The purpose of the study was to investigate whether midkine (MK) has a role at the proliferation and viability of cumulus cells (CCs) at the oocyte denudation done by using hyaluronidase.

DESIGN: This was a prospective, randomized study done with 90 females aged 21-40 and diagnosed as a male factor undergoing intracytoplasmic injection (ICSI) from September 2017 to September 2018.

MATERIALS AND METHODS: CCs taken via mechanical applications from patients were cultured. Hyaluronidases at the concentrations of 0.1 IU/ml [The lowest concentration, (n:30)],1 IU/ml (n:30), and 10 IU/ml [The highest concentration, (n:30)] were applied to CCs. Every 24 hours of 72 hours, proliferation and apoptosis indeces (Flow cytometry) of CCs were evaluated with MK levels (ELISA). Ultrastructure of CCs (n:15 per group) was also evaluated by using Transmission Electron Microscopy (TEM). One way-Anova was used and $p<0.05$ was considered statistically significant.

RESULTS: All concentrations decreased the cumulus cell numbers for 72 hours ($p<0.05$). The highest decrease in cell number was detected at the highest concentration ($p<0.05$) at the 72nd h. In concordance with this result, the highest increase in apoptotic and dead cell rates with the lowest viable

cell rate was detected at the highest concentration ($p<0.05$) at the 72nd h. The highest level led to the highest decrease in MK levels at the 72nd h ($p<0.05$). The ultrastructural analysis showed that the number of apoptotic CCs was increased from the lowest concentration to the highest concentration.

CONCLUSIONS: The inhibition of the proliferation and the viability of CCs by hyaluronidase through the inhibition of MK was firstly reported in this study. This may be one of the reason of poor oocyte quality which leads to the decrease in IVF success.

SINGLE CELL RNA-SEQ ANALYSIS OF THE HUMAN FALLOPIAN TUBE. Nicole D. Ulrich, MD,[1] Yu-chi Shen, Ph.D.,[2] Qianyi Ma, PhD,[2] Kun Yang, MD,[1] Erica E. Marsh, MD, MSCI, FACOG,[2] Jun Z. Li, Ph.D.,[2] Sue Hammoud, Ph.D.[2] [1]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.

OBJECTIVE: Single cell RNA-seq analysis has provided a novel way to characterize cell types through whole transcriptome analysis on the level of the individual cell and has been used to effectively analyze many human organs. Here we use single cell RNA-seq to define major and rare cell types of the human fallopian tube.

DESIGN: Characterizing cellular composition and heterogeneity of human fallopian tube using single cell RNA-seq analysis

MATERIALS AND METHODS: A fallopian tube sample was collected from a perimenopausal female undergoing surgery for a benign indication and was dissected into 3 anatomic segments (isthmus, ampulla, fimbria). Fresh samples from these three anatomic areas were dissociated using our in-house protocols (allowing for > 95 % viability) and analyzed separately. Single cell RNA-seq data were generated using the 10X Genomics Chromium platform. Data analysis was performed using R package Seurat, following our pipeline previously described (Green et al. 2018).

RESULTS: After data processing and QC, we analyzed a high-quality set of 2,338 cells in the isthmus, 5,918 cells in the ampulla, and 4,252 cells in the fimbria. Analysis of the three fallopian tube samples separately identified 11 distinct cell clusters in each. Cluster-cluster correlation across the three segments demonstrated a high degree of correlation of the cell clusters, suggesting that most of the cell types are present over the length of the fallopian tube. We merged the data from the 3 segments (n=12,508 cells) and analyzed together to generate a final cell atlas with 15 recognizable clusters. Using marker gene analysis we annotated the 15 cell clusters as the following cell types: ciliated, secretory (3 sub types), myofibroblast, smooth muscle, pericyte, endothelial, vascular smooth muscle, micro vessel, cytotoxic T/natural killer (two subtypes), mast, and monocyte/macrophage (2 subtypes). The diversity of observed cell types confirms the reliability of our dissociation method and collectively represent a deep census of cell heterogeneity from the fallopian tube. Well known molecular markers based on published literature were used to confirm cell identification.

CONCLUSIONS: Here we present the first comprehensive catalogue of transcriptome-defined cell types of the human fallopian tube. We annotate them to known major cell types and present a foundational reference of functional states and molecular markers for this complex organ. These data provide a new knowledge resource for studies of female reproduction and its disorders, including infertility and ovarian cancer.

NOVEL CAPA-IVM USING DIBUTYRYL-CAMP (DBCAMP) AND C-TYPE NATRIURETIC PEPTIDE (CNP): BOVINE MODEL STUDY FOR HUMAN IVM OF OOCYTES. Nami Morishita, Ph.D., Kana Shibata, B.A., Rie Matsunaga, M.A., Masanori Ochi, Ph.D., Toshitaka Horiuchi, Ph.D. OCHI YUME CLINIC NAGOYA, Nagoya, Japan.

OBJECTIVE: Spontaneous GVBD is thought to be the cause of the decrease in the development competence of IVM of immature oocytes because of less communication between cumulus cells and oocytes. In vivo, meiosis has been maintained by the action of cAMP and cGMP. CNP is mainly produced by granulosa cells, and the receptor for CNP, Npr2 is mainly located in cumulus cells. The binding of CNP to Npr2 increases cGMP level in oocytes, and it inhibits the hydrolysis of cAMP by phosphodiesterase. There have ever been no reports of CAPA-IVM using dbcAMP and CNP together. Is it effective for higher developmental competence of IVM oocytes in CAPA-IVM when dbcAMP and CNP are supplemented?

DESIGN: The study was conduced between August 2018 and July 2019. We investigated the effect of pre-IVM with dbcAMP and CNP (CAPA-IVM) on developmental competence of bovine IVM oocytes after ICSI. The concentrations of cGMP and cAMP in COCs after CAPA-IVM, GVBD rate 6 h after IVM, GSH and ROS levels in MII oocytes, cleavage rate 27 h after ICSI and blastocyst rate were compared between CAPA-IVM and conventional groups (no CAPA-IVM).

MATERIALS AND METHODS: COCs were obtained from follicles with a diameter of 2 to 8 mm of bovine ovaries. COCs were cultured in pre-IVM medium supplemented with 200 μM dbcAMP and 100 nM CNP for 2 h, followed by standard IVM for 22 h. Oocytes matured by standard IVM with 100 ng/ml Amphiregulin for 22 h (no CAPA-IVM) were used as the control. Developmental competence of IVM oocytes was assessed by ICSI.

RESULTS: First, we detected gene expression of *CNP* and *NPR2* in granulosa and cumulus cells. Second, the optimal concentration of CNP was examined. GVBD rate 6 h after IVM was markedly decreased by the supplementation of 100 nM CNP in the presence of 200 μM dbcAMP (0, 100 and 200 nM CNP: 61.9, 12.5 and 7.7%). In addition, pre-IVM treatment of dbcAMP and CNP for 2 h (CAPA-IVM) increased the levels of cGMP (374.6 vs. 14.8 fmol/COC) and cAMP (473.3 vs. 12.3 fmol/COC) in COCs. After then, CAPA-IVM increased the levels of intra-oocyte glutathione (GSH) and decreased the level of reactive oxygen species (ROS) content in MII oocytes 22 h after IVM. Cleavage rates 27 h after ICSI and blastocyst rates were significantly higher in CAPA-IVM than control groups (cleavage rates: 85.7% vs. 64.3%, and blastocyst rates: 36.4% vs. 18.4%).

CONCLUSIONS: The present study indicates that pre-IVM culture of immature oocytes with dbcAMP and CNP for 2 h significantly improved the rate of embryo developed to 2-cell stage 27 h after ICSI and blastocysts. The use of CAPA-IVM with dbcAMP and CNP resulted in more production of blastocysts after ICSI. Supplementation of CAPA-IVM medium with dbcAMP and CNP delayed germinal vesicle breakdown (GVBD), and levels of GSH increased in MII oocytes, and improved blastocyst rates.

P-607 4:30 PM Monday, October 19, 2020

LIVE MORPHOLOGY IMAGING IS A BETTER APPROACH FOR OBSERVING SPERM HEAD OSMOLALITY-INDUCED MORPHOLOGICAL CHANGES COMPARED WITH DIFF-QUIK STAINING METHOD. George C. Hsu, MSc,[1] Ming-Hsun Wu, MSc, MBA,[2] Miao O. Chien, MBA,[2] Han-Ching Tsai, MSc,[1] Cheng-Teng Hsu, PhD[1] [1]Bonraybio Co., Ltd., Taichung City, Taiwan; [2]Min-Sheng General Hospital, Taoyuan City, Taiwan.

OBJECTIVE: To compare the live morphology imaging technology of LensHooke™ X1 Pro Semen Quality Analyzer with Diff-Quik staining in sperm head morphometric analysis.

DESIGN: A blinded prospective study of osmolality-induced morphological changes (OIMC) of human sperm head exposed to hypo-, iso- and hyperosmotic solutions.

MATERIALS AND METHODS: Semen samples (n=15) were pooled to perform 5 repeated experiments. Pooled samples were first washed then resuspended with ddH_2O, human tubal fluid and 20% Glucose respectively

with or without the addition of 200 ppm $HgCl_2$. Sperms were incubated in room temperature for 2 hours and analyzed using the following methods:

(1) Live imaging: a 4.5μL drop of sample covered with a 22 x 22 mm cover slip. Snapshots were taken by microscopy (1000X, oil immersion, Ph3).

(2) LensHooke™ X1 Pro: images of live sperms were captured by AI-controlled lens automatically.

(3) Diff-Quik: sperms were fixed and stained according to the WHO 5th guideline.

400 sperms were measured in each repeated test. A total of 2000 individual sperms were analyzed in each group. The dimensions of head parameters i.e. length, width and area were measured either by X1 Pro or by using the ImageJ software manually. Statistical analysis included t-test and two-way ANOVA with significance at $p < 0.01$.

RESULTS: Live imaging and X1 Pro showed minor changes in head area after ddH_2O treatment (0.1%, $p = 0.87$; -0.4%, $p = 0.51$). Hyperosmotic exposure showed significant shrinkage (-11.5%, $p < 0.01$; -12.3%, $p < 0.01$). With the addition of aquaporin inhibitor $HgCl_2$, head area were dramatically enlarged upon hypo-osmotic exposure in both live imaging and X1 Pro (9.4%, $p < 0.01$; 8.0%, $p < 0.01$). However, hyperosmotic exposure showed no significant difference (-0.4%, $p = 0.49$; -0.7%, $p = 0.26$). On the contrary, Diff-Quik method displayed inconsistent results of head area with (hypo: -0.3%, $p = 0.67$, hyper: -23.1%, $p < 0.01$) and without $HgCl_2$ addition (hypo: -6.7%, $p < 0.01$, hyper: -7.5%, $p < 0.01$). Moreover, while X1 Pro took less analyzing time compared to microscopic live imaging (5.1 ± 0.3 vs 319.3 ± 27.4 min, $n = 30$, $p < 0.01$), there was no significant difference between head morphometrics ($p = 0.40$) in contrast to Diff-Quik method ($p < 0.01$).

	Osmolality	Parameter	Live	X1 Pro	Diff-Quik
$HgCl_2$ (–)	Iso-	Area (μm^2, Mean ± SD)	12.23 ± 2.47	12.34 ± 2.66	9.23 ± 1.68
	Hypo-		12.24 ± 2.58	12.29 ± 2.52	8.61 ± 1.57
	Hyper-		10.82 ± 2.34	10.83 ± 2.39	8.54 ± 1.75
$HgCl_2$ (+)	Iso-	Area (μm^2, Mean ± SD)	13.20 ± 2.48	13.12 ± 2.53	9.39 ± 1.91
	Hypo-		14.44 ± 3.08	14.17 ± 3.13	9.37 ± 1.91
	Hyper-		13.14 ± 2.50	13.03 ± 2.57	7.22 ± 1.63

CONCLUSIONS: LensHooke™ X1 Pro live morphology imaging technology is fast and applicable in assessing OIMC. Diff-Quik staining method is not recommended for assessing sperm morphology when OIMC occurred.

IN YOUNG WOMEN WITH POOR OVARIAN RESPONSE (POR), MICRORNA EXPRESSION IN PERIPHERAL BLOOD MONONUCLEAR (PBMN) CELLS IS ALTERED COMPARED TO NORMO-RESPONDER CONTROLS.

Mauro Cozzolino, MD,[1] Shiny Titus, PhD,[2] Sonia Herraiz, Ph.D.,[3] Antonio Pellicer, MD,[3] Richard Thomas Scott, Jr., MD,[4] Emre Seli, M.D.[1] [1]Yale School of Medicine, New Haven, CT; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVIRMA Foundation, Valencia, Spain; [4]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Micro RNAs (miRNAs) are a large family of short (21 nucleotide), evolutionarily conserved, non-coding RNAs. They repress expression of their target messenger RNAs (mRNAs) by causing degradation and/or inhibition of translation. Micro RNAs play a central role in the regulation of gene expression in a number of cell types and tissues, and altered miRNA expression is implicated in the pathogenesis of numerous disorders. The aim of the current study was to determine whether peripheral somatic cell miRNA expression show unique characteristics in women with reproductive disorders associated with abnormal follicular development. We therefore investigated miRNA profile of peripheral blood mononuclear cells (PBMNCs) in young women with polycystic ovary syndrome (PCOS) and poor ovarian response (POR), and compared to normo-responder controls.

DESIGN: Prospective experimental study.

MATERIALS AND METHODS: Young reproductive age women (<35 years old) with PCOS (n=5; selected based on Rotterdam criteria); poor ovarian response (n=5; selected based on Poseidon criteria – group 1a with number of oocytes retrieved <4); and normo-responder controls (n=5) were included in the study. Peripheral blood mononuclear cells (PBMNCs) were collected on the day of retrieval, and total RNA was extracted in the RNeasy Micro kit (Qiagen). The HiSeq sequencing results were annotated and classified by comparing the sequences with those of noncoding RNAs (miRNA, siRNA, piRNA, rRNA, tRNA, snRNA, etc.) in GenBank databases. The identified miRNA sequences were annotated by matching the sequencing results with known miRNA sequences in miRBase 21.0. MiRNAs with log2FC > 2 or <−2 were identified as differentially expressed.

RESULTS: Mean age and number of oocytes retrieved were 32.5 ± 0.7 years and 16 ± 4.9 oocytes for the PCOS group, 34.2 ± 1.4 years and 2 ± 1.5 oocytes for the POR group, and 31.0 ± 2.1 years and 21 ± 3.6 oocytes for controls. In women with POR, 11 miRNAs were differentially expressed compared to controls; 6 showed increased expression (hsa-let-7f-5p, hsa-let-7g-5p, hsa-miR-6130, hsa-miR-98-5p, hsa-miR-1246, hsa-miR-7-5p) and 5 showed decreased expression (hsa-miR-30a-5p, hsa-miR-30d-5p, hsa-miR-139-5p, hsa-miR-425-5p, hsa-miR-199a-5p). No changes were observed in the PBMNC miRNA expression in women with PCOS compared to controls.

CONCLUSIONS: Our findings demonstrate that somatic cells of women with POR have altered miRNA profiles. We found members of the let-7 family of miRNAs, which play important roles in development, cancer, and metabolism to be up-regulated in women with POR. In mice, where targeted deletion of H19 cause elevated let-7, AMH is decreased, and follicle recruitment is accelerated (1). Future studies will be needed to determine whether similar mechanisms are in effect in ovaries of women with POR, and whether these findings can be exploited for diagnostic purposes.

MATERNAL-TO-ZYGOTIC TRANSITION-RELATED MICRO RNAS ARE INCREASED IN BLASTOCYST CULTURE MEDIUM.

Amber M. Klimczak, MD,[1] Shiny Titus, PhD,[2] Nola S. Herlihy, MD,[3] Brent M. Hanson, MD,[3] Julia G. Kim, MD, MPH,[3] Emily K. Osman, MD,[3] Ashley W. Tiegs, MD,[3] Richard Thomas Scott, Jr., MD,[3] Emre Seli, M.D.[3] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Maternal-to-zygotic transition (MZT) is associated with transcriptional activation of zygotic genome and degradation of maternally-derived messenger RNAs (mRNAs) carried over from the oocyte. MZT is a crucial step in pre-implantation development and occurs at 4-8-cell stage in human embryos. Degradation of maternal mRNAS during

MZT is mediated by evolutionarily conserved microRNAs (miRNAs), such as miR-430 in zebrafish, miR-427 in Xenopus, and miR290-miR295 in mice. Using a bioinformatic approach, miR371-miR373 were identified as the human orthologues. In the current study, we investigated whether miR371-miR373 are expressed in human cleavage stage and blastocyst embryos and whether they can be detected in spent culture medium (SCM).

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: To assess expression in cleavage stage embryos and blastocysts, discarded embryos (n=4 for each developmental stage) were used. RNA was extracted using single cell RNA purification kit from Norgen Biotech. Additionally, SCM was collected from four different patients' embryos in the cleavage, morula, and blastocyst stages (n=10 per stage). The media was centrifuged at 10,000 rpm for 5 minutes. RNA was extracted using miRNA easy kit and was converted to cDNA by the miRCURY LNA RT kit. Real time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) analysis for miR-371-miR373 was performed using the MiRCURY LNA SYBR Green PCR kit from Qiagen. RNU6B (or U6 snRNA) expression was quantified in each sample for normalization. The fold change was calculated by 2^-(delta delta ct).

RESULTS: The presence of miR371, miR372, and miR373 was confirmed in the embryos. There was no significant difference in their expression between cleavage stage embryos and blastocysts (p=0.88, p=0.85, p=0.83). In contrast, there were differences found in miRNA concentrations with progressive embryonic development. miR371-3p and 372-3p were undetectable at the cleavage stage, but became detectable at the morula stage, with significantly increased levels at the blastocyst stage (miR371-3p ($p<0.01$) and 372-3p ($p<0.001$)). Expression of miR 373-3p in SCM was noted in all three developmental stages and relative concentrations increased from the cleavage stage to the morula stage ($p<0.05$) then further increased at the blastocyst stage ($p<0.005$).

CONCLUSIONS: Our findings demonstrate that miR371, miR372, and miR373 are expressed in human pre-implantation embryos and that their secretion into culture media increases progressively with the stage of embryonic development. Further studies are now indicated to determine if the variability in these increases will prognosticate the ability of embryos to sustain implantation. This simple and inexpensive assessment will now progress to clinical trials.

P-610 4:30 PM Monday, October 19, 2020

APPLICATION OF OMNI-ATAC TO PROFILE CHROMATIN ACCESSIBILITY BEFORE AND AFTER OVARIAN TISSUE CRYOPRESERVATION.

Jennifer Shannon, MD, Orhan Bukulmez, MD, Zexu Jiao, MD/PhD, Aishwarya Sundaresan, MS, Sarah M. Capelouto, MD, Kaitlin Doody, MD, Bruce R. Carr, MD, Laura Banaszynski, PhD UT Southwestern Medical Center, Dallas, TX.

OBJECTIVE: Recently, ovarian tissue cryopreservation (OTC) was declared non-experimental. Even prior to this, the technique was being rapidly adopted worldwide as a means to both restore ovarian function and preserve fertility. OTC and subsequent transplantation may be limited by "graft burnout," where hypoxia and aberrant follicular activation may play a role. The molecular mechanisms behind follicular activation are not fully defined. Our goal is to apply a new method, omni-ATAC, for chromatin accessibility profiling, both to characterize follicular transcriptional regulation and to determine whether cryopreservation affects follicular transcriptional integrity. Ideally, the cryopreservation technique should not result in significant changes in regulatory element usage after its application.

DESIGN: Ovarian cortical tissue was collected from patients (n = 6) receiving oophorectomy for benign reasons, and was processed following established OTC protocols. Omni-ATAC was applied to both fresh and cryopreserved-thawed tissue.

MATERIALS AND METHODS: Ovarian tissue was collected and transported on ice. The cortex was isolated, with part of the specimen used for fresh evaluation, and part vitrified. Tissue underwent a liberase DH (dispase high) digestion. Follicular isolation was performed under light microscopy. Omni-ATAC was performed. Transposed DNA fragments were column purified, SYBR-PCR amplified, and double-bead purified. Sequencing was performed. Thawed specimens underwent the same protocol for follicular and DNA isolation, with the addition of a nuclear red (NR) viability stain during digestion. Last, histopathology for proliferation (Ki67) and apoptosis (TUNEL) was completed.

RESULTS: Histopathology and NR staining indicate healthy follicles in all specimens. Average correlation is 0.99 among fresh specimens, and 0.92 among thawed specimens. Peak distribution is significantly enriched at promoter regions in both fresh (9.1%) and thawed (11%) data sets. Preliminary peak calling browser tracks appear similar between fresh and thawed specimens.

CONCLUSIONS: We successfully processed fresh ovarian cortical samples from six women, resulting in highly correlated data sets. Further, we compared fresh to cryopreserved-thawed cortex, and demonstrate that these specimens remain highly correlated. These data suggest that cryopreservation itself does not greatly affect transcriptional regulation. Future analysis will focus on gene ontology and motif analysis, as well as differentially expressed gene (DEG) analysis between fresh and thawed specimens. Pathway analysis will proceed via comparison to currently published transcriptome data.

P-611 4:30 PM Monday, October 19, 2020

PROGRAMMED MITOPHAGY IS ESSENTIAL FOR THE GLYCOLYSIS SWITCHING DURING SENESCENCE IN HUMAN CUMULUS CELLS.

Kuan-Hao Tsui, M.D; Ph.D, Chia-Jung Li, Ph.D. Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan.

OBJECTIVE: Cumulus granulosa cells, a group of closely associated granulosa cells that surround and nourish oocytes. Here, we show that human cumulus granulosa cell proliferation depends on mitophagy, the programmed autophagic clearance of mitochondria.

DESIGN: Experimental laboratory study.

MATERIALS AND METHODS: In a prospective study, fresh granulosa cells were obtained from 48 women aged 20–40 years who underwent IVF with embryo transfer and who were divided into two groups: the diminished ovarian reserve (DOR) group (n = 20) and the control group (n = 28). Patient characteristics including age, infertility duration, body mass index, FSH, anti-Müllerian hormone (AMH) and cumulus cell, mitophagy, mitochondrial mass were analysed.

RESULTS: The elimination of mitochondria in aged GCs proliferation was coupled to a metabolic shift with increased lactate production and elevated expression of glycolytic enzymes at the mRNA level. Pharmacological inhibition of either mitophagy or glycolysis consistently increased GCs proliferation during aging. Oxidative stress triggered expression of the mitophagy regulator BNIP3L/NIX at peak GCs during aging. Senescent granulosa cells from poor ovarian responder displayed decreased mitochondrial mass, elevated expression of glycolytic enzymes and decreased cell proliferation.

CONCLUSIONS: In summary, developmentally controlled mitophagy promotes a metabolic switch towards glycolysis, which in turn contributes to cellular proliferation in senescent granulosa cells.

CASE REPORT: RNASEQ ANALYSIS OF BLASTOCOEL FLUID FROM EUPLOID EMBRYOS ORIGINATING FROM THE SAME PATIENT RESULTING IN DIFFERENT IMPLANTATION OUTCOMES REVEAL ALTERED EXPRESSION OF GENES ASSOCIATED WITH DEUBIQUITINATION PATHWAY.

Laura Grace Wolfe, B.S.,[1] Arnav Lal,[2] Trevor Shull, B.S.,[1] Addison Paige Brandt, B.A.,[1] Carson M. Collins, na,[1] Sammy K. Khalil, n/a,[1] Shawn Zimmerman, PhD, HCLD,[3] T. Arthur Chang, PhD, HCLD, ELD,[4] Randal D. Robinson, MD,[5] J. David Wininger, PhD, HCLD,[6] William E. Roudebush, PhD, HCLD,[1] Renee J. Chosed, PhD[1] [1]University of South Carolina School of Medicine Greenville, Greenville, SC; [2]University of Pennsylvania, Philadelphia, SC; [3]Vios Fertility Institute, Swansea, SC; [4]University of Texas Health Science Center, San Antonio, TX; [5]University of Texas Health Science Center San Antonio, San Antonio, SC; [6]Atlantic Reproductive Medicine Specialists, Raleigh, SC.

OBJECTIVE: Is the gene expression profile different between two 46, XX blastocysts, with identical morphology from the same patient? While Preimplantation Genetic Testing for Aneuploidies (PGT-A) allows for identification of ploidy status and morphology scoring provides additional information when selecting an embryo for transfer, euploid embryos with the same morphology do not always result in the same implantation outcome. This study aimed to evaluate global gene expression using RNASeq in

blastocoel fluid-conditioned media from two 46, XX euploid embryos from the same 36-year old infertility patient from the same egg retrieval cycle.

DESIGN: Retrospective analysis of day-5 euploid blastocoel fluid gene expression in two 46, XX embryos with different implantation outcomes from a 36-year old patient.

MATERIALS AND METHODS: Day-5 ICSI-generated blastocysts were scored via the Gardner and Schoolcraft grading system. Blastocoel fluid-conditioned media was obtained following biopsy of the day-5 blastocysts of same morphology grade (5AA). RNA was extracted and libraries prepared using a SMART-Seq Stranded kit followed by Illumina NextSeq500 sequencing performed at the University of South Carolina Functional Genomics Core. Sequences were aligned to the human genome, reads counted and gene expression determined. The resulting data set was then analyzed with the iDEP 9.1 web application to run a PGSEA pathway analysis utilizing Gene Ontology Biological Processes Geneset (Ge et al. BMC Bioinformatics 2018;19:534).

RESULTS: Gene expression associated with various cellular pathways were compared between the blastocoel fluid sample from each blastocyst which revealed a decreased level of gene expression associated with the protein deubiquitination pathway in the positive implantation embryo, and no other analyzed pathway yielded significant difference in gene expression between the two blastocoel fluid samples. Specifically, genes encoding SHMT2, KAT2A, ASXL1 were all downregulated in blastocoel fluid from the embryo associated with successful implantation.

CONCLUSIONS: RNASeq analysis of media samples from two 46, XX embryos with the same morphology from the same patient but associated with different implantation outcomes yielded differences in gene expression. Knowledge of chromosomal status and morphology of a preimplantation blastocyst stage embryo did not provide a complete picture of the underlying biological processes taking place within the embryo, nor could these measures fully predict an embryo's implantation outcome. This case study provides evidence of a detectable difference in gene expression in blastocoel fluid obtained from embryos that would be considered indistinguishable by current methods employed by reproductive specialists. Moreover, this alteration in gene expression is associated with a difference in implantation outcome. While this case study identified the deubiquitination pathway as altered, further study is needed to determine if this difference in these euploid blastocysts is also found in embryos from other patients and/or with the same chromosomal status.

IS IMMUNOGLOBULIN IGE RELEVANT FOR PREGNANCY LOSS? David H. Barad, MD, MS,[1] Sarah K. Darmon, PhD,[1] David F. Albertini, PhD, MS,[1] Emanuela Molinari, PhD,[1] Norbert Gleicher, MD[2] [1]Center for Human Reproduction, New York, NY; [2]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY.

OBJECTIVE: To determine whether IgE levels impact miscarriage risk in association with IVF in view of anecdotal observations at our center in recent years suggesting that IgE levels were changing.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: A complete immunoglobulin profile, including IgG, IgM, IgA and igE has been atour center a routine component of an initial check list obtained on every new patient for over 20 years and we have repeatedly reported on Ig-levels relating to IVF outcomes. Over the last 3 years we, however, anecdotally have noted a significant shift in IgE results in our patient population, in principle characterized by either complete absence or extremely low levels of IgE. In a search of the general literature, we were unable to detects any clinical associations between extremely low IgE and adverse clinical outcomes, except for an association with abnormalities in IgG levels. We, therefore, decided to reinvestigate IgE levels in reference to female infertility. We here report on associations between IgE and pregnancy loss in our center's most recent 1018 new patients. This analysis was, however, restricted to 259 patients presenting for a first IVF cycle who had a previous history of pregnancy. IgE levels were divided into quartiles. The percentages of previous pregnancies lost in each quintile of IgE were then compared, adjusted for age.

RESULTS: Average age of patients was 42.2 ±5.4 years; average gravidity was 2.1 ± 1.3 pregnancies, of which 1.0 ± 1.1 ended in abortion, with 47% of previous pregnancies aborted and 61% of patients having at least one miscarriage. IgE levels ranged from 1 to 700 UI/mL (mean 83.9 ± 134 UI/mL); 66 patients in the lowest quartile (< 13.00) had a previous miscarriage rate of 37%, only nominally lower than miscarriages in other three quartiles (q2 - 47.3%, q3 - 52.7%, q4 – 52.2%). This trend suggested that lowest IgE was associated with fewest past miscarriages a hypothesis further tested by comparing patients with extremely low IgE (< 10 UI/mL) in a general linear model adjusted for age to all others and demonstrating that lowest IgE (n=48) was only associated with 33% pregnancy loss compared to 50% in remaining 211 patients (P = 0.022). Within the latter population, IgE was, however, not a strong predictor of overall pregnancy loss (ROC AUC 0.596 ± 0.36, P= 0.01).

CONCLUSIONS: IgE appears statistically predictive of pregnancy loss in female infertility patients, with very low levels actually appearing potentially protective. Since IgE is functionally associated with allergic and anti-parasitic reactions, its levels can be viewed as a reflection of anti-inflammatory immune activity, thereby, supporting the previously voiced hypothesis that inflammation increases miscarriage risks.

ALTERED EXPRESSION OF GENES INVOLVED IN JAK-STAT, ADIPOCYTOKINE AND TOLL-LIKE RECEPTOR SIGNALING PATHWAYS ARE DETECTED IN BLASTOCOEL FLUID CONDITIONED MEDIA FROM EUPLOID EMBRYOS WITH POSITIVE IMPLANTATION OUTCOMES. Arnav Lal,[1] Laura Grace Wolfe, B.S.,[2] Trevor Shull, B.S.,[2] Addison Paige Brandt, B.A.,[2] Carson M. Collins, na,[2] Sammy K. Khalil, n/a,[2] Shawn Zimmerman, PhD, HCLD,[3] T. Arthur Chang, PhD, HCLD, ELD,[4] Randal D. Robinson, MD,[5] J. David Wininger, PhD, HCLD,[6] William E. Roudebush, PhD, HCLD,[2] Alyssa Clay-Gilmour, PhD,[7] Renee J. Chosed, PhD[2] [1]University of Pennsylvania, Philadelphia, SC; [2]University of South Carolina School of Medicine Greenville, Greenville, SC; [3]Vios Fertility Institute, Swansea, SC; [4]University of Texas Health Science Center, San Antonio, TX; [5]University of Texas Health Science Center San Antonio, San Antonio, SC; [6]Atlantic Reproductive Medicine Specialists, Raleigh, SC; [7]University of South Carolina Arnold School of Public Health, Greenville, SC.

OBJECTIVE: Altered gene expression leading to modified expressions of pathways in preimplantation embryos may be a contributing factor in successful embryo implantation outcome. Identification of genes in day-5 blastocysts that are associated with successful uterine implantations would provide reproductive specialists with an additional measure of embryo quality when selecting the most viable embryo for transfer. This study evaluated global gene expression using RNASeq in blastocoel fluid-conditioned media from euploid IVF-generated embryos resulting in successful implantations versus those that failed to successfully implant.

DESIGN: Retrospective analysis of day-5 euploid blastocoel fluid gene expression in seven (three successful; four unsuccessful) euploid embryos.

MATERIALS AND METHODS: Blastocoel fluid-conditioned media was obtained following biopsy of ICSI-generated day-5 blastocysts. RNA extractions, library preparation (SMART-Seq Stranded kit) and Illumina NextSeq500 sequencing were performed at the USC Functional Genomics Core. Standard RNASeq workflow was conducted: 1) removal of adaptor sequences 2) alignment to human Gh38 genome with STAR, and 3) FeatureCount to obtain raw gene count number for each sample. Differential gene expression analysis (DGE) of raw counts was performed using DESeq2 applying negative binomial generalized linear models and taking advantage of the package to generate more accurate shrunken log fold changes and variance stabilizing estimators for data with considerations regarding low counts and high dispersion. Significance was defined as a false-discovery rate (FDR) p-value <0.05 to adjust for multiple testing. Pathway analysis was performed using GAGE, mapping genes to KEGG pathways.

RESULTS: After quality control 21,321 genes were included in the DGE analysis and 36 (FDRp<0.05) were identified as DE (6 up-regulated / 30 down-regulated). Pathway analysis revealed altered expression patterns of genes encoding proteins in the adipocytokine**,** Toll-like receptor and JAK-STAT signaling pathways between blastocoel fluid from embryos associated with successful versus unsuccessful implantation outcomes. Specifically,

gene products of these pathways were up-regulated in blastocoel fluid from embryos associated with successful implantation.

CONCLUSIONS: We identified differential gene expression in blastocoel fluid from euploid embryos associated with successful versus unsuccessful implantation. JAK-STAT pathway members were identified in this study, which is supported by a previous reports that members of this pathway are expressed during blastocyst stage development. Detection of these gene products in blastocoel fluid may represent apoptotic remnants of cells that were selectively eliminated from the developing embryo. One possibility is that the JAK-STAT pathway activates apoptotic gene expression in specific cells within the embryo as a means of embryo self-correction. Future research aims to clarify the roles of identified genes and consider bi-directionally dysregulated genes within a given pathway in the preimplantation embryo.

KIDNEY TRANSPLANT AND FERTILITY: A RETROSPECTIVE STUDY ON RECIPIENT WOMEN AND LIVING DONORS.

Rocío Soledad Iaizzo, BSc,[1] Alejandro Gustavo Martinez, PhD,[2] Marcela Claudia Irigoyen, MD,[2] Graciano Tessari, MD,[2] Carlos H. Díaz, MD[3] [1]Procrearte, Buenos Aires, Argentina; [2]Fertilis, Buenos Aires, Argentina; [3]CEMIC, Buenos Aires, Argentina.

OBJECTIVE: Compare the reproductive capacity in recipient and donor women against a control group, in kidney recipients before and after transplant and in donors before and after nephrectomy. In addition, the frequency of gynecological alterations in recipients and donors was compared against the control group, in recipients before and after transplant, and in donors before and after nephrectomy.

DESIGN: 146 individuals were divided into 3 groups: transplanted, living donors and control group. The control group consisted on fertile aged women who were neither donor nor recipients.

In order to measure reproductive capacity, biological children, time trying to conceive and performance of assisted reproduction treatments were taken into account.

MATERIALS AND METHODS: Analysis of variance (ANOVA) and Kruskal Wallis test were used to compare populations. Chi-square test was used for the analysis of frequencies between groups.

RESULTS: Transplant patients showed a lower reproductive capacitiy, while living donor's was similar to the control group. Reproductive capacity was higher in kidney patients before transplant, and in living donors before nephrectomy.

No significant differences were found in the frequency of gynecological alterations in transplant patients and living donors, in comparison with the control group. The frequency of these alterations was similar in transplant patients before and after transplant, and in donors before and after nephrectomy.

CONCLUSIONS: Transplant patients would have difficulty conceiving, either as a side effect of the surgery, due to the effect of immunosuppressive medication, or the postponement of motherhood due to emotional, psychological or medical reasons related to the transplant.

It is known that kidney transplants can restore fertility in women with kidney failure, but our study revealed it was easier for patients to achieve pregnancy before transplantation. However, being the same population before and after transplant, the mean age of the post-transplant group was greater than the pre-transplant group, and this could impact on the results. In addition, it is likely that patients had sought pregnancy during early stages of the disease, therefore behaving as a control group.

Living donors would be more likely to conceive before nephrectomy. However, there are some caveats to this study: the sample size was low, and the mean age was greater in the post-nephrectomy group.

The decrease in reproductive capacity in transplant patients is not related to physiology of the reproductive system, since this group did not present a higher frequency of gynecological alterations.

Transplant and nephrectomy neither showed significant impacts on gynecological alterations, which means that surgeries do not involve extra complications at the gynecological level.

Beyond the complications, 86% of recipients managed to have a normal life, and 100% of living donors reported a normal quality of life and being emotionally satisfied with the decision.

EFFECT OF IL-6 AND TNF ALPHA ON INVASION OF EPITHELIAL AND STROMAL ENDOMETRIAL CELLS IN AN *IN VITRO* MODEL OF HUMAN PERITONEUM.

Katherine E. Kostroun, MD, Jennifer F. Knudtson, MD, Jennifer Teague, BS, Mubeen Sultana, BS, Rajeshwar Rao Tekmal, PhD, Robert S. Schenken, MD. University of Texas Health Science Center San Antonio, San Antonio, TX.

OBJECTIVE: Endometriosis is an inflammatory process regulated by cytokines, such as IL-6 and TNF alpha, that are known to be present in higher concentrations in the peritoneal fluid of patients with endometriosis. (1) The purpose of this study was to investigate the effect of IL-6 and TNF alpha on the invasion of immortalized epithelial endometrial cells (iEECs) and human stromal endometrial cells (hESCs) from patients with endometriosis in modeled peritoneum *in vitro*.

DESIGN: *In vitro* study.

MATERIALS AND METHODS: Immortalized cells (hESCs and iEECs) were treated with either IL-6 (1,000 pg/mL,) TNF alpha (8 pg/mL), or the combination; controls were untreated. Invasion assays were completed as previously published. (2) Briefly, cells were labeled with fluorescent dye and incubated in a prepared Matrigel invasion chamber assay with immortalized peritoneal mesothelial cells (LP9). The number of cells invaded per frame was assessed using confocal laser scanning microscopy. The normally distributed data were analyzed by ANOVA with a post-hoc Dunnett's test.

RESULTS: IL-6 and TNF alpha alone did not affect invasion of iEECs. Treatment of iEECs with both IL-6 and TNF alpha resulted in increased cell invasion compared with control (30% vs 23% , p=0.01, n=3). TNF alpha alone decreased invasion of hESCs compared to control (48% vs 88%, p=0.003, n=3). There was no difference in invasion in hESCs with IL-6 or both IL-6 and TNF alpha.

CONCLUSIONS: These findings indicate a synergistic effect of IL-6 and TNF alpha on the invasion of iEECs in an *in vitro* peritoneal model and provide further evidence for the role of these cytokines in the pathogenesis of endometriosis.

MITOQ SHIFTS ENERGY METABOLISM TO INCREASE BIOGENESIS IN HUMAN GRANULOSA CELLS.

Li-Te Lin, PhD,[1] Chia-Jung Li, Ph.D,[2] Kuan-Hao Tsui, M.D; Ph.D[2] [1]Kaohsiung Veterans General Hospital, Kaohsiung City, Taiwan; [2]Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan.

OBJECTIVE: The objective of this work was to determine the specific mechanisms by which MitoQ enhance oxidative phosphorylation.

DESIGN: Experimental laboratory study.

MATERIALS AND METHODS: We used excessive oxidative stress to induce cell senescence, and examined the phenotype of aging. HGL5 cells were cultured in hydrogen peroxide medium for 24 h with or without MitoQ. Protein and gene expression of different enzymes related to metabolism in senescent granulosa cells were analyzed by qPCR, protein array or immunofluorescence.

RESULTS: We report that MitoQ causes an increase in the expression and phosphorylation of AMPK and an increase in the expression of acyl-CoA synthetase, of carnitine palmitoyl transferase 1 and of carnitine acylcarnitine translocase, all enzymes involved in lipid catabolism. On the other hand, the levels of acetyl-CoA carboxylase as well as those its product, i.e. malonyl CoA, are decreased.

CONCLUSIONS: The results suggest that MitoQ may be beneficial in protecting human GCs and may provide a useful monitoring tool for clinical studies of oral MitoQ supplements to older patients undergoing IVF treatment.

P-618 4:30 PM Monday, October 19, 2020

MITOCHONDRIAL DNA QUANTITY AND SEQUENCE VARIATION IN HUMAN CUMULUS CELLS ARE ASSOCIATED WITH PATIENT BMI BUT NOT AGE OR ASSISTED REPRODUCTION OUTCOMES. Kishlay Kumar, PhD,[1] Marta Venturas, MSc,[2] Dan Needleman, Ph.D.,[2] Catherine Racowsky, PhD,[3] Dagan Wells, Ph.D.[4] [1]University of Oxford, Oxford, United Kingdom; [2]Harvard University, Cambridge, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Juno Genetics, Oxford, United Kingdom.

OBJECTIVE: Cumulus cells (CCs) fulfil a vital role in support of oocyte developmental competency. The appropriate function of CCs relies on adequate energy production, which in turn depends on the quantity and genetic competence of mitochondria. We sought to characterize the mitochondrial DNA content of a large number of human CCs samples via a combination of quantitative (relative mtDNA copy number) and qualitative (DNA sequence) analyses. Results were considered in relation to factors of relevance to oocyte reproductive potential, such as female age and body mass index (BMI), as well as to embryo characteristics and assisted reproductive technology (ART) outcomes.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: Human CCs, associated with 347 oocytes from 110 IVF patients, were recruited in the ongoing study. Patient age, body mass index (BMI) (kg/m^2), clinical diagnosis and ART outcomes were recorded with respect to each cumulus complex. Mitochondrial DNA quantity was measured in all the samples with a validated quantitative PCR method and the entire mitochondrial genome was sequenced in a subset of 119 samples using a high-depth massively parallel sequencing approach. Sequence variants in the mtDNA were evaluated using Mitomaster and HmtVar to predict their potential impact. Generalized linear mixed model and other appropriate statistical models were used to assess significance ($P \leq 0.05$).

RESULTS: Mitochondrial genome sequencing of CCs samples showed a total of 952 synonymous (i.e. no amino acid change) single nucleotide variants (SNVs) and another 626 non-synonymous (altered amino acid sequence) SNVs. Most SNVs were homoplasmic and therefore presumed to have been inherited, but 21 were heteroplasmic variants and potentially had a somatic origin. 104 of the homoplasmic variants, detected in 63 samples, were predicted to impact protein function, potentially affecting ATP production. Significant associations were observed between BMI and the number of non-synonymous mtDNA variants ($p=0.037$) and BMI and mtDNA quantity ($P = 0.013$). Moreover, a significant difference was also detected between mtDNA levels in CCs and normal weight (BMI 18.5-24.9) and obesity-class groups (BMI-30.0-34.9, $P=0.023$; ≥ 40.0, $P=0.024$). No significant differences were observed between mtDNA quantity in CCs and oocyte fertilization status or embryo quality.

CONCLUSIONS: No significant associations were detected between cumulus cell mtDNA quantity or sequence variants and clinically relevant endpoints. These findings suggest that, analysis of mtDNA (sequence and quantity) in CCs is unlikely to provide an advantage in terms of improved embryo selection during assisted reproduction cycles. Nonetheless, our data raise interesting biological questions, particularly regarding the interplay of metabolism and BMI.

P-619 4:30 PM Monday, October 19, 2020

PATERNAL SEGMENTAL CHROMOSOME CONFUSION. Susanna McReynolds, PhD, Lauren Henry, BS, Nathan McCubbin, BS, Rachel S. Mann, BS, MS, Rachel Tucci, BS, Sue McCormick, BS, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD. Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Chromosome segmental deletions and duplications resulting in a recognizable genetic syndrome account for 0.5-1% of prenatal diagnostic testing and are mostly considered random de novo events occurring during gametogenesis. The aim of this study was to identify factors associated with the parental origin, time point and types of chromosome segmental errors in preimplantation embryos.

DESIGN: Prospective blinded cohort study.

MATERIALS AND METHODS: In total, 27 blastocysts (mean maternal age = 35.1 ±3.1years; mean paternal age = 37.9 ±5.3years) were identified following preimplantation genetic testing for aneuploidy (PGT-A) with a ≥5Mb chromosome segmental deletion (n=24) or duplication (n=3). Patient consent and parental DNA were obtained to determine the origin of error using HumanKaryomap-12 BeadChip (Vitrolife). In addition, 54 transferrable quality blastocysts (≥Grade 3BB) with chromosome segmental aneuploidies were donated with patient consent for diagnostic confirmation (mean maternal age = 36.7 ±4.2years; mean paternal age = 38.6 ±5.1years). Each blastocyst underwent dissection into three distinct sections with inner cell mass (ICM) identification, and blindly re-analyzed using the equivalent VeriSeq™ platform (Vitrolife). After un-blinding, the data was compiled, identifying representatives of the ICM and TE, for a complete picture of each individual blastocyst.

RESULTS: The overall incidence of chromosome segmental aneuploidies (≥5Mb) in PGT-A cycles is 3.6% (n=62,564 biopsied blastocysts). Origin of segmental aneuploidy of 27 blastocysts revealed the vast majority of errors were paternal in origin (84%) and of these 95.2% occurred on the metacentric or sub-metacentric larger and medium size chromosomes. In contrast, maternal origin segmental errors were predominantly located on the smaller acrocentric chromosomes as observed with maternally derived whole chromosome aneuploidies (66.7%; $P<0.05$). There were no significant differences in the number of recombination events in association with parental origin or the location of chromosome segmental errors with the majority occurring on the q arm (74.1%). Blinded dissection re-analysis of 54 blastocysts with chromosome segmental aneuploidies validated the original TE diagnosis in 51 (94.4%) embryos and included concordance in all four sections (ICM and TE) for 39 blastocysts, indicating meiotic origin (72.2%). The remaining 12 (22.2%) blastocysts that were concordant, displayed a euploid cell line in ≥1 section and/or the reverse segmental error. These findings support mitotic chromosome segmental aneuploidies occurring during embryo development.

CONCLUSIONS: This study confirms the incidence of chromosome segmental aneuploidies predominantly originating from the male genome. This is in strict contrast to whole chromosome aneuploidies that have been extensively documented to originate from oogenesis. Additionally, our results reveal no association with paternal meiotic recombination events but do involve the q arm of larger to medium size metacentric and submetacentric chromosomes during meiosis or mitosis.

INCREASED CONCORDANCE RATES BETWEEN EMBRYO CELL-FREE DNA AND TROPHECTODERM BIOPSIES ARE RELATED TO FEMALE AGE INDEPENDENTLY OF CULTURE CONDITIONS. Carmen Rubio, PhD,[1] Luis Navarro-Sánchez, PhD,[1] Carmen Maria García-Pascual, PhD,[1] Olcay Ocali, BS,[2] Danilo Cimadomo, PhD,[3] William Venier, MSc, ELD (ABB),[4] Gerardo Barroso, MD,[5] Laura J. Kopcow, MD,[6] Mustafa Bahçeci, MD,[7] Lourdes López-Yañez, MD, PhD,[8] Marcos Kulmann, MSc,[9] Emilio De La Fuente, MSc,[1] Roser Navarro, MSc,[1] Diana Valbuena, MD, PhD,[1] Denny Sakkas, PhD,[2] Laura Francesca Rienzi, MSc,[3] Carlos Simon, MD, PhD[10] [1]Igenomix, Paterna (Valencia), Spain; [2]Boston IVF, Waltham, MA; [3]GENERA, Center for Reproductive Medicine, Rome, Italy; [4]San Diego Fertility Center, San Diego, CA; [5]Nascere, Mexico City, DF, Mexico; [6]Pregna Medicina Reproductiva, Buenos Aires, Argentina; [7]Bahçeci Health Group-Fulya IVF Centre, Istanbul, Turkey; [8]ProcreaTec, Madrid, Spain; [9]Nilo Frantz Reproductive Medicine, Porto Alegre, Brazil; [10]Professor University of Valencia, INCLIVA, Founder and Head of the Scientific Advisory Board, Igenomix, Paterna (Valencia), Spain.

OBJECTIVE: The presence of embryo cell-free DNA (cfDNA) in spent blastocyst media (SBM) and concordance with trophectoderm (TE) biopsies has been reported in PGT-A patients. However, the impact of different culture media, incubator models and female age on cfDNA detection is still unknown.

DESIGN: Multicenter, prospective study including 1,301 SBM from day-6/7 blastocysts in PGT-A patients aged 20-44 years. Informative results for both cfDNA and TE biopsies were obtained in 1,108 blastocysts. Concordance rates for embryo ploidy between cfDNA and TE biopsies were estimated for each culture media and incubator model at different age ranges (ClinicalTrials.gov; NCT03520933).

MATERIALS AND METHODS: TE biopsies and SBM were collected from April 2018 to September 2019. After IVF or ICSI, embryos were

	Irvine (n=641)	LifeGlobal (n=305)	Vitrolife (n=102)	Sage (n=60)	Minc (n=396)	C-TOP (n=305)	K-Systems (n=254)	Astec (n=102)	Miri (n=51)	TOTAL (n=1108)
<=30 years	71.9	75.0	95.8	100	70.6	75.0	88.9	95.8	100	76.9
31-35 years	74.6	78.9	83.7	80.0	79.0	78.9	53.3	83.7	92.3	77.4
36-38 years	77.9	82.9	83.3	72.7	75.7	82.9	79.0	83.3	80.0	78.4
39-40 years	79.5	87.5	84.6	92.3	68.4	87.5	88.6	84.6	88.9	81.6
41-44 years	83.1	93.3	90.0	92.9	77.9	93.3	92.7	90.0	83.3	85.3
p-value	0.0425	0.0383	NS	NS	NS	0.0383	0.0256	NS	NS	0.0256

cultured using the standard culture conditions of each laboratory up to day 4, with culture media from Irvine Scientific; Life Global; Vitrolife or Sage. Embryo culture was conducted in Minc; C-top; K-Systems; ASTEC or MIRI incubators. On day 4, embryos were individually transferred to a 10μL drop of fresh media. No previous assisted hatching or embryo vitrification was allowed. Individual SBM was collected on day 6/7 and frozen until analysis. TE biopsies and SBM were analyzed by Next Generation Sequencing with proprietary algorithms for cfDNA and TE biopsies.

RESULTS: Concordance rates were similar using different culture media or incubator models. However, female age was a significant variable, with concordance rates showing a significant linear trend with increasing age (p=0.0256, Chi-squared test for trend). This trend for female age was also observed when results were stratified by culture media and incubator model, in most of the cases. The increase in concordance rates was mostly due to the significant decrease in false positive rates, from 15.0% in women below 30 years, to 5.5% in women between 41-44 years (p= 0.0011, Chi-Square). False negative rates were not affected by female age. A summary of the concordance results is shown in the table.

CONCLUSIONS: High concordance rates have been reported for embryo cfDNA and TE biopsies. Female age was positively correlated with increased concordance rates for all the culture media and incubator models tested.

SUPPORT: The study was supported by Igenomix.

P-621 4:30 PM Monday, October 19, 2020

DO SPECIFIC CHROMOSOME ANEUPLOIDIES INCREASE WITH ADVANCING PATERNAL AGE? Katrina Merrion, MS, Dusan Kijacic, MS, Michelle Kiehl, MS Natera, Inc., CA.

OBJECTIVE: Prior literature suggests there may be a chromosome-specific aneuploidy risk for offspring associated with advanced paternal age (PA), mainly trisomy 21 and sex chromosome aneuploidy.[1-5] In this study, we analyze the 24-chromosome preimplantation genetic testing for aneuploidy (PGT-A) results for trophectoderm (TE) samples from a series of men who underwent in vitro fertilization (IVF) using an oocyte donor, broken down by chromosome and PA.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: All PGT-A cases with TE biopsy and an oocyte donor between July, 2010 – April, 2020 were included in the analysis. IVF cycles and TE biopsies were performed according to each clinic's standard procedures. TE and biological parent samples were shipped to a reference lab for genotyping using Illumina Cyto12 SNP-based microarrays and a bioinformatics technique. TE samples were compared to parental samples across multiple SNP loci to determine parental origin of each chromosome and to establish chromosome copy number. Statistical analysis was performed using a two-tailed t-test.

Table 1. Aneuploidy rates of paternal and mixed origin by chromosome number and PA group (years).

Chromosome Number	<35 (%)	35-37 (%)	38-40 (%)	41-42 (%)	43-50 (%)	51-60 (%)	>60 (%)
1	0.7	0.7	1.1	1.3	1.4	1.0	2.0
2	1.1	0.7	1.5	1.3	1.7	1.6	2.0
3	1.2	1.1	1.6	1.5	1.5	1.1	1.2
4	1.2	1.1	1.6	1.4	1.6	1.4	2.0
5	1.7	0.9	1.2	1.1	1.3	0.9	2.0
6	1.7	1.0	1.6	1.7	1.3	1.6	2.7
7	1.1	0.8	1.1	1.2	1.4	1.1	1.6
8	0.9	1.3	0.9	1.4	1.3	1.3	1.2
9	0.6	0.9	1.5	1.5	1.5	1.6	0.8
10	1.0	0.8	1.2	1.1	1.3	1.2	0.8
11	1.2	0.8	1.3	1.2	1.3	1.0	1.6
12	0.8	0.8	1.4	1.9	1.2	1.1	1.2
13	1.4	0.8	1.4	1.9	1.5	1.7	2.3
14	1.4	1.1	1.2	1.6	1.6	1.7	1.6
15	1.0	0.8	1.2	1.6	1.7	1.3	2.0
16	0.8	0.8	1.1	1.7	1.3	1.1	1.6
17	1.0	0.4	1.0	1.1	1.3	0.9	1.6
18	0.8	0.8	1.0	1.8	1.5	1.2	2.0
19	1.1	0.5	1.2	0.6	1.1	1.1	2.0
20	1.2	1.0	1.2	1.2	1.2	1.3	0.8
21	1.2	1.2	1.1	1.4	1.6	1.5	1.6
22	1.0	0.9	1.6	1.1	1.3	1.4	2.0
Sex	1.8	1.6	1.8	2.0	1.8	1.6	2.0

RESULTS: Results were obtained on 14,901/15,371 (97%) of TE samples. The average PA for the patient cohort was 43.6 ± 7.0 years (range 23.1-73.1). Aneuploidy rates by chromosome are broken down using SART age groups, in addition to a further breakdown of men >42 years (Table 1). There was no statistical difference in the paternal aneuploidy rates by chromosome between PA groups (p>.05).

CONCLUSIONS: While previous literature has suggested chromosome-specific aneuploidy risks for offspring may increase with advancing PA, our large dataset shows no correlation.

INCREASED USE OF EXPANDED CARRIER SCREENING (ECS) GENETIC PANELS IDENTIFY MANY TYPES OF FACTOR XI VARIANTS: WHAT DO WE DO WITH THIS INFORMATION FOR INFERTILITY PATIENTS?

Jacquelyn Shaw, MD,[1] Andria G. Besser, MS, CGC,[2] Orah Yvonne Salamah, BSN, RN,[2] James A. Grifo, MD, PhD[3]
[1]NYU Lagnone Fertility Center, New York, NY; [2]New York University Langone Fertility Center, New York, NY; [3]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: Factor XI deficiency is an autosomal recessive (AR) bleeding disorder frequently seen in the Ashkenazi Jewish population but less common among other ethnicities. Although carriers of AR disorders are typically asymptomatic, Factor XI deficiency carriers can have reduced factor XI levels and experience increased bleeding. Any deficiency in factor XI may lead to propensity to bleed; however, the bleeding risk is unpredictable as there is poor correlation with factor XI level. As ECS becomes more commonplace in the IVF clinic and many ECS panels include the F11 gene, an increasing number of patients are being identified to carry or be affected with factor XI deficiency. Since pregnancy and gynecological surgery are encounters that potentially expose these patients to hemorrhage risk, the objective of this study was to explore how Reproductive Endocrinology and Infertility (REI) physicians might use this information.

DESIGN: Case series of factor XI deficiency identified on ECS genetic panel at a large urban university-based fertility center from 6/2018 to 3/2020.

MATERIALS AND METHODS: All cases of factor XI deficiency were identified from the same ECS panel performed by a single reference laboratory. Patient records were reviewed for medical and surgical history, infertility treatments and outcomes, and hematologic evaluation.

RESULTS: 21 patients were identified with factor XI mutations out of 1501 patients tested for an incidence of 1.4%. Of these, 10 were male. All patients were heterozygotes. No carrier couples of factor XI deficiency were identified. Seven different variants were detected: 45% (10) of patients had variant c.403G>T, a nonsense mutation that is known to be the most common mutation in Ashkenazi Jewish patients; 23% (5) had variant c.901T>C, a missense mutation also common in the Jewish population; 5 other variants were found in the remaining 6 patients. 82% (18) variants were identified as "pathogenic," and 14% (3) as "likely pathogenic." Of the 12 female patients, 5 completed fertility treatments including office-based oocyte retrieval without excessive bleeding; 4 of these patients completed retrievals before their factor XI mutation was known. 8 patients are actively trying for pregnancy via ovulation induction or embryo transfer; all of these patients were either referred to hematology for clearance or had factor XI levels ordered by their REI physician. Of the 6 patients referred to hematology, 2 have been cleared for pregnancy and surgery, while the other 4 have pending consults. 2 patients had factor XI levels available; one was normal (66%, c.901T>C variant) and one low (45%, c.1716+1G>A variant) – both patients had normal coagulation panels (coags) and were cleared for fertility treatments. 3 patients had factor XI level and coags ordered by the REI physician; all are pending results.

CONCLUSIONS: As ECS is more commonly ordered for infertility patients, our knowledge of the implication of different variant types on surgical and pregnancy bleeding risks will grow. REI physicians should establish a standard approach to identify those at increased risk of hemorrhage and adverse outcomes.

SUPPORT: There is no financial support to declare.

P-623 4:30 PM Monday, October 19, 2020

AN EVIDENCE-BASED EVALUATION OF GUIDELINES CRITERIA FOR CONDITION INCLUSION ON ECS PANELS: IDENTIFYING A GUIDELINES-COMPLIANT PANEL.

Katie Johansen Taber, PhD, Raul Torres, PhD, Rotem Ben-Shachar, PhD, Aishwarya Arjunan, MS, MPH, CGC, Jim Goldberg, MD Myriad Women's Health, South San Francisco, CA.

OBJECTIVE: The American College of Obstetrics and Gynecology (ACOG) states that expanded carrier screening (ECS) is an acceptable strategy for carrier screening and that conditions selected for inclusion on ECS panels should meet several of the following criteria: 1. have a carrier frequency of 1 in 100 or greater, 2. have a well-defined phenotype, 3. have a detrimental effect on quality of life, 4. cause cognitive or physical impairment, 5. require surgical or medical intervention, 6. have an onset early in life, and 7. can be diagnosed prenatally. These criteria lack specificity, making them difficult to interpret.

DESIGN: We drew from published, quantitative frameworks to clarify and operationalize each criterion, and then identified conditions that unambiguously met the criteria.

MATERIALS AND METHODS: Carrier frequencies were calculated from an internal database of more than 450,000 carriers of condition(s) on a 176-condition panel. "Well-defined phenotype" was defined by the ClinGen categorization of the strength of gene-disease association. The four severity-related criteria (criteria 3-6) were defined by the mapping of disease traits to each criterion by 12 independent board-certified genetics providers (genetic counselors and medical geneticists). The ability to be diagnosed prenatally was considered to be a feature of all monogenic conditions.

RESULTS: It is unclear how many criteria ACOG deems acceptable to adhere to its statement that "several" criteria should be met. Therefore, the two conditions that ACOG currently recommends for panethnic carrier screening, cystic fibrosis (CF) and spinal muscular atrophy (SMA), were used to establish baseline thresholds. Both conditions have carrier frequencies greater than 1 in 100 in any ethnicity, have Definitive gene-disease associations, meet at least one severity-related criterion (CF met one and SMA met four), and can be diagnosed prenatally. 176 conditions were then analyzed using these thresholds: 40 had carrier frequencies greater than 1 in 100 in any ethnicity, 173 had Definitive gene-disease associations, 170 met at least one severity-related criterion, and all 176 could be diagnosed prenatally. Combining these thresholds yields a guidelines-compliant panel of 37 conditions (Table), with a combined carrier detection rate of 30.4% and an ARC detection rate of 1.0%. Relative to a 176-condition panel, the 37-condition panel would detect 84.6% of ARCs.

CONCLUSIONS: Evidence-based application of the ACOG severity criteria resulted in the identification of a guidelines-compliant panel consisting of 37 conditions.

HOW EFFECTIVE IS UNIVERSAL CARRIER SCREENING TO ENCOMPASS TURKISH POPULATION MUTATION PROFILE?

Suleyman Aktuna, PhD,[1] Volkan Baltaci, MD, PhD,[2] Evrim Unsal, Assoc Prof,[3] Leyla Ozer, MD, PhD,[1] Merve Polat, PhD[1] [1]Yuksek Ihtisas University, Ankara, Turkey; [2]Yozgat Bozok University, Yozgat, Turkey; [3]cinnah caddesi 47/1, ankara, Turkey.

OBJECTIVE: According to WHO, 8000 people (in every 100000) are affected with rare diseases and in Turkey 6-8 million people are affected by rare diseases. There are around 8000 rare diseases known in the world and an average of 5 new diseases are described every week. Since the vast majority of genetic diseases cannot be cured, it is of great importance to identify carrier status of partners and prevent affected child births with prenatal or preimplantation genetic methods. Consanguineous marriages have been a major health burden in our country highlighting crucial need of eradication of single gene disorders.

DESIGN: In this study, we investigated the adequacy of carrier panels screening 200-600 different conditions. Our approach was to investigate all pathogenic and likely pathogenic variants in 200 whole exom sequencing (WES) cases without considering the clinical phenotype and combine this data with variant list of all PGT-M cases to obtain rare mutaion profile of Turkish population.

MATERIALS AND METHODS: We compared gene overlap for 2 different commercially available carrier screening tests encompassing 201 and 647 genes and WES mutation results in 301 genes for 200 patients. WES was performed using Twist Human Core Exome Plus kit. Data were analysed using Ingenuity Variant Analysis software according to ACMG guidelines. Variants were filtered according to QC scores (read depth, allel fraction, call quailty), minor allele frequency (%1> in all major databases) and pathogenicity status (in HGMD, Clinvar or predicted pathogenic/likely pathogenic). Additionally, we have included 264 genes from PGT-M data.

RESULTS: 26 out of 965 genes (2.7%) were present in all 4 groups. 360 genes were solely observed in Panel 1, while this number was 13 in Panel 2, 176 for WES and 124 for PGT-M. 304 genes observed in WES and PGT-M cases were not covered by both panels. WES reveals that the variant frequency of the most common genes (top 15 genes) constitute only 34% of all variants detected.

CONCLUSIONS: Carrier screening is an essential public health requirement, especially in countries where high consanguineous marriage is observed. Since commercially available panethnic panels do not fully meet the needs of geographical regions, no panel can be designated as universal. This hypothesis is supported by the comparison results revealing that 360 genes in Panel 1 do not overlap with any other group. The most important reason for this is high consanguinity in our country underlying rare genetic variants and it is noteworthy that 65% of the families applying for PGT-M are carriers of rare diseases. This is also highlighted in the outcome of the study, where variant frequency of the most common genes (top 15 genes) in WES cases constitutes only 34% of all variants detected. Furthermore, since mutation databases are not well-established in our population, especially in rare diseases, variants of uncertain significance (VUS) are frequently encountered. Therefore, these kind of studies constitute an important source of information for the creation of community-specific panels.

P-625 4:30 PM Monday, October 19, 2020

STRUCTURAL AND GENOMIC CHARACTERIZATION OF GLOBOZOOSPERMIC MEN. Alessandra Parrella, M.Sc., Philip Xie, B.S., Stephanie Cheung, B.S., Danielle Rebecca Tavares, B.A., Brianne Barker, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To characterize the structural abnormalities, genetics, and transcriptomic profile of globozoospermic (GZ) men.

DESIGN: During the last 8 years, 11 GZ men undergoing treatment at our center were screened by ultrastructural analysis and categorized as having partial (PG) or complete (CG) globozoospermia. CG men, according to their ability to sustain a term pregnancy, underwent whole genome karyotyping, gene mutation analysis, and transcriptomic profiling.

MATERIALS AND METHODS: GZ men underwent standard semen analysis, and ultrastructural details were evaluated by transmission electron microscopy (TEM). Aniline blue staining measured histone content (normal threshold $\leq$20%). SCF was performed by TUNEL (normal threshold $\leq$15%). PLCζ was detected with immunofluorescence staining (normal threshold $\geq$30%). Genome and transcriptome analyses were obtained by DNA- and RNA-seq, respectively.

RESULTS: A total of 11 men were diagnosed as PG (N=4) and CG (N=7) by TEM, revealing 98 $\pm$ 1% and 100 $\pm$ 0% occurrence of round heads, respectively (P=0.01).

PG men (32.6±4 years) had a sperm concentration of 31 $\pm$ 42 x10^6/ml, 15 $\pm$ 12% motility, and normal morphology of 0.7 $\pm$ 0.5%; CG men (36.1 $\pm$ 4 years) had a sperm concentration of 36.5 $\pm$ 39 x10^6/ml, 24.4± 21% motility, and 0% normal morphology. Residual histones were 40±19% and 53.8±24% and SCF was 16.3 $\pm$ 2 and 19.5 $\pm$ 12 in PG and CG men, respectively. PLCζ was 34 $\pm$ 4 in PG men and 7.4 $\pm$ 4 in CG men (*P*=0.001). Aneuploidy was 3.6% in PC men and 8.2% in CG men. Genetic analysis of 3 men showed common mutations in DPY19L2, SPATA16, and PICK1 genes, which are all associated with spermiogenesis.

A patient unable to achieve a pregnancy (CG1) was found to have a mutation on NLRP5, which is essential for zygote development. In a patient whose female partner suffered a miscarriage (CG2), exome sequencing revealed a heterozygous deletion on BSX, which is associated with neonatal development. Genetic assessment of a patient whose female partner had a term pregnancy (CG3) showed a single nucleotide insertion on PIWIL1, which is related to sperm phenotype. CG1 had 71 imbalanced genes involved in reproductive processes, with 19 associated with spermatogenesis (*KLHDC3/chr 6, KLHL10/chr 17, MORN2/chr 2, PAPPA/chr 9, UBR2/chr6*), sperm maturation (*ADAM21/chr 14, CNBD2/chr 20, SPEM1/chr17, TXNRD3/chr 3*), DNA condensation (*H1FNT/chr 12, NEK2/chr 1, RNF8/chr 6*), fertilization (*CALR3/chr 19, HSPA1L/chr 6, IQCF1/chr 3*), and embryo development/implantation (*OVGP1/chr 1, STC2/chr 5, WNT9B/chr 17*).

CG2 had 37 imbalanced genes, with 13 down-regulated ones involved with spermatogenesis (*CSF1/chr 1, NAMPT/chr 7, SEMG1/chr 20, SEMG2/chr 20, SMCP/chr 1)*, DNA double-strand break repair *(RMI1/chr 9)*, and embryo development (*ACVR1C/chr 2, CBX2/chr 17, CRHR1/chr 17, TGFB3/chr 14)*. CG3 had only 2 underexpressed genes involved with cell adhesion, migration, and signaling receptor binding: *HAS2*/Chr 8 and *TGFB2*/Chr 19.

CONCLUSIONS: Globozoospermia is a rare but severe form of male infertility that requires extensive structural and genomic analysis to identity treatment options and the ability to support a term pregnancy.

HUMAN GROWTH HORMONE (GH) AND EMBRYONIC CHROMOSOMAL CHANGES: WHAT WE CAN EXPECT. Michelle Nagai, MD,[1] Larissa Matsumoto, MD,[1] Mariana Moraes Piccolomini, MS,[2] Orcar Duarte, MD,[3] Edson G. Lo Turco, PhD,[4] Carolina Rebello Costa, MD,[1] Ekaterini koutsantonis Pires, MD,[1] Fernanda Imperial Granjo, MD,[1] Lucas Yamakami, MD,[5] Eduardo Hideki Miyadahira, MD[1] [1]MD, São Paulo, Brazil; [2]Senior Embryologist, São Paulo, Brazil; [3]Clinical Chief in Lab For Life Laboratory, São Paulo, Brazil; [4]IonMedicine - Precision Medicine, Sao Paulo, Brazil; [5]Clinical Chief, São Paulo, Brazil.

OBJECTIVE: To evaluate the effect of adjuvant human growth hormone (hGH) on the aneuploid rate in women undergoing IVF PGT-A cycles.

DESIGN: Retrospective chart review at a private infertility center.

MATERIALS AND METHODS: This study includes patients with poor prognosis and low chances for treatment success who underwent IVF-PGT-A with and without hGH as complementary medication. The inclusion criteria are: women were stratified as Poor Responders by Bologna criteria or patients with low rates of blastulation and low rates of euploidy in previous treatment without hGH. It was used 2,66 mg /day of hGH, started on the first day of ovarian stimulation until the trigger. Statistic analysis: ANOVA test was performed to assess the comparison between the groups, with an IC 95%, with a statistical significance of p< 0,05.

RESULTS: A total of 137 cycles were analyzed, of which 103 used hGh and 34 without hGh. There was no significant statistical diference between the groups on the average age (38.44 +- 3.4 vs 38.82 +- 2.96), AMH(1.48 +- 0.80 vs 1.65 +- 1.28, p= 0.115), basal FSH(9.00 +- 5.04 vs 9.01 +- 6.12, p=0.941), basal LH (7.04 +- 6.37 vs 6,43 +- 8.79, p=0,718) and antral follicle count (11.05 +- 4.80 vs 12.31 +- 5.27, p=0.688). Although the blastulation rates are similar(p=0,952), an increase in number of embryo biopsy rate was observed in the hGH group(2,64 +- 1,86 vs. 1,82 +- 1,14 p=0.017) as well as the euploid rate (33.57%) if compared to the group that did not use hGH (16.62%) (p=0.017). However no statistical difference was found between the blastulation and miscarriage rates.

CONCLUSIONS: Despite the advancement of technology, the success rate of IVF remains relatively stable in one group of patients: poor responders, over 40 years old, with a history of failure of previous IVF cycles and/or formation of poor quality embryos. Different strategies have been used to improve the IVF outcome and euploidy rate, including GH as an adjunct treatment. In the present study, the use of GH was related to an increase in the euploidy rate. No significant statistical difference was observed in the miscarriage rate, nevertheless, there is a tendency to be lower in the hGh group. The mechanism by which GH can decrease the rate of aneuploidy is still uncertain.

PRENATAL GENETIC DIAGNOSTICS FOR FAMILIES WITH MITOCHONDRIAL DNA DISEASE. Amy Koski, BA,[1] Nuria Marti-Gutierrez, PhD,[1] Eunju Kang, PhD,[2] Hayley Darby, MS,[1] Ying Li, MS,[1] Crystal Van Dyken, BS,[1] Aleksei Mikhalchenko, PhD,[1] Dan Liang, PhD,[1] Hong Ma, PhD,[1] Sally Shields, BSN,[3] Paula Amato, MD,[1] Shoukhrat Mitalipov, PhD[1] [1]Oregon Health & Science University, Portland, OR; [2]ASAN Medical Center, Seoul, Korea, Republic of (South); [3]Medical University of South Carolina, Charleston, SC.

OBJECTIVE: This study sought to evaluate the feasibility of predicting the 13513G>A mitochondrial DNA (mtDNA) disease causing mutation in newborns by prenatal testing. Reproductive options to prevent or lower the passage of pathogenic mtDNA mutations from carrier parents to children are limited to preimplantation or prenatal genetic diagnostics. However, in vitro fertilization procedures followed by preimplantation genetic testing is accessible to few families due to high cost.

DESIGN: We report our clinical experience with prenatal diagnostic testing and birth of two asymptomatic children for a family with m13513G>A mutation associated with Leigh Syndrome following natural conception.

MATERIALS AND METHODS: Biopsies of a gestational sac and/or chorionic villi (CVS) and amniotic fluid were collected from the first pregnancy at 10 weeks and 16 weeks gestation and subsequently tested for the m13513G>A heteroplasmy using whole mtDNA sequencing (MiSeq platform). This pregnancy was carried to term and resulted in vaginal delivery of an asymptomatic newborn. Cord blood, foreskin, urine, and venous blood samples were collected from newborn 1 and underwent whole mtDNA sequencing as well. Two years following, a second pregnancy conceived by natural conception was evaluated by chorionic villus sampling only. The intended mother opted out of amniocentesis testing.

RESULTS: Mutation load for the first pregnancy was measured at 27.5% in the chorionic villi and 29.5% post amniocentesis; individual cells isolated from the amniotic fluid ranged between 9-48%. Samples collected from newborn 1 had a mutation load of 15% in cord blood, 14% in foreskin, 11.7% in urine and 0.07% in venous blood. Mutation load for the second pregnancy was evaluated solely via CVS at 0.11%. This pregnancy also resulted in the birth of healthy child with undetectable mutation in cord blood, foreskin and venous blood.

CONCLUSIONS: This case study suggests feasibility of predicting 13513G>A mtDNA mutation in newborns by prenatal testing.

POSTER SESSION: MALE REPRODUCTION

P-628 4:30 PM Tuesday, October 20, 2020

CLARIFYING THE RELATIONSHIP BETWEEN TOTAL MOTILE SPERM COUNTS (TMSC) AND INTRAUTERINE INSEMINATION (IUI) PREGNANCY RATES. Akhil Muthigi, MD,[1] Samad Jahandideh, PhD,[2] Lauren A. Bishop, MD,[3] Firoozeh K. Naeemi, Bs,[2] Sharon K. Shipley, MS,[4] Jeanne E. O'Brien, MD, MSc,[2] Paul Shin, MD,[2] Kate Devine, MD,[2] Cigdem Tanrikut, MD[2] [1]MedStar Georgetown University Hospital, Washington, DC; [2]Shady Grove Fertility Center, Rockville, MD; [3]NIH, Bethesda, MD; [4]Shady Grove Fertility Center, Rockville, MD.

OBJECTIVE: The use of post-wash TMSC in predicting pregnancy outcomes in IUI has been a subject of debate. Limitations of previous reports have been due to small sample sizes and attempts to identify clinically meaningful thresholds rather than define gradual pregnancy rate trends across a continuum of TMSC. To clarify the relationship between post-wash TMSC and IUI outcomes, we provide an updated evaluation of a large single institution sample.

DESIGN: Retrospective review.

MATERIALS AND METHODS: All stimulated clomiphene citrate, letrozole, and/or injectable gonadotropin IUI cycles performed at a single institution from 2002 through 2018 were reviewed. Generalized estimating equations (GEE) analysis was used to account for multiple cycles by individual patients and to adjust for female partner age, body mass index, stimulation protocol, and serum estradiol. Primary outcome was successful clinical pregnancy defined as ultrasound confirmation of an intrauterine gestational sac.

RESULTS: 92,471 insemination cycles were available to evaluate the relationship between TMSC and clinical pregnancy. Pregnancy rates were highest with ≥9 million TMSC, and declined gradually as TMSC decreased (Table 1).

Complete data for the adjusted GEE analysis were available for 62,758 cycles. Adjusted GEE analysis among cycles with ≥9 million TMSC (n=46,557) confirmed that TMSC in this range was unrelated to pregnancy (p=0.46). Conversely, TMSC was highly predictive of pregnancy (Wald χ^2=39.85) in adjusted GEE analysis among cycles with <9 million TMSC (n=16,201), with a statistically significant decline (p<0.001).

CONCLUSIONS: IUI pregnancy is optimized with TMSC ≥9 million, below which rates gradually decline. Although rare, pregnancies were achieved with TMSC <0.25 million. Since the decline in pregnancy is gradual and continuous, there is no specific threshold above which IUI should be recommended. Rather, these more specific quantitative predictions can be used to provide personalized counseling and guide clinical decision making.

Table 1. Clinical pregnancy rates per intrauterine insemination cycle according to post-wash TMSC

Total Motile Sperm Count (millions)	Number of Insemination Cycles	Number of Clinical Pregnancies	Clinical Pregnancy per Cycle
<0.25	263	11	4.18%
0.25-0.49	341	14	4.11%
0.50-0.99	627	23	3.67%
1.00-1.99	1611	120	7.45%
2.00-3.99	4561	462	10.13%
4.00-4.99	2845	331	11.63%
5.00-5.99	3109	400	12.87%
6.00-6.99	3474	484	13.93%
7.00-8.99	6810	976	14.33%
≥9	68830	11496	16.70%

P-629 4:30 PM Tuesday, October 20, 2020

FOXO4-DRI ALLEVIATES AGE-RELATED TESTOSTERONE SECRETION INSUFFICIENCY VIA TARGETING SENESCENT LEYDIG CELLS IN AGED MICE. Guihua Liu, Ph.D.,[1] Xing Yang, Ph.D.,[1] Tingting Li, Doctor[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the effects and mechanism of targeted inhibition of FOXO4 -p53 interaction on testicular aging in mice.

DESIGN: Animal study was designed.

MATERIALS AND METHODS: Three-month-old and 20-month-old male C57BL/6 mice were used as research objects. The mice were divided into FOXO4-DRI treated group, old control group and young control group, with 10 mice in each group. The FOXO4-DRI treated group were intraperitoneally injected with FOXO4-DRI (5 mg/kg/d) every other day for three administrations, and the old control group and young control group were injected with the same amount of normal saline, and the observation period is 30 days. Upon the endpoint of experiment, assess muscle performance of mice in each group through an upside down suspension test, and analyze

testicular weight/body weight ratio and seminal vesicles weight/body weight ratio. Then, epididymal sperm counts and motility, serum testosterone, myocardial enzymes (CK and CK-MB), liver function (ALT and AST) and renal function (CREA and BUN) were measured. Immunohistochemical staining was performed to detect the expression of FOXO4 in testes. SA-β-Gal staining was performed to assess the quantity of senescent cells in testes. Western blot was performed to measure protein levels of testosterone synthesis-related enzymes (3β-HSD and CYP11A1), senescence-related proteins (p53, p21, and p16) and SASP factors (IL-1α, IL-1β, IL-6, IL-10, TNF-α, and TGF-β) in testes. Immunofluorescence staining was performed to detect the expression of meiotic marker SCP3.

RESULTS: FOXO4 was expressed in LCs of the old mice, but not the young mice. Compared with old control group, the quantity of senescent LCs and expression of aging-related proteins (p53, p21 and p16) in the testes of FOXO4-DRI treatment group were significantly decreased (P <0.05). Levels of SASP factors including IL-1β, IL-10 and TGF-β were decreased (P<0.05). Testicular endocrine function-related indicators including serum testosterone concentration, expression of 3β-HSD and CYP11A1, and muscle performance were significantly improved (P<0.05). Spermatogenic function indicators including epididymal sperm counts and vitality (P<0.05) and expression of SCP3 were also improved. The testicular weight/body weight ratio (P >0.05) showed no significant changes, but the seminal vesicles weight/body weight ratio decreased significantly (P <0.05). Indicators of systemic organ function or injury including CK, CK-MB, ALT, AST, CREA and BUN showed no significant changes (P >0.05).

CONCLUSIONS: Targeted inhibition of FOXO4-p53 interaction can safely and effectively eliminate senescent LCs in testes and repair testicular aging in mice, which may become a new strategy for the treatment of testicular aging.

THE PUBLICATION FATE OF MALE FERTILITY ABSTRACTS PRESENTED AT THE ANNUAL MEETINGS OF THE AMERICAN SOCIETY FOR REPRODUCTIVE MEDICINE.

Kevin Xie, BA,[1] Sarah M. Brink, MD,[2] David Shin, MD[3] [1]Sidney Kimmel Medical College at Thomas Jeffeson University, Philadelphia, PA; [2]Hackensack University Medical Center, Hackensack, NJ; [3]Hackensack Meridian School of Medicine at Seton Hall University, Nutley, NJ.

OBJECTIVE: Approximately 1000 abstracts are presented every year at the annual meeting of the American Society for Reproductive Medicine (ASRM), of which 10% involve male fertility. This study was undertaken to determine the publication rate among these abstracts, time to publication, and factors associated with publication.

DESIGN: Cross-Sectional Study.

MATERIALS AND METHODS: All accepted abstracts related to male fertility that were presented at the 2012-2014 ASRM annual meetings were reviewed. Comprehensive PubMed and internet searches were conducted for evidence of publication in full-length manuscript form up to April 2020. Chi-square analysis was performed to determine predictive factors for publication.

RESULTS: A total of 393 abstracts involving male fertility were presented from 2012 to 2014. By April 2020, 136 (35%) achieved a median time to publication of 15 months (range 0-76 months). Manuscripts were most commonly published in: *Fertility and Sterility* (17%), *Urology* (8%), *Human Reproduction* (7%), and *Journal of Urology* (4%). A higher trend in publication was seen with podium compared to poster presentations (41.4% vs 31.9%, p =0.08). Publication rates by category were: Society for Male Reproduction and Urology (SMRU) Traveling Scholars 75% (12/16), Testis 50% (9/18), Male Reproductive Urology 44% (47/106), Sperm Biology 38% (17/45), Male Reproductive Endocrinology 33% (7/21), Male Factor 31% (49/158), Sperm Preparation 14% (6/43). Most abstracts were submitted by US institutions 52% (205/393), with a 38% (77/205) publication rate. International publication rates were similarly seen from Asian 36% (32/88), South American 33% (16/49), and European 24% (12/51) institutions. Higher publication rates were observed when studies originated from Department of Urology 45% (57/127) or in collaboration with Department of Obstetrics & Gynecology [OB/GYN] 46% (18/39) compared to OB/GYN alone 26% (50/196) [p < 0.01].

CONCLUSIONS: Overall publication rate of 35% for male fertility studies is similar to publication rates of abstracts presented at international urological meetings. SMRU Traveling Scholars had the highest publication rate and should continue to showcase their findings at the ASRM annual meeting. Urology department-only affiliations or collaborations with OB/GYN department were more likely to publish their results after presentation. Continued efforts should be made to increase publication of male fertility related abstracts presented at the ASRM annual meetings.

TRANSPLANTATION OF HUMAN URINE-DERIVED STEM CELLS AMELIORATES ERECTILE FUNCTION AND CAVERNOSAL ENDOTHELIAL FUNCTION BY PROMOTING AUTOPHAGY OF CORPUS CAVERNOSAL ENDOTHELIAL CELLS IN DIABETIC ERECTILE DYSFUNCTION RATS.

Guihua Liu, Ph.D.,[1] Xing Yang, Ph.D.,[1] Tingting Li, Doctor[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: The main mechanism of diabetic erectile dysfunction (DED) is cavernosal endothelial dysfunction, but the origins of cavernosal endothelial dysfunction are unclear. The present study aimed to determine the contribution of autophagy in cavernosal endothelial dysfunction of DED rats, and explain therapeutic effect of urine-derived stem cells (USCs).

DESIGN: Animal study was designed.

MATERIALS AND METHODS: After rat corpus cavernosal vascular endothelial cells (CCECs) were isolated and cultured *in vitro*, CCECs were treated with advanced glycation end products (AGEs) to mimic the diabetic situation. Autophagy flux, proliferation and apoptosis of CCECs were determined by mRFP-GFP-LC3 adenovirus transfection combined with immunofluorescence observation and western blot analysis. USCs were isolated from the urine of six healthy male donors, and co-culture systems of USCs and CCECs were developed to assess the protective effect of USCs for CCECs *in vitro*. The contribution of autophagy to the cellular damage in CCECs was evaluated by the autophagic inhibitor, 3-methyladenine (3-MA). Then, DED rats (n=15 per group) were induced by streptozotocin (50 mg/kg) and screened by apomorphine (100 μg/kg), and another 15 normal rats served as positive controls. In DED rats, USCs or PBS as vehicle was administrated by intracavernous injection. Four weeks after injection, erectile function was evaluated by measuring the intracavernosal pressure (ICP) and mean arterial pressure (MAP). Endothelial function and autophaic activity were examined by western blot analysis, immunofluorescence and transmission electron microscopy.

RESULTS: *In vitro,* AGEs-treated CCECs displayed fewer LC3 puncta formation, and expressed less LC3-II, Beclin1 and PCNA, but expressed more p62 and cleaved-caspase3 than controls (P<0.05). Co-culture of USCs with CCECs demonstrated USCs were able to protect CCECs from AGEs-induced autophagic dysfunction and cellular damage, which could be abolished by 3-MA (P<0.05). DED rats showed lower ratio of ICP/MAP, reduced expression of endothelial markers, and fewer autophagic vacuoles in cavernosal endothelium when compared with normal rats (P<0.05). Intracavernous injection of USCs improved erectile function and endothelial function of DED rats (P<0.05). Most importantly, our data showed the repaired erectile function and endothelial function were result from restored autophagic activity of cavernosal endothelium in DED rats (P<0.05).

CONCLUSIONS: Impaired autophagy is involved in the cavernosal endothelial dysfunction and erectile dysfunction of DED rats. Intracavernous injection of USCs upregulates autophagic activity in cavernosal endothelium, contributing to ameliorate cavernosal endothelial dysfunction, and finally improved the erectile dysfunction induced by diabetes.

TRENDS IN TESTOSTERONE THERAPY.

Jesse Ory, MD,[1] Josh Theodore White, MD,[1] Jonathan Moore, MD, FRCSC,[2] John Grantmyre, MD, FRCSC[1] [1]Dalhousie University, Halifax, NS, Canada; [2]Mayo Clinic Arizona, Phoenix, AZ.

OBJECTIVE: Rates of testosterone therapy (TT) prescribing dropped dramatically following the 2014 FDA warning on the potential for cardiovascular morbidity. Since then, prescription rates appear to be increasing in North America[1]. Current database studies tracking these trends suffer from incomplete prescription capture, lack of information on continued use, and confounding from concurrent population growth.

DESIGN: Nova Scotia (NS) is a Canadian province with minimal population growth over the past decade. NS tracks every testosterone prescription and refill through their prescription monitoring program (NSPMP). All testosterone prescriptions must be written on triplicate forms, allowing for comprehensive tracking.

MATERIALS AND METHODS: Data were extracted from the NSPMP database on all prescriptions and prescription refills of androgens for men over 18 years of age from 2007 to 2019. Population statistics were gained using publicly available data from Statistics Canada. Analysis of patterns by patient age decile and by year were examined for number of patients, prescriptions, and prescribers as well as formulation.

RESULTS: The population of Nova Scotia stayed relatively stable throughout the study period (2007: 936,203; 2019: 965,249; population increase of 3.1%) Throughout the study period, a total of 8837 men (0.9% of the population) received a testosterone prescription, and 6005 men (0.6%) remained on TT for longer than 6 months. Men aged 55-64 received the most prescriptions for TT (31%). 25% of men receiving TT were under age 45. There has been a steady decrease in oral formulations prescribed since 2007 (36% in 2007, 13% in 2019) with an increase in injectable esters (34% in 2007, 49% in 2019) and transdermal gels (24% in 2007, 35% in 2019). Primary Care Providers (PCPs) wrote 92% of all prescriptions on average (range 89-93%). Amongst all men, TT rates increased yearly from 2007 until 2014, at which point TT rates plateaued or decreased, depending on age group. The only exception to this trend was in men aged 18-34, in which TT rates have increased every year since 2007.

CONCLUSIONS: In a large Canadian province with stable population growth, prescriptions of testosterone increased until 2014, and then either stabilized or decreased. TT prescriptions in young men have continued to increase yearly. Injectable and gel-based formulations have increased in popularity over the past decade. Future efforts to educate prescribers, especially surrounding the effects on fertility in young men, should be largely focused on PCPs.

TARGETED ICSI TREATMENT IN GLOBOZOOSPERMIC MEN ACCORDING TO SPERM PLCZ CONTENT.

Alessandra Parrella, M.Sc., Danielle Rebecca Tavares, B.A., Philip Xie, B.S., Stephanie Cheung, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: We assessed the PLCζ content of sperm from globozoospermic (GZ) men to determine the best treatment protocols for these patients.

DESIGN: Eleven men diagnosed with globozoospermia after morphological and ultrastructural assessment and treated at our center during the last 8 years were included. To identify their fertilization capacity, spermatozoa were screened for PLCζ. Patients were treated by ICSI or by ICSI with assisted gamete treatment (AGT) depending on PLCζ content. Embryological and pregnancy outcomes were compared between the two treatment methods.

MATERIALS AND METHODS: GZ men underwent standard semen analysis and transmission electron microscopy (TEM). Sperm oocyte activation was quantified by a PLCζ test on ≥200 cells per specimen, with a normal threshold of ≥30%. Genome and transcriptome analyses were compared to donor specimens. ICSI was performed in the standard fashion or with AGT by exposing both gametes to calcium ionophore.

RESULTS: Globozoospermia was confirmed by TEM, which showed 93.3 ± 12% occurrence of round heads. Eleven GZ men (34.6 ± 5 years) had the following semen parameters: a concentration of 36 ± 44 x10^6/ml, 20.3 ± 20% motility, and normal morphology of 0.2 ± 0.4%. Of these, 7 men (32.6 ± 4 years) with PLCζ content of 34 ± 4% underwent 17 ICSI cycles with their female partners (31 ± 4 years), achieving a fertilization rate of 24.6% (64/260). The implantation rate was 11.4% (4/35) with a clinical pregnancy and delivery rate of 12.5% (2/16) per cycle. The success rate was 28.5% (2/7) per patient. Men in the remaining 4 couples (men, 34.2 ±7 years; women, 33.2 ± years) had negative PLCζ assays, indicating only 7.4 ± 4% content. These couples underwent 6 ICSI cycles with AGT, achieving 37.5% (24/64) fertilization, 18.7% (3/16) implantation, and 33.3% (2/6) clinical pregnancy rates per cycle, yielding a 16.6% (1/6) delivery rate. The success rate was 25% (1/4) per patient. All treatment outcomes were comparable, except the fertilization rate, which was significantly higher in the cohort treated by ICSI with AGT ($P = 0.04$). Genetic analysis of these men identified mutations in the DPY19L2, SPATA16, and PICK1 genes, confirming the absence of the subacrosomal perinuclear theca. We identified mutations in PIWIL1, which is involved in late spermiogenesis, supporting the use of AGT. The transcriptomic profile showed 1,866 genes significantly imbalanced; of these, 111 were reproductive genes, of which 34 were underexpressed. These downregulated genes are associated with spermatogenesis (*KLHDC3*, *KLHL10*, *MORN2*, *PAPPA*, *UBR2*, *CSF1*, *NAMPT*, *SEMG1*, *SEMG2*, *SMCP*), sperm maturation (*ADAM21*, *CNBD2*, *SPEM1*, *TXNRD3*), DNA condensation and DNA-binding transcription factor activity (*H1FNT*, *NEK2*, *RNF8*, *FOXL2*, *GATA1*, *LHX9*, *RMI1*), fertilization capacity (*CALR3*, *HSPA1L*, *IQCF1*), and embryo development and implantation (*OVGP1*, *STC2*, *WNT9B*, *ACVR1C*, *CBX2*, *CRHR1*, *TGFB3*); *MFSD14A* is known to be found within GZ patients.

CONCLUSIONS: It is difficult to determine the best treatment protocol for GZ men. To avoid overtreatment, we assessed sperm PLCζ content and determined that if it is ≥30%, standard ICSI can be carried out.

IMPACT OF METABOLIC AGE ON SEXUAL AND ANDROGENIC FUNCTION IN YOUNG PATIENTS.

Ahmad Majzoub, MD, Haitham Elbardisi, MD, Kareim Khalafalla, MD, Sami Alsaid, MD, Mohamed Arafa, MD. Hamad Medical Corporation Doha, Qatar.

OBJECTIVE: Erectile dysfunction is increasingly prevalent with age. Metabolic Age (metAge) refers to the number calculated by comparing Basal Metabolic Rate (BMR) of an individual to BMR average of his chronological age (chAge) group. It hence serves to reflect the metabolic status which is believed to influence sexual function. The aim of this study is to assess the relation between metAge & sexual function in men younger than 40 years of age

DESIGN: Prospective observational study.

MATERIALS AND METHODS: A total of 120 male healthcare workers of a tertiary medical center were randomly selected through computer generated randomization tables. Subjects receiving exogenous testosterone or erectogenic medications were excluded. In addition to providing an early morning serum testosterone (T) sample, subjects were requested to fill the International Index of erectile function questionnaire (IIEF-5) & to undergo Bioelectric Impedance Analysis [BIA] of their metabolic status using TANITA body analyzer (TBF-410GS) (Illinois, USA). Risk factors for erectile dysfunction (ED) such as diabetes mellitus, hypertension, coronary artery disease & dyslipidemia were also assessed. Participants were divided according to their chAge into two groups (<40 & > 40 years).

RESULTS: Ninety subjects were included (< 40 years, n=53; > 40 year, n=37). ED was reported by 48 (53%) subjects, while a low T level was detected in 18 (20%). Risk factors were detected in 41% of subjects. No significant relationship between risk factors & serum T or IIEF-5 results were observed. Participants with ED had significantly lower T levels (12.7 ± 4.6 vs.14.8 ± 3.9, p=0.02) compared to those without ED. Older chAge & metAge were observed in ED vs no ED participants as well, however without statistical significance. 24 (45.3%) subjects < 40 years of age had ED. Significantly lower T levels & significantly higher metAge & BMI were observed in participants <40 years with ED compared with their counterparts without ED (table 1). In this participant group (< 40years), significant correlations were observed between metAge & T (r-0.347, p=0.01), chAge (r0.384, p=0.005), visceral fat (r0.747, p<0.001), fat % (r0.78, p<0.001), weight (r0.524. p<0.001), BMI (r 0.635, p<0.001) & BMR (0.347, p=0.01).

CONCLUSIONS: Metabolic status may significantly influence the sexual & androgenic status of young men. An older metAge is observed in young men with ED & hypogonadism.

Parameters	< 40 years with ED (n=24)	< 40 years without ED (n=29)	P value
Testosterone (nmol/L)	19.8 ± 4.1	14.5 ± 4.1	0.002
metAge (years)	44.6 ± 6.8	39.9 ± 8.5	0.034
BMI (kg/m^2)	30.4 ± 4.2	27.9 ± 4.4	0.044
Fat% (%)	27.5 ± 5.3	24.5 ± 5.9	0.064
Visceral fat (rate)	10.6 ± 3.8	8.7 ± 3.8	0.072
Muscle mass (kg)	63.8 ± 8.8	61.4 ± 8.1	0.296
BMR (Kj)	8413.5 ± 1277.8	8022.0 ± 1128.9	0.242

P-635 4:30 PM Tuesday, October 20, 2020

DOES SPERM TOTAL NORMAL MOTILE COUNT IMPACT PGT-A AND IVF OUTCOMES?

Christopher P. Moutos, MD,[1] William G. Kearns, PhD,[2] Sarah E. Farmer, MS,[3] Jon P. Richards, MS,[3] Antonio F. Saad, MD,[1] John R. Crochet, Jr., MD[3] [1]University of Texas Medical Branch, Galveston, TX; [2]AdvaGenix, Johns Hopkins University School of Medicine, Rockville, MD; [3]Center of Reproductive Medicine, Houston, TX.

OBJECTIVE: Male factor is the sole cause of infertility in about 20% of cases and is at least partially involved in up to 40% of cases. Sperm total normal motile count (TNMC) integrates the semen analysis components of morphology, motility, and total count to yield a single clinical value. The objective of this study is to assess whether a relationship exists between TNMC and preimplantation genetic testing for aneuploidy (PGT-A) as well as *in vitro* fertilization (IVF) outcomes.

DESIGN: Retrospective, observational study.

MATERIALS AND METHODS: In this retrospective, observational study, unidentified data sets were included of couples who visited our fertility center between October 2012 to December 2018 and had PGT-A (N= 1492) and elective single embryo transfer (N=242) performed. Inclusion was limited to those with a semen analysis within 90 days of IVF start. TNMC was calculated by multiplying total sperm count by percent motility and percent normal forms (Kruger's strict criteria). For analyses, we categorized TNMC into three groups: Group 1 (<1 million), 2 (1-4.99 million), and 3 (≥5 million). Primary endpoint was IVF outcomes. Secondary endpoints included embryo quality, morphology, ploidy, and gender. Pearson's chi-squared test was used for statistical analysis with $p<0.05$ considered significant.

RESULTS: A total of 1492 embryos (Group 1 N=395, 2 N=558, and 3 N=539) were analyzed. For all groups, embryos were more likely to be female; however, embryos from the <1 million group had the highest percentage of female embryos (58.5% vs 50.4% and 54.2%; p=0.046), and were more likely to be high-grade (69.1% vs 62.7% and 63.5%; p=0.015), compared to Groups 2 and 3, respectively. Embryos from the 1-4.99 million group were more likely to be low-grade (21.0% vs 14.4% and 15.8%; p=0.015), have a poor inner cell mass grading (14.9% vs 9.6% and 9.8%; p=0.027), and a poor trophectoderm grading (16.8% vs 12.2% and 12.4%; p=0.039), compared to those in Groups 1 and 3, respectively. There was no difference in embryo development (p=0.076), day of blastocyst transformation (p = 0.368) or ploidy status (p=0.324) among the different TNMC groups.

Subpopulation analysis of 242 transferred embryos (Group 1 N=50, 2 N=92, and 3 N=100), showed no statistical difference in implantation (p=0.311), clinical pregnancy (p=0.214), chemical pregnancy (p=0.426), miscarriage (p=0.685), ectopic pregnancy (p=0.417), or ongoing pregnancy rates (p=0.069) between the different TNMC groups.

CONCLUSIONS: This large-scale study is the first to examine the relationship of sperm TNMC to PGT-A and IVF outcomes. While it is possible that TNMC may impact certain embryo characteristics, such as gender, inner cell mass, trophectoderm, and overall grade, TNMC does not appear to impact IVF outcomes. Further studies are needed to further elucidate these relationships.

NOVEL TREATMENT FOR SPERM CAPACITATION IMPROVES EMBRYO DEVELOPMENT IN MOUSE INTRACYTOPLASMIC SPERM INJECTION (ICSI).

Melissa Paziuk, AS, Felipe Navarrete, PhD, Kathleen Seyb, PhD Ohana Biosciences, Cambridge, MA.

OBJECTIVE: Ohana has developed a novel *ex-vivo* sperm enhancement treatment designed to mimic sperm capacitation during natural conception. Previous non-clinical data have shown that this approach improves human sperm hyperactivation in samples from men in couples seeking treatment for infertility and from healthy men, as well as sperm hyperactivation, fertilization, and blastocyst development from 2-cell embryos in a mouse *in-vitro* fertilization (IVF) model (Seyb K, et al, ASA 2020; Poster 109). The impact of the Ohana sperm enhancement treatment on mouse embryo development from fertilized eggs indicates that this approach may also improve embryo development when used with ICSI. This study was conducted to evaluate the impact of the Ohana sperm enhancement treatment on embryo development in a mouse model of ICSI-IVF compared with standard mouse sperm activation.

DESIGN: Sperm were processed using the Ohana sperm enhancement treatment and standard control conditions. The percentage of mouse oocytes that developed into 2-cell embryos and blastocysts following ICSI were evaluated and compared between groups.

MATERIALS AND METHODS: Oocytes were collected from superovulated CD1 females and sperm isolated from epididymis of C57Bl/6 males. Sperm were capacitated using either TYH buffer (control) or using the Ohana sperm enhancement treatment. Sperm in both groups were washed in TYH buffer, then sperm tails removed, and sperm heads injected with an ICSI micropipette into oocytes stripped of cumulus cells. Injected oocytes were cultured overnight, and 2-cell embryos were assessed as a measure of successful fertilization. Embryos were then cultured to blastocysts. Data are from 10 experiments, with a total of 562 oocytes per arm. Statistical significance was evaluated by t-test.

RESULTS: The rate of 2-cell embryo formation per mouse oocyte between control (24.4±6.1%) and the Ohana sperm enhancement treatment (25.3±5.1%) were similar, as expected when fertilization is performed using ICSI. However, 2.3x more 2-cell embryos developed into blastocysts when sperm was prepared using the Ohana sperm enhancement treatment compared to control-processed sperm (74.7±11.1 vs 31.8±11.5%, respectively).

CONCLUSIONS: While ICSI prevents failed fertilization in some cases, it does not improve other outcomes such as embryo development, pregnancy, or birth (Boulet SL, et al. JAMA 2015;313:255). The Ohana sperm enhancement treatment significantly increased the probability of a 2-cell embryo developing into a blastocyst compared to control in a mouse ICSI study. These results confirm earlier observations that the Ohana sperm enhancement treatment has an impact beyond fertilization and indicate that the Ohana sperm treatment may improve sperm-mediated oocyte activation and early embryo development. These data suggest that the Ohana treatment for human sperm may also improve embryo development for people undergoing IVF with ICSI. The Ohana sperm enhancement treatment is being tested in an on-going clinical study evaluating fertilization and embryo development in conventional IVF.

P-637 4:30 PM Tuesday, October 20, 2020

INSIGHTS IN THE MECHANISMS OF DEFECTIVE SPERM MATURATION IN INFERTILE MEN USING A COMPARATIVE PROTEOMICS APPROACH.

Manesh Kumar Panner Selvam, PhD,[1] Luna Samanta, PhD,[2] Ashok Agarwal, PhD[1] [1]American Center for Reproductive Medicine, Cleveland Clinic, Cleveland, OH; [2]Redox Biology Laboratory, Department of Zoology, Ravenshaw University, Cuttack, Odisha, India.

OBJECTIVE: Ejaculated semen harbors not only mature and motile spermatozoa, but also spermatozoa at different stages of maturation, immature germ cells, and morphologically aberrant gametes, and may therefore be utilized to analyze the mechanism behind sperm dysfunction in infertile men. Transcription and translation are silent in post-testicular spermatozoa. Therefore, it is important to focus on alterations of the protein profiles in various phenotypes of spermatozoa present in ejaculated semen from fertile and infertile individuals to identify specific proteomic signatures that may shed light on defective sperm maturation and/or function in infertile men. In the

present study, a comparative proteomic approach was undertaken to understand the mechanism(s) involved.

DESIGN: Semen samples from fertile (n=12) and infertile (n=6) men were subjected to multi-layer density gradient (40%, 60%, and 80%) centrifugation to separate different phenotypes (F1, F2, F3 and F4; F1 least mature and F4 most mature). The proteome profile of each faction was compared between infertile and fertile group.

MATERIALS AND METHODS: Proteomic profiling of sperm phenotypes from both groups was performed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). MASCOT- and SEQUEST-identified sperm proteins were compared and differentially expressed proteins (DEPs) were subjected to ingenuity pathway analysis (IPA) to detect the molecular networks affected. The key proteins of top networks were validated by western blot.

RESULTS: Sperm in the F4 fraction (matured) from fertile and interfile men showed high motility (>60%). A total of 119, 167, 373 and 262 DEPs were identified in the F1, F2, F3 and F4 fractions of fertile men compared with infertile men, respectively. The dysfunctional mTOR signaling with anomalous expression of downstream factors EIF2, eIF4 and p70S6K implies defective protein synthesis and abortive apoptosis in F1 and F2 fractions limiting sperm maturation. Conversely, mitochondrial dysfunction, particularly of oxidative phosphorylation pathways, was more prominent in F3 and F4 sperm fractions of infertile men along with proteins involved in sperm binding function. Validation of key proteins by western blot revealed that oxidative phosphorylation complex and HSPA2 were over-expressed in all sperm fractions of fertile men compared to infertile, whereas ACR was over-expressed only in mature (F4) spermatozoa.

CONCLUSIONS: Our results suggest that abortive apoptosis is responsible for presence of more immature spermatozoa in the ejaculate of infertile men. A decline in mitochondrial function, particularly oxidative phosphorylation in F4 fraction, implies an energy deprived hypoxic state; thus, resulting in impairment of sperm function in infertile men.

COMPARING EUPLOIDY IN TESE, MESA, AND EJACULATE FROM PATIENTS WITH AND WITHOUT MALE FACTOR INFERTILITY.

Isaac J. Chamani, M.D.,[1] David H. McCulloh, Ph.D.,[2] Bobby B. Najari, MD MSc,[3] Frederick L. Licciardi, M.D.[4] [1]NYU School of Medicine, New York, NY; [2]NYU Langone Fertility Center, New York, NY; [3]New York University School of Medicine, New York, NY; [4]NYU Langone Health, New York, NY.

OBJECTIVE: Sperm retrieval via testicular sperm extraction (TESE) or microsurgical epididymal sperm aspiration (MESA) have been used to treat men with obstructive and non-obstructive azoospermia. Here we compare fertilization rates, blastocyst formation, euploidy, and euploidy rates, in IVF cycles with intracytoplasmic sperm injection (ICSI) and preimplantation genetic testing for aneuploidy (PGT-A), with sperm obtained via TESE, MESA and ejaculation.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Patients who underwent IVF or embryo banking with ICSI and PGT-A at NYU Fertility Center from 2/1/15 to 3/31/19, were separated into four groups for comparison based on the method of sperm procurement: TESE, MESA, ejaculate of males with male factor infertility (initial motility < 40% and/or count < 20 M/ml) (Ejac+MF), and ejaculate of males without male factor infertility (Ejac-MF). Demographics, total IUs gonadotropin received, trigger-day estrogen levels, number of oocytes retrieved, number of mature oocytes, fertilization rates, number of blastocysts formed, number of euploid embryos formed, and euploidy rates, were compared by performing a one-way ANOVA using 0.05 as the alpha level, and *a posteriori* testing.

RESULTS: Altogether, 283 patients were compared in the four groups: 56 TESE patients, 5 MESA patients, 160 Ejac+MF patients, and 62 Ejac-MF patients. There were no significant differences in maternal age, total IUs gonadotropin received, trigger-day estrogen levels, number of oocytes retrieved, or number of mature oocytes, between all four groups. TESE patients had significantly lower fertilization rates, blastocyst formation, and euploid embryos (64%, 3.7, 1.1, respectively) than both Ejac+MF (73%, 4.7, 1.4, respectively) and Ejac-MF (78%, 5.8, 2.1, respectively). The euploidy rates (euploid embryos/number of blastocyts) were not significantly different between the three groups (TeSE 23%, Ejac+MF 27%, Ejac-MF 30%). Finally, Ejac+MF patients had a significantly lower number of euploid embryos (1.4) that Ejac-MF patients (2.1).

CONCLUSIONS: In patients undergoing IVF with ICSI and PGT-A, significantly lower fertilization rates, and numbers of blastocysts and euploid embryos, were found when comparing TESE to Ejac+MF and Ejac-MF. However, the euploidy rates were not significantly different, suggesting that the number of embryos formed is the point of distinction. Ejac+MF patients also produced a smaller number of euploid embryos, than Ejac-MF patients.

P-639 4:30 PM Tuesday, October 20, 2020

USING GENE EXPRESSION PROFILES OF EJACULATES OF NOA MEN TO HELP PREDICT SUCCESSFUL TESTICULAR SPERM RETRIEVAL.

Brianne Barker, B.S., Alessandra Parrella, M.Sc., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To use gene expression profiles of ejaculates of non-obstructive azoospermic (NOA) men to determine whether testicular biopsy will yield spermatozoa.

DESIGN: During the last 12 months, a prospective study was carried out on specimens from 10 consenting men who yielded no sperm after extensive semen analysis (ESA). RNA expression analysis was performed and compared to fertile donors and men with obstructive azoospermia (OA). All men consented to undergo testicular biopsy (TESE) to attempt sperm retrieval. Transcriptomic profiling was correlated to successful sperm retrieval.

MATERIALS AND METHODS: ESA was carried out in the andrology laboratory for diagnostic purposes with the same rigor as ICSI for NOA patients. RNA was isolated from ejaculated specimens using a commercial spin column kit. Samples were then made into paired-end libraries; pilot paired-end 76-bp RNA-Seq using Illumina platform (NextSeq 500) was performed and expanded to 60M reads. Expression values were calculated in fragments per kilobase (FPKM) and normalized read counts. Expression with $P<0.001$ and absolute log2fold change >1 were considered significant.

RESULTS: Ten men (37.3±6.0 yrs) were included in this study. All underwent ESA in multiple ICSI dishes searched by several andrologists for about 90 minutes; no spermatozoa was found. After a NOA diagnosis following urological evaluation, the 10 men underwent micro-TESE: spermatozoa was retrieved from 5 (+sTESE). The paternal ages between +sTESE and –sTESE were comparable.

Quantitative analysis of RNA extracted from ejaculated samples averaged a concentration of 2.3±1 ng/ul and RNA integrity of 7.0±1. Compared to the donor, we found 45 significantly imbalanced genes common among all 10 patients. Most were underexpressed (95%) and associated with spermatogenesis (PRM2, SPATA42, CABS1) and spermatid development (KLHL10, H1FNT).

The +sTESE group had 87 significantly imbalanced genes, of which 62% were underexpressed. These included genes related to spermatogenesis (PRM1, ODF1) and spermatid development (CAPZA3). The –sTESE group had 37 imbalanced genes that were mostly underexpressed (89%) and associated with apoptosis (SEPT7P2, MKNK2), DNA repair (RNF138), cell cycle arrest (MLF1, NUPR2), and spermatid development (ADAD1, RBMXL2).

Gene expression analysis was also done between all men in the study and OA controls. There were no common significantly imbalanced genes among all 10 men. Among the +sTESE group, there were 8 underexpressed genes, of which half were non-protein coding. Interestingly, only one common gene (MSMB) was underexpressed in all –sTESE men. MSMB has inhibin-like activity and is secreted into the seminal plasma.

CONCLUSIONS: Gene expression profiling by RNA-seq on the ejaculates of NOA men may help to predict whether spermatozoa will be surgically retrieved. Most interestingly, all men who failed TESE had an underexpression of genes related to apoptosis, DNA repair, and cell cycle arrest compared to fertile donors, and the MSMB gene compared to OA controls.

P-640 4:30 PM Tuesday, October 20, 2020

A NOVEL ONLINE SYSTEM LINKING AT-HOME SMARTPHONE SEMEN TESTS WITH EMBRYOLOGISTS. Yoshitomo Kobori, MD, PhD, Akiyoshi Osaka, MD, Toshiyuki Iwahata, MD, PhD, Kei-ichiro Uemura, MD, PhD, Hiroshi Okada, MD, PhD. Dokkyo Medical University Saitama Medical Center, Koshigaya, Japan.

OBJECTIVE: Infertility is a serious disease requiring timely treatment. If treatment is delayed, the condition of patients may deteriorate over time. The coronavirus (COVID-19) pandemic has seriously affected couples in need of immediate infertility treatment. Because of stay-at-home guidance, fewer people are visiting medical facilities, and thus it may become necessary to provide online medical services, including infertility treatment. Male-factor infertility contributes to about 50% of the incidence of infertility in couples. Semen analysis is key to diagnosing reproductive potential in men. In current practice, men must visit a clinic or other medical facility for semen analysis. However, there are cases in which visiting a medical facility is problematic, as in the current pandemic. To address this issue, many devices for at-home testing of semen samples have been developed and commercialized. We have developed a service enabling infertility patients to receive medical advice by allowing them to easily share at-home smartphone semen test data with embryologists. To verify the effectiveness of this system, we evaluated the correlation between at-home smartphone semen test data analyzed by embryologists and semen test results measured by computer assisted semen analysis (CASA).

DESIGN: Laboratory investigation.

MATERIALS AND METHODS: We developed an online system that allows sperm videos captured using a smartphone microscope to be uploaded and shared with embryologists. After receiving training on the online system, the embryologists viewed the videos on a large computer screen and recorded motile and static sperm counts. Because the appearance of sperm captured in videos can differ depending on the type of smartphone, the embryologists measured sperm concentration and motility by estimating the size of the sperm head and tail. A total of 45 human semen samples were analyzed using both the developed system and CASA software. Each test was evaluated for compliance with World Health Organization semen testing criteria.

RESULTS: Sperm concentration measured using the online system showed a very strong correlation with CASA results ($P < 0.01$, $r = 0.89$). Sperm motility analyzed by embryologists using the online system were significantly correlated with CASA results ($P < 0.01$, $r = 0.74$).

CONCLUSIONS: Online medical care will likely become increasingly important during the COVID-19 pandemic. The system we developed is a useful service allowing infertility patients to share at-home semen test data with embryologists. Analysis of the test data by embryologists resulted in few mistakes compared with automatic machine analysis. The system enables patients to connect with doctors and receive medical treatment online. Services like this one could be become more common in the future.

SUPPORT: none.

EPIGENETIC EFFECT OF ABSTINENCE TIME ON THE REPRODUCTIVE POTENTIAL OF INFERTILE MEN. Brianne Barker, B.S., Alessandra Parrella, M.Sc., Sherina Lawrence, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To perform transcriptomic analysis of spermatozoa from infertile men to determine whether different abstinence times affect embryo development and implantation.

DESIGN: Over the past 2 years, we assessed the semen profiles, sperm chromatin fragmentation (SCF), and transcriptomic profiles of 23 men whose specimens were used for ICSI. Samples were collected from 2 consecutive ART cycles: the first ICSI cycle utilized specimens with an abstinence range of 2-14 days (LongA), and the second used specimens with an abstinence range of 30-120 minutes (ShortA). Semen parameters, SCF, and transcriptomic and clinical outcomes were assessed and compared in relation to the abstinence time.

MATERIALS AND METHODS: Ejaculated spermatozoa from consenting men were analyzed per WHO 2010. TUNEL was used to assess SCF on at least 500 sperm, using a threshold of $\leq$15%. ICSI was done in the standard fashion. Total RNA was isolated from the specimens of consenting men using a commercial spin column kit. Pilot paired-end 76bp RNA-Seq using Illumina platform (NextSeq 500) was performed to 60M reads. Comparisons were made to a fertile donor and between the two specimens from the same individual according to abstinence time.

RESULTS: Twenty-three couples (paternal age, 36.7±6 years; maternal age, 35.8±5 years) underwent 2 ICSI cycles. The initial ICSI cycles (LongA) had an abstinence of 10.9±3 days, a concentration of 66.8±73 10^6/ml, 27.0±15% motility, and an SCF of 23.2±17%. Fertilization and implantation rates were 71% (152/214) and 6.7% (4/60), respectively, and the clinical pregnancy rate was 17.39%. Epigenetic analysis of this group showed a total imbalance of 71 genes, with most underexpressed (74.6%). These included genes associated with fertilization (SMCP, ADAM21), calcium ion concentration (PLCZ1, TRPC1), motility (PGK2), and fetal organ development (ZNHIT2, CA2).

The subsequent cycles (ShortA) had an abstinence period of 51.9±19 minutes. These specimens had a comparable concentration and motility (55.2±64 10^6/ml, 31.2±15%), and a lower SCF (10.2±0.6%; $P<0.05$). There was improved fertilization (162/203; 79.8%; $P<0.03$), implantation (13/53; 24.5%; $P<0.01$), and clinical pregnancy rates (51.7%; $P<0.05$). There were 67 imbalanced genes for this group, with only 26% underexpressed; none of these are associated with fertilization, implantation, or embryo development.

When comparing the LongA and ShortA specimens for each individual, 16-68 genes were imbalanced. For the couples with successful clinical pregnancies, the ShortA had a higher expression of genes associated with DNA repair (CHEK1), fertilization (SPINK2, SERPINA5), and embryo development (ENDOG) compared to couples in the LongA group.

CONCLUSIONS: This analysis shows that specimens with shorter abstinence times yield spermatozoa with higher genomic integrity, leading to enhanced fertilization, implantation, and clinical pregnancy rates. Transcriptomic analysis confirms this finding and indicates that a specific gene imbalance is associated with a better ICSI outcome in couples where the semen sample used has a shorter abstinence time.

P-642 4:30 PM Tuesday, October 20, 2020

MALE INFERTILITY DIAGNOSES AMONG PATIENTS WHO USED ASSISTED REPRODUCTIVE TECHNOLOGY IN THE UNITED STATES, 2016-2018. Amy Jewett, MPH,[1] Lee Warner, PhD,[2] James M. Dupree, M.D., M.P.H.,[3] Stan Honig, MD,[4] A. J. Nangia, MBBS,[5] Michael L. Eisenberg, M.D.,[6] Jennifer F. Kawwass, MD,[7] James Hotaling, MD,[8] Akanksha Mehta, M.D., M.S.,[9] Dmitry M. Kissin, MD, MPH[1] [1]Centers for Disease Control and Prevention, Chamblee, GA; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of Michigan, Ann Arbor, MI; [4]Yale University, New Haven, CT; [5]University of Kansas Medical Center, Kansas City, NY; [6]Stanford University, Stanford, CA; [7]Emory University (Emory GYN / OB, Emory Reproductive Center), Atlanta, GA; [8]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT; [9]1365 Clifton Road NE, Building B, Atlanta, GA.

OBJECTIVE: To describe patient and treatment characteristics among assisted reproductive technology (ART) cycles with a male infertility diagnosis in the United States (US).

DESIGN: Cross-sectional analysis of the US National ART Surveillance System (NASS).

MATERIALS AND METHODS: We used data from NASS for reporting years 2016-2018 to describe patient and treatment characteristics of ART cycles among patients with diagnosed male factor infertility. Subgroups of male infertility include medical condition, genetic or chromosomal abnormality, abnormal sperm parameters (azoospermia, oligospermia, low motility or low morphology, other abnormal sperm parameters), other male factor (less common diagnoses), and more than one male factor.

RESULTS: Among 596,044 cycles started with the intent to transfer an embryo between 2016 and 2018, 30.9% (n=184,060) reported a diagnosis of male factor infertility as a reason for using ART. Abnormal sperm parameters were the most commonly reported diagnoses for male infertility (58.7%), including low motility or low morphology (34.9%), oligospermia (11.5%), other abnormal sperm parameter (6.3%), and azoospermia (5.9%). Other reasons for male factor infertility included other male factor (35.2%), medical condition (2.9%), genetic or chromosomal abnormality (0.5%), and more than one male factor (2.7%). In nearly 45% of the cycles with male factor infertility, male age was not reported. When reported, the age distribution for males among cycles

with male factor infertility was less than 35 years (18.3%), 35-40 years (20.1%), 41-50 years (14.1%), over 50 years (3.1%). Among cycles with a male genetic or chromosomal abnormality, 67.7% reported male age of 40 or less years. For cycles with reported male factor infertility, 33.0% had a concurrent female factor infertility diagnosis. Sperm donors were used in less than 1% of all cycles reporting male factor infertility, but in 10.0% of cycles with abnormal sperm parameters. Intracytoplasmic sperm injection was the primary method of fertilization in all male factor infertility (80.7%) cycles and for subgroups: abnormal sperm parameters (84.4%), medical condition (77.0%), genetic or chromosomal abnormality (76.7%), and other male factor (75.1%). Preimplantation genetic testing was used in 24.4% of male infertility cycles and varied by infertility diagnosis: genetic or chromosomal abnormality (37.0%), medical condition (28.4%), abnormal sperm parameters (25.0%), and other male factor (22.5%). Single embryo transfer, used in 62.3% in all male infertility cycles, varied by male infertility subgroup: genetic or chromosomal abnormality (74.3%), medical condition (68.8%), abnormal sperm parameters (63.7%), and other male factor (58.9%).

CONCLUSIONS: Male infertility is a substantial contributor to infertility treatments, accounting for nearly one-third of ART cycles. Continued assessment of prevalence and characteristics of ART cycles with male infertility may inform treatment options and improve ART outcomes.

P-643 4:30 PM Tuesday, October 20, 2020

UTILIZATION OF PREIMPLANTATION GENETIC DIAGNOSIS IN MEN WITH Y-CHROMOSOME MICRODELETION. Danielle Velez, MD, William T. Berg, MD, Rachel Morgan Greenberg, MD, Tsikata Yaovi Apenyo, BS, Mark Sigman, MD, Gabriella Avellino, MD Brown University, Providence, RI.

OBJECTIVE: Y-chromosome microdeletion (YCMD), a genetic cause of male infertility, should prompt genetic counseling and possible pre-implantation genetic testing in those pursuing assistive reproductive technologies (ART). It is unknown whether patients utilize these resources. We sought to characterize how a YCMD diagnosis influences a couple's reproductive decisions.

DESIGN: This was a retrospective cohort study of severe oligo- or azoospermic men for whom a YCMD assay was ordered. Men with a positive YCMD were then prospectively surveyed on their reproductive decision making following their diagnosis.

MATERIALS AND METHODS: All men who presented for fertility evaluation from 2010 to 2020 and were found to have <5 M/mL sperm were included. After excluding men with obstructive azoospermia, 284 male patients were identified that met inclusion and exclusion criteria. Data was collected on ethnicity, semen analysis, karyotype, serum FSH, testosterone, and female partner's age and factor. Patients with a positive YCMD were then contacted and queried on their specific reproductive decisions following their diagnosis. Patients were surveyed on whether they pursued IVF, with or without ICSI, and with or without PGD, or whether they elected for donor sperm insemination, adoption, or nothing. Patients were also queried on what factors influenced these decisions.

RESULTS: Twenty-nine patients (10.21%) were diagnosed with a YCMD, of which 19 (65.5%) were AZFc, two were AZFb, one was AZFa, and the remainder were "other." Sixteen of the YCMD patients identified as Caucasian (55.2%), four African-American, one Hispanic/Latino, and 8 "other" or not available. All patients with YCMD were contacted by our researchers, with a 58.6% response rate. Seven patients (5 AZFc, 1 SRY deletion, 1 p6 single deletion) underwent sperm retrieval. The average number of ART cycles was 1.7, with only one patient pursuing IVF with ICSI and PGD. Commonly cited reasons for not pursuing further fertility treatments were "couple broke up or got divorced, due to the stress of the diagnosis," and "concern about success of microTESE." Of the four patients who used donor sperm, commonly cited reasons were "no other option available" or "failed microTESE." AZFa and b deletion patients were unlikely to be offered genetic counseling. Sixteen patients recalled being referred to genetic counseling, of whom only eight actually saw a counselor.

CONCLUSIONS: In our cohort of YCMD patients, only one patient chose to utilize IVF with ICSI and PGD. Additionally, for this patient population genetic counseling appears to be severely underutilized. Given the high number of relationships that ended after receiving the YCMD diagnosis, providers must be sensitive to the stress this diagnosis can impart on patients and their partners.

P-644 4:30 PM Tuesday, October 20, 2020

PREDICTORS OF CHANGES IN SEMEN PARAMETERS IN MEN WHO RECEIVED NATESTO IN AN OPEN-LABEL SINGLE CENTER CLINICAL TRIAL. Ruben Blachman-Braun, M.D., M.Sc.,[1] Thomas A. Masterson, III, MD,[1] Ranjith Ramasamy, MD[2] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami, Miami, FL.

OBJECTIVE: To determine if there are clinical, hormonal characteristics that might predict which men are more likely to have change in sperm concentration after 3 months of treatment with 4.5% nasal testosterone gel (Natesto), a short-acting testosterone replacement therapy.

DESIGN: Post-hoc analysis of a single institution, prospective, single-arm clinical trial conducted between November 2017 and September 2019 at the University of Miami.

MATERIALS AND METHODS: Men aged 18-55 diagnosed with symptomatic hypogonadism (total testosterone < 300ng/dL) and total motile sperm count >5million were enrolled, the participants applied Natesto 3 times a day. We evaluated concentration change between baseline and 3 months follow-up and compared those that had an increase or decrease of more than 20% in sperm concentration. Using the statistical program SPSS 24, we also performed a univariable logistical regression analysis to determinate the association between 20% increase or decrees in sperm concentration and the clinical, demographic, hormonal and semen analysis variables.

RESULTS: A total of 49 men received Natesto three times a day as part of the clinical trial. The median concentration at baseline was 26 million [17.5 –

Table. Variables representation. In addition, to a univariable analysis between the independent variables and increase or decrees in sperm concentration at 3 months follow-up.

	Overall n = 49 (100%)	Concentration decrees by 20% n = 21 (42.8%)			Concentration increase by 20% n = 15 (30.6%)		
		OR	CI 95%	p-value	OR	CI 95%	p-value
Age in years	36.5 ± 7.4	0.97	0.90 - 1.05	0.513	0.99	0.91 - 1.08	0.812
BMI (kg/m^2)	30.2 ± 5.6	0.99	0.89 - 1.09	0.772	1.01	0.91 - 1.13	0.844
Baseline							
Testosterone (ng/dl)	237.5 [199 – 280]	1.00	0.99 - 1.01	0.323	1.01	0.99 - 1.02	0.239
FSH (mIU/mL)	3.2 [2.2 - 4.8]	0.96	0.78 - 1.18	0.709	1.15	0.93 - 1.43	0.204
LH (mIU/mL)	3.2 [2.2 - 4.9]	1.00	0.84 - 1.17	0.975	1.10	0.91 - 1.34	0.310
Concentration	26 [17.5 – 36]	1.06	1.01 - 1.10	**0.014**	0.95	0.90 - 1.00	0.063
Motility	55 [46.8 - 60.3]	1.04	0.98 - 1.10	0.234	0.98	0.93 - 1.04	0.500
TMSC	32.5 [16 - 56.7]	1.02	0.99 - 1.04	0.056	0.99	0.96 - 1.01	0.202

36] and was similar (22 million [13.8 -35]) at 3 months follow up. Overall, after 3 months of treatment 30.6% of the men had a concentration increase by >20%, and 42.8% had decrease by >20%. Higher sperm concentration at baseline predicted a >20% decrease in sperm concentration. No other clinical, demographic, endocrinological, and semen analysis characteristics were associated with change in sperm concentration ($p > 0.05$) (Table).

CONCLUSIONS: Although 43% of men who received Natesto had a decline in sperm concentration, only 5% of them became azoospermic. There does not appear to be any baseline characteristics that can predict who adversely reacts to Natesto.

SUPPORT: This was an investigator-initiated trial sponsored in part by Aytu BioSciences

P-645 4:30 PM Tuesday, October 20, 2020

SPERM DNA FRAGMENTATION INDEX AND HIGH DNA STAINABILITY DO NOT INFLUENCE PREGNANCY ACHIEVEMENT FOLLOWING ICSI.

Ruben Blachman-Braun, M.D., M.Sc.,[1] Jordan C. Best, B.S.,[1] Victor Sandoval, M.D.,[2] Soum D. Lokeshwar, BS, MD, MBA,[1] Premal Patel, M.D.,[3] Taylor P. Kohn, MD, MPhil,[4] Elaine de Quadros, DHSc,[5] Michael H. Jacobs, M.D.,[5] Ranjith Ramasamy, M.D[1] [1]University of Miami Miller School of Medicine, Miami, FL; [2]Hospital Valentin Gomez Farias, Universidad de Guadalajara, Zapopan, JA, Mexico; [3]University of Manitoba, Winnipeg, Mexico; [4]Johns Hopkins University School of Medicine, Baltimore, Mexico; [5]Fertility and IVF Center of Miami, Miami, FL.

OBJECTIVE: To evaluate the ability of sperm DNA fragmentation index (DFI) and high DNA stainability (HDS) to influence the chance of achieving pregnancy in couples undergoing intracytoplasmic sperm injection (ICSI) cycles.

DESIGN: A retrospective study evaluating couples that underwent an ICSI cycle between 2009 - 2018 at a reproductive center.

MATERIALS AND METHODS: We included all couples who underwent an ICSI cycle and had a semen analysis with subsequent DFI and HDS testing. Clinical and demographic characteristics of the couples were recorded; couples with missing data, those who previously underwent ICSI and those that used donor eggs or sperm. In couples that achieved pregnancy, the number of ICSI cycles were considered until the first clinical intrauterine pregnancy, subsequent pregnancies were not considered in this analysis. Using the statistical software SPSS 24, means or medians were analyzed with U Mann-Whitney or Student T-test as required. We then performed a multivariable-adjusted logistical regression analysis to determine the association between pregnancy and couples independent variables.

Table. Multivariable analysis showing the association between pregnancy and independent variables in the 550 studied couples.

	Multivariable		
	OR	95% CI	p-value
Male age at first cycle (per year)	1.01	0.98 - 1.04	0.514
Male prior fertility			
No (%)	1		
Yes (%)	1.17	0.79 - 1.72	0.436
Male smoking history			
No (%)	1		
Yes (%)	0.98	0.59 - 1.63	0.939
Varicocele history			
No (%)	1		
Yes (%)	2.06	0.81 - 5.23	0.127
TMSC (10^6 motile sperm)	1.00	0.99 - 1.01	0.128
Female age at first cycle (per year)	0.83	0.79 - 0.89	**< 0.001**
Female BMI at first cycle (per kg/m^2)	1.01	0.97 - 1.05	0.727
DFI (%)	1.00	0.98 - 1.01	0.716
HDS (%)	1.01	0.98 - 1.04	0.551
ICSI attempts (per attempt)	0.60	0.49 - 0.72	**< 0.001**

RESULTS: A total of 550 couples who underwent 1050 ICSI cycles were analyzed, 220 couples achieved pregnancy. In couples that achieved pregnancy, females were younger (35.3 ± 3.4 vs. 33.7 ± 3.6 years; $p < 0.001$) and underwent fewer cycles (2 [1 – 3] vs. 2 [1 – 2]; $p = 0.001$). Importantly, the DFI% (no pregnancy: 12.2 [7.1 – 20.2] vs. pregnancy: 12.9 [8 – 20]; $p = 0.735$) and HDS% (no pregnancy: 9.1 [6.7 – 14] vs. pregnancy: 9.3 [6.1 - 14.6]; $p = 0.914$) were similar. A multivariable analysis showed that an increased female age and couples that underwent a greater number of ICSI attempts had a lower probability of getting pregnant. Furthermore, neither the DFI% nor HDS% were associated with an increase chance of achieving pregnancy (Table).

CONCLUSIONS: Neither DFI nor HDS at baseline influence the chances of a couple to achieve pregnancy after ICSI. Increased female age and couples who underwent more ICSI cycles were associated with lower chances of achieving pregnancy.

SUPPORT: No

P-646 4:30 PM Tuesday, October 20, 2020

CAN REACTIVE OXYGEN SPECIES (ROS) ESTIMATION PREDICT FERTILISATION RATES AND LIVE BIRTH RATES IN OBSTRUCTIVE AZOOSPERMIC MEN WITH SPERMATOCELE?

Ratnaboli Bhattacharya, MD, DNB, FNB, MRCOG,[1] Ratna Chattopadhyay, MBBS, PhD,[2] Kanad Dev Nayar, M.D., DGO., FICOG,[1] Sanghamitra Ghosh, MBBS,[2] Gunja Bose, MSc,[2] Shovandeb Kalapahar, MS, DNB, FNB[2] [1]Akanksha IVF Centre, Delhi, India; [2]Institute of Reproductive Medicine, Kolkata, India.

OBJECTIVE: To determine whether altered Reactive Oxygen species(-ROS) levels in men with obstructive azoospermia(OA) due to Spermatocele impairs sperm quality leading to poor In-Vitro Fertilisation (IVF) outcome.

DESIGN: Prospective study; sperm isolated from spermatocele of 19 men with OA and Testicular sperm extraction (TESE) sperm from testis of 22 men with other causes of OA served as study cohort and control respectively. 155 oocytes and 140 oocytes were retrieved from women(age<30) with normal hormonal profile in the study group and the control group respectively. Intra-cytoplasmic sperm injection(ICSI) was done in both the groups. The study was conducted from October 2002 to September 2019 at the Institute of Reproductive Medicine, Kolkata, India.

MATERIALS AND METHODS: 19 couples with OA due to spermatocele and 22 couples with OA for other reasons underwent IVF with antagonist protocol using recombinant FSH. Surgical sperm retrieval and ICSI was done . Fertilisation check was done after 17 hours and 2-3 Grade I embryos were transferred in the female partner on Day3. ROS levels were evaluated in the spermatocele fluid and the testicular fluid by chemiluminescence assay using luminol (5-amino-2,3-dihydro-1,4-phthalazinedione; Sigma Chemical Co., St. Louis, MO, USA) as a probe. β-hCG (β-Human chorionic gonadotrophin) was done 2 weeks after embryo transfer. Clinical pregnancy was confirmed using Transvaginal ultrasound. The primary outcome measures are fertilization rate, number of Grade I/II embryos and clinical pregnancy rate. Miscarriage rate and live birth rates are the secondary outcome measures. Statistical significance was set at $p<0.05$ with Pearson's correlation test and student's T-test.

RESULTS: The study group and control group were comparable regarding demographic and cycle characteristics. The fertilisation rate (61.4% vs 79.4%) and number of Grade I/II embryos (53.4% vs 70.9%) was significantly lower in the study group than the control group ($p<0.05$). The pregnancy rate in the two groups (39.1% vs 34.1%) were comparable ($p>0.05$). However the miscarriage rate was higher in the study group than control group(38.8% vs 13.3%)($p<0.05$), hence the live birth rates in the study group were lower than the control group (23.9% vs 29.5%)($p>0.05$), though it did not reach statistically significance. The ROS levels in the spermatocele fluid was also found to be significantly higher in the study group than the control group (92.15 ± 68.73 cps vs 61.39 ± 12.82 cps)($p<0.05$).

CONCLUSIONS: High ROS levels in spermatocele fluid can be the reason behind poor quality sperms in these patients than the sperms retrieved from the testis in the control group. Hence patients with spermatocele and OA show lower fertilization rates, lower number of good quality embryos and lower live birth rates than their counterparts with OA due to other causes.

Thus for patients with spermatocele, it is important to seek reproductive medical help as soon as the fatherhood desire is felt. As sperms collected from spermatocele confers a proinflammatory milieu, sperm collected by TESE from the testicular compartment of OA male is a better option.

P-647 4:30 PM Tuesday, October 20, 2020

RAISED SPERM DNA FRAGMENTATION –RANDOMISED CONTROLLED TRIAL OF MACS VS TESA TO OPTIMISE REPRODUCTIVE OUTCOMES.

Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Durga Rao Gedela, MBBS, DGO, MRCOG, fellowship in infertility and reproductive endocrinology,[2] Sandeep Karunakaran, Sr., MBBS, MS[2] [1]Oasis fertility, Hyderabad, India; [2]oasis fertility, Hyderabad, India.

OBJECTIVE: In Individuals with raised Sperm DNA Fragmentation (SDF), randomization with magnetic activated cell sorting (MACS) or surgical retrieval of testicular sperms (TESA) will it reduce SDF and optimize the reproductive outcomes?

DESIGN: This is an ongoing Randomized Control Trial (RCT) with prior approval from institutional Ethical Committee (IEC) conducted at a Private Teaching ART Clinic. This is preliminary data of the pilot study. Study duration 7months (January – July 2019). Couples undergoing IVF stimulation with raised SDF were randomized into MACS group (n=30) and TESA group (n=30) for sperm selection.

MATERIALS AND METHODS: Couples with history of one failed IVF cycle were offered testing for SDF. Individuals with SDF > 30% were included in the study. SDF testing was done with SCSA method and couples randomized using software into respective intervention groups. TESA was done as per our clinic's Standard Operating Protocol (SOP) and MACS was done as per the instruction from the manufacturer. Intra Cytoplasmic Sperm Injection (ICSI) was the method of insemination in all cases. Extended embryo culture till blastocyst stage was done and a freeze all policy was opted. Two Blastocysts that showed 100% survival were transferred in a Frozen Embryo transfer (FET) cycle. Mean of Implantation Rates (IR) and Clinical Pregnancy Rates (CPR), Miscarriage Rates (MR) & Live Birth Rates (LBR) were compared between both groups.

RESULTS: Mean Reproductive Outcomes for MACS & TESA groups were as follows:

Blastocyst formation rates – 38% Vs 31% (P=0.5717)
CPR – 50% Vs 83% (P= 0.0072)
IR – 43% Vs 72% (P= 0.0243)
MR- 33% Vs 16% (P= 0.1290)
LBR – 17% Vs 67% (P= 0.0001)

Blastocyst formation was comparable between the groups; However, TESA group had significantly higher CPR, IR, LBR and lesser MR.

Testicular sperm seem to have better DNA quality than ejaculated sperm. In couples with failed IVF attempts and raised SDF, we can offer TESA as an active intervention to optimize reproductive outcomes. Poor outcomes in MACS group needs further research.

LIMITATIONS, REASONS FOR CAUTION:

Small sample size. TESA is a surgical intervention.

CONCLUSIONS: TESA seems like a beneficial intervention to optimize sperm selection and reproductive outcomes for Individuals with raised sperm DFI.

SUPPORT: N/A

P-648 4:30 PM Tuesday, October 20, 2020

SPERM RETRIEVAL RATES AND PREGNANCY OUTCOMES IN MEN WITH KLINEFELTER SYNDROME.

Nahid Punjani, MD MPH,[1] Ryan Flannigan, MD,[2] Kathleen Hart, BSN RN MA,[1] Peter N. Schlegel, M.D.[1] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: To report sperm retrieval rates and outcomes from men with Klinefelter Syndrome (KS) undergoing microsurgical testicular sperm extraction (mTESE), and to explore predictive factors of sperm retrieval and pregnancy.

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: KS patients undergoing mTESE by a high-volume surgeon at Weill Cornell between 1995 and 2019 were reviewed. Men were included if sperm retrieval data was available. Demographic data included male and partner age. Testicular size was documented. History of previous mTESE was recorded. Sperm retrieval and pregnancy were captured dichotomously (yes/no) and fertilization rate per injected oocyte was quantified. Adjusted logistic regression modelling was used to examine predictors of sperm retrieval and pregnancy.

RESULTS: A total of 287 men with KS were included. Median age was 32 (IQR 28-36). Median partner age was 29 (IQR 26-33). Mean FSH values were 34.6 ± 16.0 IU/mL. Mean testis size on the left was 2.8 ± 2.5 cc, and right 2.9 ± 2.6 cc. A total of 15 (5.22%) of men had prior failed sperm retrieval procedure. Sperm was retrieved in 175 men (61.0%). Fertilization rate per injected oocyte was 3.7 ± 4.6. A total of 120 (41.8%) were able to achieve a pregnancy. Of those with prior mTESE, 6 of 15 (40.0%) had sperm retrieved and 2 of 15 (13.3%) were able to achieve a pregnancy. Adjusted logistic regression models (Table 1) indicate that testis size was associated with sperm retrieval (OR 1.52, 95% 1.18-1.98) and pregnancy (OR 1.24, 95%CI 1.08-1.42). Although no age cut-off precluded retrieval, increasing male age was marginally associated with a decreased likelihood of sperm retrieval when examined continuously (OR 0.89, 95%CI 0.85-0.94) and when examined in categories (Table 1). A similar trend was seen for pregnancy (continuous age: OR 0.87, 95% CI 0.79-0.95).

CONCLUSIONS: The sperm retrieval rates in KS patients was 61.0% in our series, with a total of 41.8% able to achieve a clinical pregnancy. Only testis size was associated with both sperm retrieval and pregnancy in our series, and increasing age only portends a slight decreased association with success.

Table 1 – Adjusted models of clinical outcomes

	Sperm Retrieval (OR, 95%CI)	Pregnancy (OR, 95%CI)
Continuous Age		
Male Age (continuous)	**0.89 (0.85-0.94)**	0.87 (0.79-0.95)
Female Age	-	1.09 (0.98-1.21)
Male FSH	1.02 (0.99-1.03)	1.02 (0.99-1.03)

UNDERSTANDING MOLECULAR MECHANISMS ASSOCIATED WITH INFERTILITY IN MEN WITH LOW LEVELS OF SEMINAL REACTIVE OXYGEN SPECIES THROUGH COMPARATIVE PROTEOMICS.

Manesh Kumar Panner Selvam, PhD,[1] Luna Samanta, PhD,[2] Ashok Agarwal, PhD[1] [1]American Center for Reproductive Medicine, Cleveland Clinic, Cleveland, OH; [2]Redox Biology Laboratory, Department of Zoology, Ravenshaw University, Cuttack, Odisha, India.

OBJECTIVE: Approximately 30% to 80% of idiopathic infertile men having increased seminal reactive oxygen species (ROS) levels suffer from a condition known as male oxidative stress infertility (MOSI), which affects about 37 million men with idiopathic infertility around the world. Although low concentrations of ROS are critical for spermatozoa physiological functions and fertilization, increased ROS are harmful to the spermatozoa. Hence, it is important to understand why patients with low ROS levels are still infertile despite the fact that low ROS are involved in physiological function. The current study was planned to identify molecular pathways defective in infertile men with low ROS levels using a comparative proteomic approach.

DESIGN: Semen samples with low ROS levels from fertile (n=5) and infertile men (n=5) were subjected to sperm global proteomic analysis. *In silico* analysis was carried out on differentially expressed proteins (DEPs) detected in spermatozoa of infertile patients with low seminal ROS levels in comparison to fertile men with low ROS levels. Based on the *in silico* analysis, key proteins associated with sperm function and oxidative stress mechanisms were validated using western blot.

MATERIALS AND METHODS: Proteomic profiling of sperm from low-level ROS fertile and infertile men was performed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). Proteins and peptides were identified using search programs MASCOT and SEQUEST. Spermatozoal proteins in fertile men were compared with those in infertile men. DEPs were subjected to bioinformatics analysis using ingenuity pathway analysis (IPA) software.

RESULTS: A total of 132 DEPs were found in sperm of infertile men compared to fertile men with low ROS levels. Among these, 84 proteins were under-expressed and 37 over-expressed in infertile men with low ROS levels. Further, 7 proteins and 4 proteins were unique to fertile men and infertile men, respectively. Bioinformatic analysis revealed that proteins involved in production of nitric oxide and ROS were dysregulated in the infertile group suggesting physiological ROS-mediated signaling is impaired in infertile men. Validation of key proteins by western blot revealed that APOA1, HSP90β, PRKAR1A, SERPINA5 were under-expressed and FASN was over-expressed in infertile men with low ROS levels.

CONCLUSIONS: The current study provides an in-depth understanding about proteins involved in the carbohydrate and lipid metabolism, small molecule biochemistry, cellular compromise and inflammatory response in infertile men with low levels of ROS. Furthermore, it is evident that redox signaling pathways are dysfunctional in sperm of infertile men, which in turn may affect its physiological functions.

OOCYTE ABILITY TO REPAIR SPERM DNA FRAGMENTATION: THE EFFECT OF MATERNAL AGE ON ICSI OUTCOMES. Assumpto Iaconelli, Jr., MD,[1] Daniela Paes de Almeida Ferreira Braga, PhD,[1] Amanda Souza Setti, MSc,[1] Rodrigo Rosa Provenza, Sr., BSc,[2] Joana Noguères Simas, MSc,[3] Edson Borges, Jr., PhD[1] [1]Fertility Medical Group / Sapientiae Institute, Sao Paulo, Brazil; [2]Fertility Medical Group, São Paulo, Brazil; [3]Sapientiae Institute, São Paulo, Brazil.

OBJECTIVE: Sperm DNA integrity is crucial for the adequate transmission of paternal genetic information and has been recognized as a biomarker of male infertility. Previous studies have suggested a negative correlation between sperm DNA fragmentation (SDF) index and pregnancy after ICSI, while others have found no association between SDF and pregnancy, but have suggested an association with pregnancy loss. Spermatozoa have no mechanism to repair SDF, DNA-repairing activity depends on the oocyte machinery once fertilization takes place. The ability of the oocyte to repair SDF depends not only on the level SDF, but also on the quality of the oocyte. Increasing maternal age has a well-established negative effect on fertility and reproductive success. Therefore, the goal for the present study was to evaluate the effect of SDF on clinical outcomes of assisted reproductive technology in women in different age groups.

DESIGN: Retrospective clinical study.

MATERIALS AND METHODS: This study included data from 540 ICSI cycles, performed from June/2017 to December/2019, in a private university-affiliated IVF center. Cycles were split into three groups according to the maternal age: ≤36 years old (n=285), 37-40 years old (n=147), and >40 years old (n=108). Semen samples were evaluated for SDF using the Sperm Chromatin Dispersion method and for each age group, the cycles were divided again according to SDF index: low fragmentation index (≤30% SDF) and high fragmentation index (>30% SDF). Clinical outcomes were compared between groups using generalized linear models with linear distribution followed by Bonferroni post hoc test, with adjustment for potential confounders or Chi-square test.

RESULTS: For younger patients (≤36 years old) and those between 37 and 40 years old, no significant differences were noted in pregnancy (≤36 years old: 40.0% vs. 39.1%, p=0.840 and 37-40 years old: 27.7% vs. 28.6%, p=0.781), implantation (≤36 years old: 42.3% vs. 41.5%, p=0.880 and 37-40 years old: 28.9% vs. 30.6%, p=0.757), or miscarriage rates (≤36 years old: 9.3% vs. 11.1%, p=0.665 and 37-40 years old: 31.2% vs. 22.2%, p=0.875), for cycles with ≤30% SDF or >30% SDF respectively. However, when maternal age was >40 years old, a significant lower pregnancy (20.0% vs. 7.7%, p=0.040), implantation (19.7% vs. 11.9%, p=0.040), and increased miscarriage rate (12.5% vs. 100.0%, p<0.001) was observed for cycles with ≤30% SDF or >30% SDF respectively.

CONCLUSIONS: High SDF index leads to worse clinical outcomes such as lower implantation rates, pregnancy rates and higher miscarriage rates, in cycles with increased maternal age. The same is not observed when maternal age is < 40 years old. This evidence indicates that the age may affect the oocyte DNA-repairing ability, leading to a poor embryo development, when the oocyte is injected with a DNA-damaged spermatozoon.

VALIDATION OF LENSHOOKE™ X1 PRO AND COMPUTER-ASSISTED SEMEN ANALYZER COMPARED WITH LABORATORY-BASED MANUAL SEMEN ANALYSIS. Ashok Agarwal, PhD,[1] Manesh Kumar Panner Selvam, PhD,[1] Li-Sheng Chang, PhD,[2] Fang-Zong Wang, MSc,[2] Cheng-Teng Hsu, PhD[2] [1]American Center for Reproductive Medicine, Cleveland Clinic, Cleveland, OH; [2]Bonraybio Co., Ltd, Taichung City, Taiwan.

OBJECTIVE: To compare two automated semen quality analysis systems [LensHooke™ X1 PRO (X1 PRO) and IVOS CASA] for accuracy, precision and agreement with laboratory-based manual semen analysis (MSA).

DESIGN: Semen analysis was conducted using X1 PRO (Bonraybio®), IVOS CASA (Hamilton Throne) and MSA according to WHO 5th Edition (2010) guidelines in andrology laboratory.

MATERIALS AND METHODS: Semen samples (n=31) were obtained from healthy male volunteers with normal semen parameters and infertile men with a minimum abstinence period of 2 to 3 days. After complete liquefaction, a total of 101 seminal aliquots were prepared and tested using X1 PRO, IVOS CASA and MSA. The test results obtained by X1 PRO and IVOS CASA were compared to MSA using Passing-Bablok regression analysis. Additionally, 10 samples were used to evaluate the intra- and inter-rater agreement for X1 PRO and MSA.

RESULTS: The semen analysis results (sperm concentration, total motility, progressive (PR) motility, motile sperm concentration, and progressively motile sperm concentration) showed strong correlation and agreement for both automated semen analyzers (X1 PRO and IVOS CASA) and MSA with Pearson correlation above 0.92 (P<0.0001). X1 PRO and IVOS CASA were able to differentiate oligozoospermic samples with an accuracy of 100% and 93%, respectively. Furthermore, the positive predictive value for X1 PRO (86.5%) was higher than IVOS CASA (71.7%) in differentiating asthenozoospermic samples. Semen parameter (sperm concentration, total motility and PR motility) showed a high degree of inter- and intra-rater agreement evaluated using X1 PRO and MSA (Table 1). X1 PRO showed an intra-rater precision of coefficient variation, CV <15% for sperm concentration, total motility and PR motility, and was comparable with MSA.

CONCLUSIONS: Both automated semen analyzers (X1 PRO and IVOS CASA) showed high level of accuracy and precision, and their performance was comparable with laboratory-based MSA. Furthermore, high-levels of inter-and intra-rater reliability for semen analysis indicates that new device, X1 PRO can be used in a clinical diagnostic laboratory to offer accurate test results.

Table 1. Inter- and intra-rater agreement for semen parameters measured using LensHooke™ X1 PRO and MSA

	Inter-rater agreement*		Intra-rater agreement**	
Semen parameters	MSA (N=10)	X1 PRO (N=10)	MSA (N=10)	X1 PRO (N=10)
Concentration (10^6/mL)	0.94	0.95	0.98	0.99
Total motility (%)	0.94	0.91	0.99	0.94
Progressive motility (%)	0.88	0.93	0.98	0.92

*Three operators were involved. **Three readings were taken.

THE INFLUENCE OF VARICOCELE AND MICROSURGICAL VARICOCELECTOMY ON SEMEN QUALITY: A UHPLC-QE-MS UNTARGETED METABOLIC ANALYSIS. Xinzong Zhang, MD,[1] Cuncan Deng, MD,[1] Wujiang Liu, MD,[2] Xiaohua Liu, MD,[2] Huang Liu, MD,[3] Yu Zhou, MD,[2] Tao Pang, dr,[4] Qingguo Zhao, MD,[2] Yunge Tang, Master degree[3] [1]Family Planning Special Hospital of Guangdong Province, Guangzhou, China; [2]Family Planning Research Institute of Guangdong Province, Guangdong, China; [3]Family Planning Research Institute of Guangdong Province, Guangzhou, China; [4]Family Planning Research Institute of Guangdong Province, guangzhou, China.

OBJECTIVE: To study whether varicocele affects the metabolism of semen and whether microsurgical varicocelectomy can reverse the metabolism of semen.

DESIGN: A origina article.

MATERIALS AND METHODS: The semen samples from 30 varicocele patients, 30 patients after microsurgical varicocelectomy, and 30 healthy males were selected to conduct non-targeted metabolomics by liquid chromatography-mass spectrometry. Different metabolites between three groups were analyzed and the metabolic pathways were analyzed by KEGG database. Potential biomarkers were determined by t-test and receiver operating characteristic (ROC) curve analysis.

RESULTS: 275 different expressed metabolites involving in 39 pathways were found between varicocele group and normal group. A total of 8 metabolites were selected as varicocele potential biomarkers by HPLC-QE-MS high-throughput untargeted metabolomics analyses [Area under the curve

(AUC)>0.90]. Varicocele influence semen quality through amino acids metabolism, reactive oxygen species and anti-oxidation relative metabolism, phenylalanine, tyrosine and tryptophan biosynthesis pathway and phenylalanine metabolism pathway. Microsurgical varicocelectomy may improve semen quality by rebalancing dipeptide metabolism which has an antioxidant effect, and regulating ceramide and Sphingolipid metabolism, which is associated with ROS production, oxidative stress, mitochondrial respiratory chain, mitophagy and apoptosis.

CONCLUSIONS: These results suggested that varicocele could change the sperm metabolism, and microsurgical varicocelectomy could improve the sperm quality by changing the sperm metabolism. Further study is needed!

Key words: Varicocele, varicocelectomy, metabolomics, 5-L-Glutamyl-taurine, Amino acid metabolism.

INFERTILITY INSURANCE: WHAT COVERAGE EXISTS FOR RESIDENTS AND FELLOWS?

Wade Muncey, MD, Erin Jesse, MD, Aram Loeb, MD, Nannan Thirumavalavan, MD. Case Western Reserve University - University Hospitals Cleveland Medical Center, Cleveland, OH.

OBJECTIVE: We aimed to evaluate infertility insurance coverage provided to physician trainees at institutions that offer advanced infertility training.

DESIGN: A descriptive study examining health insurance documentation regarding coverage for infertility services.

MATERIALS AND METHODS: Health insurance summary plan documents from US institutions with post-graduate physician training in Andrology and/or Reproductive Endocrinology and Infertility (REI) fellowships were obtained either from fellows themselves, the GME office, or the program website. The summary of benefits documents were individually examined for their descriptions of coverage for infertility services by two authors (WM and EJ). Assessment of coverage for diagnosis, treatment and any discussion of shared costs or maximum lifetime coverage were included. We also assessed for descriptive text specifically indicating services for male infertility care as well as coverage for cryopreservation. Statistical analysis using a fisher exact test was used to evaluate whether having an Andrology program was predictive of an institution including male-specific language in its insurance policy.

RESULTS: We reviewed documents from 24 unique institutions, which included 14 out of the 18 US Andrology fellowships and 18 out of the 48 US REI fellowships. There were 15 of 24 (62.5%) institutions reporting coverage for the treatment of infertility, 6 (25%) institutions that covered diagnosis but not treatment, and 3 (12.5%) institutions that excluded diagnostic or treatment coverage completely. Among the 15 institutions that provided coverage for treatment, 13 reported the lifetime maximum amount, which averaged $14,885 (range of $2,500 - $25,000). In total, we identified only 7 out of 24 (29%) policies that included male-specific language. Only 4 out of 24 (16.7%) plans explicitly described a covered male-specific treatment. Having an Andrology program did not significantly increase the likelihood of including male-specific language in institutional insurance policies.

CONCLUSIONS: We found that for physician trainees, infertility insurance coverage is variable and treatment for male factor infertility is commonly omitted or minimally mentioned in insurance coverage documents. With high costs of infertility treatment, residents and fellows may represent a particularly vulnerable population when faced with fertility concerns.

SPERM RETRIEVAL RATES AND PREGNANCY OUTCOMES IN MEN WITH AZF DELETIONS.

Nahid Punjani, MD MPH,[1] Ryan Flannigan, MD,[2] Kathleen Hart, BSN RN MA,[1] Peter N. Schlegel, M.D.[1] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: To report outcomes in men with AZF deletions following microsurgical testicular sperm extraction (mTESE), as well as assess for predictive factors of sperm retrieval and pregnancy.

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: Between 1995 and 2019, all patients undergoing mTESE by a high-volume surgeon at Weill Cornell in New York City were reviewed. Men with known AZF deletions were included if sperm retrieval data was available. All patients had a repeat extended sperm preparation on the morning of planned retrieval. Patient demographic data was recorded and included both male and female partner age. Testicular size was recorded. Sperm retrieval and pregnancy rates were captured as well as number of fertilized eggs. Multivariable regression models were utilized to assess for predictive factors of sperm retrieval and pregnancy including demographic data and testicular size.

RESULTS: A total of 72 men with AZF deletions were included. Of these, a total of 67 men (93.1%) had AZFc deletions. Of the remaining 5 men, 2 had an AZFb deletion (4.1%), 2 had AZFb+c deletion (2.7%) and 1 had a partial AZFb deletion (1.4%). Median male age was 34 (IQR 30-38), and median partner age was 32 (28-36). Mean FSH levels were 19.1 ± 10.5 IU/mL. Mean testicular size was 10.7 ± 4.7cc on the left side and 10.7 ± 4.9cc on the right. Sperm was retrieved in 0 of 5 men (0%) with non-AZFc deletions and was retrieved in 43 men (64.2%), with AZFc deletions. Fertilization rate per injected oocyte was 2.8 ± 4.1. A total of 31 of 73 men (42.5%) were able to achieve a clinical pregnancy. Using multivariable logistic regression (Table 1) FSH was associated with both sperm retrieval and pregnancy (OR 1.07, 95% CI 1.01-1.14).

CONCLUSIONS: Sperm retrieval rates in men with AZF deletions are approximately 60% in keeping with previously documented numbers in the literature. Higher levels of male FSH are slightly associated with increased successful sperm retrieval and pregnancy.

Table 1 – Adjusted Modelling of Clinical Outcomes

	Sperm Retrieval (OR, 95%CI)	Pregnancy (OR, 95%CI
Male Age	1.00 (0.91-1.09)	0.99 (0.84-1.16)
Female Age	-	0.95 (0.81-1.11)
Male FSH	**1.07 (1.01-1.14)**	**1.07 (1.01-1.14)**
Testis Size	1.07 (0.95-1.20)	1.04 (0.92-1.17)

P-657 4:30 PM Tuesday, October 20, 2020

FRESH MICRODISSECTION TESTICULAR SPERM EXTRACTION RESULTS IN A HIGHER RETRIEVAL RATE OF SPERM ACCEPTABLE FOR ICSI COMPARED TO FROZEN-THAWED MICRODISSECTION TESTICULAR SPERM EXTRACTION.

Darren J. Bryk, MD,[1] Scott Lundy, MD PhD,[2] Nicholas J. Farber, MD,[3] Neel Parekh, MD,[1] Nina Desai, Ph.D., HCLD,[4] Edmund Sabanegh, Jr., MD,[2] Sarah C. Vij, MD[1] [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH; [3]Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH; [4]Cleveland Clinic, Beachwood, OH.

OBJECTIVE: Men who do not make it to intracytoplasmic sperm injection (ICSI), due to poor post-thaw results, are not included in studies comparing fresh and frozen microdissection testicular sperm extraction (mTESE). We hypothesized that fresh mTESE results in a higher rate of obtaining sperm acceptable for ICSI compared to FT mTESE.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We retrospectively reviewed all patients with non-obstructive azoospermia who underwent mTESE at a tertiary care institution from April 2007 to April 2020. The primary endpoint was rate of obtaining sperm usable for ICSI, which was defined as motile sperm at the time of fresh mTESE or post-thaw motile sperm after FT mTESE. Fisher's exact test was used to compare fresh and frozen-thawed mTESE results.

RESULTS: One hundred and nine men underwent 128 mTESEs. Table 1 compares sperm retrieval rates for fresh and FT mTESE. In the entire cohort, fresh mTESE yielded significantly higher retrieval rates of motile sperm acceptable for ICSI compared to FT mTESE ($p<0.0001$). The motile sperm retrieval rate in FT mTESE was 31/97 (32.0%), but post-thaw motile sperm was identified in 17 of these 31 FT mTESEs. Of the 31 fresh mTESEs, 4 (12.9%) found no sperm; all 27 fresh mTESEs where motile sperm was found proceeded to ICSI. Fresh mTESE had significantly higher retrieval rate of sperm acceptable for ICSI compared to FT mTESE ($p=0.01$). Seven patients had a FT mTESE followed by a fresh mTESE based on poor post-thaw results as assessed by an embryologist. Of these, 6/7 (85.7%) had motile sperm retrieved, but just 2/7 (28.6%) had post-thaw motility, both with reported very poor samples; all 7 (100%) had motile sperm on fresh mTESE acceptable for ICSI.

CONCLUSIONS: Our data suggests that there is a percentage of men whose decision to undergo FT mTESE precluded their ability to proceed with an ICSI cycle based on the results of that operation. Patients should be adequately counseled on the likelihood that FT mTESE may result in successful sperm retrieval but inability to proceed to ICSI.

Table 1. Sperm Retrieval Rates in Fresh versus Frozen-thawed Microdissection Testicular Sperm Extraction. FT mTESE = Frozen-Thawed microdissection testicular sperm extraction

	FT mTESE (n=97)	Fresh mTESE (n=31)	p-value
Motile Sperm (n=128)			<0.0001
Yes (n, %)	31 (32.0)	27 (87.1)	
No (n, %)	66 (68.0)	4 (12.9)	
	FT mTESE (n=31)	Fresh mTESE (n=31)	
Sperm Acceptable for ICSI (n=62)			0.01
Yes (n, %)	17 (54.8)	27 (87.1)	
No (n, %)	14 (45.2)	4 (12.9)

P-658 4:30 PM Tuesday, October 20, 2020

PATIENT DESIRE FOR DISPOSITION OF CRYOPRESERVED SPERM UPON DEATH AS A SURROGATE MARKER FOR LIKELIHOOD OF CONSENT FOR POSTHUMOUS SPERM RETRIEVAL.

Brooke A. Harnisch, MD,[1] Dylan M. Buller, MD,[1] Vikram Lyall, BS,[1] Michael E. Goltzman, MD,[1] Stan Honig, MD[2] [1]University of Connecticut, Farmington, CT; [2]Yale University, New Haven, CT.

OBJECTIVE: Decision-making regarding posthumous sperm retrieval can be ethically and legally challenging, as most cases do not clearly delineate in writing whether the deceased would consent for sperm retrieval. We sought to collect and analyze data regarding patient preferences for the disposition of their sperm in the possible event of their death to help better inform this process.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: An IRB approved, retrospective chart review was conducted on patients who froze sperm from January, 2016 through October, 2019 at a single fertility center. We reviewed the disposition of cryopreserved sperm should death occur to a patient. Collected data included age, race/ethnicity, occupation, insurance status, marital status and duration of marriage, prior biological children, and cause of fertility. Patients were excluded if they were not trying to get pregnant at present, prior to cancer therapy, prior to starting gender affirming treatments, or not in a committed relationship.

RESULTS: After review of 550 charts, 403 patients met criteria for inclusion. The mean age was 38.2 years +/- 6.7 (SD). Reasons for sperm cryopreservation were female factor (46.2%), male factor (34.7%), or combined factor (8.9%) infertility; a diagnosis was unknown or unspecified in 9.4% of patients. Overall, 84.9% of patients consented to transfer their sperm to their partner in

case of death. Male-factor infertility (OR for transfer 2.14, 95% CI 1.12 – 4.07, p= .02) and having commercial insurance (OR for transfer 2.11, 95% CI 1.07 – 4.15, p= .03) were predictors of electing to transfer sperm; there was no difference in "transfer to partner" rates with age, race/ethnicity, marital status, duration of marriage, having prior children, or occupation.

CONCLUSIONS: 84.9% of patients who cryopreserved sperm consented to transfer their sperm to their partners if death should occur. There does not appear to be a clear factor that would impact this decision, based on demographic information, prior children, or occupation. Since there is rarely written consent to perform posthumous sperm retrieval, this information is valuable in assessing whether most men who are married or in a committed relationship would consider proceeding in this fashion. This data may be useful to guide physician-institution-patient decision making in these complex situations.

THE RELATIONSHIP BETWEEN MEDICAL TREATMENT MODALITIES FOR MALE HYPOGONADISM AND ICSI OUTCOMES.

Brent M. Hanson, MD,[1] Philip J. Cheng, MD,[1] Julia G. Kim, MD, MPH,[1] Emily K. Osman, MD,[1] Ashley W. Tiegs, MD,[1] Nola S. Herlihy, MD,[1] Amber M. Klimczak, MD,[1] Richard Thomas Scott, Jr., MD,[2] James Hotaling, MD[3] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]IVI RMA New Jersey, Basking Ridge, NJ; [3]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT.

OBJECTIVE: Male hypogonadism is characterized by testosterone deficiency. For men with hypogonadism who desire fertility, it has been reported that medications such as clomiphene citrate can improve luteinizing hormone (LH) and follicle stimulating hormone (FSH) levels without negatively impacting semen parameters (1). However, it is unclear whether medical treatment for male hypogonadism leads to meaningful improvements in reproductive outcomes following intracytoplasmic sperm injection (ICSI). This study sought to determine whether treatment modalities used for male hypogonadism affect fertilization rates or blastulation rates after ICSI.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: This study was performed at a university-affiliated fertility practice. Men were included for analysis if they had a total testosterone level of less than 300 ng/dL and subsequently underwent a first cycle of ICSI. Men were divided into three treatment categories: no treatment, clomiphene citrate, or an alternative regimen which included any medications aside from clomiphene citrate or a combination of medications. Kruskal-Wallis testing and the Wilcoxon Rank-Sum test were utilized to assess the relationship between treatment groups for hypogonadism and rates of fertilization and blastulation.

RESULTS: A total of 171 male patients (mean age 34.7 ± 4.1 years) met the inclusion criteria. Among them, 44 patients (25.7%) received no medical treatment for hypogonadism, 69 patients (40.4%) received clomiphene citrate, and 58 patients (33.9%) received an alternative regimen. There were no statistically significant differences in patient age (p=0.71), initial FSH level (p=0.72) or initial LH level (p=0.09) between the treatment groups. However, patients receiving an alternative treatment regimen were noted to have lower mean serum total testosterone levels than the other groups (255.3 ng/dL for the no treatment group, 230.9 ng/dL for the clomiphene citrate group, and 217.2 ng/dL for the alternative regimen group, p=0.02). Embryology outcomes were assessed for all patients following ICSI. For men who did not receive any treatment for hypogonadism prior to ICSI, fertilization rate was 73.6% and blastulation rate was 44.3%, for the clomiphene citrate group fertilization rate was 79.1% and blastulation rate was 51.9%, and for the alternative regimen group fertilization rate was 71.5% and blastulation rate was 47.5%. There were no statistically significant differences noted for either fertilization rate or blastulation rate between the treatment groups (p=0.14 and p=0.35, respectively).

CONCLUSIONS: While medical therapy for male hypogonadism may alleviate symptoms associated with testosterone deficiency, various treatment regimens do not appear to have a significant impact on embryology outcomes. Specifically, the type of treatment does not affect fertilization rate or blastulation rate in men with testosterone deficiency.

DOES CONSULTATION BY A REPRODUCTIVE UROLOGIST (RU) VERSUS REPRODUCTIVE ENDOCRINOLOGIST (RE) IMPACT MALE PARTNER FERTILITY QUALITY OF LIFE (QOL)?

Rachel Blair Danis, MD,[1] Jesse L. Stone, MS,[2] Intira Sriprasert, MD,[1] Richard J. Paulson, MD, MS,[3] Kristen Bendikson, MD,[1] Jacqueline Ho, MD MS,[1] Mary Katherine Samplaski, MD[1] [1]University of Southern California, Los Angeles, CA; [2]USC Fertility, Los Angeles, CA; [3]Keck School of Medicine of the University of Southern California, Los Angeles, CA.

OBJECTIVE: Limited data have shown that male partners of infertile couples may feel ashamed or stigmatized when labeled as "infertile." While most couples start with a RE, men may undergo RU evaluation. We sought to determine if male partners evaluated by a RU reported different motivating factors and fertility QoL (FertiQoL) compared to those seen by a RE.

DESIGN: Cross-sectional survey.

MATERIALS AND METHODS: Anonymous surveys were given to male partners of couples undergoing evaluation, in-person at a RE clinic or electronically after RU consultation. One part assessed demographics, history, and fertility motivating factors. The second was the validated FertiQoL, which assessed psychological effects of infertility. It contained 2 domains: "Core" (psychosocial and interpersonal QoL) and "Treatment" (fertility environment and treatment tolerability QoL). Responses were scaled 0-100; higher scores indicated more favorable QoL. Descriptive statistics, chi-square, and t-tests were used for data analysis.

RESULTS: Forty-eight men participated: 60.4% (n=29) with the RE and 39.6% (n=19) with the RU. Ethnicity, education, history, and motivating factors were similar between groups (p>0.05). Known male factor was more common in men with a RU versus RE (68.4% (n=13) versus 10.3% (n=3)).

Men undergoing RU consultation scored lower in overall Core, Treatment, and total FertiQoL, indicating differences in the global impact of infertility (p<0.05, Table). Scores were lower in every subscale but not significant for Relational, Social, and Tolerability (p>0.05), indicating that RU consultation did not affect these factors. All men undergoing RU consultation reported this was helpful for understanding fertility, and 95% (n=18) said it was helpful to have a "sperm doctor" as an adjunct to their partners' "egg doctor."

CONCLUSIONS: RU-consulted men reported worse QoL than those seen by a RE, experiencing more sadness, disrupted cognitive function, and negative treatment effects on QoL. These men were more likely to have known male infertility, and all found the RU consultation helpful. While impossible to know, the lower QoL may be from having known male infertility, or due to men feeling freer to express their personal experiences to a RU patient advocate.

TABLE. FertiQoL Scores for men seen by a RE versus RU

	RE (n=29) Mean (std dev^)	RU (n=19) Mean (std dev^)
Core*		
Mind/Body*	85.8 (11.7)	70.2 (19.6)
Emotional*	78.0 (17.5)	63.8 (17.2)
Relational	73.2 (14.9)	69.7 (17.2)
Social	80.0 (15.8)	70.2 (17.6)
Treatment*		
Environment*	81.1 (14.1)	62.8 (16.2)
Tolerability	80.2 (14.4)	75 (20.1)
Total*	79.7 (11.4)	68.2 (12.5)

^std dev= standard deviation; *p<0.05

ACCESS TO CARE FOR INFERTILE MEN: WEBSITE EDUCATIONAL CONTENT AMONG ASSISTED REPRODUCTIVE TECHNOLOGY (ART) CLINICS IN THE UNITED STATES.

Julie M. Shabto, BA,[1] Katherine Poulose, BA,[1] Mackenzie P. Bennett, BS,[1] Angel X. Xiao, BSE, MSE,[1] Heather S. Hipp, MD,[1] Akanksha Mehta, M.D., M.S.,[2] Jennifer F. Kawwass, MD[3] [1]Emory University School of Medicine, Atlanta, GA; [2]1365 Clifton Road NE, Building B, Atlanta, GA; [3]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA.

OBJECTIVE: To characterize United States (U.S.) assisted reproductive technology (ART) clinic websites with regards to inclusion of male factor infertility educational content.

DESIGN: Cross-sectional study of ART clinic website content.

MATERIALS AND METHODS: Using the 2017 and 2018 Centers for Disease Control (CDC) Fertility Clinic Success Rates Reports, 537 ART clinics in the United States were identified. Thirty-eight clinics were excluded from this analysis because either the clinic closed or did not have a website.

Each website was evaluated for presence or absence of the following content: 1) any educational content for patients seeking infertility treatment, 2) educational content about male factor infertility specifically, 3) webpage section dedicated to male factor infertility, 4) discussion of the male fertility testing (i.e. semen analysis), 5) discussion of male factor infertility medical and surgical treatment, and 6) presence of urologist on the infertility team. Specific terms evaluated to identify male factor infertility educational content included: male factor infertility, azo-/oligospermia, hypogonadism, varicocele, semen analysis, surgical sperm extraction, and hormone therapy. Differences in variables were evaluated with respect to clinic location (state) and total number of cycles per year, as reported in the 2018 CDC Clinic Success Rates Reports.

RESULTS: Websites of 499 ART clinics were evaluated. Most websites (94.6%, n=472) include educational content in general, with 85.8% (n=405; 81.2% of the total) discussing male factor infertility specifically and 64.3% (n=321) including a webpage section devoted to male factor infertility. Many clinics (17.8%; n=89) include educational content such as blog posts, podcasts, and videos specific to male factor infertility. The majority (75.8%; n=378) of all clinic websites discuss the male fertility testing evaluation. Less than half (44.1%; n=220) mention treatment options for male factor infertility, with 23.0% discussing medical and 40.7% discussing surgical options. Finally, 10% (n=50) of all clinic websites note the presence of a urologist on the infertility team.

Clinics located in the 17 states with fewer than 4 total ART clinics are less likely to note the presence of a urologist on the infertility team. Additionally, clinics with a greater total number of cycles per year are more likely to include male educational content on their websites.

CONCLUSIONS: Our findings corroborate previous studies that showed U.S. ART clinic websites lack important information about male infertility.[1,2] The variability in information available on U.S. ART clinic websites may act as a barrier to access for male infertility care, particularly in states with few ART clinics or clinics with fewer total cycles. U.S. ART clinics should aim to address the evaluation of and treatment options for male factor infertility on their websites in order to overcome barriers to access for male infertility care.

SPERM WITH VERY LOW MOTILE DENSITY (MD) MAY BE A CAUSE OF REDUCED CHANCE OF LIVE DELIVERY DESPITE TRANSFER OF NORMAL MORPHOLOGIC EMBRYOS.

Jerome H. Check, M.D., Ph.D.,[1] Carrie K. Wilson, B.A.,[2] Jung Choe, M.D.,[1] Donna Summers, M.S.,[2] Aniela Bollendorf, M.T.,[2] Diane L. Check, BS, MT[2] [1]Cooper Medical School of Rowan University, Camden, NJ; [2]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ.

OBJECTIVE: To determine if a male factor, specifically low MD, can reduce the chance of a live baby despite normal fertilization and the production of embryos with good morphology.

DESIGN: Prospective comparison study.

MATERIALS AND METHODS: To eliminate an oocyte factor as a confounding variable, the study selected pairs of patients sharing donor oocytes. The only couples selected were those where the male partners of 1 couple had a MD below $<10x10^6$/mL and the other male partner $\geq 10x10^6$/mL. The low MD group when evaluating outcome was further divided into very low MD of $<5x10^6$/mL and 5-9.9x10^6/mL. Only cycles where both couples had a fresh embryo transfer (ET) on day 3 were included. Intracytoplasmic sperm injection (ICSI) was used for couples where MD was $<10x10^6$/mL unless strict morphology was $\leq 4\%$ when ICSI was used even with normal MD.

RESULTS: There were 242 ETs in low MD groups and 245 in normal MD group.

Comparison of in vitro fertilization (IVF) outcome according to MD in pairs sharing oocytes

Motile Density ($10x10^6$/mL)	<5	5-9.9	≥10
# transfers	143	99	245
% fertilized	72.1%	70.9%	70.9%
% 6-8 cell day 3	57.3%	60.2%	62.4%
% clinical preg./transfer	47.6%	49.5%	56.3%
% miscarriage/clinical preg. live	20.6%	8.2%	16.7%
% delivered	37.8%	45.5%	46.9%
% implantation	26.5%	26.7%	30.9%

Chi-square = NS. Power analysis showed one would need to triple the number of subjects to show that the difference in live delivery rates comparing very low MD vs. normal MD was significant. Evaluating a subset with normal morphology using strict criteria, the live delivered pregnancy rate for very low MD was 36.1% (26/72) vs. 48.3% and miscarriage rate was 29.7% vs. 13.3%. Thus, low strict morphology was not a confounding variable. Since both low MD groups had ICSI performed, and the less severe group did as well as the normal MD group, ICSI did not seem to be a confounding variable. There was an average of 1.8 embryos transferred in the very low MD group vs. 1.9 in the normal MD group.

CONCLUSIONS: Though the differences were not significant, possibly the results could suggest that even using the best quality oocytes, males with very low MD may be responsible for unexplained failure to achieve a live birth even with the transfer of normal quality embryos by morphologic criteria. Since good oocytes can sometimes correct sperm defects, it may be that these differences may be even greater if the oocytes retrieved are of less quality. Thus, in cases of repeated failure to achieve live deliveries in couples where the sperm has very low MD, instead of switching to donor oocytes, one could consider first trying donor sperm. A larger possibly multicenter study is needed to support or refute this suggested cause of unexplained infertility.

IDENTIFYING THE BEST METHOD OF RETRIEVING SPERMATOZOA WITH THE HIGHEST GENOMIC INTEGRITY. Danielle Rebecca Tavares, B.A., Alessandra Parrella, M.Sc., Philip Xie, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine whether the best way to retrieve spermatozoa with an intact genome is to obtain specimens directly from the testicle or from the ejaculate through a microfluidic device.

DESIGN: During the course of 48 months, men with high DNA fragmentation in their ejaculate and related ART failure were offered testicular biopsy or microfluidic selection in order to identify spermatozoa with the highest genomic integrity. Spermatozoa from these two different origins were used for ICSI while controlling for maternal age. Fertilization, implantation, and pregnancy outcomes according to the sperm source used were recorded and compared.

MATERIALS AND METHODS: A total 111 consenting men had their ejaculated spermatozoa screened for SCF by TUNEL using a commercial kit on a minimum of 500 cells with a normal threshold of £15%. Testicular biopsy was carried out by micro-TESE. Ejaculated spermatozoa were selected by microfluidic processing. Both sources of spermatozoa were used for ICSI.

RESULTS: A total of 111 men (paternal age 36.6±5) with normal semen parameters (concentration of 41.5±25 x 10^6/mL, 42.1±14% motility, and increased SCF (22.4 ± 9%)) underwent 167 ICSI cycles with their female partners (maternal age 33.7±3) without achieving pregnancy. Subsequently, 22 couples underwent testicular biopsy. Those testicular specimens (concentration of 1.8±4 x 10^6/mL (P<0.01) and 5.0±11% motility (P<0.01), and an SCF of 12.6 ± 6% (P<0.0001)) were used in 37 ICSI cycles, yielding a fertilization rate of 61.6% (204/331, P<0.01), a superior implantation rate of 10.6% (9/85, P<0.01), a CPR of 23.5% (8/34, P<0.01), and a delivery rate of 17.6% (6/34, P<0.01). Another 22 couples underwent 28 ICSI cycles with ejaculated spermatozoa processed by a microfluidic device (concentration of 1.5±13 x 10^6/mL (P<0.01), 97.4±5% motility (P<0.01), and an SCF of 1.2 ±1%, lower than both raw and testicular specimens (P<0.0001)), resulting in a fertilization rate of 76% (203/266, P<0.01), an implantation rate of 26% (15/57, P<0.05), and a CPR of 50% (13/26, P<0.01), of which 2 patients delivered and 10 pregnancies are ongoing.

CONCLUSIONS: Our study demonstrates that sperm DNA fragmentation can severely lower the chances of achieving pregnancy by impairing embryonic development with consequent implantation failure. While retrieving spermatozoa directly from the germinal epithelium represents a valuable option, microfluidic sperm selection provides an optimal alternative by reducing surgical risks and costs.

P-664 4:30 PM Tuesday, October 20, 2020

ASSESSING SPERM RETRIEVAL AND PREGNANCY OUTCOMES IN RE-DO MTESE PROCEDURES AMONG MEN WITH NOA. Nahid Punjani, MD MPH,[1] Ryan Flannigan, MD,[2] Kathleen Hart, BSN RN MA,[1] Peter N. Schlegel, M.D.[1] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: To report the outcomes of redo microsurgical testicular sperm extraction (mTESE) procedures and assess predictors of sperm retrieval and pregnancy outcomes.

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: All patients undergoing mTESE by a high-volume surgeon at Weill Cornell in New York City between 1995 and 2019 were reviewed. Men were included if they had a documented prior mTESE for sperm retrieval either completed either outside or at our institution. Demographic data included both male and partner age. Testicular size was reported and testicular histopathology when possible was reported as a percentage. mTESE outcomes includes sperm retrieval (yes/no), fertilized eggs per injected oocyte (rate), and pregnancy (yes/no). Adjusted logistic regression models were utilized to determine factors predictive of sperm retrieval including male age, male FSH levels and testicular size. Factors assessed which may predict pregnancy included male age, female age, male FSH and testis size.

RESULTS: A total of 144 men with re-do mTESE were included. The average age was 36 (IQR 32-40). Average partner age 33 (IQR 29-37). Mean left testicular size was 7.3 ± 5.2 cc and right testicular size was 7.7 ± 5.5 cc. Mean FSH values were 26.3 ± 16.4 IU/mL. Sperm retrieval occurred in 74 men (51.4%). Mean fertilized eggs were 2.3 ± 3.6. Pregnancy occurred in 26 of 138 men (18.8%). Using multivariable logistic regression (Table 1) testis size was associated with sperm retrieval (OR 1.14, 95% 1.03-1.27), and although not significant trended towards increased pregnancy rates (OR 1.12, 95% 0.99-1.27).

CONCLUSIONS: Re-do mTESE is a feasible option for those interested. Testis size is marginally associated with sperm retrieval in repeat procedures. Although it may be possibly more technically challenging and with limited pre-operative factors predictive of success, it is a reasonable choice for a high volume and skilled reproductive urologist.

Table 1 – Adjusted logistic regression models

	Sperm Retrieval (OR, 95%CI)	Pregnancy (OR, 95%CI)
Male Age	1.05 (0.98-1.13)	0.91 (0.79-1.05)
Female Age	-	1.13 (0.94-1.35)
Male FSH	1.02 (0.99-1.05)	1.02 (0.98-1.06)
Testis Size	**1.14 (1.03-1.27)**	1.12 (0.99-1.27)

P-665 4:30 PM Tuesday, October 20, 2020

REPRODUCTIVE OUTCOMES OF COUPLES WITH SEVERE MALE FACTOR AND ADVANCED PATERNAL AGE. Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Gayathri Gedela, Master in Clinical Embryology,[1] Vijay Kumar Sharanappa, Sr., MBBS, MD, MCE,[2] Shankhadeep Debnath, MSC Molecular Biology and Biotechnology,[1] Rajesh Mani Raghupathy, MBBS, PGDCE,[1] Durga Gedela Rao, Sr., MRCOG,[1] Sandeep Karunakaran, Sr., MS, PGDHM, PGDMLE[1] [1]Oasis fertility, Hyderabad, India; [2]OASIS FERTILITY, Hyderabad , TELANGANA, India.

OBJECTIVE: To evaluate whether couples with advanced paternal age and severe male factor infertility have altered embryo euploidy rates and analyse the reproductive outcomes with transfer of an euploid embryo

DESIGN: Retrospective Case Control Comparative Study. Private Teaching Fertility Clinic

MATERIALS AND METHODS: Couples with women <37 and severe male factor infertility underwent Pre-Implantation Genetic Testing for Aneuploidy (PGT-A) at our clinic during 2014 January and June 2019 were only evaluated in this study (n = 84). This study group was further sub-classified based on the male partners' age into men (< 39 years) (n = 54) and men (>40 years) (n = 13). Couples with women with advanced maternal age (>37 years) were excluded from this study (n = 70).

All women underwent controlled ovarian stimulation, Transvaginal oocyte retrieval and ICSI for severe male factor infertility as per our clinics standard operating procedures (SOP). Embryos were cultured till blastocyst stage and subjected to Trophectoderm biopsy and a freeze all policy was adopted. Biopsied tissue was sent for genetic evaluation by next generation sequencing (NGS). Couples with at least one Euploid embryo were offered elective single embryo transfer (eSET) in a frozen cycle. Mean euploid embryo rates and reproductive outcomes after eSET in younger and older men group were compared.

Control group underwent FET with two blastocysts (DET) and reproductive outcomes were compared between the two groups.

RESULTS: 307 embryos subjected for PGT-A with mean euploidy in Young and old men was 47.23 % and 36.23 % respectively.

The reproductive outcomes for Young and Older men were as follows:

Clinical Pregnancy Rate: 68.5 % Vs 46.15 % (P=0.1415)

Implantation Rate: 65 % Vs 38 % (P=0.0769)

Miscarriage Rate: 7 % Vs 12 % (P=0.3297)

Live Birth Rate: 61 % Vs 38 % (P=0.1361)

The reproductive outcomes for Older men with PGT-A and eSET and older men without PGT-A with DET were as follows

Clinical Pregnancy Rate: 46.15 % Vs 45.71 % (P=0.9483)

Implantation Rate: 38 % Vs 33.6 % (P=0.7603)

Miscarriage Rate: 12 % Vs 15.71 % (P=0.7333)

Multiple Pregnancy Rate: 0 % Vs 17 % (P=0.1104)

Live Birth Rate: 38 % Vs 27.14 % (P=0.4301)

Data from this study is suggestive that, Younger men with Younger women seem to have better embryo euploidy rates and reproductive outcomes.

Advancing paternal age seems to affect the reproductive outcomes in spite of transferring a euploid embryo. In spite of an euploid embryo older men had vert low IR and LBR.

Couples undergoing ART cycles with severe male factor infertility, advanced paternal age can be a detrimental factor.

Role of PGT-A to optimize reproductive outcomes for older men with severe male factor infertility doesn't seems encouraging in this study. Smaller sample size is the biggest limiting factor of this study, but calls for further research on the advanced paternal age and effects on reproductive outcomes.

CONCLUSIONS: Advanced paternal age can be detrimental factor and alter reproductive outcomes in severe male factory infertility couples.

P-666 4:30 PM Tuesday, October 20, 2020

OLDER AGE AND LOWER SPERM MOTILITY ARE ASSOCIATED WITH ELEVATED SPERM DNA FRAGMENTATION INDEX. Jordan C. Best, B.S.,[1] Ruben Blachman-Braun, M.D., M.Sc.,[1] Daniel Gonzalez, B.S.,[1] Premal Patel, M.D.,[2] Taylor P. Kohn, MD, MPhil,[3] Ranjith Ramasamy, MD[4] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Manitoba, Winnipeg, Mexico; [3]Johns Hopkins University School of Medicine, Baltimore, Mexico; [4]University of Miami, Miami, FL.

OBJECTIVE: To analyze the association of elevated sperm DNA fragmentation index (DFI) with clinical demographics and gross semen parameters.

DESIGN: A retrospective study was performed to evaluate consecutive men that underwent semen analysis in combination with sperm DFI testing between 2009-2018 at a reproductive medical center.

MATERIALS AND METHODS: We included men who underwent semen analysis as well as DFI testing evaluated by Sperm Chromatin Structure Assay (SCSA), regardless of their underlying etiology for infertility evaluation. An adjusted multiple linear regression analysis was performed to determine the relationship of clinical characteristics and gross semen parameters with sperm DFI%. All statistics were performed with SPSS 24.

RESULTS: A total of 441 men were included in this analysis, with overall median DFI of 12.8% [7.6 – 20]. Our multiple regression model predicts 37.9% of DFI variation ($R^2 = 0.392$, adj. $R^2 = 0.379$). The analysis showed that every additional year of life leads to a DFI increase of 0.54% (CI 95%: 0.38 to 0.71; $p < 0.001$), and an observed decrease in total sperm motility of -0.33% (CI 95%: -0.39 to -0.27; $p < 0.001$) for each percent increase in DFI% (Table 1). Due to the association between age and DFI, we evaluated the effect of advance paternal age on DFI comparison between age groups. DFI independently increased with advancing paternal age (20 – 30 years = 11% [6.5 - 15.2], 30.1 – 40 years = 11.1% [7.1 - 17.2], 40.1 – 50 years = 16.6% [10 27.1] , >50 years = 23.5% [14.5 - 35]; $p < 0.001$).

CONCLUSIONS: Older age and lower sperm motility were strongly associated with increased DFI. Men above the age of 40 appeared to have a steep increase in sperm DFI compared to men younger than 40. Further, studies should be performed to assess the clinical implications of assessing DFI in older men and those with isolated low sperm motility.

P-667 4:30 PM Tuesday, October 20, 2020

SPERM RETRIEVAL RATES BY MICRO-TESE VERSUS CONVENTIONAL TESE IN MEN WITH HISTOPATHOLOGY CONFIRMED NON-OBSTRUCTIVE AZOOSPERMIA: A SYSTEMATIC REVIEW. Sandro C. Esteves, M.D., Ph.D.,[1] Thairo Alves Pereira, MD.[2] [1]ANDROFERT & University of Campinas (UNICAMP), Campinas, Brazil; [2]University of Campinas (UNICAMP), Campinas, Brazil.

OBJECTIVE: Summarize the evidence from a variety of study designs on the effectiveness of sperm retrieval (SR) techniques, microdissection testicular sperm extraction (micro-TESE) and conventional TESE (cTESE), in patients with histopathology-confirmed non-obstructive azoospermia (NOA).

DESIGN: Systematic review.

MATERIALS AND METHODS: We conducted a systematic search using Pubmed to identify all relevant studies published from 1999 to 2019. Articles were only included if they were written in English, provided histopathology confirmation for the NOA diagnosis, and were not review articles or letters. Studies were analysed for inclusion independently by the two authors, any discrepancies were resolved by discussion. A total of 109 articles were identified from the title. This was reduced to sixty-three suitable articles using the full-text, due to the lack of histopathology data. A total of 11,472 patients were included, 5861 and 5611 subjected to micro-TESE and cTESE, respectively.

RESULTS: In non-comparative studies, SR success was higher (p=002) using micro-TESE (49.9%) vs. cTESE (47.4%) (Relative risk [RR]: 1.06; 95% confidence interval [CI]: 1.02-1.10). In this analysis, the number need to treat (NNT) by micro-TESE vs. cTESE to achieve an additional successful SR was 35 (95% CI: 21-101). Among patients with Sertoli cell-only (SCO) or tubular atrophy/hyalinization, SR success by micro-TESE vs. cTESE were 34.7% and 31.2%, respectively (p=0.02; RR: 1.11; 95% CI: 1.01-1.21),

Table 1. Overall clinical and gross semen parameters of the analyzed men. In addition to a multiple linear analysis showing the association between DFI and the clinical characteristics and gross semen parameters.

		Multiple linear analysis			
			95% CI		
	Variables n = 411 (100%)	B	Lower	Upper	p-value
Age in years	37.1 [33.3 - 40.9]	0.54	0.38	0.71	**< 0.001**
Prior fertility					
No (%)	263 (64%)	Ref.			—
Yes (%)	148 (36%)	0.02	-2.10	2.14	0.983
Smoking history					
No (%)	358 (87.1%)	Ref.			—
Yes (%)	53 (12.9%)	-1.54	-4.56	1.47	0.314
Varicocele history					
No (%)	394 (95.9%)	Ref.			—
Yes (%)	17 (4.1%)	3.73	-1.32	8.77	0.147

B = Unstandardized regression coefficient; Ref: Reference value

with a NNT by micro-TESE vs. cTESE of 28.6 (15.5-178). When the analysis was limited to those studies directly comparing both techniques, SR success by micro-TESE vs. cTESE were 49% and 35.8% (p=0,0004; RR: 1.37; 95% CI: 1.14-1.65), with a NNT of 7.5 of 7.5 (95% CI: 4.9-16.6). In this subset analysis, SR success among patients with SCO or tubular atrophy/hyalinization were 36.1% vs. 13.3% (p<0.001; RR: 2.7, 95% CI: 1.72-4.24), with a NNT of 4.4 (95% CI: 3.2-7.1).

CONCLUSIONS: Micro-TESE provides higher SR success than cTESE in men with histopathology confirmed NOA, in particular, SCO and tubular atrophy/hyalinization. The magnitude of effect was remarkably higher in studies directly comparing both techniques, which highlights the heterogeneity of study populations of non-comparative studies. Therefore, pooled analysis of studies directly comparing SR techniques are preferred to guide clinical decision-making.

REPRODUCTIVE EFFECTS OF DIABETES, DYSLIPIDEMIA AND HYPERTENSION IN TESTICULAR SPERM EXTRACTION (TESE) WITH INTRACYTOPLASMIC SPERM INJECTION (ICSI) FROM VASECTOMIZED MALES.

Lorena Valls, M.D,[1] Irene Hervas, MSc,[2] Jose Maria Martinez-Jabaloyas, M.D,[3] Rocio Rivera-Egea, PhD,[3] Maria Gil Julia, MSc, MRes,[2] Nicolas Garrido, PhD[4] [1]Hospital Clínico de Valencia, Valencia, Spain; [2]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [3]IVIRMA Valencia, Valencia, Spain; [4]IVI Foundation - IIS La Fe Biomedical Research Institut, Valencia, Spain.

OBJECTIVE: TESE-ICSI is common approach for vasectomized males aiming to reverse infertility, yielding shorter time to pregnancy compared with surgical reversion when female infertility factors are present. During vasectomized period, the male may have developed pathologies that can affect the later success of ICSI. We aim to assess if the presence of male comorbidities, as diabetes mellitus (DM), dyslipidemia (DL) and hypertension (HTA), impact the likelihood of achieving a newborn after TESE-ICSI in these couples, both in cycles with their own and donated oocytes.

DESIGN: Retrospective study.

MATERIALS AND METHODS: From data since 1995, study population was screened according to the presence of these pathologies. Main outcomes were live birth rate (LBR) by embryo transfer (ET), by complete donation cycle (CDC) and by couple, using Chi-square to compare proportions and Kaplan Meier curves compared with Breslow tests, to estimate cumulative live birth rates (CLBR), per embryos consecutively replaced until achieving a newborn.

RESULTS: Mean time since vasectomy using their own oocytes (n=390) was 11.7 years (CI95% 11.1-12.3). 3.4% of them showed DM. The LBR were not significantly different when comparing DM *vs* non-DM per ET (55.6% *vs* 33.3%), per CDC (27.8% *vs* 22.8%) and per couple (38.5% *vs* 43.1%), but the DM group had a higher CLBR (p=0.02), needing fewer embryos to obtain the same LBR as the non-DM group. The LBR were not statistically different in males with DL (4.2% of all) and in non-DL: 25.0% *vs* 34.0% per ET, 13.8% *vs* 23.4% per CDC, and 25.0% *vs* 43.8% per couple. Also, the CLBR were comparable between DL and non-DL group: when 2 embryos were transferred was 37.5% and 33.3%, with 4 embryos replaced, rates were 68.7% and 56.6% respectively. Similar live birth rate (p>0.05) were observed in vasectomized men suffering HTA (5.5% of all) and non-HTA ones: 20.7% *vs* 34.6% per ET, 12.2% *vs* 23.7% per CDC and 28.6% *vs* 43.8% per couple. The CLBR was equivalent, 33.6% *vs* 28.2% and 44.9% *vs* 37.2% when 2 and up to 3 embryos were transferred. A total of 123 couples used donated eggs. Mean time since vasectomy was 13.3 years (CI95% 12.0-14.5); a 7.6% had DM, 4.2% DL and a 6.7% HTA. Non-significant differences in LBR between those with DM and non-DM patients: 13.3% *vs* 37.1% per ET and 18.2% *vs* 47.9% per CDC. LBR was statistically significant (p=0.03) when calculated per couple (22.2% *vs* 62.7%). The CLBR was comparable between them (p>0.05). The overall results of DL patients were not statistically different from non-DL men; LBR was 50.0% *vs* 34.9% per ET, 75.0% *vs* 45.0% per CDC and 60.0% *vs* 59.7% per couple. The CLBR was equivalent. HTA group showed no significant differences with respect non-HTA: 30.8% *vs* 35.6% per ET, 50.0% *vs* 45.6% per CDC and 50.0% *vs* 60.4% per couple. The CLBR were up to 52.9% *vs* 57.1% when a total of 4 embryos were transferred consecutively, but it was not statistically significant.

CONCLUSIONS: Diabetes seems to negatively impact oocyte donation treatments in patients undergoing TESE-ICSI after vasectomy, while on the cases with own eggs such effect disappears, deserving deeper exploration. HTA and DL seem irrelevant for success in these cases.

A NEW METHOD FOR ACCURATE PREDICTION OF SPERMATOGENESIS: FSH/T AND T IN SEMINAL PLASMA.

Huang Liu, MD,[1] Xinzong Zhang, Medical doctor,[2] Houbin Zheng, dr,[3] Tao Pang, dr,[3] Yu Zhou, dr,[3] Cuncan Deng, MD,[1] Wujiang Liu, MD[4] [1]Family Planning Research Institute of Guangdong Province, Guangzhou, China; [2]National Health Council Key Laboratory of Male Reproduction and Genetics, Guangzhou, China; [3]Family Planning Research Institute of Guangdong Province, guangzhou, China; [4]Family Planning Research Institute of Guangdong Province, Guangdong, China.

OBJECTIVE: To find a new method to predict spermatogenesis.

DESIGN: FSH, LH, T in serum and seminal plasma of spermatozoa and azoospermia were detected. The relationship between these hormones and their ratio and the number of spermatozoa were analyzed to find the best balance ratio which can stimulate spermatogenesis during the interaction of these hormones.

MATERIALS AND METHODS: We randomly selected 140 men for the study using a random number table. They were divided into the spermatozoa group (70 people) and the azoospermia group (70 people) depending on whether any sperm could be found after centrifugation of their ejaculated semen at 3000 g/min. The FSH, LH and T in their seminal plasma and serum were measured by *ELISA*, and the correlations between these indicators and sperm count were determined in order to find a new method to predict spermatogenesis.

RESULTS: There was no difference between the two groups in terms of age, height, weight, *BMI*, days of abstinence, semen volume, semen pH value or semen liquefaction time ($P>0.05$). The levels of *s*-FSH (17.07±4.09) and *s*-LH (37.85±44.08) of the spermatozoa group were higher than those of the azoospermia group (8.64±5.81, 22.26±31.30) (t_1=9.924, p_1=0.000; t_2=2.412, p_2=0.017), but the *b*-FSH (7.17±7.56) and *b*-LH (4.04±2.95) values of the spermatozoa group were lower than those of the azoospermia group (21.05±16.82, 10.03±7.82) (t_1=-6.299, p_1=0.000; t_2=-6.004, p_2=0.000). The level of *s*-T (65.59±24.04) of the spermatozoa group was higher than that of the azoospermia group (47.13±13.99)(t=5.551, p=0.000), but there was no difference in the level of *b*-T (17.33±8.62, 15.35±8.38) between the two groups (t=1.378, p=0.171). After controlling for the interference due to grouping factors, individually, *s*-FSH, *s*-LH, *b*-FSH, *b*-LH, *b*-T and *b*-FSH/T were not correlated with spermatogenesis (r_1=-0.112, r_2=0.111, r_3=-0.055, r_4=-0.018, r_5=-0.039, r_6=-0.049; p_1=0.189, p_2=0.195, p_3=0.519, p_4=0.835, p_5=0.649, p_6=0.569). However, *s*-FSH/T was positively correlated with spermatogenesis (r=0.201, p=0.018), while *s*-T was negatively correlated with spermatogenesis (r=-0.474, p=0.000). The composition analysis showed that among these eight factors, three main components could be extracted: blood gonadotropin (contained *b*-FSH, *b*-LH, and *b*-FSH/T), seminal plasma gonadotropin (contained *s*-FSH, *s*-LH, and *s*-FSH/T) and T (contained *s*-T and *b*-T), among which *s*-FSH/T and *s*-T are the most important factors for spermatogenesis. When *s*-FSH/T was greater than 0.13 (*AUC* 0.735, sensitivity 0.986, specificity 0.486, and prediction probability 0.87) and *s*-T was less than 63.0 (*AUC* 0.723, sensitivity 0.557, specificity 0.929, and prediction probability 0.87), spermatogenesis increased.

CONCLUSIONS: *s*-FSH/T and *s*-T can be used to accurately predict spermatogenesis.

TRPV1 AS A MODULATOR OF ROS-INDUCED SPERM FUNCTION AND ITS CORRELATION WITH PREGNANCY OUTCOME (NATURAL CONCEPTION AND ART).

Nirlipta Swain, M.Phil,[1] Luna Samanta, Ph.D,[1] Sujata Kar, MBBS MD DNB,[2] Chandan Goswami, Ph.D,[3] Rakesh Kumar Majhi, Ph.D,[3] Smriti Sanchita, B.S.[4] [1]Redox Biology Laboratory, Department of Zoology, Ravenshaw University, Cuttack, Odisha, India; [2]A-32, Unit-4, Kharvel Nagar, Bhubaneswar, India; [3]School of Biological Sciences, National Institute of Science Education and Research, Jatni, Odisha, India; [4]UCLA, Los Angeles, CA, India.

OBJECTIVE: Being both thermo and redox sensitive, the transient receptor potential vanilloid 1 (TRPV1) constituted a group of relevant ion channels influencing sperm function. This study aims to investigate the expression profile of TRPV1 in sperm and its correlation with pregnancy outcome both by natural means and ART. Further, the role TRPV1 in mediating reactive oxygen species (ROS)-induced sperm function was examined.

DESIGN: Perspective case-control study and *in-vitro* experimental study.

MATERIALS AND METHODS: Semen samples were collected from male partners of couples who conceived either by natural means (NC) where fertile donors (NC+, n=10) were compared to partners of recurrent pregnancy loss (RPL; NC-, n=7) or by ART where the spermatozoa of male partners who achieved pregnancy by IVF (IVF+, n=10)/ICSI (ICSI +, n=9) were compared with their respective experimental group with failed pregnancy (IVF-, n= 23/ICSI-, n=10). TRPV1 expression was probed with immunocytochemistry and flow cytometry. Effect of TRPV1 modulators (RTX/ iRTX) +/- H_2O_2 on sperm function and calcium influx was evaluated. A secondary in-silico analysis of TRPV1 was undertaken with candidate fertility proteins to find out the probable pathways involved. Data were analysed by 1-way ANOVA or Kruskal-wallis test depending on normality distribution of data, and $p<0.05$ was considered significant.

RESULTS: Reduced expression of TRPV1 in sperm of IVF+/- and ICSI+/- men with respect to NC+ men imply the relevance of TRPV1 in mediating a successful fertilization in female reproductive tract. Unsuccessful pregnancy outcome with an under expression of TRPV1 in sperm of NC-/IVF-/ICSI- men, as compared to their successful counterparts postulate the role of channel in conception and maintenance of pregnancy. Enhancement of motility and triggering of acrosomal reaction post TRPV1 agonist (RTX) treatment, suggested that disruption of these signalling cascades *in-vivo*, in IVF+/ ICSI+ males would explain their need to undertake assisted techniques for a successful fertilization *in-vitro*. A significant increment in percentage of spermatozoa with reacted acrosome was observed after H_2O_2 treatment +/- RTX, as compared to untreated groups. The effect was attenuated by incubating with TRPV1 antagonist iRTX, implicating the role of TRPV1 in mediating the H_2O_2 response. The augmented Ca^{2+} influx due to channel activation in H_2O_2 +/- RTX, was demonstrated by calcium imaging. Cross-talk between TRPV1 with fertility candidate proteins showed that networks associated with cell death and survival were primarily affected.

CONCLUSIONS: The current study is a novel work, which demonstrated that reduced expression of TRPV1 in spermatozoa of RPL and IVF/ICSI failure patients compromised their fecundity potential. Influence of TRPV1 activation on motility and acrosomal reaction is also established. This is also the first report showing the direct role of TRPV1 in mediating H_2O_2 induced Ca^{2+} influx and acrosomal reaction in spermatozoa. If validated in larger population with different semen parameters, it would have therapeutic significance especially in ART setup.

P-671 4:30 PM Tuesday, October 20, 2020

AN EVALUATION OF SEMEN PARAMETERS IN MEN WITH CONFIRMED COVID-19 INFECTION.

Jordan C. Best, B.S.,[1] Manish Kuchakulla, B.S.,[1] Thiago Fernandes Negris Lima, MD,[2] Belén Mora, B.S.,[1] Fabio Frech, B.S.,[1] Justin K. Achua, MS,[1] Himanshu Arora, PhD,[1] Emad Ibrahim, MD, HCLD(ABB),[1] Ranjith Ramasamy, MD[2] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami, Miami, FL.

OBJECTIVE: Our aim was to evaluate the semen parameters of men with COVID-19 infection.

DESIGN: A prospective study was performed to evaluate the gross semen parameters in men with COVID-19 infection. Samples of saliva and semen were collected and analyzed.

MATERIALS AND METHODS: We included men age 18-70 years old who tested positive for COVID-19. Subjects were contacted about willingness to participate. Packages with sterile specimen containers were mailed to the subject's house with a preaddressed package included to return to our lab. The semen then underwent gross semen analysis for volume, concentration, pH and motility.

RESULTS: A total of 12 men were enrolled in the study with a median age of 35.5 (IQR = 19.5) (Table 1). The median duration of infection was 37 days (IQR = 21) and 2/12 (16.7%) had associated orchitis symptoms during the infective period. For the 11/12 men who returned a semen specimen, median

volume was 1.6cc (IQR = 1.65), median pH was 7.2 (IQR = 0.2), median concentration was 14 million/cc (IQR = 30.25), and median motility of 0% (IQR = 12.5).

CONCLUSIONS: We evaluated 11 men's gross semen parameters after confirmed infection with COVID-19. The median concentration for these men is abnormally low compared to World Health Organization guidelines, and further evaluation is needed to determine the impact that COVID-19 infection can have on the testis and for what duration.

Table 1. The age, duration of infection and gross semen parameters of enrolled men.

Subject	Age	Duration (DAYS) of Infection at time of SA	Volume	pH	Concentration (million/cc)	Motility
1	30	35	1.6	7.2	5	0
2	39	27	3.9	7.2	30	32
3	56	16	1.1	7.2	317	0

IMPACT OF TESTICULAR DELIVERY AND VASAL VEIN LIGATION ON CLINICAL OUTCOMES IN MEN UNDERGOING MICROSURGICAL VARICOCELECTOMY. Gal Wald, BA,[1] Nahid Punjani, MD MPH,[1] Christopher Gaffney, MD,[2] Marc Goldstein, M.D.,[3] James A. Kashanian, MD[4] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Weill Cornell Medical College- New York Presbyterian Hospital, New York, NY; [3]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [4]Weill Cornell Medicine - New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To assess the impact of microsurgical varicocelectomy technique on clinical outcomes in patients with severe oligospermia.

DESIGN: Retrospective data collection.

MATERIALS AND METHODS: Men diagnosed with varicocele between 2017 and 2020 were reviewed. We included men who underwent microsurgical varicocelectomy at Weill Cornell by two high-volume surgeons who differed slightly in surgical technique in addition to ligating routine dilated veins: Method 1) testicle delivery with gubernacular vein ligation, ligation of dilated vasal veins >2.5mm, and preservation of normal vasal veins and Method 2) no testicle delivery and only ligation of markedly dilated vasal veins in recurrencent cases. Patients were stratified according to their preoperative sperm concentration (SC): >5 M/mL and <5 M/mL with and without azoospermia. Post-operative SC improvement and TUNEL were compared based on technique using the Wilcoxon ranked-sum test (Stata v14).

RESULTS: 313 men patients were included; a 162 with Method 1 and 151 with Method 2. The two cohorts were of similar age (35, IQR 27-42 and 34, IQR 28-39, respectively) and BMI (25.4, SD 4.0 vs 25.9, SD 4.5, respectively). For Method 1, 84 (51.9%) had bilateral surgery, 76 (46.9%) left only, and 2 (1.2%) right only. For Method 2, 63 (41.7%) had bilateral surgery, 84 (55.6%) left only, and 4 (2.6%) right only. Both methods produced a similar improvement in the TUNEL assay (p=0.33). In patients with SC >5 M/mL, there was no observed difference between Method 1 and 2 (p=0.24) post-operatively. Similarly, there was no statistical difference in patients with SC <5M/mL (p=0.48) and after excluding azoospermic men (p=0.55).

CONCLUSIONS: Delivery of the testis and ligation of dilated vasal veins does not influence changes in semen aparameters or TUNEL assay after microsurgical repair. Future studies will assess whether the differences in technique effect the short and long term recurrence rates.

Table 1 – Testicular Delivery and Vasal Vein Ligation Effeect on Clinical Outcomes

	No Delivery	Testicular Delivery	
> 5 M/mL			
Pre-op	20.7 (20.2), n=36	18.8 (19.9), n=51	
Post-op	34.7 (33.2), n=36	26.9 (27.0), n=51	
Difference	14.5 (20.3), n=35	8.1 (19.7), n=51	p=0.24
<5 M/mL (all)			
Pre-op	0.8 (1.1), n=12	0.4 (0.8), n=26	
Post-op	2.7 (5.4), n=12	6.8 (14.4), n=26

PREDICTORS OF DETERIORATION OF SEMEN PARAMETERS IN MEN TREATED WITH CLOMIPHENE CITRATE FOR INFERTILITY. Christopher M. Deibert, MD, MPH,[1] Jacob T. Pfeifer, BS,[2] Thomas Schroeder, BA[2] [1]University of Nebraska, Omaha, NE; [2]University of Nebraska Medical Center, Omaha, NE.

OBJECTIVE: To better understand the correlations associated with decreases in Total Motile Sperm Count (TMSC) after a clomiphene challenge and predict which men would be ideal candidates for clomiphene citrate (Clomid) therapy.

DESIGN: We retrospectively analyzed male patients treated for infertility with clomiphene citrate at the University of Nebraska Medical Center from 2015-2019. We excluded patients with no follow-up semen analysis or hormonal labs, concurrent HCG treatment, and/or prior varicocele surgery. Our final samples size was 45 patients, from this sample we tracked testosterone response and the men's semen analysis parameters.

MATERIALS AND METHODS: 45 patients were categorized into 7 groups based on changes in the semen parameter TMSC: increased >10 million, increased >5 million, increased >2 million, decreased >2 million, decreased >5 million, decreased >10 million, or stayed the same. From these groups we tracked how many men doubled their TMSC and performed statistical analysis to correlate Testosterone response and TMSC response while on Clomiphene citrate.

RESULTS: While using Clomiphene citrate, 57.8% of patients (n=25) showed an increase in total motile sperm production with 48.9% of men doubling their sperm production. However, 24.4% of men (n=11) had no increase in sperm production and 17.8% of men (n=8) paradoxically had a decrease in sperm production. Of the patients who had an increase of >10 million, 89.5% doubled their initial TMSC. Of those men that had a decrease in sperm production, 37.5% had a TMSC that decreased by greater than 10 million (Table 1). Increased testosterone response showed positive correlation with increased TMSC.

CONCLUSIONS: Clomiphene citrate is a well-established option for the treatment of male hypogonadism. However, nearly 1 in 5 men experience a paradoxical effect resulting in decreased TMSC. Though counseling on

therapy has always included that counts may not increase, discussing possible decrease is also necessary.

Table 1. Categories based on TMSC response showing the total % of patients, and the number of patients that doubled their TMSC.

TMSC response	# of patients	% of TOTAL Patients	# of TMSC Doubled	% of patients that Doubled TMSC in Respective TMSC response
Increased >10 million	19	42.2%	17	89.5%
Increased >5 million	3	6.7%	3	100.0%
Increased >2 million	4	8.9%	2	50.0%
Decreased >2 million	4	8.9%	0	0.0%
Decreased >5 million	1	2.2%	0	0.0%
Decreased >10 million	3	6.7%	0	0.0%
Stayed the same	11	24.4%	0	0.0%
TOTAL	45		22

ANTIRETROVIRAL THERAPY IN HIV-POSITIVE MEN AND IVF OUTCOMES IN EGG DONATION PLUS SURROGACY PROGRAMS. Diana Obidniak, Dr.,[1] Alexander Gzgzyan, Prof.,[2] Dariko Niauri, Prof.,[2] Igor Kogan, Prof.[3] [1]AVA-Peter, Saint-Petersburg, Russian Federation; [2]Saint Petersburg State University, Saint-Petersburg, Russian Federation; [3]FSBSI "The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O. Ott", Saint-Petersburg, Russian Federation.

OBJECTIVE: The aim of the study was to investigate if antiretroviral therapy (HAART) in HIV-positive men brings significant impact on outcomes of assisted reproductive technology.

DESIGN: Study Design: observational

Size: 38 cycles of embryo transfers

Duration: 24 months

MATERIALS AND METHODS: With the aim to minimize bias associated with female infertility impact on IVF outcomes we have indicated following inclusion criteria: egg donation cycle with preimplantation genetic testig (PGT-A) and surrogacy program in couples with HIV – positive and HIV- negative men. Exclusion criteria: severe male factor, abnormal karyotype, absence of antiretroviral therapy in HIV-positive men. From January 2018 till December 2019 38 cycles satisfying matching were included. The cases were divided into study group - HIV-positive +HAART (N = 19) and control group – HIV- negative (N = 19). In all cases selective embryo transfer was performed with endometrial preparation being carried out according to standartized protocol of hormone replacement therapy with ultrasound monitoring. The primary assessed outcome was clinical pregnancy rate. The secondary assessed outcome was miscarriage rate.

RESULTS: As a primary assessed outcome the clinical pregnancy rate was analysed: there was no difference comparing between groups (13/19 (68.4%), 13/19 (68.4%) X^2=0.0, p>0.05). The secondary assessed outcome was miscarriage rate being 7-fold higher in study group in comparison to control group (7/13 (53.8%) vs 1/13 (7.6%), X^2=6.5, p=0.011).

CONCLUSIONS: These data demonstrate that HAART in HIV-positive men seems may cause significantly (7-fold) elevated risk of pregnancy loss.

There is need for proper investigation of HAART effect on sperm quality and DNA fragmentation as possible reasons for elevated risk of miscarriage.

Given strict matching criteria the number of included cases is highly limited. Further investigation is needed.

ASSOCIATION OF AGING AND OBESITY WITH DECREASED INTRATESTICULAR TESTOSTERONE. Thiago Fernandes Negris Lima, MD,[1] Fabio Stefano Frech, BS,[2] Ruben Blachman-Braun, M.D., M.Sc.,[2] Evgeniya Rakitina, MS,[2] Premal Patel, M.D.,[3] Ranjith Ramasamy, MD,[1] [17]ohp[1]University of Miami, Miami, FL; [2]University of Miami Miller School of Medicine, Miami, FL; [3]University of Manitoba, Winnipeg, MB, Canada.

OBJECTIVE: To evaluated the association between BMI and LH, BMI and ITT (using serum 17-hydroxyprogesterone (17-OHP) as a biomarker) in a cross-sectional study. Obesity's negative association with serum testosterone (T) levels can be explained by either decreasing luteinizing hormone (LH) production from the pituitary gland and/or directly impact intratesticular testosterone (ITT) production. We hypothesize that obesity will negatively impact ITT production when compared to non-obese men.

DESIGN: We performed a cross-sectional analysis of men with symptoms of testosterone deficiency and male infertility between July/2018 - April/2020.

MATERIALS AND METHODS: We included men with symptoms of testosterone deficiency and/or infertility and measurements of 17-OHP, serum testosterone, serum estradiol and LH levels. We excluded men receiving agents that alter ITT, exogenous testosterone, CC or hCG during the baseline assessment. Primary outcome was to evaluate the effect of BMI on 17-OHP and LH. Univariable and multiple linear regression analysis were performed using confounding variables to predict 17-OHP and T.

RESULTS: A total of 340 men were selected. Median age was 38 [33 - 44] years, BMI 27.8 [25.4 - 31.1] kg/m^2, T 363 [256.3 - 469.6] ng/dL, 17-OHP 60.5 [39.3 - 85.8]ng/dL, estradiol 22 [16.3 - 30], and LH 4.2 [2.8 - 5.7] mIU/mL. As expected, older and obese men were associated with having a lower T level as compared to younger and non-obese men. Interestingly, increasing age and higher BMI were associated with a lower 17-OHP level. Contrarily, age and BMI weren't associated with LH levels (p=0.478). In the multiple regression model, increasing BMI and older age predicted a decrease in 17-OHP ($p < 0.001$). (Table 1).

CONCLUSIONS: Obesity and aging negatively affected 17-OHP independent of LH. This suggests that obesity-related changes in serum T and 17-OHP (ITT) could be due to direct effect to testicular function, rather than secondary effect from decline in pituitary function.

Table 1. Univariable and multivariable logistic regression analysis for 17-OHP (ng/dL)

TESTICULAR ULTRASOUND AS A PROGNOSTIC FACTOR FOR IMPROVEMENT IN SEMEN PARAMETERS AFTER VARICOCELECTOMY.

Vanessa Peña, BS,[1] Taylor P. Kohn, MD, MPhil,[2] Yasin Bhanji, MD,[1] Ridwan Alam, MD, MPH,[1] James Liu, MD,[1] Andrew T. Gabrielson, MD,[1] Matthew J. Rabinowitz, BS,[1] Amin S. Herati, MD[3] [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, Mexico; [3]John Hopkins University School of Medicine, Baltimore, MD.

OBJECTIVE: It is difficult to identify the sub-groups of infertile men who will benefit most from varicocelectomy. We theorize that advanced processing of ultrasound images can predict testicular sperm density as posterior acoustic enhancement could result in increased echogenity and heterogeneity as ultrasound waves pass through larger seminiferous tubules. The objective of our study was to evaluate testicular ultrasound heterogeneity as a predictor for improved semen parameters after varicocelectomy.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Infertile men undergoing varicocelectomy were included if they had a pre-operative testicular ultrasound plus pre- and post-operative semen analysis. Azoospermic men were excluded. Greyscale testicular ultrasound images were assessed with pixel intensity histogram. The standard deviation (SD) of the histogram was theorized to measure heterogeneity and thus representative of testicular sperm density. The average histogram SD of bilateral testicles was taken. Linear regression was performed to assess the correlation between the pre-operative average histogram SD and the change in total motile sperm count (TMSC) following varicocelectomy.

RESULTS: Twenty-two men were included. Median preoperative TMSC was 22.1 million sperm (IQR: 9.0-44.5). Fifteen men experienced an increase in TMSC after varicocelectomy: median increase 16.1 million sperm (IQR: 2.9-24.0) and median pixel SD 10.94 (IQR: 9.53-12.54). The remaining seven men experienced a decline in TMSC: median decrease 27.6 million sperm (IQR: 19.9-29.6) and median pixel SD 8.04 (IQR: 7.69-9.30). A greater pre-operative average histogram SD was associated with a greater improvement in TMSC following varicocelectomy ($p=0.004$, $R^2=0.34$).

CONCLUSIONS: This novel method to evaluate testicular heterogeneity may help predict which men will experience an improvement in semen parameters after varicocelectomy.

P-677 4:30 PM Tuesday, October 20, 2020

INTRACYTOPLASMIC SPERM INJECTION OUTCOME OF EJACULATED VERSUS TESTICULAR SPERM IN CRYPTOZOOSPERMIC MEN.

Sonia Mnallah, Dr, Mohamed Khrouf, Dr, Mariem ben Khelifa, PhD, Hanen Elloumi, Dr, Walid Kerkeni, Dr, Fethi Zhioua, Dr, Moncef Benkhalifa, PhD, Khaled Mahmoud, Dr FERTILLIA center, Tunis, QC, Tunisia.

OBJECTIVE: Cryptozoospermic men have very low quality of spermatozoa in their ejaculates, resulting in poor ICSI outcomes. It is widely discussed that spermatozoa may damage when passing through the male reproductive tract by affecting sperm DNA intgrity. In the other hand, potential immaturity of testicular spermatozoa could have a negative impact on ICSI outcomes affecting fertilization and embryo developement. Nowadays, the use of testicular spermatozoa in ICSI when ejaculate sperm is available remain controversial and has not been applied yet to routine.the aim of our study is to evaluate if testicular sperm superior could be superior to ejaculated sperm for intracytoplasmic sperm injection in cryptozoospermia cases?

DESIGN: Prospective cohort study held in a Fertillia ART center in Tunisia from october 2018 to december 2019. A total of 41 couples, who underwent ICSI cycles followed by embryo transfer were included. Our study was conducted on couples with cryptozoospermic partner. Cases with female infertility factor were excluded. Fertilization rate (FR), embryo quality, implantation rate (IR) and pregnancy rate (PR) were reproductive variables considered to be compared among study groups.

MATERIALS AND METHODS: Fourty one patients with cryptozoospermia were randomly allocated to two groups. Groupe 1 (n=21) used ejaculated sperm, and group 2 (n=20) had testicular sperm. There was no differences in age, duration of infertility and type of infertility between the two groups.

RESULTS: The mean female and male age were respectively comparable between group 1 and 2 (32.55 VS 33.2 years ; $p>0.05$) ; (41.6 VS 42.5 years ; $p>0.05$). No differences regarding number of oocytes retrieved or MII oocytes were reported but it was observed, a slight improvement in sperm count and progressive motility in testicular sperm comparing to ejaculated sperm. Fertilization rate was significantly higher in testicular sperm group (Group 1) when compared to ejaculated sperm (57% VS 48% ; $p<0.01$). Furthermore, statistical significance was also achieved when comparing IR (6.5% vs 19%) and PR (11% vs 31%) between respectively group 1 and group 2. Comparing the two groups, no differences were found in the quality and the number of embryos transferred.

CONCLUSIONS: We conclude that the use of testicular sperm should be applied to patients with cryptozoospermia undergoing ICSI

P-678 4:30 PM Tuesday, October 20, 2020

THE IMPACT OF TESTICULAR DELIVERY AND VASAL VEIN LIGATION ON SERUM TESTOSTERONE IN MEN UNDERGOING MICROSURGICAL VARICOCELECTOMY.

Nahid Punjani, MD MPH,[1] Gal Wald, BA,[1] Christopher Gaffney, MD,[2] James A. Kashanian, MD,[3] Marc Goldstein, M.D.[4] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Weill Cornell Medical College- New York Presbyterian Hospital, New York, NY; [3]Weill Cornell Medicine - New York Presbyterian Hospital, New York, NY; [4]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To determine if microsurgical varicocelectomy technique impacts serum testosterone levels.

DESIGN: Retrospective data collection.

MATERIALS AND METHODS: Men undergoing microsurgical varicocelectomy between 2017 and 2020 for any indication by two high-volume surgeons at Weill Cornell were reviewed. Surgeon 1 (Method 1) used testicle delivery with gubernacular vein ligation as well as ligation of dilated vasal veins >2.5mm. Surgeon 2 (Method 2) did not perform testicle delivery and therefore no ligation of gubernacular veins, and only removed vasal veins in the case of a recurrence. Pre-operative and post-operative serum testosterone levels were compared based on the two methods, for all patients, as well as for unilateral and bilateral cases using the Wilcoxon ranked-sum test (Stata v14).

RESULTS: 313 patients were included. Of these, 162 (51.8%) had microsurgical varicocelectomy using Method 1 and 151 (48.2%) using Method 2. Demographic data was similar between groups. Median age for Method 1 was 35 (IQR 27-42) and 34 (IQR 28-39) for Method 2. Mean BMI was 25.4 ± 4.0 kg/m^2 for Method 1, and 25.9 ± 4.5 kg/m^2 for Method 2. The majority had bilateral surgery for Method 1 (n=84, 51.9%), and 78 (48.1%) had a unilateral procedure. For Method 2, 63 (41.7%) patients had bilateral surgery with the remaining 88 (58.3%) having a unilateral procedure. A statistically significant difference was observed for testosterone levels between groups, with a difference of 145.0 ± 232.7 ng/dl for Method 1 as compared to 37.8 ± 105.0 ng/dl for Method 2 ($p=0.03$). When subdivided as unilateral and bilateral, the difference was 187.4 ± 254.7 for Method 1 examining only unilateral varicocelectomies, versus 55.0 ± 112.1 for Method 2 ($p=0.09$). For bilateral cases the difference was 115.5 ± 215.2 for Method 1 versus 16.3 ± 95.6 for Method 2 ($p=0.11$).

Table 1 – Comparison of pre-operative and post-operative testosterone based on technique

Testosterone	Method 1	Method 2	
All			
Pre-op	362.5 (128.3), n=56	337.4 (116.7), n=27	
Post-op	507.5 (236.6), n=56	375.2 (135.4), n=27	
Difference	145.0 (232.7), n=56	37.8 (105.0), n=27	**p=0.03**
Unilateral			
Pre-op	326.5 (105.6), n=23	288.3 (89.2), n=15	
Post-op	513.9 (248.7), n=23	343.3 (123.5), n=15	
Difference	187.4 (254.7), n=23	55.0 (112.1), n=15	**p=0.09**
Bilateral			
Pre-op	387.5 (138.0), n=33	398.8 (121.2), n=12	
Post-op	503.0 (231.6), n=33	415.1 (144.2), n=12	
Difference	115.5 (215.2), n=33	16.3 (95.6), n=12	**p=0.11**

CONCLUSIONS: Microsurgical varicocelectomy improves serum testosterone levels with both techniques, but improvement appears to be greater with gubernacular and enlarged vasal vein ligation. Future prospective studies investigating this observation are warranted.

P-679 4:30 PM Tuesday, October 20, 2020

IS TESTICULAR SIZE DISCREPANCY ASSOCIATED WITH SEMEN PARAMETERS IN BOYS WITH VARICOCELES?. Justin M. Dubin, MD,[1] Belen Mora, BA,[1] Nehizena S. Aihie, MD,[1] Laura Angulo-Llanos, MD,[1] Thomas A. Masterson, III, MD,[1] Alireza Alam, MD[2] [1]University of Miami Miller School of Medicine, Miami, FL; [2]Nicklaus Children's Hospital, Miami, FL.

OBJECTIVE: Varicocele is the most common surgically correctable cause of infertility in adult men; however, >80% are asymptomatic. While believed to cause a progressive decline in semen parameters, treating varicoceles in the pediatric population is controversial because of uncertain pathogenesis. Current recommendations are to correct a varicocele when there is a >20% ipsilateral testicular size discrepancy, but associations with semen parameters are not well studied. We hypothesized that boys with varicoceles and >20% testicle size discrepancy will have lower sperm concentration and motility compared to boys with varicoceles and <20% size discrepancy

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: We retrospectively identified boys <18 years old diagnosed with a varicocele from a large regional pediatric urological practice from 2013 to 2020. We included patients with at least one semen analysis and scrotal ultrasound with measurements of the right and left testicles. We then compared semen sperm concentration and motility of boys with >20% testis size discrepancy to those with <20% discrepancy, calculated as (right-left)/(total testis volume). Unpaired t test was used to determine significance.

RESULTS: We identified 819 boys with a diagnosis of varicocele. Of them, 72 had a semen analysis and testicular ultrasound. There were 26 boys with >20% ipsilateral testicular size discrepancy and 46 with <20% ipsilateral testicular size discrepancy. For boys with >20% ipsilateral testicular size discrepancy, the mean semen concentration and motility were 55.7 $\pm$ 65.9 million and 44.8 $\pm$ 23.9% compared to 59.9 $\pm$ 48.7 million (p= 0.76) and 52.1 $\pm$ 20.7% (p= 0.17) for boys with <20% testis size discrepancy, respectively. We also compared semen parameters for those with >20% testicular discrepancy vs those with <10% discrepancy (28 boys), for which there was no significant difference.

CONCLUSIONS: Based on a single institution cohort, it appears that testicular size discrepancy is not associated with semen concentration or motility in boys with varicoceles.

SUPPORT: None

P-680 4:30 PM Tuesday, October 20, 2020

PRESENCE OF VARICOCELE-ASSOCIATED PAIN DOES NOT PREDICT SEMEN ANALYSIS OUTCOMES FOLLOWING MICROSURGICAL REPAIR. Nahid Punjani, MD MPH,[1] Gal Wald, BA,[1] Christopher Gaffney, MD,[2] Marc Goldstein, M.D.,[3] James A. Kashanian, MD[4] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Weill Cornell Medical College- New York Presbyterian Hospital, New York, NY; [3]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [4]Weill Cornell Medicine - New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To assess whether varicocele-associated pain predicts semen analysis parameters after microsurgical varicocelectomy.

DESIGN: Retrospective data collection.

MATERIALS AND METHODS: We assessed all men who were diagnosed with a varicocele by two surgeons at Weill Cornell Medicine between 2017 and 2020. Men with varicocele who did not undergo surgical treatment and who did not have both pre-operative and post-operative semen analysis data available were excluded. All included patients had a microsurgical varicocelectomy. Patients were stratified based on the presence of pain at the time of clinical assessment. Contrast between demographics (t-test and chi-square) and semen parameters (Wilcoxon-rank sum) between the two groups were assessed using Stata v14.

RESULTS: A total of 313 men were included, with relatively similar proportions completed by both surgeons (48.2% and 51.8%). A total of 98 (31.3%) had typical varicocele-associated pain at the time of assessment, and the remainder (n=215, 68.7%) did not. The pain group was younger than the no pain group (30.5 vs. 35.0, respectively, p<0.01). Although not statistically different, there was a greater portion of left sided-only varicoceles compared to right sided-only or bilateral varicoceles in the pain group (58.2% vs. 47.9%, respectively, p=0.09). No significant differences were demonstrated between sperm concentration, motility, volume or morphology pre-operatively, or post-operatively in the pain versus no-pain group (Table 1).

CONCLUSIONS: In our series, almost 1/3 of men presented with typical varicocele-associated pain. Pain does not predict response to varicocelectomy, but individuals with pain tend to be younger, and trend toward more left sided varicoceles.

Table 1 – Comparison of demographics and semen parameters for pain vs. no pain

	Pain (N=98)	No Pain (N=215)	p-value
Demographics (mean, n)			
Age (median, IQR)	30.5 (23-41)	35.0 (31-41)	p<0.01

POSTWASH TOTAL MOTILE SPERM COUNT EFFECT ON PREGNANCY OUTCOMES IN INTRAUTERINE INSEMINATION. Melissa A. Mathes, MD, Elizabeth A. Kastrick, MD, Stephanie Gustin, MD The University of Nebraska Medical Center, Omaha, NE.

OBJECTIVE: Intrauterine insemination (IUI) is a frequently used method to treat couples with infertility. There is evidence of decreased pregnancy rates with total motile sperm count (TMSC) less than 5 and 10 million (1,2), yet there has been efficacy of reported IUI success with TMSC under 1 million (2). As such, there remains to be a consensus on semen parameters for which to recommend IUI in the infertile population. Further defining TMSC and associated pregnancy rates allows for more precise patient counseling and may also delineate a clearer threshold for escalation of care to in vitro fertilization. This may decrease the time to pregnancy and the financial burden of offering infertility treatment that is less likely to be effective. The aim of this study was to determine a minimum threshold of TMSC on semen analysis to offer IUI cycles.

DESIGN: A retrospective cohort study of all IUI cycles at a private practice infertility center from June 2014 to May 2018.

MATERIALS AND METHODS: This is a retrospective cohort study of all IUI cycles at a private practice infertility center from June 2014 to May 2018. We obtained female characteristics including age, gravida, parity, BMI,

AMH, AFC, tubal patency, stimulation, number of dominant follicles, and ET. Semen was processed with a gradient centrifugation process and the following semen parameters were collected: post wash TMSC, concentration, motility, and wet mount morphology. Our primary outcome of interest was the presence or absence of clinical pregnancy after each cycle. Clinical pregnancy was defined as fetal cardiac activity on ultrasound.

RESULTS: A total of 999 women underwent 2169 IUI cycles during this four-year period. The average couple underwent 2.17 IUIs. The overall clinical pregnancy rate was 19.8% per cycle while pregnancy rate of only the first IUI per patient was 19.2%. Overall, clinical pregnancy rate per couple was 40.2%. During the first IUI each couple underwent, there was an increase in clinical pregnancy with increasing TMSC, OR 0.44 for TMSC $\leq$1M, 0.56 for TMSC 2-5M, and 0.99 for TMSC 6-10M, compared to TMSC >10M with p-values of 0.27, 0.057 and 0.975 respectively. Using receiver operating characteristic curves, we did not identify a TMSC threshold to offer IUI but rather a linear increase of sensitivity and specificity to predict pregnancy with increased TMSC. The lowest TMSC resulting in pregnancy was 660,000. With TMSC 6-10M, pregnancy outcomes improved with morphology >4% OR 0.84, compared to morphology <4% OR 0.25. There were 39 multifetal gestations, 9.1% of all clinical pregnancies.

CONCLUSIONS: Although no distinct threshold of TMSC was identified to offer IUI versus proceeding with ART, there is a positive correlation between TMSC and IUI success. There appears to be improved outcomes with morphology >4% when TMSC <10. A follow up study, using a larger sample size, is necessary to further characterize the upper limits of efficacy of IUI specimens. Well-defined pregnancy rates based on semen parameters will allow for more direct counseling of infertility patients and also allow for more targeted therapy recommendations based on pregnancy success rates.

DOES MICROSURGICAL VARICOCELECTOMY IMPROVE CLINICAL OUTCOMES IN ALL VARICOCELE GRADES.

Gal Wald, BA,[1] Nahid Punjani, MD MPH,[1] Omar Al Hussein Alawamlh, MD,[1] Vanessa L. Dudley, MSHS,[2] Marc Goldstein, M.D.[2] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To assess the impact of varicocele grade on microsurgical varicocelectomy.

DESIGN: Retrospective data collection.

MATERIALS AND METHODS: Men between 2008 and 2020 diagnosed with varicocele were reviewed. We included men who had documented sonographic assessment and underwent microsurgical varicocelectomy (unilateral or bilateral) at Weill Cornell by a single high volume surgeon. Patients were stratified according to varicocele grade based on physical examination. Clinical outcomes (sperm concentration (SC), TUNEL and testosterone (T) levels) were compared among men pre-operatively and post-operatively using the nonparametric Wilcoxon signed-ranked test (Stata v14).

RESULTS: A total of 396 patients were included. Median age was 36 (IQR 31-42) and median BMI was 25.3 (IQR 23.1-27.6). On physical exam, median orchidemeter assessed testis size was 18cc (IQR 15-20) on the right and 15cc (IQR 12-18) on the left. 136 patients underwent varicocelectomy on the left (34.3%), 8 on the right (2.0%), and 252 bilateral (63.6%). Of these men, 389 had documented physical exam grade on the left (Grade III: 55.8%, Grade II: 25.7%, Grade I: 9.3%, None: 9.3%) and on the right (Grade III: 5.1%, Grade II: 21.1%, Grade I: 21.1%, None: 52.7%). For Grade III varicoceles, T, TUNEL and SC has significant improvement on the left ($p<0.05$, $p<0.01$, $p<0.0001$, respectively) and SC on the right ($p<0.05$). For grade II varicoceles, significant differences were seen in T on the left ($p<0.0001$) and SC on the right ($p<0.01$). Patients with grade I had significant improvement in T on the left ($p<0.01$) and both T and SC on the right ($p=0.001$, $p<0.05$, respectively) (Table 1).

CONCLUSIONS: Microsurgical varicocelectomy improves testosterone levels and semen concentration irrespective of clinical grade. Repair of grade III varicocele had statistically significant improvements in all three parameters: SC, T and TUNEL.

P-683 4:30 PM Tuesday, October 20, 2020

URINE-DERIVED STEM CELLS DERIVED EXOSOMES FACILITATE ENDOGENOUS SPERMATOGENESIS RESTORATION OF BUSULFAN-INDUCED NON-OBSTRUCTIVE AZOOSPERMIA MICE.

Guihua Liu, Ph.D.,[1] Xing Yang, Ph.D.,[1] Tingting Li, Doctor[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: Non-obstructive azoospermia (NOA) is the most severe issue without effective treatments in male infertility. The aim of this study is to investigate whether transplantation of urine-derived stem cells (USCs) or USCs-exosomes (USC-exos) could promote endogenous spermatogenesis restoration in a busulfan-induced NOA mice model.

DESIGN: Animal study was designed.

MATERIALS AND METHODS: USCs were cultured and characterized by flow cytometry. High-density USCs were cultured in hollow fiber bioreactor for exosomes collection. USC-exos were isolated from USCs conditional media and identified by transmission electron microscopy, western blot and Flow NanoAnalyzer. USC-exos exhibited a sphere- or cup- shaped morphology with a mean diameter of 66.5±16.0 nm and expressed CD63 and CD9. USCs and USC-exos were transplanted into interstitial space in testes of NOA mice (40 mg/kg) as following groups: Normal group, groups treated with no injection, PBS or USCs on the 0 days after busulfan administration respectively, and groups treated with no injection, PBS, USCs or USC-exos on the 36 days after busulfan treatment separately.

RESULTS: Thirty days after USCs and USC-exos transplantation, the spermatogenesis was restored by both USCs and USC-exos in NOA mice of 36 days after busulfan-treated confirmed by immunofluorescence staining and hematoxylin and eosin (H&E) staining. Moreover, spermatogenic genes (*Pou5f1*, *Prm1* and *SYCP3*) and spermatogenic protein UCHL1 were significantly increased in both USCs 36 and USC-exos36 group compared to PBS treated group demonstrated by using *qRT-PCR* and western blot analysis. However, transplantation of USCs at day 0 after busulfan treatment didn't improve the spermatogenesis of NOA mice.

CONCLUSIONS: Our study demonstrated that USCs could facilitate endogenous spermatogenesis restoration of busulfan-induced NOA mice through paracrine exosomes, but could not protect the mice testicles at early stage of destruction caused by busulfan. This study provides a novel insight in the treatment of NOA.

THE IMPACT OF ADVANCED MALE AGE ON ASSISTED REPRODUCTION PROCEDURES' OUTCOMES.

Bibiana Cunegatto, Msc,[1] Marta Ribeiro Hentschke, MD, PhD,[1] Claudio Teloken, MD, PhD,[1] Alvaro Petracco, MD, PhD,[1] Mariangela Badalotti, MD, MSc, PhD,[1] Charles Francisco Ferreira, MSc. PhD.,[2] Ricardo Azambuja, DVM, PhD,[1] Maria Teresa V Sanseverino, MD, PhD,[3] Mirela Foresti Jimenez, MD, Msc[4] [1]Fertilitat-Centro de Medicina Reprodutiva, Porto Alegre, Brazil; [2]Federal University of Rio Grande do Sul, Porto Alegre, Brazil; [3]Fertilitat, porto alegre, Brazil; [4]UFRGS, PORTO ALEGRE, Brazil.

OBJECTIVE: Male reproductive aging may affect several determinants in ART outcomes. The literature usually considers the age of 40 as the upper limit. After this period, the semen seems to have changes in qualitative factors that may modify fertility and cause adverse events in future generations. Does male age influence assisted reproduction techniques when laboratory and clinical parameters are evaluated?

DESIGN: A retrospective cross-sectional study was conducted using a database from an assisted reproduction clinic, in Brazil, between 2015 and 2018. A total of 2125 procedures met the eligible criteria.

MATERIALS AND METHODS: The sample was divided into two groups according to male age: group 1 (n=1429) ≤40 years and group 2 (n=696) men ≥41 years. ICSI was performed in all cases. Mann-Whitney test, Student's t-test and Chi-square test were applied for statistical analysis. Data were adjusted for "female age" and "vasectomy" by Analysis of Covariance (ANCOVA), when applicable. The null hypothesis was rejected when $p < 0.05$.

RESULTS: A decrease in seminal volume and sperm motility was observed in group 2 (p=0.001), with no changes in seminal concentration (p>0.05). A higher number of cleavage embryos were transferred in group 2, while a higher number of blastocysts were transferred in group 1 (p≤0.001). Apgar index in the first and fifth minutes were lower in group 2 for single and twin pregnancies (p<0.05). The IVF indication due to oligospermia was the highest in group 1, while the highest in group 2, was the vasectomy.

CONCLUSIONS: Advanced male age appears to be a possible influential factor on seminal characteristics, specially sperm volume and motility. Hence, even though previous literature points out female age as the main IVF outcome influencer, male age should not be left aside.

P-685 4:30 PM Tuesday, October 20, 2020

THE USE OF SERUM INHIBIN B TO ASSESS RECOVERY OF SPERMATOGENESIS IN MALES WITH HISTORY OF RECENT EXOGENOUS ANDROGEN EXPOSURE.

Kurt R. Peterson, DO,[1] Shane Russell, MD,[2] Julie Sroga Rios, MD[3] [1]University of Cincinnati, Cincinnati, OH; [2]The Urology Group/Male Reproductive Medicine, Cincinnati, OH; [3]University of Cincinnati and Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

OBJECTIVE: Predicting adequate recovery of spermatogenesis in post-vasectomy males seeking vasectomy reversal or sperm aspiration in a setting of recent testosterone replacement therapy (TRT) is clinically challenging. The time to recovery of spermatogenesis after cessation of TRT varies from 6 months to 2 years, or never in some cases. FSH levels are not reliably predictive as they are affected by TRT itself and common treatments administered post TRT. Diagnostic aspirations can confirm the presence of spermatogenesis, though they carry inherent procedural risk and cost without producing any usable sperm. Accurate, non-invasive, and predictive screening is needed. This study assesses the value of serum inhibin B levels in accurate prediction of the return of spermatogenesis in this unique population.

DESIGN: An IRB approved retrospective case series of ten consecutive post-vasectomy patients with recent testosterone replacement therapy (TRT) who underwent a vasectomy reversal or sperm aspiration procedure between January 1st, 2016 and March 1st, 2018 performed by a reproductive urologist.

MATERIALS AND METHODS: FSH, testosterone & inhibin B levels were followed after cessation of TRT. A cutoff value of serum inhibin > 130 pg/mL was used to predict the presence of adequate spermatogenesis for timing of surgical intervention with vasectomy reversal or sperm aspiration procedures. Sperm motility and density (number of sperm per high performance field) were assessed in the extracted testicular tubules in all sperm aspiration procedures. For vasectomy reversals, intraoperative vasal/epididymal fluid was assessed for the presence of sperm and/or sperm parts. Post-reversal total sperm counts were measured using standard semen analysis testing by independent laboratories.

RESULTS: Evidence of adequate spermatogenesis was noted in eight patients with inhibin B levels > 130 pg/mL around the time of their procedures (five sperm aspirations, three vasectomy reversals). Decreased spermatogenesis was noted in two patients with inhibin B levels of < 130 pg/mL (both were sperm aspiration procedures). Time to normalization of inhibin B ranged from 1 to 15 months. Shorter times (1 to 6 months) were seen in men who used injectable testosterone and longer times (9 to 15 months) for those with implanted testosterone pellets.

CONCLUSIONS: Serum inhibin B levels provided accurate, non-invasive prediction of the recovery of spermatogenesis in males with recent TRT. If validated in larger studies, serum inhibin B levels could help optimize the timing of vasectomy reversals and sperm aspiration procedures.

P-686 4:30 PM Tuesday, October 20, 2020

IMPACT OF SPERM DNA FRAGMENTATION ON PRE- AND POST-WASH SEMEN SAMPLES AND PREGNANCY OUTCOME WITH INTRACYTOPLASMIC SPERM INJECTION.

Kareim Khalafalla, MD, Mohamed Arafa, MD, Haitham Elbardisi, MD, Hasan Burjaq, MSc, Moza Al Badr, MSc, Sami Alsaid, MD, Ahmad Majzoub, MD Hamad Medical Corporation, Doha, Qatar.

OBJECTIVE: The spermatozoa nuclear component especially it's DNA integrity is essential for normal fertilization, pregnancy & embryo development. Currently sperm DNA fragmentation (SDF) testing is one advanced sperm function test used along other conventional tests to evaluate male infertility.We aim to assess the impact of SDF on pre- & post-wash semen parameters and to investigate effect of various SDF cut-off values on pregnancy outcome with Intracytoplasmic sperm injection (ICSI).

DESIGN: Retrospective, Chart review.

MATERIALS AND METHODS: The charts of 2277 patients who underwent ICSI were reviewed. 481 infertile men who had SDF testing were included. Patients demographic & laboratory data along with ICSI cycle

outcome were included. Semen samples & SDF were analyzed according to WHO 5thedition guidelines & sperm chromatin dispersion (Halosperm kit, Halotech, Madrid, Spain) respectively. Patients were divided according to SDF cut-offs; <20, 20-30 & >30%. Variables were reported as mean ± SE and compared using Kruskal Wallis Test. P value of <0.05 was considered statistically significant

RESULTS: The mean patient age was 36.88 ± 0.362, while mean SDF was 25.41± 0.72. The pre & post wash semen parameters in patients with SDF cut-offs <20, 20-30 & >30% were compared (Table 1). Significantly worse results were obtained with increasing SDF cut-offs for pre- & post-wash sperm concentration, total motility & post-wash normal morphology.

SDF was significantly inversely correlated with **pre wash parameters** (concentration: r -.140, p=o.oo3; total Motility: r -.282, p<0.001; normal morphology: r -.143, p=0.003) and **post wash parameters** (concentration: r -.156, p=o.oo1; total Motility: r -.218, p<0.00; normal morphology: r -.140, p=0.002)

The clinical pregnancy rate decreased with increasing SDF cut-offs (44.4% with SDF <20%, 31.4% with SDF 20-30% and 24.3% with SDF >30), though the result was not statistically significant

CONCLUSIONS: SDF negatively impacts pre-& post-processing semen parameters for patients undergoing ICSI. This may influence ICSI pregnancy rate, though the impact was not statistically significant in this cohort.

RESULTS: 390 patients performed TESE-ICSI cycles with their own oocytes, with a mean time postvasectomy of 11.7 years (CI95% 11.1-12.3) and a BMI of 26.5 kg/m^2 (CI95% 26.1-27.0). Of all of them, 130 (33.9%) were smokers. No statistical differences were found between groups based on time since vasectomy in LBR per ET (Q1:30.5%, Q2:40.0%, Q3:40.7%, Q4:26.9%) and per COS (Q1:21.3%, Q2:23.3%, Q3:28.1%). However, significantly lower live birth rate per couple (p=0.02) was shown in the group with the highest vasectomy time: Q1:41.4%, Q2:48.3%, Q3:52.3%, Q4:31.2%. No significant differences were found in CLBR depending on the number of embryos transferred comparing post-vasectomy periods. When two embryos were replaced, CLBR were in Q1:34.5% and in Q4:27.7% and reached 52.5%(Q1) and 48.7%(Q4) when four embryos were consumed, increasing the chances of having a newborn by 18% in the first group and 21% in Q4. When up to 7 embryos were replaced, the CLBR was 72.4% in Q1 and 74% in Q4. When considering the BMI, none of the LBR compared were statistically significant. CLBR were higher in the lower BMI quartiles (Q2:46.5 % *vs* Q4:28.6% with two embryos replaced, Q2:55.0% *vs* Q4:59.9% and Q2:63.4% *vs* Q4:67.6% when four and even six embryos were transferred, respectively), without statistically significant differences. The live birth rate of smokers was comparable to those of non-smokers: 33.7% *vs* 33.8% per ET, 22.5% *vs* 23.2% per COS, and 43.8% *vs* 42.50% per couple. Cumulative LBR per embryo was similar in both groups with no statistical difference between them (p>0.05).

Parameters	Total	SDF <20	SDF 20-30	SDF >30	P Value
Pre wash Concentration (M/ml)	38.94 ± 1.69	45.24 ± 2.79	35.82 ± 2.61	30.57 ± 2.87	0.016
Pre wash Total Motility %	38.61 ± 0.9	44.18 ± 1.28	37.82 ± 1.62	29.26 ± 1.68	<0.001
Pre wash Normal Morphology %	12.49 ± 0.61	12.01 ± 0.78	14.53 ± 1.35	11.18 ± 1.27	0.121
Post Wash Concentration (M/ml)	13.93 ± 0.63	15.96 ± 0.95	13.854 ± 1.12	9.95 ± 1.16	<0.001
Post Wash Total Motility %	4.21 ± 0.27	5.24 ± 0.45	3.99 ± 0.43	2.45 ± 0.47	<0.001
Post Wash normal Morphology %	12.31 ± 0.65	12.12 ± 0.89	13.36 ± 1.31	11.53 ± 1.37	0.010

P-687 4:30 PM Tuesday, October 20, 2020

TIME SINCE VASECTOMY, BUT NEITHER SMOKING NOR BODY MASS INDEX (BMI) INFLUENCE IN VASECTOMIZED MEN REPRODUCTIVE OUTCOMES UNDERGOING TESTICULAR SPERM EXTRACTION WITH INTRACYTOPLASMIC SPERM INJECTION (TESE-ICSI). Nicolas Garrido, PhD,[1] Lorena Valls, M.D,[2] Irene Hervas, MSc,[3] Rocio Rivera-Egea, PhD,[4] Maria Gil Julia, MSc, MRes,[3] Jose Maria Martinez-Jabaloyas, M.D[4] [1]IVI Foundation - IIS La Fe Biomedical Research Institut, Valencia, Spain; [2]Hospital Clínico de Valencia, Valencia, Spain; [3]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [4]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: Vasectomy is the most common male contraceptive method, but changes in personal circumstances may result in regret and consideration of a reversal or undergoing an assisted reproduction treatment (ART). Although suspected relevant, little is known about the influence of factors conditioning their reproductive outcomes and data available so far are limited. This information would aid counseling and medical care. The objective of this study is to evaluate if time since the seminal duct was intervened, BMI and smoking habits negatively affect the reproductive success of TESE-ICSI

DESIGN: Retrospective study.

MATERIALS AND METHODS: Data from vasectomized patients who underwent TESE-ICSI were assessed. Quartiles (Q_n) were established to compare time since vasectomy and BMI, and tobacco consumption. Main outcome was live birth rate (LBR) per embryo transfer (ET), per controlled ovarian stimulation (COS) and per couple. Chi-square test were applied to compare proportions and Survival curves using the Kaplan Meier and Breslow's tests were built to compute the cumulative live birth rate (CLBR) considering the number of embryos consecutively transferred until a newborn was achieved.

CONCLUSIONS: The time since the vasectomy renders worse reproductive success rates per patient, while BMI and tobacco consumption seem not to be influencing outcomes in a program of ICSI using own oocytes from vasectomized males.

P-688 4:30 PM Tuesday, October 20, 2020

THE IMPACT OF HIGH SPERM CHROMATIN FRAGMENTATION ON INTRAUTERINE INSEMINATION OUTCOME. Mounia Haddad, M.D., Derek Keating, B.A., Alessandra Parrella, M.Sc., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To evaluate how the genomic integrity of spermatozoa affects IUI pregnancy outcomes in couples with unexplained infertility.

DESIGN: During the last 4 years, 132 couples with unexplained infertility who were undergoing IUI treatment at our center were included. In these couples, the male partners had normal semen parameters and the female partners had negative infertility workups. To identify an eventual male factor, we screen all men for sperm chromatin fragmentation (SCF) assay. IUI clinical outcome was assessed and compared between couples with normal and abnormal SCF.

MATERIALS AND METHODS: Men with normal semen parameters consented to have their SCF measured by a terminal deoxynucleotidyl dUTP transferase nick-end labeling (TUNEL) assay. At least 500 spermatozoa were assessed per patient, and a threshold of ≤15% was considered normal. Female partners (≤37 years old) with negative infertility workups underwent IUI in a natural or stimulated cycle.

RESULTS: Of 335 IUI cycles, 261 were carried out in 91 couples in which the male partner had normal SCF. The average maternal age was 34.1 ± 3

years, and the average paternal age was 36.3 ± 4 years. The men had the following semen parameters: a volume of 2.3 ± 1 mL, a concentration of 46.2 ± 29 x10^6 per mL, 43.8 ± 3% motility, and an average SCF of 9.5 ± 3%. There were 29 documented clinical pregnancies (29/261, 11.1%), determined by the presence of at least one fetal heartbeat detected by ultrasound; 9 patients have delivered babies, 18 pregnancies are ongoing, and 2 were spontaneous abortions.

A total of 41 couples in which the male partner (36.9 ± 5.9 years) had abnormal SCF underwent 96 IUI cycles (maternal age, 33.5 ± 2.7 years). The men had the following semen parameters: an average SCF of 21.7 ± 6 ($p<0.0001$), a volume of 2.6 ± 1 mL, a significantly lower concentration of 32.1 ± 20 x10^6, and a lower motility of 44.9 ± 4%. These IUI attempts yielded a clinical pregnancy rate of only 4.1% (4/96; $p<0.0001$); 3 pregnancies are ongoing, and 1 patient has delivered.

CONCLUSIONS: In couples with unexplained infertility in which the male partner has normal semen parameters and the female partner has a negative infertility workup and is of young reproductive age (≤37 years old), SCF screening can help identify a stealth male factor. An assessment of the genomic integrity of the male gamete may serve as a useful tool for predicting pregnancy outcome and tailoring reproductive treatments.

P-689 4:30 PM Tuesday, October 20, 2020

THE IMPACT OF SPERMATOZOA RETRIEVED FROM DIFFERENT REGIONS OF THE EPIDIDYMIS ON REPRODUCTIVE OUTCOMES.

Alessandra Parrella, M.Sc., June Wang, B.A., Danielle Rebecca Tavares, B.A., Mounia Haddad, M.D., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determinate the area of the epididymis that yields spermatozoa most capable of supporting embryonic development.

DESIGN: During the last 9 years, 46 men affected by obstructive azoospermia (OA) consented to have spermatozoa surgically retrieved from three areas of the epididymis: caput, corpus, and cauda. Sperm characteristic were analyzed and compared among the retrieval sites that were used for ICSI with their female partners. Clinical outcomes were compared among the different sources of spermatozoa.

MATERIALS AND METHODS: Consenting men underwent epididymal sperm retrieval, with specimens evaluated according to WHO 2010 criteria. A total of 36 specimens retrieved from the caput, 7 from the corpus, and 3 from the cauda were used for ICSI, controlling for maternal age (≤37 years old). Fertilization, implantation, and delivery rates were assessed and compared for all three areas of the epididymis. Unpaired *t* and Fisher's exact tests were used to compare outcomes. A *P* value of <0.05 was considered significant.

RESULTS: A total of 46 men were divided into three groups according to the spermatozoa source used: caput, corpus, and cauda. Paternal age was comparable among the three groups (39.7± 12). Average and standard deviation of spermatozoa concentration was 35.1± 39 in the caput, 40±29 in the corpus, and 30.2± 59 x10^6/ml in the cauda. The mean motility was 15.8±15% in the caput, rising to 40.1±29% in the corpus ($P<0.01$), and decreasing to 7±12% in the cauda ($P<0.05$). The mean numbers of injected oocytes were comparable at 12.7, 11, and 12.5, for the caput, corpus, and cauda, respectively. The fertilization rate with specimens from the caput was 65.8% (303/460), it rose to 77.6% (59/76) with specimens from the corpus ($P<0.05$), and reached the highest level at 88% (44/50, $P<0.05$) with spermatozoa from the cauda. The proportion of high-quality embryos was 73.5% (25/34) from sperm retrieved from the caput, 75% (3/4) from the corpus, and reached 100% (3/3) from the cauda. There was a trend of increasing implantation rates through the regions of the epididymis. With specimens retrieved from the caput, the implantation rate was 34.8% (23/66), it rose to 44.4% (4/9) from the corpus, and increased to 57.1% (4/7) from the cauda. The same trend was observed for delivery rates. In cycles using caput spermatozoa, the delivery rate was 48.4% (16/33) with 5.8% (1/17) pregnancy loss. In cycles using spermatozoa from the corpus, the delivery rate was 75% (3/4) with no pregnancy loss. Ultimately, the cycles with cauda had the highest delivery rate, with 100% (3/3).

CONCLUSIONS: This study supports the current knowledge that while progressing through the epididymal regions, testicular spermatozoa undergo structural and metabolic changes that translate in phenotypic and functional processes. During the epididymal journey, spermatozoa appeared to enhance their ability to support embryonic development and implantation. Although they have poorer kinetic characteristics, we have found that spermatozoa retrieved from the cauda epididymis yield higher fertilization and pregnancy rates. Larger studies are needed to confirm these findings.

THE ROLE AND MECHANISM OF SPERMATOGONIAL STEM CELLS NECRPTOSIS IN MOUSE MODEL OF HYPOSPERMATOGENESIS.

Guihua Liu, Ph.D.,[1] Xing Yang, Ph.D.,[1] Tingting Li, Doctor[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the effects and mechanisms of necroptosis of Spermatogonial Stem Cells(SSCs) on testicular spermatogenesis in a mouse pathological model.

DESIGN: Animal study was designed.

MATERIALS AND METHODS: The C57BL/6 mouse model was induced by two intraperitoneal injections of busulfan with a three-hour interval. The changes of spermatogenesis were observed at at different time points (0, 9, 18, 27, and 36 days). Meanwhile, Western blotting and immunofluorescence were used to test the expression of UCHL1 (a SSCs marker) and the core components of necroptosis, including RIPK3 and pMLKL

RESULTS: The testicular histology was dramatically different on day 18, with frequent disarrangement of spermatogenic cells, the reduced height of the seminiferous epithelium and SSCs depletion and all the germ cells including SSCs were cleared by day 36. Further analysis showed that the appearance of pMLKL in testes accelerated the cell death of SSCs, resulting in the loss of $UCHL1^+$ SSCs and damage to spermatogenesis in mice with busulfan-induced gonadotoxicity.

CONCLUSIONS: Two intraperitoneal injections of busulfan at a dose of 40 mg kg^{-1} with a three-hour interval could establish a safe, stable and efficient mouse model of hypospermatogenesis. The RIPK1/RIPK3/pMLKL pathway mediates SSC necroptosis resulting in the decreased spermatogenic function in mouse testes.

SUPPORT: no

REPRODUCTIVE OUTCOMES OF ADVANCED PATERNAL AGE MEN USING TESTICULAR SPERMS IN ASSISTED REPRODUCTIVE CYCLES?.

Ramya Sai Rayapati, MSc Bio Medical Genetics,[1] Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Rajesh Mani Raghupathy, MBBS, PGDCE,[2] Yedluri Rupasree, M.Sc Biotechnology, PhD Biotechnology, PGDCE,[1] Afsha Firdouse, M.Sc Biochemistry, PGDCE,[1] Durga Rao Gedela, MBBS, DGO, MRCOG, fellowship in infertility and reproductive endocrinology,[2] Sandeep Karunakaran, Sr., M.B.B.S, MS, PGDHM, PGDMLE[2] [1]Oasis fertility, Hyderabad, India; [2]oasis fertility, Hyderabad, India.

OBJECTIVE: To evaluate reproductive outcomes of Advanced Paternal Age (APA) men using Surgically Retrieved Testicular Sperm (SRS) in Assisted Reproductive Technology (ART) cycles.

DESIGN: Retrospective Observational Longitudinal Cohort study In Private Teaching ART centre.

MATERIALS AND METHODS: Men over the age of 40 were classified as APA and recruited in this study. Age range of male partners was in between 40-50 years. Couples where women were young (<37yrs age) and male partners underwent SRS in ART cycles were considered for this study during January 2014 to July 2019 (n=103). Couples undergoing self-gamete cycles were considered for the study and couples undergoing PGT-A were excluded from the study.

APA men & Younger women in whom ejaculated sperm was used in ART cycles acted as control group for this study (n=71).

All women underwent controlled ovarian stimulation and Transvaginal oocyte retrieval (OPU). Male partner's underwent either fresh SRS on OPU day or frozen SRS was used for ICSI as per our clinics standard operating procedures (SOP). Embryos were cultured till blastocyst stage and a freeze all policy was adopted. Two Blastocysts were transferred in a Frozen Embryo Replacement Cycle (FET).

Reproductive outcomes were compared between the two groups.

RESULTS: The reproductive outcomes for Study Vs Control group were as follows:

Clinical Pregnancy Rate – 45.71% Vs 56.16% (p value 0.1767)
Implantation Rates -33.6% Vs 42.15% (p value 0.2525)
Miscarriage Rates – 15.71% vs 8.22% (p value 0.1457)
Live Birth Rates – 27.14% vs 53.33% (p value 0.0005)
Multiple Pregnancy rate – 21.42% Vs 5.48% (p value 0.0038)

Data from this study is suggestive that, testicular sperms from APA men could alter reproductive outcomes in ART cycles. APA men undergoing ART cycles with SRS need to be counselled appropriately about the limitations. Role of PGT-A in such group of men to optimize reproductive outcomes needs further research.

CONCLUSIONS: Testicular Sperm of advanced paternal age men seems to have detrimental effects on reproductive outcomes.

P-692 4:30 PM Tuesday, October 20, 2020

A MORE EFFICIENT METHOD FOR RECIPIENT PREPARATION IN SPERMATOGONIAL STEM CELL TRANSPLANTATION IN MICE INDUCING BY INTRAPERITONEAL INJECTION OF BUSULFAN. Guihua Liu, Ph.D.,[1] Xing Yang, Ph.D.,[1] Tingting Li, Doctor[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To establish an efficient and hypotoxic spermatogonial stem cells (SSCs) recipient preparation method in mice.

DESIGN: Experimental laboratory study.

MATERIALS AND METHODS: A total of 70 twelve-week-old male C57BL/6J mice were performed intraperitoneal injection of busulfan at different doses (20, 30 and 40mg kg^{-1} body weight) and investigated the effects 36 days later. And further analysis the effects at the different time points (0, 9, 18, 27, 36, 45, 63 days) after busulfan-treated at the total of dose of 40 mg kg^{-1} .Survival rate, testicular histology, Western Blot analysis and immunofluorescence of UCHL1, levels of inhibin B in serum and growth factors gene expressions in testes.

RESULTS: The survival rates of the mice after the administration of different doses of busulfan were 100%. Compared to control or that in lower dose of busulfan (20 or 30 mg kg^{-1}), mice treated with 40 mg kg^{-1} busulfan was optimal used to recipient preparation, by depleting substantially all of the germ cells and a friendly niche microenvironment in testes 36 days later after busulfan-treated. In addition, long-term observation at the day 63, there was still hardly germ cell in testes.

CONCLUSIONS: Double intraperitoneal injections of busulfan (40 mg kg^{-1} in total) at an interval of 3 hours to mice was an efficient and hypotoxic method for recipient preparation in SSCs transplantation, which could promote the exploration of the mechanism of azoospermia and the treatment of infertility.

P-693 4:30 PM Tuesday, October 20, 2020

PCA3 AND TMPRSS:ERG ASSESSMENT IN SEMEN: RESULTS OF A PHASE I STUDY. Nahid Punjani, MD MPH,[1] Russell P. Hayden, M.D.,[2] Peter Y. Cai, MD,[1] John T. Wei, MD,[3] Javed Siddiqui, MS,[3] Vanessa L. Dudley, MSHS,[2] Miriam Feliciano, BSc,[2] Marc Goldstein, M.D.[2] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [3]University of Michigan, Ann Arbor, MI.

OBJECTIVE: To assess if quantification of PCA3 and TMPRSS2:ERG levels in semen provides an improved prostate cancer assay to be used in prostate cancer algorithms, commencing with a phase I feasibility study.

DESIGN: Phase I Clinical Trial.

MATERIALS AND METHODS: Research ethics approval was obtained for our phase I feasibility study. Patients with semen volumes greater than 3mL were enrolled to donate discarded semen specimens. Our collaborators at the University of Michigan have developed a unique assay to test PCA3 and T2:ERG in human semen. De-identified samples were processed in two different ways to determine the most effective methods for shipment and minimization of sample degradation to Michigan, but also to determine if the presence of absence of sperm was required for the PCA3/T2:ERG assay.

RESULTS: Data was collected prospectively on a total of 8 patients with semen volumes greater than 3mL. Four patients had no centrifugation of their samples (sperm present) and the other four were centrifuged and separated (sperm absent). PCA3 and T2:ERG levels were assessed in all patients. The T2:ERG levels in the sperm present samples were 383, 1519, 172 and 166 c/mL with an average of 560 c/mL. In the sperm absent samples, T2:ERG levels were 137, 13567, 300, 870 c/mL with an average of 3719 c/mL.

CONCLUSIONS: Our results indicate that our PCA3/T2:ERG semen assay is able to detect T2:ERG in both the presence and absence of sperm. We also demonstrate feasibility of specimen shipment. Phase II studies are underway to validate the assay in prostate cancer patients, define appropriate cut-offs, as well as further optimization including whether digital rectal massage is necessary. This assay may have the potential to be a game-changer for prostate cancer screening, obviating the need for prostate biopsy in a large number of men.

P-694 4:30 PM Tuesday, October 20, 2020

NEWBORN RATE IS NOT IMPAIRED BY TIME FROM VASECTOMY, SMOKING AND BODY MASS INDEX (BMI) IN COUPLES WITH VASECTOMIZED MALE REQUIRING AN ASSISTED REPRODUCTIVE TECHNIQUE USING OOCYTE DONATION (OD). Irene Hervas, MSc,[1] Lorena Valls, M.D,[2] Nicolas Garrido, PhD,[3] Rocio Rivera-Egea, PhD,[4] Maria Gil Julia, MSc, MRes,[1] Jose Maria Martinez-Jabaloyas, M.D[4] [1]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [2]Hospital Clínico de Valencia, Valencia, Spain; [3]IVI Foundation - IIS La Fe Biomedical Research Institut, Valencia, Spain; [4]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: The most employed definitive contraceptive method for men is vasectomy, although a non-negligible percentage of vasectomized men have regrets and express a renewed desire to have a child. In the case a relevant female factor infertility is present, OD has emerged the last years as a valid and widely employed option. In these cases, the main alternative is testis sperm extraction (TESE) together with intracytoplasmic sperm injection (ICSI) technique. To date there is little reports evaluating the clinical outcomes of vasectomized patients requiring the use of OD and the factors that may adversely affect reproductive outcome, such as time since the vasectomy, smoking or high BMI. The aim of this study is to analyze the influence of these male risk factors on TESE-ICSI outcomes from vasectomized men in an OD program.

DESIGN: Retrospective study.

MATERIALS AND METHODS: Data from couples who underwent TESE-ICSI treatment (using donor' oocytes) were assessed, and variables of interest (time since vasectomy, BMI and smoking) were compared using quartiles (Q_n). The live birth rate (LBR) by embryo transfer (ET), by complete donation cycle (CDC) and by couples was analyzed. Proportions were compared with Chi-square tests. Survival curves based on Kaplan Meier and Breslow tests were constructed to calculate the cumulative live birth rate (CLBR) per number of embryos transferred consecutively until the first newborn.

RESULTS: From 123 couples, the average male of BMI was 27.0 kg/m^2 (CI95% 26.3-27.7) and 21.8% consumed tobacco. Mean time since surgery was 13.8 years (CI95% 12.0-14.5). Based on time since vasectomy, no statistical differences were found between groups in LBR per ET (Q1:25.4%, Q2:34.4%, Q3:36.20%, Q4:42.6%), per CDC (Q1:34.1%, Q2:41.2%, Q3:48.60%, Q4:60.6%) and per couple (Q1:50.0%, Q2:58.3%, Q3:68.0%, Q4:62.5%). The CLBR comparing post-vasectomy periods were, when two and four embryos replaced, 39.2% (Q1) and 44.0% (Q3), and 46.0% (Q1) and 69.5% (Q3) respectively, but it was non-significant. None of the LBR compared were statistically significant by BMI groups by ET, by CDC and by couple. The cumulative LBR was not influenced when compared based on the BMI: Q:36.0%, Q2:47.6%, Q3:40.7% and Q4:33.2%, and Q1:64.4%, Q2:66.7%, Q3:78.6% and 65.6% when two and four embryos were replaced accordingly. The smoking groups presented comparable LBR with non-smokers males: 34.1% *vs* 35.7% per ET, 53.6% *vs* 44.1% por CDC, and 57.7% *vs* 60.2% per couple. Cumulative livebirth rate per embryo transferred was no statistically significative among smokers and non-smokers when two embryos replaced (43.8% *vs* 37.7%), three embryos (50.1% *vs* 47.6%) and four embryos (66.7% *vs* 66.3%) were transferred.

CONCLUSIONS: The time since the vasectomy and the male risk factors analyzed, BMI and tobacco consumption, seem not to impair the probability

of achieve a newborn in couples with vasectomized males undergoing an ICSI treatment with donated oocytes.

P-695 4:30 PM Tuesday, October 20, 2020

EVALUATION OF A NEWLY ENGINEERED DEVICE FOR PENILE VIBRATORY STIMULATION IN MEN WITH SPINAL CORD INJURY. Emad Ibrahim, MD, HCLD(ABB),[1] Christian F. S. Jensen, MD,[2] Ivan Sunara, MD,[3] Kajal Khodamoradi, MS,[1] Teodoro C. Aballa, MS,[1] Stacy Elliott, MD,[4] Jens Sonksen, MD, PhD,[5] Dana A. Ohl, MD,[6] Claes Hultling, MD, PhD,[3] Charles M. Lynne, MD,[1] Stephen W. J. Seager, DVM,[7] Nancy L. Brackett, PhD, HCLD[1] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Copenhagen, Herlev, Denmark; [3]Karolinska Institute, Stockholm, Sweden; [4]University of British Columbia, Vancouver, BC, Canada; [5]Herlev & Gentofte Hospital, University of Copenhagen, Herlev, Denmark; [6]University of Michigan, Ann Arbor, MI; [7]National Rehabilitation Hospital, The Plains, VA.

OBJECTIVE: Most men with spinal cord injury are anejaculatory and will require medical assistance to obtain their sperm in order to achieve biologic fatherhood. Penile vibratory stimulation is generally recognized as the first line of treatment for semen retrieval in anejaculatory men with spinal cord injury. The purpose of this study was to evaluate the performance of a newly-engineered device available in October 2019 (Ferticare 2.0) for penile vibratory stimulation in men with spinal cord injury.

DESIGN: Cohort study.

MATERIALS AND METHODS: The Ferticare 2.0 device was applied to 15 men with spinal cord injury in a three-step protocol. Step 1: one device (2.5mm amplitude, 100 Hz) was applied to the glans penis for 2 minutes. Step 2: If no ejaculation occurred, the amplitude was increased to 4.0mm (100 Hz) and the device similarly applied. Step 3: If no ejaculation occurred, two devices, each 2.5mm and 100 Hz were applied to the dorsum and frenulum of the glans penis. Subjects at risk for autonomic dysreflexia were pretreated with sublingual nifedipine (20mg), 15 minutes prior to simulation. Blood pressure and other symptoms of autonomic dysreflexia were monitored. Following stimulation, subjects answered a questionnaire about their experience with the device. The measured distance from zero of a vertical mark on a 10 cm line indicated a rating between 0 and 10. Questionnaires were not requested from subjects who did not respond to PVS.

RESULTS: Thirteen of 15 subjects had antegrade ejaculation with the device. Blood pressure and other symptoms of autonomic dysreflexia were well-managed. No adverse events occurred. The two subjects that were failures to PVS with other devices were also failures to PVS with the Ferticare 2.0. Two of the 15 subjects had retrograde ejaculation (subjects 6 and 8). The remaining 13 subjects had no retrograde ejaculation, including the two PVS failures. All subjects commented they would recommend the device to other men with spinal cord injury.

CONCLUSIONS: A newly engineered device, the Ferticare 2.0, is safe and effective for inducing ejaculation in men with spinal cord injury.

P-696 4:30 PM Tuesday, October 20, 2020

ASSOCIATION OF THE SERUM METABOLOMIC PROFILE BY NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY WITH SPERM PARAMETERS: A CROSS SECTIONAL STUDY OF 325 MEN. Karema Alrashid, MD,[1] Scott M. Nelson, MD, PhD,[1] Deborah A. Lawlor, PhD,[2] Mary Ann Lumsden, MD,[1] Neil Goulding, PhD[2] [1]University of Glasgow, Glasgow, United Kingdom; [2]MRC Integrative Epidemiology Unit at the University of Bristol, Bristol, United Kingdom.

OBJECTIVE: Are 155 circulating metabolic measures relevant to lifestyle and metabolic health associated with sperm parameters (as measured by concentration, motility and total motile sperm count (TMSC))?

SUMMARY ANSWER: An extensive range of metabolites were not associated with semen parameters, however, several metabolites exhibited differential direction of associations with the odds of a low TMSC and warrant replication.

WHAT IS KNOWN ALREADY: Robust identification of additional modifiable and non-modifiable risk factors for poor semen quality have had limited success. An alternative approach to identify risk factors for an abnormal semen analysis would be to examine circulating metabolites by means of a high throughput cost efficient NMR platform, which may provide insights into downstream factors as well as more upstream exposures.

DESIGN: Cross-sectional study of 325 men prospectively recruited between 1 April 2017 and 31 March 2019.

MATERIALS AND METHODS: Men intending to undergo assisted conception at a University Hospital, had a detailed demographic, lifestyle, fertility and medical history and semen analysis. Non-fasting serum lipids, lipoprotein subclasses, and low-molecular weight metabolites (including amino acids, glycolysis and inflammatory markers) were quantified by NMR spectroscopy. Multivariable linear and logistic regression were used to examine the associations of serum metabolic profiles (exposures), with functional sperm concentration, motility and TMSC (outcomes) with adjustment for confounders.

RESULTS: Participants were mean 37.2 (SD 5.7) years and had a median sperm concentration of 35 million/ml (IQR 15, 69 million/ml) and median motility of 53% (IQR 42,67). 76% of men had a TMSC >15 Million, 10% 5-15 Million and 14% <5 Million. In both univariate and confounder adjusted analyses an extensive range of lipids and lipoproteins, glycolysis related metabolites, amino acids, ketone bodies, creatinine or albumin, did not show strong statistical evidence of associated with sperm concentration, motility, or the odds of having a reduced or low TMSC (all $P_{Bonferroni} > 0.0029$).

LIMITATIONS: Sperm parameters were measured on a single sample, in accordance with recent WHO guidance, and by non-automated techniques which may have introduced random measurement error that could have attenuated to the null.

CONCLUSIONS: This study provides preliminary data on a range of metabolic pathways and their association with semen parameters. The differential direction of associations with sperm motility and potentially of important clinical effect sizes warrant further exploration and replication in a larger prospective study.

Keywords: semen analysis, sperm, metabolomics

P-697 4:30 PM Tuesday, October 20, 2020

LEPTIN SECRETED FROM HUMAN LEYDIG STEM CELLS TARGETS HEDGEHOG SIGNALING TO AUGMENT ENDOGENOUS FUNCTION. Himanshu Arora, PhD,[1] Kajal Khodamoradi, MS,[1] Madhumita Parmar, BS,[1] Rehana Qureshi, PHD,[2] Ranjith Ramasamy, M.D[1] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami Miller School of Medicine, MIAMI, FL.

OBJECTIVE: Although testosterone deficiency (TD) can be present among 1 in 5 men 40 years or older, the factors responsible for TD remain largely unknown. Leydig cells produce testosterone in the testes under the pulsatile control of luteinizing hormone (LH) from pituitary gland. Leydig stem cells have the potential to differentiate into adult Leydig cells that can lead to increasing testosterone however the factors underlying reasons for differentiation remain unknown. In the present study we evaluated the paracrine factors released from testicular microenvironment (TME), which is comprised of Sertoli and peritubular myoid cells, in modulating differentiation of Leydig stem cells to Adult Leydig cells and production of Testosterone. Additionally, we explored the underlying mechanism of action of these paracrine factors.

DESIGN: A total of 13 men with testicular failure underwent testis biopsies for sperm retrieval were used for the study.

MATERIALS AND METHODS: Using an IRB approved protocol, about 10mg of testicular tissue from each of these men were processed for Leydig stem cell isolation, culture and characterized. Cytokine antibody array was performed to identify the paracrine factors released by Sertoli and Peritubular Myoid cells using unsorted and $CD146^{+ve}$ sorted cells. The cells were treated with hedgehog signaling agonist and antagonist to validate the specificity of paracrine factors identified. Immunostaining was performed to validate the changes at protein levels. Flow cytometry was performed to study the shift in the population of cells post Leptin treatment. GraphPad Prism was used for statistical analysis. All data were presented as the means ± SEM. The statistical significance between two groups was estimated by unpaired two-tailed t test.

RESULTS: The current study revealed that the testicular microenvironment (TME), which is comprised of Sertoli and peritubular myoid cells, plays an instrumental role in Leydig stem cell differentiation and testosterone production under the regulation of the desert hedgehog signaling pathway (DHH). Additionally, identifying the paracrine factors that are released by TME and understanding their impact on Leydig stem cell (LSC) differentiation is key to unraveling and developing new niche-based therapy for TD. In the current study, LSCs were isolated from 13 men undergoing testis biopsies

for sperm retrieval and evaluated the paracrine factors in the presence or absence of TME. TME-secreted leptin induces LSC differentiation and increases T production. These effects of Leptin on LSC differentiation and T production, however, are inversely concentration-dependent: positive at low doses and negative at higher doses. Mechanistically, Leptin acts on LSCs upstream of DHH; Leptin-DHH regulation functions unidirectionally insofar as DHH gain or loss of function has no effects on Leptin levels.

CONCLUSIONS: Taken together these findings identify leptin as a key paracrine factor released by cells within the TME that modulates LSC differentiation and testosterone release from mature Leydig cells, a finding with important clinical implications for TD.

SUPPORT: Supported by the American Urological Association Research Scholar Award to HA and RR

P-698 4:30 PM Tuesday, October 20, 2020

SERUM TESTOSTERONE LEVEL RISES DRASTICALLY AT THE MOMENT OF EJACULATION. Yoshitomo Kobori, MD, PhD, Akiyoshi Osaka, MD, Toshiyuki Iwahata, MD, PhD, Hiroshi Okada, MD, PhD Dokkyo Medical University Saitama Medical Center, Koshigaya, Japan.

OBJECTIVE: Testosterone is the major sex hormone in males and plays an important role in development of the penis and testes, muscle size, bone growth, sex drive, and sperm production. Changes in serum testosterone level at ejaculation are unclear, although sexual function is influenced by testosterone. We measured pre- and post-ejaculatory testosterone levels over time and evaluated changes in these levels. We also measured levels of prolactin and cortisol, which are hormones that also affect sexual function.

DESIGN: Laboratory investigation.

MATERIALS AND METHODS: We enrolled 7 men (age 32–41 years, mean 35.7 years) with normal sexual function, and collected blood samples before, during, and after masturbation. Testosterone, prolactin, and cortisol levels were evaluated before erection, after erection, just before ejaculation, at ejaculation, and 10 min after ejaculation.

RESULTS: Serum testosterone level increased significantly over time from before erection to the moment of ejaculation, and decreased to the pre-erection level 10 min after ejaculation (pre-erection, 5.86±2.45ng/mL; at ejaculation, 7.01±3.61 ng/mL; 10 min after ejaculation, 6.22±2.89 ng/mL; $p < 0.05$). Cortisol increased significantly over time from before erection to after ejaculation (pre-erection, 5.63±3.82μg/dL; at ejaculation, 6.94±4.59 μg/dL; 10 min after ejaculation, 7.70±4.99 μg/dL; $p < 0.05$). And prolactin increased approximately 2-fold over time from before erection to after ejaculation (pre-erection, 12.83±2.36ng/mL; at ejaculation, 17.48±4.51 ng/mL; 10 min after ejaculation, 23.47±6.27 ng/mL; $p < 0.05$).

CONCLUSIONS: All 3 hormones changed drastically with ejaculation. The increase in testosterone level may be due to prostate contraction and testicular secretion. In addition, prolactin and cortisol levels changed before and after ejaculation. Changes in hormone secretion due to ejaculation may affect daily health and sexual function.

	before	erection	climax	ejaculation	after 10 min
Testosterone	5.06±2.45	5.26±2.79	5.44±3.39	5.61±3.61	5.27±2.89
Cortisol	5.63±3.82	5.98±3.71	6.53±4.30	6.94±4.59	7.70±4.99
Prolactin	12.83±2.36	12.51±2.22	14.68±3.59	17.48±4.51	23.47±6.27

TREATING HYPERPROLACTINEMIA DOESN'T IMPROVE SEXUAL FUNCTION IN END STAGE RENAL DISEASE PATIENTS. Haitham Elbardisi, MD, Kareim Khalafalla, MD, Mohamed Arafa, MD, Sami Alsaid, MD, Ahmad Majzoub, MD Hamad Medical Corporation, Doha, Qatar.

OBJECTIVE: Chronic kidney disease is associated with gonadal dysfunction. Patient usually present with deceased libido, erectile dysfunction & defective ejaculation. Significant derangements of the hypothalamic pituitary axes is commonly identified in uremic patients with reduced total & free serum testosterone levels and increased LH & FSH levels. Elevated levels of prolactin is usually seen in ESRD & is thought to contribute to the high prevalence of hypogonadism & sexual dysfunction. This study aims to evaluate the effect of treatment of hyperprolactinemia on sexual function in ESRD patients.

DESIGN: Prospective Cohort study.

MATERIALS AND METHODS: All patients attending the clinic with ESRD in Hamad general hospital dialysis service during the study period from 1/3/2017 - 1/7/2017 were screened for eligibility. A total of 102 patients were included. Patients receiving treatment for fertility, erectile dysfunction & other medications that may affect sexual functions e.g. cytotoxic drugs, androgens, estrogens, thiazides were excluded.

Patients were evaluated and were asked to fill the International index of erectile function (IIEF) and Premature ejaculation diagnostic tool (PEDT) to assess their sexual function. Serum hormones were collected. Patients with hyperprolactinemia were then offered treatment with Gabergolin 0.5mg once per week for 3 months. In the follow up visit, patients were reevaluated with hormones and IIEF/PEDT questionnaires.

RESULTS: Patients had a mean age of 52.4 ± 12.1 years & mean BMI of 29.9 ± 9.3. 75 patients (73.5%) were on hemodialysis & 13 (12.7%) on peritoneal dialysis. All patients were diabetic, 35 patients (34.3%) had chronic heart disease, while 99 patients (97.1%) were hypertensive. Premature ejaculation a& moderate to severe ED were reported by 88.2% (N) and 52.9% (N) of patients. Mean basal testosterone levels were 12.95 ± 6.46 while mean basal prolactin levels were 514.22 ± 592.89. 55 patients (53.9%) were diagnosed with hyperprolactinemia. 26 patients (25.5%) agreed to receive cabergoline treatment. No statistically significant improvement in prolactin levels (P= 0.597), testosterone levels (P= 0.1), PEDT score (P= 0.923) and IIEF score (P=0.393) was seen in the treated group in comparison to the non-treated group.

CONCLUSIONS: Correction of hyperprolactinemia in ESRD appears not to affect sexual function.

Table

Parameters	Pre-treatment	Post-treatment	P Value
Prolactin	916.91 ± 985.73	394.55 ± 366.77	0.597
Testosterone	12.43 ±7.95	12.77±6.039	0.10
IIEF Score	11.48 ± 4.79	12.28 ± 4.86	0.393
PEDT Score	14.60 ± 4.40	16.28 ± 4.99	0.923

P-700 4:30 PM Tuesday, October 20, 2020

A NORTH AMERICAN PROSPECTIVE COHORT STUDY OF ANTHROPOMETRIC FACTORS AND SEMEN QUALITY. Marlon D. Joseph, MPH,[1] Elizabeth E. Hatch, Ph.D.,[1] Michael L. Eisenberg, M.D.,[2] Kenneth J. Rothman, Dr.P.H.,[1] Tanran R. Wang, MPH,[1] Lauren A. Wise, Sc.D.[1] [1]Boston University School of Public Health, Boston, MA; [2]Stanford University, Stanford, CA.

OBJECTIVE: We prospectively evaluated the association between anthropometric variables and selected semen parameters.

DESIGN: A prospective cohort study.

MATERIALS AND METHODS: We analyzed data from 301 men (520 samples) participating in a semen testing substudy of Pregnancy Online Study (PRESTO), a preconception cohort of North American couples. After enrollment, male participants aged ≥21 years were invited to perform semen testing using the Trak™ system. Selected anthropometric variables (weight at age 17 years, current weight, height, and waist circumference) and covariate data were obtained via baseline questionnaire. We estimated the percent difference in mean log-transformed semen parameter values (%D) and 95% confidence intervals (CI) for associations between selected anthropometric variables and semen volume (mL), total sperm count (TSC, million), sperm concentration (million/mL), motility (%) and total motile sperm count (TMSC, million). Models were adjusted for abstinence time, age (years), current or occasional smoker (yes vs. no), hours of work per week, alcohol

intake (drinks/week), sugar-sweetened sodas (drinks/week), average hours of sleep per night, vigorous exercise (hrs/week), education (years), depressive symptoms, anxiety symptoms and use of psychotropic medications.

RESULTS: The distribution of current BMI (kg/m^2) in the cohort at baseline was: 32.2%, 33.2%, 19.6%, and 15.0% for categories of <25, 25-29, 30-34, and ≥35 kg/m^2, respectively. Adjusted %Ds (CIs) comparing current BMI ≥35 vs. <25 kg/m^2 were 6.6 (-8.9, 24.7), -16.4 (-40.4, 17.1), -10.9 (-38.7, 29.5), -4.3 (-26.1, 24.0) and -14.0 (-47.9, 42.0) for semen volume, sperm concentration, TSC, motility, and TMSC, respectively. Adjusted % Ds (CIs) comparing waist circumferences of ≥42 vs. <31 inches were -1.2 (-16.7, 17.2), -19.2 (-45.0, 18.5), -20.2 (-48.3, 23.3), -10.7 (-30.8, 15.1), and -28.4 (-59.6, 27.2) for semen volume, sperm concentration, TSC, motility, and TMSC, respectively. Additionally, few consistent associations between weight change since age 17 and semen parameters were observed.

CONCLUSIONS: Preliminary results indicate slight inverse associations between waist circumference and semen parameters, particularly sperm concentration and motility.

P-701 4:30 PM Tuesday, October 20, 2020

A RE-EVALUATION OF THE EFFICACY OF TREATING SPERM WITH LOW HYPO-OSMOTIC SWELLING (HOS) TESTS WITH THE PROTEIN DIGESTIVE ENZYME CHYMOTRYPSIN-GALACTOSE (CG). Jerome H. Check, M.D., Ph.D.,[1] Carrie K. Wilson, B.A.,[2] Aniela Bollendorf, M.T.,[2] Donna Summers, M.S.,[2] Diane L. Check, BS, MT[2] [1]Cooper Medical School of Rowan University, Camden, NJ; [2]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ.

OBJECTIVE: Since 1989 there have been several publications concluding that males whose semen specimens show a low HOS test almost never achieve a live pregnancy following intercourse, intrauterine insemination (IUI) or in vitro fertilization-embryo transfer (IVF-ET) using conventional oocyte insemination. The studies find that sperm with low HOS allow normal fertilization but implantation failure. Yet IVF with intracytoplasmic sperm injection (ICSI) fully corrects the problem and allows normal live delivered pregnancy rates. These findings led to the hypothesis that the sperm with low HOS scores are associated with a toxic factor causing functional impairment of the embryo membrane leading to implantation failure. Some studies suggest that treating the sperm with the protein digestive enzyme CG prior to IUI and avoidance of unprotected intercourse can allow live deliveries. The purpose of this study was to corroborate or refute these previous studies, and determine the confounding effect of motile density, normal morphology and % motility in influencing IUI success with sperm with low HOS scores treated with CG prior to IUI.

DESIGN: Prospective comparison study.

MATERIALS AND METHODS: Males with 2 low HOS test scores <50%, who chose IUI with CG treated sperm over IVF with ICSI, were the test subjects. They were advised to avoid unprotected intercourse during the follicular phase. The pregnancy rates in their first IUI cycle were determined. Only males where the CG treatment increased the HOS score to ≥50% were included.

RESULTS: The pregnancy rates according to certain semen parameters are seen in the table. In males with normal motile density irrespective of strict normal morphology or % motile density had a live delivered pregnancy rate of 10.9%. The confounding effect of other parameters being abnormal cut this success rate to half or less compared to normal motile density. Nevertheless, live deliveries occurred even with these confounding abnormalities.

CONCLUSIONS: The results corroborate that IUI with CG-treated sperm and avoidance of unprotected intercourse allows normal live deliveries with sperm with low HOS scores. The presence of other male factors reduces the success rate in half.

FUTURE FERTILITY AND PRESERVATION BELIEFS: PRACTICES AMONG A COHORT OF KLINEFELTER SYNDROME MEN. Douglas Timmons, MD, MPH,[1] Steven Gay, MD,[2] Alan H. DeCherney, MD[3] [1]University of Miami Miller School of Medicine/Jackson Memorial Hospital; [2]Program in Reproductive Endocrinology and Gynecology, NICHD, NIH, Bethesda, MD; [3]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

OBJECTIVE: Our clinic routinely evaluates patients with sex chromosome disorders and among these is XXY, Klinefelter Syndrome. Klinefelter Syndrome (KS) has a prevalence of 2 in 1000 males, and is most commonly associated with a 47, XXY karyotype.[1] The most common symptoms are: gynecomastia and low sexual drive, psychosocial problems and infertility.[2] The diagnosis of Klinefelter Syndrome is often suspected in patients with infertility, and approximately 90% of patients with KS suffer from non-obstructive azoospermia with advancing age-related hyalinization of testicular tissue driving premature gonadal failure.[3] Historically, patients with KS had no fertility options, but now with advancements in Assisted Reproductive Technologies (ART), specifically microsurgical Testicular Sperm Extraction (TESE), almost half of patients can father their own biological children with early enough evaluation and treatment.[4] Younger age is associated with an increased likelihood to obtain viable sperm via TESE.[5] Our objective was to evaluate men with the diagnosis of Klinefelter Syndrome to specifically look at previous attempts at fertility preservation, and desires for future fertility and preservation.

DESIGN: A retrospective chart review was performed on all patients with the diagnosis of Klinefelter Syndrome who were seen by our Reproductive Endocrinology and Infertility team between January, 2018 and August, 2019.

MATERIALS AND METHODS: Basic demographic data was obtained as well as information on age at diagnosis, hormonal medication use, previous fertility preservation, and attitudes towards future fertility preservation. Descriptive statistics were used, and t-tests with significance set to $p<0.05$.

RESULTS: Twenty one (n=21) patients were ultimately identified and included for review. Mean age at time of visit was 35.2 (SD = 11.5), and the mean age at diagnosis was 17.2 (SD = 10.9). Of these 21, 7 reported a desire for future fertility potential; 3 of these 7 had already undergone TESE, and 2 of these reported retrieval of usable sperm. 1 patient had micro-TESE performed without successful retrieval of sperm and 1 patient was referred for microTESE. All available semen analysis (n=10) documented azoospermia. An additional four patients reported azoospermia at outside clinics. 24% of patients with KS were diagnosed during an infertility evaluation. 38% of patients desire or are unsure if they want fertility preservation. Those who desire or are unsure of future fertility were significantly younger than those who do not desire future fertility (25.6 ± 6.4 vs. 41.2 ± 9.8; $p<0.001$).

CONCLUSIONS: Improvements in ART now provides men with Klinefelter Syndrome fertility options that previously did not exist and a significant proportion of our cohort desired these fertility options. Younger patients have

Pregnancy rates per IUI cycle with CG-treated sperm according to various semen parameters

	MD <10	MD ≥10	Normal morphology strict criteria <5	Normal morphology strict criteria ≥5	Motility <30%	Motility ≥30%
# IUI's	118	55	82	64	44	128
% pregnant	11.0%	16.4%	8.5%	18.8%	6.8%	14.8%
% clinical pregnancy	6.8%	16.4%	6.1%	15.6%	2.3%	12.5%
% miscarriage/clinical preg.	25.0%	33.3%	20.0%	40.0%	0.0%	31.3%
# live delivered	6	6	4	6	1	11
% live delivered	5.1%	10.9%	4.9%	9.4%	2.3%	8.6%
Avg. age female	37.8	39.1	37.4	37.8	37.6	38.4

stronger desires for future fertility, and men with KS who are interested in fertility preservation would benefit from earlier evaluation and sperm extraction.

DOES TESTICULAR SPERM ALTER REPRODUCTIVE AND PERI-NATAL OUTCOMES IN ART CYCLES? 10 YEARS' EXPERIENCE OF AN INDIAN CLINIC.

Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Yedluri Rupasree, M.Sc Biotechnology, PhD Biotechnology, PGDCE,[1] Afsha Firdouse, M.Sc Biochemistry, PGDCE,[1] Rajesh Mani Raghupathy, MBBS, PGDCE,[1] Durga Rao Gedela, MBBS, DGO, MRCOG, fellowship in infertility and reproductive endocrinology,[2] Sandeep Karunakaran, Sr., M.B.B.S, MS, PGDHM, PGDMLE[3] [1]Oasis fertility, Hyderabad, India; [2]oasis fertility, Hyderabad, India; [3]OASIS FERTILITY, Hyderabad , TELANGANA, India.

INTRODUCTION:

It is well known that introduction of intracytoplasmic sperm injection (ICSI) is a breakthrough in the treatment of male infertility. The use of epididymal and testicular sperm has been beneficial in the treatment of azoospermic men.

OBJECTIVE: To identify the impact of surgically retrieved sperm (SRS) on reproductive and peri-natal outcomes in Assisted Reproductive Treatment (ART) cycles.

DESIGN: This is a retrospective study design at our private IVF clinic duration is from 2009 to 2019.

MATERIALS AND METHODS: The sample size of this study is a total of 989 subjects underwent SRS under general anaesthesia. Of these only 552 couples were included in this study with female partner's age $\leq$ 37 and had self-gamete cycles. Among them only 342 subjects (till June 2019) had embryo transfer.

Couples with ejaculate sperm (ES) and self-oocytes who had ICSI cycles acted as control group for this study (n=425).

In study group male partners underwent SRS and female partner's underwent controlled ovarian stimulation and trans vaginal oocyte retrieval as per our clinic's standard operating protocols (SOP). Embryos were cultured till blastocysts and a freeze all policy was followed. Frozen Embryo transfer with two good grade blastocysts (grading done as per Istanbul Consensus by Alpha scientists) was done in subsequent cycles.

Primary Outcomes: Live birth rates (LBR) and Peri-Natal outcomes- Obstetric complications (Gestational diabetes (GDM), Pregnancy Induced Hypertension (PIH), Intra-Uterine Growth Restriction (IUGR), and foetal anomalies.

Secondary Outcomes: Reproductive out comes – Fertilization rate (FR); blastocyst rate (BR); Implantation rate (IR); Clinical pregnancy rate (CPR); Miscarriage rate (MR) and Multiple Pregnancy rates (MPR).

RESULTS: Mean Reproductive and Perinatal outcomes of Study Vs Control group are as follows:

FR – 92.6% Vs 92.3% (P=0.8760)
BR – 37.18% Vs 48.4% (P=0.0018)
CPR – 58.18 Vs 62.93% (P=0.1807)
IR – 40.63% Vs 48.97% (P=0.0212)
MR- 7.02% Vs 9.98% (P=0.1477)
MPR – 10.81% Vs 17% (P=0.0148)
LBR – 40.06% Vs 51.4% (P=0.0018)
GDM – 3.8% Vs 1.8% (P=0.0891)
PIH – 2.63% Vs 2.12% (P=0.6431)
IUGR – 0% Vs 0.71%
Lost to Follow up – 10% Vs 0% (P=0.8760)

Congenital Anomalies – One baby with Angleman's Syndrome in study groups Vs one baby with hydrocephalus, one death due to Respiratory distress and 3 deaths in NICU after preterm birth in control group.

Data from this study is suggesting that use of SRS seems to offer beneficial reproductive and perinatal outcomes.

Though Blastocycst rate and LBR is significantly higher in control group, SRS groups still has acceptable outcomes.

CONCLUSIONS:Use of SRS in ART cycles do not seem to alter reproductive and peri-natal outcomes and couples should be reassured and counselled appropriately. However, long term follows up of the health of such off springs is still warranted.

P-704 4:30 PM Tuesday, October 20, 2020

CLINICAL OUTCOMES IN PATIENTS WITH CONGENITAL BILATERAL ABSENCE OF THE VAS DEFERENS (CBAVD) UNDERGOING TESTICULAR SPERM EXTRACTION-INTRACYTOPLASMIC SPERM INJECTION (TESE-ICSI).

Tomomoto Ishikawa, M.D., Kotaro Kitaya, M.D. Reproduction Clinic Osaka, Osaka, Japan.

OBJECTIVE: Obstructive azoospermia (OA) is caused by congenital including bilateral absence of the vas deferens (obstructed in the long term) or acquired (vasectomy, inguinal hernioplasty in childhood, etc.). It is known that long-term obstruction is related to a defect of spermatogenesis, however, clinical outcomes after ICSI with testicular sperm in the etiology OA, classified as congenital or acquired causes have hardly been investigated.

DESIGN: A retrospective study.

MATERIALS AND METHODS: We performed a retrospective study based on two reproduction centers in Japan and evaluated 206 NOA patinets including 50 cases with CBAVD performed in our clinic between September 2013 and December 2019. In addition, a total of 108 TESE-ICSI cycle with 47 couples for CBAVD and 293 TESE-ICSI cycles with 138 couples for other obstruction were performed. Sperm retrieval rate was 100% and TESE-ICSI was performed with only motile spermatozoa. The diagnosis of CBAVD is based on normal-size testes (>16mL), normal FSH and nonpalpable vas deferens. The diagnosis of OA also required confirmation of normal spermatogenesis by testicular biopsy. TESE-ICSI cycles were evaluated in embryonic development rates and CPR. Additionally, paternal and maternal age, numbers of oocytes retrieved, baseline FSH, LH and E2 levels of women, and FSH, LH and Testosterone of men were compared between the two groups.

RESULTS: The wives age at ICSI was 33.9±4.4 years for CBAVD and 35.9±5.1 years for other obstruction. The sperm retrieval rate with TESE was 100%, in which motile spermatozoa were retrieved and used for ICSI for all patients. Two pronuclei (2PN), blastocysts development, and good-quality blastocysts rates were 57.2%, 44.8%, and 19.6% in CBAVD and 64.0%, 53.3%, and 23.0% in other obstruction, respectively. 2PN and blastocysts development rate in CBAVD was significantly lower than in other obstruction (P<0.001). However, no significant difference was found in good-quality blastocysts rates. Embryo transfer was performed 44 couples with CBAVD patients undergoing TESE-ICSI which were divided into clinical pregnancy positive (n=37) and negative (n=7) groups. There was no difference for paternal and maternal age, numbers of oocytes retrieved, baseline FSH, LH and E2 levels of women, and FSH, LH and Testosterone of men. CPR per ET cycle and per couple were similar in CBAVD (40.2% and 84.1%, respectively) and in other obstructive (41.3% and 79.4%, respectively).

CONCLUSIONS: Long-term obstruction is not related to a sperm retrieval by conventional TESE and clinical pregnancy, however, embryonic development were not similar as the other OAs. In CBAVD couples, the selection of motile sperm from testicular tissue could be a critical key to succeed and rationale for good embryonic development.

VARICOCELECTOMY IS ASSOCIATED WITH IMPROVEMENT IN SPERM CAPACITATION AND THE PROBABILITY OF GETTING PREGNANT IN INFERTILE MEN. Christopher Gaffney, MD,[1] Philip Xie, B.S.,[2] Nahid Punjani, MD MPH,[3] Jonathan Fainberg, MD,[3] Aaron Brant, MD,[3] Alessandra Parrella, M.Sc.,[2] Gianpiero D. Palermo, M.D., Ph.D.,[2] James A. Kashanian, MD[4] [1]Weill Cornell Medicine, New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [3]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [4]Weill Cornell Medicine - New York Presbyterian Hospital, New York, NY.

OBJECTIVE: Male infertility is associated with poor sperm capacitation function as measured by Cap-Score™. We sought to determine if Cap-Score™ would improve following microsurgical varicocelectomy.

DESIGN: We performed a prospective cohort study comparing the preoperative and post-operative Cap-Scores™ (Androvia LifeSciences) and routine semen analyses parameters in men who presented with infertility, were found to have a unilateral or bilateral varicocele on physical exam, and were treated with unilateral or bilateral microsurgical varicocelectomy.

MATERIALS AND METHODS: Varicoceles were diagnosed and graded by a single urologist in the standing position. Semen analyses were performed on fresh ejaculates according to WHO criteria. We recorded semen volume, concentration, motility, percent normal forms, Cap-Score™ and the probability of getting pregnant (PGP) and compared pre-operative values with post-operative values using Wilcoxon Rank-Sum tests in R Studio®. PGP is a validated calculated metric based on semen volume, concentration, and Cap-Score™ .

RESULTS: We identified 11 men (mean age 37.6 +/- 6.7) who presented with male factor infertility, were diagnosed with unilateral or bilateral varicoceles, and were treated with microsurgical varicocelectomy. Each of these men had a semen analysis and Cap-Score™ preoperatively and 3 months post-operatively. There was no statistical difference between semen volume, concentration, motility, or morphology before and after varicocelectomy, though there was a trend toward improvement in concentration (**Table**). Of the 11 men, 9 (81.8%) demonstrated improved Cap-Score™ and PGP after treatment. On average, Cap-Score™ increased 5.0% (p=0.03) and PGP increased 8.9% (p=0.03) after varicocelectomy **(Table).** The change in Cap-Score™ was not associated with the grade of varicocele or whether the patient had a unilateral or bilateral repair. Thus far, 2 men reported a clinical pregnancy, 1 from an IUI cycle and 1 spontaneous conception.

CONCLUSIONS: It is known that varicocelectomy improves semen parameters and conception. This study confirms that microsurgical varicocelectomy may augment male fertility by improving sperm capacitation ability. In doing so, varicocelectomy improves the probability of getting pregnant.

Table. Semen parameters and Cap-Score™ before and after microsurgical varicocelectomy

	Before Varicocelectomy		After Varicocelectomy		
	Mean	STD	Mean	STD	p-value
Volume (ml)	2.6	1.1	2.1	0.8	0.24
Concentration (million/ml)	24.4	17.4	35.6	27.1	0.19
Motility (%)	41.0	8.0	42.4	5.4	0.22
Morphology (%)	2.7	1.1	2.5	1.1	0.13
CAP Score (%)	26.7	4.5	31.7	5.2	**0.03**
PGP (%)	31.5	7.4	40.4	9.5	**0.03**

P-706 4:30 PM Tuesday, October 20, 2020

RELATION BETWEEN SPERM MORPHOLOGY AND PREGNANCY RATE AFTER AN INTRAUTERINE INSEMINATION. Mario Alfonso Patron Vazquez, Sr., Ob-Gyn,[1] Julio C. Rosales, M.D.,[2] Genaro Garcia Villafaña, Sr., MD,[1] Karla Mariel Alcalde, MD,[2] Karla Alejandra Cantú, M. Sc.,[2] Marianna Perez Vargas, MD[1] [1]IECH Fertility Center, Monterrey, NL, Mexico; [2]IECH, Monterrey, NL, Mexico.

OBJECTIVE: To determine if sperm morphology after capacitation affects intrauterine insemination outcomes.

DESIGN: Retrospective cohort study between December 2018 and April 2019.

MATERIALS AND METHODS: A total of 166 couples with unexplained infertility and 284 cycles of ovarian stimulation for intrauterine insemination were done at the IECH Fertility Center in Monterrey, Nuevo León, México and were divided between two groups: Group 1 (study group) were patients with teratospermia (sperm morphology <4%) and Group 2 (control group) were patients with normal sperm morphology (>4%). The main variable results were pregnancy rate per cycle. Sperm count, progressive motility, total count and morphology were analyzed in spermogram.

RESULTS: Demographic outcomes were homogeneous among two groups. Male patients between 31-35 years had major proportion of severe teratospermia. No statistical significance pregnancy rate was observed with the two groups (17 vs 23 p=0.2 OR=1.6). Cohort point to predict birth rate in this studied population was 5.5% with a specificity of 81% and sensibility of 30%. Patients with teratospermia had primary infertility with statistical significance comparable with control group (79.79% vs 68.42&, p= 0.0493, OR 1.82).

CONCLUSIONS: Teratospermia can't be count as a parameter to predict pregnancy in this population. Couples with unexplained infertility and sperm morphology greater that 5.5% increases chances of getting pregnant.

P-707 4:30 PM Tuesday, October 20, 2020

REPRODUCTIVE PARAMETERS IN MEN WITH SOLITARY TESTIS. Andrew Hany Rezk, BA,[1] Michael B. Tradewell, MD, MS,[1] Jesse Ory, MD,[2] Emad Ibrahim, MD, HCLD(ABB),[1] Ranjith Ramasamy, M.D[1] [1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami, Miami, FL.

OBJECTIVE: Men with solitary testis frequently report difficulties with fertility yet there is limited data available to help guide counseling. Expanding our knowledge about sperm parameters and gonadotropin levels in men with solitary testis is essential. The objective of this study was to evaluate the reproductive parameters in men with solitary testis presenting for male infertility evaluation.

DESIGN: An observational study of semen parameters and hormonal evaluation of infertile men with solitary testis.

MATERIALS AND METHODS: Data was gathered from a male infertility clinic database between January 2016 and March 2020. All men had semen analysis data, serum FSH, LH, and total testosterone (T) collected within +/-90 days. Etiology and timing of testis loss was collected. We excluded data from men with recent testosterone or steroid use.

To further assess spermatogenesis, sperm concentration and sperm motility data from men with solitary testis (case) were paired with matching semen parameters in men with bilateral descended testis (control). Medians and interquartile ranges [25-75] are reported. Statistical analysis including univariate and multivariate analysis using continuous variables (median, IQR, and range) were performed in *R*. P-values <0.05 were deemed statistically significant.

RESULTS: We identified 34 men with solitary testis. The median age was 36.27 [32.31-40.51] years. 19 men had solitary testis due to cancer, 8 due to cryptorchidism, and 7 due to trauma/torsion. Eight men did not have a recorded time of testis loss. In the remaining 26 men, the median time between orchiectomy and clinic visit was 7.75 [3.27-19.58] years and eight had a prepubertal orchiectomy.

A total of 11 / 34 men were azoospermic. In the remaining men with sperm, the median sperm concentration was 8.00 [1.50-17.00] mill/ml. Among all men, the median LH level was 6.6 [3.47-10.81] IU/L and the median T was 400 [303.00 - 499.00] ng/dl. We performed a case-control analysis with 1:1 sperm concentration and motility match between men with solitary testis and bilateral testis was completed. FSH in men with solitary testis was 14.6 [7.70-26.07] IU/L, which was significantly more elevated than men with bilateral testis (FSH: 6.8 [3.57-12.28]), p=0.012. There was no difference in T and LH.

CONCLUSIONS: Infertile men with solitary testis may have underlying sub-fertility compounded by loss of a testicle. One third of men with solitary testis were azoospermic. The elevated FSH levels in men with solitary testis compared to men with bilateral testis and matched semen parameters indicates the compensatory mechanism in these men to continue spermatogenesis and may indicate a higher degree of testicular strain.

P-708 4:30 PM Tuesday, October 20, 2020

EXPRESSION AND SIGNIFICANCE OF C1ORF100 IN TESTIS OF PATIENTS WITH NON-OBSTRUCTIVE AZOOSPERMIA. Wujiang Liu, MD,[1] Xinzong Zhang, MD,[1] Huang Liu, MD,[2] Yu Zhou, MD,[3] Cuncan Deng, MD,[3] Qingguo Zhao, MD,[3] Yunge Tang, Master degree[3] [1]Family Planning Special Hospital of Guangdong Province, Guangzhou, China; [2]Family Planning Research Institute of Guangdong Province, Guangzhou, China; [3]Family Planning Research Institute of Guangdong Province, Guangdong, China.

OBJECTIVE: To investigate the expression and significance of c1orf100 in testis of patients with non obstructive azoospermia.

DESIGN: An original ariticle.

MATERIALS AND METHODS: With informed consent, testis tissue of 20 cases of non obstructive azoospermia with different stage of spermatogenesis block were collected for affymetrix gene-chip test after mTESE surgery. Testis tissue of 20 cases of obstructive azoospermia were used as control after testicular puncture. The stage of spermatogenesis block was confirmed by tissue pathology. RT-PCR, real-time PCR, Western blot and immunohistochemistry were performed to confirm the finding of gene chip.

RESULTS: The expression of c1orf100 in testis of non obstructive azoospermia was significantly decreased compared with obstructive azoospermia, which was related to the stage of spermatogenesis block. RT-PCR, real-time PCR and Western blot confirmed the above rusults from mRNA and protein levels respectively. Immunohistochemistry showed that c1orf100 was mainly expressed in the nucleus and cytoplasm of spermatogenic cells at all stages, and its expression intensity was related to the stage of spermatogenesis block. The expression of c1orf100 was significantly reduced in testis of patients with sertoli cell only syndrome.

CONCLUSIONS: c1orf100 may be a new molecular marker related to spermatogenesis, which is worthy of further study.

P-709 4:30 PM Tuesday, October 20, 2020

VARICOCELE INDUCE OXIDATIVE STRESS AND SPERM DNA DAMAGES IN INFERTILES PATIENTS. Mariem ben Khelifa, PhD, Hanen Elloumi, Dr, Sonia Mnallah, Dr, med Habib BEN Aribia, Dr, Mohamed Khrouf, Dr, Fethi Zhioua, Dr, Khaled Terras, Dr, Moncef Benkhalifa, PhD, Khaled Mahmoud, Dr FERTILLIA center, Tunis, QC, Tunisia.

OBJECTIVE: Varicocele is one of the most common andrological pathologies in the general population and particularly common in infertile men. The pathogenesis of varicocele related infertility is not completely defined to explain the correlation of varicocele and infertility. Imbalance between excessive reactive oxygen species production and antioxidant protection causes sperm DNA injuries, thus rendering the spermatozoa less fertile in a subset of varicocele patients.Therefore we studied the relationship between OS levels, DNA integrity and sperm parameters in infertile men with or without varicocele.

DESIGN: This is a prospective comparative study, performed between januray and december 2019, includes patients with primary or secondary infertility (>3 years). Semen samples were obtained from 115 patients. The patients were grouped into 2 groups : 31 patients with a clinically diagnosedof a grade II or III varicocele and a control group (84 men). Exclusion criteria for control group were presence of varicocele, evidence of urogenital infections, and a history of smoking or excessive alcohol.

MATERIALS AND METHODS: In each semen sample, which was collected after sexual abstinence of 2–5 days in addition to conventional sperm parameters the following parameters were measured : (i) Spermatozoa with DNA strand breaks were assessed by TUNEL (cut-off value<30%), (ii) Abnormal chromatin condensation using Aniline Blue assays (cut-off value<20%), (iii) Oxidative stress was measured by MioXSYS Analyzer. Data were analyzed with SPSS and a correlation analysis was performed using non transformed values. Statistical significance was set at p<0,05.

RESULTS: There were no difference in age and duration of infertility the two groups. No difference exist between patients of control group and patients of varicocele groups concerning semen parameters, h: sperm concentration (34.48 vs 31.83 x 10^6 sperm/mL) progressive motility (30% vs 29%), and vitality (61.45% vs 59%). However all parameters showed a tendency towards being lower in the group with varicocele. There is a significative difference between OS and DNA fragmentation and chromatin decondensation between the two groups. The varicocele group showed a positive correlation between OS and DNA fragmentation and also between OS and chromatin decondensation.

CONCLUSIONS: The presence of varicocele may impair sperm DNA integrity and fertility. Given the extant literature, varicocele repair and antioxidant should be considered to reduce DNA damage in sperm.

P-710 4:30 PM Tuesday, October 20, 2020

EFFECT OF MICROSURGICAL VARICOCELECTOMY ON NONOBSTRUCTIVE AZOOSPERMIA (NOA) AND SEVERELY OLIGOZOOSPERMIA. Tomomoto Ishikawa, M.D., Kotaro Kitaya, M.D. Reproduction Clinic Osaka, Osaka, Japan.

OBJECTIVE: Varicoceles are the most frequent physical abnormality found in infertile men and surgical ligation of spermatic vein is generally accepted as the treatment of choice for this condition. The aim of this study is to assess the treatment outcome and the benefits after microsurgical varicocelectomy in men with nonobstructive azoospermia (NOA) and severely oligozoospermia.

DESIGN: Retrospective clinical analysis.

MATERIALS AND METHODS: The records were retrospectively evaluated for 41 patients with NOA and 259 severely oligozoospermic patients who underwent microsurgical inguinal varicocele ligation. The age was 34.34.3 (meanSD) years. Two hundred sixty-nine (90%) underwent a unilateral left-sided procedure (33 of 41 with NOA, 236 of 259 with severe oligospermia), and 31 (10%) underwent a bilateral procedure. Severely oligozoospermia was defined as $<5x10^6$/ml in all analyses submitted. Our indication of varicocelectomy for NOA patients was more than 12 ml of testicular volume preoperatively and the palpable varicocele. We obtained institutional review board approval as well as individual patient signed consents. Chi-square test was used to compare continuous variables between the groups. In all cases, statistical significance was set at $P < 0.05$. ±

RESULTS: After ligation, induction of spermatogenesis was achieved in six men (14.6%). We could not find the predictive factor retrospectively (e.g. hormone levels or testicular volume). The sperm concentration increased from 2.71.4 to 12.16.5 million/mL ($P<0.001$) with severely oligozoospermic patients. The sperm motility did not change significantly. Twenty seven (10.4%) of the 259 oligospermia men have contributed to unassisted pregnancies. Among 259 patients with severely oligozoospermia, improvement of sperm concentration was seen in 152 patients (responders, 59%). Between responders and non-responders with severely oligozoospermia, no significant differences were seen in FSH level (9.25.5 and 10.44.9 IU/L, respectively), LH level (4.72.2 and 5.13.5 IU/L, respectively), testosterone level (4.32.2 and 4.52.4 ng/mL, respectively), left testicular volume (15.63.3 and 16.13.4 mL, respectively), the percentage of varicocele grade III (52 and 54 %, respectively), and the volume of semen (2.80.7 and 2.91.2 mL, respectively).

CONCLUSIONS: Microsurgical varicocelectomy resulted in the induction or enhancement of spermatogenesis for several men with NOA or severely oligozoospermia. It is reasonable to be considered an option in selective patients with NOA before testicular sperm extraction and severely oligozoospermia.

THE CONFOUNDING EFFECT OF ADDITIONAL ABNORMAL SEMEN PARAMETERS ON PREGNANCY OUTCOME FOLLOWING IN VITRO FERTILIZATION-EMBRYO TRANSFER (IVF-ET) USING SPERM FROM MEN WITH ABNORMAL HYPO-OSMOTIC SWELLING (HOS) TESTS. Jerome H. Check, M.D., Ph.D.,[1] Carrie K. Wilson, B.A.,[2] Donna Summers, M.S.,[2] Diane L. Check, BS, MT,[2] Jung Choe, M.D.[1] [1]Cooper Medical School of Rowan University, Camden, NJ; [2]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ.

OBJECTIVE: In the early days of IVF-ET, before the advent of intracytoplasmic sperm injection (ICSI), a low HOS test was found to be by far the best single semen parameter to predict failure to achieve a live delivery

despite normal fertilization and normal embryo development. Unfortunately, for unknown reasons, this simple inexpensive test is not performed in most fertility centers when evaluating the male's semen analysis. The purpose of the present study was to evaluate whether the association of an additional abnormal semen parameter, i.e., either low motile density, low normal morphology by strict criteria, or low % motility, negatively effected the live delivered pregnancy rate in males with low HOS test scores with IVF with ICSI.

DESIGN: Prospective observational comparative study.

MATERIALS AND METHODS: The male partners of couples seeking help for infertility had semen analyses performed for standard parameters and also for the HOS test. If the HOS test score was <50% the couples were explained that successful live deliveries with this abnormality is extremely rare without treatment. The two treatment options were either IVF with ICSI or performing intrauterine insemination (IUI), but with this toxic protein causing the implantation defect, the sperm would first be treated with the protein digestive enzyme chymotrypsin. The first IVF cycle of those choosing IVF with ICSI was evaluated. The data were sub-analyzed into 3 sets of pairs – low motile density vs. normal ($<10x10^6$/mL vs. $\geq 10x10^6$/mL), subnormal morphology vs. normal by strict criteria ($\leq$4% vs. >5%) and low percent motility vs. normal (<30% vs. $\geq$30%).

RESULTS: The results are seen in the table below.

	MD $<10x10^6$/mL	MD $\geq 10x10^6$	Normal morphology strict criteria <5%	Normal morphology strict criteria ≥5%	% motility <30%	% motility ≥30%
# transfers	106	76	95	74	71	111
Avg. age	38.6	40.6	39.1	40.0	39.1	39.8
% clinical preg./transfer	32.1%	25.0%	37.9%	21.6%	25.4%	31.5%
% delivered	27.4%	15.8%	31.6%	13.5%	22.5%	22.5%

CONCLUSIONS: Having an additional abnormal semen parameter, in addition to a subnormal HOS test score, does not reduce success with IVF with ICSI. The HOS abnormality increases in frequency with advancing age of the male. Older men are more likely to try to conceive with women that are also of mildly advanced reproductive age. One could interpret the data that sperm of males with low HOS test scores have a trend for lower pregnancy rates if other semen parameters are normal. However, the most likely explanation for the trend for lower live delivery rates using sperm with additional semen parameter normal was slightly higher female age in these groups. Though only 1-2 years different, the age for the normal group was at a critical age where pregnancy rates plummet.

THE EFFECT OF PATERNAL AGE ON ICSI OUTCOME IN UNEXPLAINED INFERTILITY. Mohamed Arafa, MD, Kareim Khalafalla, MD, Ahmad Majzoub, MD, Hasan Burjaq, MSc, Moza Al Badr, MSc, Sami Alsaid, MD, Haitham Elbardisi, MD Hamad Medical Corporation, Doha, Qatar.

OBJECTIVE: Unexplained infertility is reported in 15%-30% of infertile cases. The most effective treatment in such cases is IVF/ICSI. Advanced male age is reported to negatively affect semen parameters, however its effect on ICSI outcome is controversial. This study aims at evaluating the effect of paternal age on ICSI outcome in couples with unexplained infertility.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: Male patients with normal semen parameters undergoing ICSI in the assisted reproduction center using ejaculated sperm during the period from January 1st, 2014 till June 1st, 2019 were screened for inclusion in the study. Couples with female factor (wife age ≥40yrs, AMH level <2.8pmol/L, and/or other gynecologic problems) were excluded.

Patients demographics, clinical and laboratory data were collected. Semen data at time of ICSI was collected; semen analysis results (WHO 5th edition), Oxidation reduction potential (ORP) (MiOXSYS analyzer) and sperm DNA fragmentation (SDF) (Halosperm kit, Ref ≤30%). Female demographics and clinical data as well as ICSI outcome was also collected.

Numbers (percentages) were used to report categorical values while mean ± SE was used to report numerical values. Results were compared using Kruskal Wallis Test and a p value of <0.05 was considered statistically significant. The SPSS version 20 (IBM, Armonk, NY) was used to conduct the statistical analysis.

RESULTS: A total of 117 couples with unexplained infertility were included in the study. The mean age of the male was 35.6±0.4years while that of the female was 33.2 ± 1.3 years. There was no significant correlation for age with most semen parameters except for normal sperm morphology (positively correlated, r -.232, p=0.012) and SDF (negatively correlated, r .276, p=0.010).

The overall clinical pregnancy rate was 29.1%. Patients were divided into 2 groups, clinical pregnancy and No clinical pregnancy (Table 1). The male age was significantly lower in clinical pregnancy group. Semen volume, sperm concentration, total motility, normal morphology, SDF and ORP were better in the Clinical pregnancy group but the difference was not statistically significant.

CONCLUSIONS: In patients with unexplained infertility, younger paternal age favors success of ICSI.

Parameters	Clinical Pregnancy (n=34)	No Clinical Pregnancy (n=83)	P value
Male Age	35.4 ±0.92	37.93 ±0.79	0.04*
Vol (ml)	3.3±0.22	2.9±0.14	0.72
Concentration (millions/ml)	57.2±6.8	53.8±3.5	0.66
Motility (%)	56.3±1.79	55.8±1.05	0.79
Normal Morph (%)	9.8±0.99	10.9±0.78	0.39
DNA Fragmentation (%)	17.8±1.17	20.7±1.23	0.096
ORP (mV/106 sperm/mL)	1.5±0.36	1.3±0.14	0.62

PERINATAL OUTCOMES OF SURGICALLY RETRIEVED SPERMS IN NON OBSTRUCTIVE AZOOSPERMIA, 10 YEARS EXPERIENCE OF AN INDIAN CLINIC. Amaz Areeb N, Jr., Master in Bio Technology,[1] Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[2] Durga Rao Gedela, MBBS, DGO, MRCOG, fellowship in infertility and reproductive endocrinology,[3] Sandeep Karunakaran, Sr., M.B.B.S, MS, PGDHM, PGDMLE,[4] Rajesh Mani Raghupathy, MBBS, PGDCE,[5] Yedluri Rupasree, M.Sc Biotechnology, PhD Biotechnology, PGDCE,[5] Afsha Firdouse, M.Sc Biochemistry, PGDCE[5] [1]Oasis Fertility, Chennai, India; [2]Oasis center for reproductive medicine, Hyderabad, India; [3]oasis fertility, Hyderabad, India; [4]OASIS FERTILITY, Hyderabad , TELANGANA, India; [5]Oasis fertility, Hyderabad, India.

OBJECTIVE: To look at the perinatal outcome of surgically retrieved spermatozoa (SRS) in individuals with Non obstructive Azoospermia (NOA).

DESIGN: This is a Retrospective Study at our Private IVF clinic from 2010 to 2019. 989 patients underwent SRS under general anaesthesia. Of

these 264 patients were indicated for NOA. 155 patients had successful Sperm retrieval and 93 patients finally had successful frozen embryo transfers with two good grade blastocysts and 425 ICSI cycles with Ejaculate sperms (EjS) were in control group.

MATERIALS AND METHODS: In this study couples who had successful SRS from testes and Intra-Cytoplasmic Sperm Injection (ICSI) with self-Oocytes and had blastocysts frozen for transfer were included.

All NOA patients underwent SRS either before the oocyte retrieval (OPU) and frozen for subsequent use or SRS was done at OPU and fresh testicular sperms used for ICSI. SRS was done as per our clinics standard operating protocol (SOP). All women underwent controlled ovarian stimulation, OPU and ICSI with fresh or frozen SRS. Embryos cultured till blastocyst stage and a freeze all policy was followed. Two blastocysts were transferred in a frozen cycle.

PRIMARY OUTCOMES – Live Birth rate (LBR) and Perinatal outcomes

SECONDARY OUTCOMES – Reproductive Outcome Fertilization rate (FR), Blastocyst rate (BR), Implantation Rate (IR), clinical pregnancy rate (CPR), Miscarriage rate (MR), Multiple Pregnancy Rate(MPR) and Lost for follow up (LFU).

RESULTS: Mean outcomes of Study Vs Control group were as follows:

FR - 92.35% Vs 92.30% (P= 1.0000)
BR - 42.59% Vs 48.8% (P=0.2779)
CPR - 64.52% Vs 62.93% (P= 0.7735)
IR - 45.35% Vs 48.97% (P= 0.5273)
MR -7.53% Vs 9.98% (P=0.4667)
LFU is 9.78% Vs 0%
LBR - 46.47% Vs 51.4% (P=0.3895)
MPR -27.27% Vs 17% (P=0.0219)

Maternal complications

Gestational Diabetic Mellitus - 3% Vs 1.8% (P= 0.4562)

Pregnancy Induced Hypertension (PIH) – 0% Vs 2.1% (P=0.1590)

Intra-Uterine Growth Restriction (IUGR) – 0% Vs 0.3% (P= 0.5973)

Perinatal outcomes –

Average BW - 2.52 Kg Vs 3.01 kg

%Normal BW (>2.5kgs)– 59.52% Vs 63% (P= 0.5307)

% Low BW (1.5-2.5kgs)- 30.95% Vs 31% (P=0.9925)

%Very Low BW (<1.5kgs) - 9.52% Vs 6% (P= 0.2170)

pre-term Birth (<37weeks gestation) - 15.5% Vs 12.8% (P= 0.4876)

Congenital Anomalies in Study Group

one baby was diagnosed with Angelman syndrome (AS), one infant diagnosed with Rabdomyoma at 5th month in study group

Congenital Anomalies in Control Group

one baby with hydrocephalus, one ARDS due to meconium aspiration and the baby died after 18 days, 3 babies died in NICU after pre term delivery.

Data from this study doesn't seem to adversely affect Reproductive and Perinatal outcomes with use of Testicular sperms for ICSI in NOA men.

CONCLUSIONS: In NOA use of SRS doesn't seem to alter reproductive and perinatal outcomes. However, long term follow up of these children is still advised.

P-714 4:30 PM Tuesday, October 20, 2020

IDENTIFICATION OF A NOVEL SOMATIC STEM CELL POPULATION IN ADULT MOUSE TESTIS INVOLVED IN TISSUE HOMEOSTASIS AND REGENERATION. Adrienne N. Shami, B.S.,[1] Yu-chi Shen, Ph.D.,[1] Hailey Larose, Ph.D.,[1] Lindsay Moritz, B.S.,[1] Gabriel Manske, B.S.,[1] Qianyi Ma, Ph.D.,[1] Xianing Zheng, B.S.,[1] Meena Sukhwani, Ph.D.,[2] Kyle E. Orwig, Ph.D.,[2] Jun Z. Li, Ph.D.,[1] Sue Hammoud, Ph.D.[1] [1]University of Michigan, Ann Arbor, MI; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.

OBJECTIVE: The somatic cells of the testes have critical functions in maintaining spermatogenesis and testosterone production. Similar to other tissues, these functions decline with age, but whether adult testis somatic cells maintain the ability to repair or regenerate remains unclear. Here, we test the functional significance of a recently identified adult mouse testis interstitial cell population expressing the transcription factor Tcf21 in testis homeostasis, aging, and injury.

DESIGN: We utilized single-cell RNA-sequencing (scRNAseq), *in vitro* cell differentiation assays, genetic lineage tracing, and targeted ablation methods to characterize the fate and potential of Tcf21$^+$ cells *in vitro* and *in vivo*.

MATERIALS AND METHODS: To determine whether this population has mesenchymal stem cell properties, we enrich for Tcf21$^+$ cells using flow cytometry and perform clonogenic and trilineage differentiation assays. Using knowledge from our scRNAseq data, we direct the differentiation of adult Tcf21$^+$ cells to testosterone producing Leydig cells and smooth muscle cells. We further characterize the molecular mechanism of *in vitro* differentiation using scRNAseq across several timepoints, and compare *in vitro* derived cells to *in vivo* cells. Finally, to examine the fate and potential of the cells *in vivo* during gonadogenesis, homeostasis and aging, we combine genetic lineage tracing with or without genetic and chemical ablation approaches.

RESULTS: Through genetic lineage tracing experiments we show that the Tcf21$^+$ cells in the fetal gonad contribute to all somatic lineages of the fetal testis, as well as the ovary. In the adult testis, Tcf21$^+$ cells serve as a reserve somatic progenitors in response to tissue injury and maintain testis tissue homeostasis during aging. *In vitro*, we demonstrate that the Tcf21$^+$ cells are multipotent mesenchymal progenitors which give rise to multiple somatic lineages, including two terminally differentiated testis somatic cell types: Leydig and myoid. Consistent with this multipotency, we find that the testis Tcf21$^+$ population has high transcriptomic similarity to resident fibroblast populations in other organs.

CONCLUSIONS: In summary, we show that the recently described population of Tcf21$^+$ cells are bipotential somatic progenitors in the fetal gonad, and this population persists in the adult testis where it can replenish somatic cells during aging and following injury. We also show that the testis Tcf21+ population resembles resident fibroblast populations in multiple organs which have been previously implicated in tissue homeostasis and regeneration. Therefore, we believe that the testis, like other organs, maintains a reserve multipotent somatic cell progenitor. Here, we demonstrate methods for enrichment and differentiation of adult Tcf21+ cells *in vitro*, with potential as a platform for further study of testicular pathology and therapeutics. Future translational studies will determine if an analogous cell population exists in humans, as these somatic progenitor cells have enormous potential for the development of novel treatments for hypogonadism and infertility.

P-715 4:30 PM Tuesday, October 20, 2020

RAISED SPERM DNA FRAGMENTATION – WILL INTERVENTION WITH SURGICAL RETRIEVAL OF TESTICULAR SPERMS OPTIMIZE REPRODUCTIVE AND PERI-NATAL OUTCOMES ?A DECADE'S OBSERVATIONAL STUDY FROM AN INDIAN CLINIC. Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Afsha Firdouse, M.Sc BioChemistry, PGDCE,[1] Rajesh Mani Raghupathy, MBBS, PGDCE,[2] Yedluri Rupasree, M.Sc Biotechnology, PhD Biotechnology, PGDCE,[1] Durga Rao Gedela, MBBS, DGO, MRCOG, fellowship in infertility and reproductive endocrinology,[2] Sandeep Karunakaran, Sr., M.B.B.S, MS, PGDHM, PGDMLE[3] [1]Oasis fertility, Hyderabad, India; [2]oasis fertility, Hyderabad, India; [3]OASIS FERTILITY, Hyderabad , TELANGANA, India.

OBJECTIVE: For Individuals with Raised Sperm DNA Fragmentation (SDF), will intervention with Surgical Retrieval of Sperms (SRS) from testes optimize Reproductive and Peri-Natal outcomes in Assisted Reproductive Techniques (ART) cycles.

DESIGN: This is a retrospective study at our private IVF clinic from 2010 to 2019.

MATERIALS AND METHODS: SAMPLE SIZE: Couples with history of at least one failed IVF cycle were offered testing for SDF by SCSA method. SDF >30% was considered high and such couples were offered SRS from testes and testicular sperms were used for ICSI (n= 342). Couples were counselled about the risks, benefits and experimental nature of this intervention. Written consent was obtained from the couple and taken through an ART cycle with SRS from tests. Women underwent controlled ovarian stimulation and oocyte retrieval as per our clinic's standard operating protocol (SOP). Fertilized oocytes were cultured till blastocyst stage and freeze all policy was adopted. Two blastocysts were transferred in a frozen embryo replacement cycle.

INCLUSION CRITERIA: Individuals who had successful SRS with self-gamete cycles were included in this study.

Exclusion CRITERIA: Donor gamete cycles and individuals who had failed SRS were excluded from this study.

Primary Outcomes: Implantation rate (IR), Live birth rates (LBR) and Perinatal outcomes

(Gestation Diabetes (GDM), Pregnancy Induced Hypertension (PIH), Intra Uterine Growth Restriction (IUGR), mean Pre-Term Birth rate (PTB), Birth weight (BW Normal - >2.5kgs), Low Birth weight (LBW – 1.5-2.5kgs), Very LBW (VLBW - <1.5kgs)

Secondary Outcomes: Fertilization rate (FR); blastocyst rate (BR), Clinical pregnancy rate (CPR); Miscarriage rate (MR) and Multiple Pregnancy rate (MPR)

RESULTS: Mean of the outcomes were as follows:

FR - 93.35%, **BR** - 35%, **IR** - 40.34%, **CPR** - 56.90 %, **MR** was 12.03 %, **MPR** – 17.2% , **LBR** - 35.23, **GDM** – 6.06%, **PIH** – 6.82%, No IUGR reported in the study group. 17.4% had PTB. Mean BW was 2.5 kg. Out of this **Normal BW** was 55.6 %, **LBW** was 36.7 % and **VLBW** was 13.3 %.

Use of SRS in couples with raised SDF seems to offer optimal reproductive and perinatal outcomes. Couples seeking ART with raised SDF, SRS can be offered as an active intervention.

CONCLUSIONS: Testicular sperm for Raised SDF seem to offer beneficial reproductive and perinatal outcomes in ART cycles. TESA can be offered as an active intervention.

POSTER SESSION: PCOS

P-716 4:30 PM Tuesday, October 20, 2020

POLYMORPHISMS AND HAPLOTYPE OF MITOCHONDRIAL DNA CONTROL REGION ARE ASSOCIATED WITH POLYCYSTIC OVARY SYNDROME IN A CHINESE POPULATION. Dongmei Ji, master,[1] Xiaohong Deng, bachelor,[2] Kai Zong, master,[3] Xinyuan Li, bachelor,[2] Yu Cao, bachelor,[2] Yunxia Cao, Doctor[2] [1]reproductive genetics, mitochondrial disease, Hefei, China; [2]The First Affiliated Hospital of Anhui Medical University, Hefei, China; [3]molecular biology, Heifei, China.

OBJECTIVE: To investigate the relationship between mitochondrial DNA (mtDNA) D-loop region mutations, mtDNA haplogroup and polycystic ovary syndrome (PCOS), as well as the correlation of D-loop variants and clinical characteristics of PCOS, in a Chinese population.

DESIGN: Case-control study.

MATERIALS AND METHODS: A total 420 PCOS patients and 390 controls were enrolled in this study.PCOS patients were divided into BMI matched and mismatched groups relative to controls.Biochemical estimation of basal hormone levels, fasting glucose and insulin levels were carried out. The D-Loop region of whole blood samples was amplified and sequenced, and polymorphisms identified by comparison to the Cambridge Reference Sequence. Patient haplogroup was identified from D-Loop single nucleotide polymorphisms (SNPs). Polymorphisms and haplotype was subsequently correlated with disease state and clinical characteristics via regression analysis. For analysis of clinical characteristics, subjects were grouped according to high or normal levels.

RESULTS: Significant differences were detected at 6 loci in comparison of BMI matched patients and controls; T16086C, C16234T, G207A, 16049Gins, 16036GGins and A16051G.The T16086C variant was associated with PCOS while the other 5 SNPs were associated with the control group.In the same groups, A189G was found to be positively associated with hyperandrogenemia, and T489C negatively. Polymorphism T16086C was associated with increased ratio of LH:FSH whereas 16049Gins, 16036GGins, C16234T, A16463G were associated with normal LH:FSH. Polymorphism T152C was associated with normal insulin resistance (IR). In the patient group with high BMI relative to controls, C151T, 249d and A16203G were associated with PCOS, whereas C150T and T16362C where associated with the control group. Polymorphism A16203G showed a further association with hyperandrogenemia group. Polymorphism T16357C was associated with increased LH:FSH, while 16036GGins, 16049Gins, T16093C and C16266T were associated with normal LH:FSH. Polymorphisms A93G, 249d, C16187T and T16203C were associated with high IR, while G207A and 16049Gins were associated with normal IR. Analysis of haplogroups suggested that A15 is negatively associated with PCOS.

CONCLUSIONS: A number of mtDNA D-loop mutations appear to confer susceptibility or resistance to PCOS in Chinese women, whereas haplotype A15 decreases risk. However, BMI influences which D-loop variants confer risk and must be taken into account.

P-717 4:30 PM Tuesday, October 20, 2020

THE IMPACT OF POLYCYSTIC OVARY SYNDROME ON PLACENTAL HISTOPATHOLOGY PATTERNS IN IVF SINGLETON LIVE BIRTHS. Ginevra Mills, MD, FRCSC,[1] Alexander Volodarsky-Perel, M.D.,[1] Michael H. Dahan, M.D.[2] [1]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Centre, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada.

OBJECTIVE: The objective of this study was to evaluate placental histopathology patterns in placentas of women with polycystic ovary syndrome (PCOS) who underwent in-vitro fertilization.

DESIGN: This is a retrospective study utilizing full gross and histopathologic assessment of placentas of 100% of women who had IVF and delivered at the Royal Victoria Hospital (RVH) from 2009-2017, regardless of complications or mode of delivery. Women with pre-existing diabetes were excluded from analysis.

MATERIALS AND METHODS: Placentas were examined in one pathology department and pathological reports were revised by one perinatal gynecology pathologist. Pathologic findings were categorized into anatomic, inflammation, villous maturation, and vascular malperfusion features. A multivariate logistic regression model was used to adjust the results for confounding factors potentially associated with significant placental and perinatal characteristics including (but not limited to) age at embryo transfer (ET), embryo stage at ET, embryo quality, BMI, gravidity, hypothyroidism, development of gestational diabetes (GDM), gestational age at delivery, placental delivery method, birth weight, and placental weight,. Adjusted odds ratios (aOR) with 95% confidence intervals (95% CI) were calculated.

RESULTS: Demographic characteristics of women with PCOS (n=47) and ovulatory controls (n=1121) were comparable with respect to age at oocyte retrieval (p=0.12) and embryo transfer (ET) (p=0.11), BMI (p=0.92), smoking history (p=0.69), gravidity (p=0.69), and parity (p=0.11). There was also no difference between the two groups with respect to mode of delivery (p=0.84), gestational age at delivery (p=0.29), or preterm labour rate (p=0.37). Women with PCOS developed GDM more often compared to those without PCOS (38.3% vs. 9.8% p<0.001). Placentas from PCOS women were more likely to have anatomical differences including circumvallate placentas (aOR 8.3, 95% CI 1.9-37.3) and hypercoiled umbilical cord (aOR 6.8 95% CI 1.3-36.8). Villitus of unknown etiology (VUE) occurred more often in placentas from women with PCOS compared to controls (aOR 6.1, 95% CI 1.5-25.6). There was an increased likelihood of chorangiosis (aOR 2.7, 95% CI 1.3-5.8), evidence of fetal vascular malperfusion based on one criteria (aOR 2.7, 95% CI 1.1-7.4), or more than one criteria (aOR 6.4, 95% CI 1.6 – 25.9), more nucleated fetal red blood cells (aOR 5.2, 95% CI 1.1-24.5), and higher likelihood of chorangiomas (aOR 9.4, 95% CI 1.6-55.1) in placentas from PCOS women than in controls.

CONCLUSIONS: Placental histopathological characteristics are significantly impacted by an underlying diagnosis of PCOS at the time of pregnancy initiation. Placentas in women with PCOS are more likely to have important anatomic changes and vascular placental abnormalities. The effect of these features, as well as the underlying mechanism of their development should be evaluated in further studies.

P-718 4:30 PM Tuesday, October 20, 2020

CYTOKINE CONTENT OF FOLLICULAR FLUID IN WOMEN WITH POLYCYSTIC OVARIAN SYNDROME (PCOS). Lauren Rouleau, MD, PhD,[1] Anna K. Knight, PhD,[1] Sabrina A. Gerkowicz, MD,[2] Shang Weirong, PhD,[1] Laurie J. McKenzie, M.D.,[3] Alicia K. Smith, PhD,[1] Heather S. Hipp, MD[1] [1]Emory University School of Medicine, Atlanta, GA; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [3]Baylor College of Medicine, Houston, TX.

OBJECTIVE: Polycystic ovarian syndrome (PCOS) is one of the most common endocrine disorders among women and is often associated with infertility. Previous studies have shown that women with PCOS have higher levels of proinflammatory markers (IL-1, IL-6, and TNF-alpha), but they have focused on a limited number of inflammatory biomarkers in peripheral blood only. We investigated differences in cytokine concentration of follicular fluid between women with and without PCOS, hypothesizing that women with PCOS will have significantly higher levels of pro-inflammatory cytokines.

DESIGN: Nested case control study.

MATERIALS AND METHODS: Follicular fluid was obtained at a single time point during oocyte retrieval from women undergoing a cycle of in vitro fertilization. Women with PCOS were identified according to the Rotterdam criteria, while control women were those undergoing oocyte retrieval for planned fertility delay, oocyte donation, male factor infertility, uterine factor infertility, or unexplained infertility. 58 unique samples of follicular fluid were collected at the time of oocyte retrieval. Descriptive statistics for age, body mass index (BMI), parity, and ovarian reserve parameters of the cohort were examined, followed by t-tests to determine any significant differences between the groups. The follicular fluid samples were analyzed using Ray Biotech Quantibody® Human Cytokine Antibody Array 440, which is a multiplexed sandwich enzyme linked immunosorbent assay (ELISA) quantitative array platform. Primary outcome was cytokine concentrations and secondary outcomes were number of oocytes retrieved, embryo quality, miscarriage rates, and live birth rates. The cytokine data was analyzed using quantile regression, while controlling for age and BMI.

RESULTS: There were no significant differences in age, BMI, number of blastocyst stage embryos, or estradiol level on trigger day between women with PCOS and controls in our cohort. Women with PCOS did have higher anti-Müllerian hormone ($p=0.014$) and number of oocytes retrieved ($p=0.021$). After controlling for age and BMI, out of 440 cytokines, 12 had statistically significant differences between patients with PCOS and controls: IL-1 receptor 2, IL-17, MMP9, MMP13, XEDAR, IL-37, decorin, TGFb2, matrilin3, trapin2, thrombopoietin, and AgRP ($p<.05$). Although IL-17, a pro-inflammatory cytokine, was elevated, IL-37, an anti-inflammatory cytokine was also elevated, clouding the overall impact of pro-inflammatory cytokines in follicular fluid of PCOS patients. No cytokines were statistically significant after multiple test correction using FDR <0.05.

CONCLUSIONS: There were few significant differences in cytokine content of follicular fluid in patients with PCOS compared to controls. MMP9, MMP13, decorin, and matrilin3 are all involved in collagen/extracellular matrix rearrangement, raising the possibility of an intrinsic structural difference in the ovaries of these patients on a cellular level. The results suggest inflammatory content of follicular fluid may not be the driving pathology in differences in IVF outcomes in patients with PCOS.

P-719 4:30 PM Tuesday, October 20, 2020

DIFFERENCES IN PCOS PRESENTATION AMONG BLACK WOMEN IN CALIFORNIA AND ALABAMA. Katherine VanHise, MD,[1] Sahar Wertheimer, MD,[1] Roy G. Handelsman, MD,[1] Rae A. Buttle, BA,[1] Jessica L. Chan, MD, MSCE,[1] Erica T. Wang, MD, MAS,[1] Ricardo Azziz, MD, MPH,[2] Margareta D. Pisarska, MD[1] [1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of Alabama at Birmingham, Birmingham, AL.

OBJECTIVE: To compare the PCOS phenotype among Black women in California vs. Alabama.

DESIGN: Tertiary-care based cohort study.

MATERIALS AND METHODS: Black women and adolescents (age $\geq$12) from Los Angeles and Birmingham presented for consultation from 1980 to 2010. Demographic data were obtained including age, hyperandrogenism and menstrual cycle history. A modified Ferriman-Gallwey (mFG) was performed to assess clinical hyperandrogenism (defined as mFG$\geq$4). Markers of metabolic dysfunction were measured including body mass index (BMI), waist-to-hip ratio (WHR), glucose and insulin during a 2-hour glucose tolerance test. Categorical variables between the groups were compared using student's t-tests, rank sum or X^2 tests, as appropriate. A logistic regression was performed to adjust comparisons for BMI.

RESULTS: Three hundred twenty-three Black patients were identified, of which 184 were diagnosed with PCOS by Rotterdam criteria. Alabama patients were younger in age and had higher BMI (Table 1). Even after adjusting for BMI, women in Alabama were more likely to be hirsute, adjusted odd ratio (aOR) 3.08 (CI95%: 1.8-5.2, $p<0.001$), and were more likely to have oligo-ovulation (aOR 1.97, CI95%: 1.2-3.2, $p=0.007$). 0 min. and 60 min. glucose, and 60 min. insulin values, were higher in the Alabama cohort.

Table 1

	California	Alabama	Unadjusted p-value
Total Black, n=323	134	189	
PCOS (%)	73 (62.9%)	111 (95.7%)	<0.001
Age (SD), yr	32.2 (8.0)	28.8 (9.1)	0.0007
BMI (SD), kg/m^2	31.4 (8.7)	34.1 (8.4)	0.006
WHR (SD)	0.85 (0.1)	0.84 (0.1)	0.35
Mean mFG score (SD)	5.6 (5.0)	8.1 (5.3)	<0.001
Clinical HA (%)	78 (58.2%)	155 (82.0%)	<0.001
Oligo-ovulatory (%)	75 (56.8%)	138 (74.2%)	0.001
% elevated glucose, 0 min.	2 (5.4%)	14 (19.2%)	0.04
% elevated glucose, 60 min.	0 (0%)	7 (9.6%)	0.048
% elevated glucose, 120 min.	5 (13.2%)	12 (16.4%)	0.44
% elevated insulin, 0 min.	10 (29.4%)	33 (42.3%)	0.20
% elevated insulin, 60 min.	24 (68.6%)	37 (47.4%)	0.037
% elevated insulin, 120 min.	19 (52.8%)	38 (48.7%)	0.69

CONCLUSIONS: In this study, Black women with PCOS in Alabama had a higher prevalence of oligo-ovulation and clinical HA compared with Black women with PCOS in California, even after adjusting for BMI. Some markers of metabolic dysfunction were also higher in Black women with PCOS in Alabama, even after adjusting for BMI. These data suggest that there are geographic differences in PCOS phenotypes, reinforcing the need for more investigation on the environmental determinants of PCOS.

METABOLIC AND REPRODUCTIVE PCOS-LIKE TRAITS FOLLOWING ESR1 KNOCKDOWN IN THE MEDIOBASAL HYPOTHALAMUS OF ADULT FEMALE RHESUS MONKEYS. David H. Abbott, Ph.D,[1] Emily P. Greinwald, BS,[2] Jesi A. Felton, BS,[2] Matthew T. Flowers, PhD,[2] Molly M. Willging, BS,[2] Robert A. Shapiro, PhD,[2] Kim L. Keen, BS,[2] Ei Terasawa, PhD,[2] Daniel J. Uhlrich, PhD,[2] Jon E. Levine, PhD[2] [1]University of Wisconsin, Madison, WI; [2]University of Wisconsin, Madison, WI.

OBJECTIVE: In primates, including humans, the estrogen receptor mediating neural hypothalamic control of metabolic and reproductive function is unknown. This study therefore tests the hypothesis that diminished estradiol (E2) action by neuronal ESR1 in the female nonhuman primate mediobasal hypothalamus (MBH) causes weight gain and hyperandrogenism resembling polycystic ovary syndrome (PCOS) in women.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Eleven, ovary intact, adult female rhesus macaques, pair housed with female peers, received five 12μl MRI-guided MBH infusions into the rostral-to-caudal extent of both right and left ARC. Each infusion comprised gadolinium contrast agent and adeno-associated virus 8 (AAV8) particles containing either a shRNA specific for ESR1 (n=6, ERaKD) or scrambled shRNA (n=5, control). Mid-surgery MRI scans identified targeting accuracy. 1-2.5 years following AAV8 infusion, EIA-determined P4 values were obtained from twice weekly serum samples; samples obtained during the follicular phase of menstrual cycles or anovulatory periods were submitted to liquid chromatography, tandem mass spectrometry (LCMS) for additional steroid hormones.

RESULTS: ERaKD females, while gaining more body weight than controls, did not increase their daily calorie consumption. Both ERaKD and control female groups exhibited comparably regular menstrual cycles. ERaKD females, however, exhibited hyperandrogenism and elevated LH levels.

CONCLUSIONS: Taken together, these results suggest that knockdown of ARC ESR1 disrupts metabolic regulation and LH stimulation of ovarian function, contributing to female monkey hyperandrogenism and weight gain emulating PCOS in women.

INSULIN RESISTANCE INCREASES OBSTRUCTIVE SLEEP APNEA RISK IN NON-OBESE WOMEN WITH POLYCYSTIC OVARY SYNDROME. Xiaojie P. Zhou, MD,[1] Eleni Greenwood Jaswa, MD, MSc,[2] Nikolaus J. Lenhart, BS,[1] Jamie Corley, BA,[1] Marcelle I. Cedars, MD,[1] Heather G. Huddleston, MD[2] [1]University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco School of Medicine, San Francisco, CA.

OBJECTIVE: Reproductive-aged women with polycystic ovary syndrome (PCOS) experience increased rates of obstructive sleep apnea (OSA). Although obesity is a well-known risk factor for OSA, prior studies suggest that obesity does not fully account for the increased OSA risk observed in women with PCOS. The aim of this study was to evaluate the effect of insulin resistance, independent of body mass index (BMI), on OSA risk.

DESIGN: Cross-sectional study

MATERIALS AND METHODS: All patients seen at a university-based clinic between 2017-2020 with a confirmed PCOS diagnosis by the Rotterdam criteria were included. Clinical and laboratory measurements were collected. A body mass index $\geq$ 30 kg/m^2 was considered obese. A homeostatic model assessment of insulin resistance (HOMA-IR) score $\geq$ 2 was considered insulin resistant. Participants completed the validated Berlin questionnaire consisting of 3 categories related to OSA risk. A positive score in 2 or 3 categories is considered high-risk for OSA. Multiple imputation was performed to account for missing data. Multivariate logistic regression was used to assess the association between obesity and OSA risk with adjustment for age, insulin resistance, free testosterone level and depression symptoms as measured by the Patient Health Questionnaire-9. An interaction term between BMI and insulin resistance was included to assess for effect modification.

RESULTS: A total of 182 women with PCOS were included, of which 38.5% screened high-risk for OSA. For all participants, the mean age was 28.2 years (SD 6.2) and the mean BMI was 31.0 kg/m^2 (SD 9.0). Of those who screened high-risk for OSA, 85.7% were obese and 14.3% were non-obese. We found evidence of an interaction between obesity and insulin resistance in that the degree of association between insulin resistance and OSA risk varied according to the presence of obesity (interaction coefficient -2.32, 95% CI -4.70 to -0.10, p=0.041). Participants who were obese without insulin resistance had substantially higher odds of being high-risk for OSA as compared to those who were non-obese (OR 100.9, 95% CI 13.0-784.9). Among the obese women, being insulin resistant did not affect the odds of being high-risk for OSA compared to not being insulin resistant (OR 0.69, 95% CI 0.12 to 4.06). However, among the non-obese women, being insulin resistant led to increased odds of being high-risk for OSA (OR 7.6, 95% CI 1.8-32.6).

CONCLUSIONS: Although obesity is the predominant driver of OSA risk in women with PCOS, features unique to PCOS such as insulin resistance help explain the increased risk of OSA in non-obese women in this population. Given the diverse phenotypes of PCOS, better understanding the particular OSA risk factors experienced by different subgroups will aid in personalizing treatment.

P-722 4:30 PM Tuesday, October 20, 2020

THE EFFECTS OF MELATONIN ON *IN VITRO* CULTURE OF MOUSE EMBRYOS FROM EXPERIMENTAL MODELS OF POLYCYSTIC OVARY SYNDROME. Marcela de Oliveira Pinheiro, Bs,[1] Doris Ferreira Moriyama, M.Med.Sci,[2] Gabrielle Ferrante Alves de Moraes, Ms,[1] Edson G. Lo Turco, PhD[3] [1]São Paulo Federal University, São Paulo, Brazil; [2]Sao Paulo Federal University, School of Medicine, Department of Surgery, Division of Urology, Human Reproduction Section, Sao Paulo, Brazil; [3]IonMedicine - Precision Medicine, Sao Paulo, Brazil.

OBJECTIVE: Analyse the effects of embryo culture media with melatonin supplementation on the development and quality of mouse embryos from experimental models of PCOS and control groups.

DESIGN: Prospective study.

MATERIALS AND METHODS: This work used C57BL/6J mice strain (n = 60) divided into 3 large groups: PCOS (20μL of testosterone cypionate), placebo (20μL of peanut oil), and control. When these mice reached 28 days of age, superovulation was achieved with i.p. injections of 5 IU of pregnant mare's serum gonadotrophin, followed by 5 IU of equine chorionic gonadotrophin 42-48 hours later. A few hours after equine chorionic gonadotrophin administration, females were paired with males and left together overnight. On the following morning (18-24 hours later), the presence of vaginal plug was checked and the positive females were culled by cervical dislocation, 1-cell embryos were then flushed from the oviducts. Collected embryos (n=316) were then divided into each study group and cultured in single step medium with or without melatonin supplementation at 37$\underline{o}$C and 6% CO_2. Once the blastocyst stage was reached it was evaluated: i) cleavage, morula and blastocyst rate; (ii) morphological assessment of the blastocysts; (iii) DNA fragmentation in blastocyst cells by TUNEL test.

RESULTS: We observed that the blastocyst rate (n=316) was lower in the PCOS group when compared to the placebo and control groups. Melatonin supplementation did not have a positive effect on embryonic development on the PCOS group. morphological assessment, a significant difference was found for the variables quality index (PCOSm: 7,3±1,66, PCOS: 7,5±1,50, Placm: 13,2±0,90, Plac: 14,3±1,21, Contrm: 14,2±1,17, Contr: 13,7±1,42), blastocyst expansion (PCOSm: 3,3±0,37, PCOS: 3,4±0,32, Placm: 4,2±0,93, Plac: 4,2±0,10, Contrm: 4,1±0,13, Contr: 4,0±0,12) and trophectoderm (PCOSm: 1,4±0,12, PCOS: 1,2±0,11, Placm: 1,6±0,05, Plac: 1,6±0,06, Contrm: 1,7±0,06, Contr: 1,6±0,08), with the placebo and control groups showing consistently higher scores. In the TUNEL test (n=142), the supplemented PCOS group had a higher mean rate of apoptotic cells/total cells (A/T) when compared to the group without supplementation, indicating a poorer quality of the blastocysts (PCOSm: 16,5±3,61, PCOS: 11,9±2,14).he placebo and control groups supplemented with melatonin showed a lower mean A/T (Placm: 6,6±0,76, Contrm: 6,2±0,78) when compared to the non-supplemented groups, indicating a superior blastocyst quality (Plac: 7,1±0,85, Contr: 8,4±1,33).

CONCLUSIONS: This study concluded that melatonin supplementation in the embryonic culture media did not have a positive effect on the PCOS group consideringhe blastocyst rate, morphological assessment and DNA fragmentation on blastocyst cells. In contrast, the melatonin supplementation on the control group had a positive effect on all variables analysed.

TRANSCRIPTOMIC LANDSCAPE OF GRANULOSA CELLS AND PERIPHERAL BLOOD MONONUCLEAR (PBMN) CELLS IN WOMEN WITH PCOS AND POOR OVARIAN RESPONSE (POR). Mauro Cozzolino, MD,[1] Shiny Titus, PhD,[2] Sonia Herraiz, Ph.D.,[3] Antonio Pellicer, MD,[3] Richard Thomas Scott, Jr., MD,[4] Emre Seli, M.D.[1] [1]Yale School of Medicine, New Haven, CT; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVIRMA Foundation, Valencia, Spain; [4]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: To investigate transcriptomic characteristics of follicular and somatic cells in young women with PCOS and poor ovarian response (POR), compared to normo-responder controls.

DESIGN: Prospective experimental study.

MATERIALS AND METHODS: Young reproductive age women (<35 years old) with PCOS (n=5; selected based on Rotterdam criteria); poor ovarian response (n=5; selected based on Poseidon criteria – group 1a with number of oocytes retrieved <4); and normo-responder controls (n=5) undergoing IVF were included in the study. Peripheral blood mononuclear cells (PBMNCs) and granulosa cells (GCs) were collected on the day of retrieval, and total RNA was isolated using RNeasy Micro kit (Qiagen). RNA sequencing libraries were constructed using the Nextera® XT DNA Library Preparation Kit (Illumina, San Diego, CA) and multiplexed using Nextera® XT Index Kit (Illumina, San Diego, CA). Libraries were quantified by Qubit and Tapestation 4200. Differentially expressed genes were determined using false discovery rate (FDR) of p-value $<$ 0.01, fold change $>$ 2. Ingenuity Pathway Analysis (IPA) software was used to perform pathways analyses.

RESULTS: Mean age was similar between the groups (PCOS: 32.5 $\pm$ 0.7; POR: 34.2 $\pm$ 1.4; controls: 31.0 $\pm$ 2.1), while, as expected, women with POR had significantly lower number of oocytes retrieved (PCOS: 16 $\pm$ 4.9; POR: 2 $\pm$ 1.5; controls: 21 $\pm$ 3.6; p<0.05). In PBMNCs, 65 genes were differentially expressed in PCOS (55 increased, 10 decreased; affecting STAT3 and AKT pathways), and 16 were differentially expressed in POR (4 increased, 12 decreased; affecting cytokine signaling pathways), compared to controls. Direct comparison of PCOS to POR revealed 16 genes (9 increased, 7 decreased;) to be differentially expressed. In GCs, 4 genes were differentially expressed in PCOS (all 4 decreased; affecting inositol synthesis pathways), and none in POR, compared to normal controls. Importantly, when GCs

from women with POR were compared to those from PCOS, 58 genes were found to be differentially expressed (13 increased, 45 decreased), affecting pathways related to mitochondrial function and oxidative phosphorylation (down-regulated), and aging/sirtuin (up-regulated).

CONCLUSIONS: Our findings suggest that somatic PBMNCs and GCs from young reproductive age women with PCOS and POR have unique transcriptomic signatures. Specifically, GCs from women with POR demonstrate suppression and activation of pathways, associated with mitochondrial function and aging, respectively. Our findings could be exploited for future mechanistic studies and to develop novel diagnostic approaches.

THE ROLE OF GENETICS IN HYPERANDROGENIC PCOS: WHAT'S THE BIG, HAIRY DEAL? Emma Radley, M.A.,[1] Nepheli I. Raptis, B.A., M.A.,[1] Hanna Mandell, M.A.,[1] Christy Oso, B.A.,[1] Lauren Grimm, M.A.,[1] Jessi Anderson, MPH,[1] Zoran J. Pavlovic, M.D.,[2] Angeline Beltsos, MD,[1] Roohi Jeelani, MD[1] [1]Vios Fertility Institute, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.

OBJECTIVE: To determine if patients with clinically presenting hyperandrogenic Polycystic Ovary Syndrome (PCOS) are at increased risk of producing aneuploid embryos in order to further define the unique characteristics of this sub-classification.

DESIGN: Although hyperandrogenism is one of the three pillars of a PCOS diagnosis, only a portion of patients present with the associated clinical symptoms, such as adult acne and hirsutism. PCOS patients have been shown to have significantly decreased embryo quality, which is hypothesized to be due to hyperandrogenism. Both PCOS patients and those presenting with hyperandrogenism have shown increased miscarriage rates. As studies continue to produce evidence supporting the association between hyperandrogenism and aberrant gene expression, we sought to examine if patients with clinically presenting hyperandrogenic PCOS were more likely to develop aneuploid embryos compared to PCOS patients without hyperandrogenic symptoms. Understanding the pathophysiology of clinically presenting hyperandrogenic PCOS may be key in appropriately treating this specific patient population.

MATERIALS AND METHODS: Retrospective chart review was performed at a private multi-site infertility center. Patients with a serum anti-mullerian hormone level of >5 ng/mL, who underwent in-vitro fertilization, and utilized pre-implantation genetic testing for aneuploidy between April 2017 and September 2019 were included. Patients were then separated into two groups, consisting of those with self-reported hyperandrogenism symptoms (hyperandrogenic PCOS) and those who self-reported an absence of hyperandrogenic symptoms (classical PCOS). The average rate of aneuploid embryos were then calculated for each group. Two sample t-tests and chi square analysis were used to analyze the data (SPSS Inc., Chicago, IL).

RESULTS: A total of 349 embryos biopsied within the hyperandrogenic PCOS group and 256 embryos biopsied within the classical PCOS group were analyzed. Those with hyperandrogenic PCOS had average aneuploidy rate of 54.2%. Those with classical PCOS had an average aneuploidy rate of 45.1%. There was no significant difference in aneuploidy rate between the hyperandrogenic or classical PCOS groups ($p = 0.10$). There was no significant difference in age between the two groups ($p = 0.4$).

CONCLUSIONS: The lack of a significant difference in aneuploidy rates between patients with hyperandrogenic PCOS and classical PCOS continues to improve our understanding of the characteristics and mechanisms underlying pregnancy outcomes. Our data supports that the unique outcomes of hyperandrogenic presenting PCOS patients are not in fact due to increased embryonic genetic abnormalities. These findings emphasize the importance of continuing to analyze the unique characteristics of this sub-classification of PCOS to further understand the mechanisms affecting pregnancy outcomes and create more appropriate treatment protocols.

IMPACT OF NEW 2018 INTERNATIONAL DIAGNOSTIC CRITERIA FOR THE DIAGNOSIS OF POLYCYSTIC OVARY SYNDROME. Katherine E. Kostroun, MD,[1] Kathryn M. Goldrick, MD,[1] Jessica N. Mondshine, BS,[1] Randal D. Robinson, MD,[2] Cheria C. Brown, RN,[1] Jennifer F. Knudtson, MD[1] [1]University of Texas Health Science Center San Antonio, San Antonio, TX; [2]University of Texas Health Science Center San Antonio, San Antonio, SC.

OBJECTIVE: Polycystic Ovary Syndrome (PCOS) has been historically diagnosed based on the Rotterdam criteria of 2 of 3 factors: irregular menses, clinical or biochemical evidence of hyperandrogenism, and ≥ 12 ovarian follicles in an ovary or ovarian volume or ≥ 10 mL. The recommendations from the International Evidence-Based Guideline for the Assessment and Management of Polycystic Ovary Syndrome published in 2018 changed the ultrasound criteria from ≥ 12 to ≥ 20 antral follicles in an ovary for the diagnosis of PCOS (1). The purpose of this study was to evaluate whether application of the new guidelines would decrease the rate of diagnosis of PCOS.

DESIGN: Retrospective Chart Review

MATERIALS AND METHODS: This study evaluated women, age 12-65, with the ICD code of 'Polycystic Ovary Syndrome' in 2017 in a university hospital system with a large Hispanic population. Data regarding demographics, as well as clinical, laboratory, and ultrasound criteria for diagnosis of PCOS was collected as available for the patients via electronic health records into REDCap. Analysis was performed with SAS 9.4 (Cary, NC) software with Chi-square tests used to determine significance, and p-value <0.5 was determined to be significant.

RESULTS: Of the 500 women included in the study, 183 had ultrasounds with antral follicle data. Of those, 153 (84%) demonstrated ≥ 12 follicles on a single ovary, whereas only 43 (23.5%) had ≥ 20 follicles on a single ovary ($p<0.001$). Taking into account all available diagnostic information on chart review, 258 (52%) patients met criteria for PCOS based on Rotterdam criteria, whereas only 195 (39%) met criteria based on the new 2018 guidelines ($p<0.0001$).

CONCLUSIONS: There is a significantly decreased rate of diagnosis of PCOS in patients with the application of the 2018 recommendations from the International Evidence-Based Guideline for the Assessment and Management of Polycystic Ovary Syndrome. This study confirms the importance of a detailed, skilled ultrasound exam, that includes antral follicle count, in patients who do not meet diagnostic criteria for PCOS based on hyperandrogenism and oligomenorrhea alone. Because of the high percentage of Hispanic patients in our study, these findings may not apply to other populations.

P-726 4:30 PM Tuesday, October 20, 2020

IS VITAMIN D SUPPLEMENTATION RELATED TO SEXUAL DYSFUNCTION (SDY) AND DEPRESSION IN WOMEN WITH PCOS?. Rachel Booth, DO,[1] Rachel Blair Danis, MD,[2] Rose Maxwell, PhD,[3] Marilyn Kindig, DO,[1] Richard S. Legro, M.D.,[4] Frank Stanczyk, PhD,[2] Steven R. Lindheim, M.D.[1] [1]Wright State University, Dayton, OH; [2]University of Southern California, Los Angeles, CA; [3]Wright State University, OB/GYN, Dayton, OH; [4]Penn State College of Medicine, Hershey, PA.

OBJECTIVE: Polycystic ovary syndrome (PCOS) has been reported to be associated with significant health-related quality of life (HR-QOL) morbidities including depression and SDy. Clinical hyperandrogenism, obesity, and Vitamin D (Vit D) have also been associated with HR-QOL issues. Therefore, we conducted a pilot study to determine if dietary Vit D supplementation could reduce depression and SDy in women with PCOS.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: We recruited women of reproductive age (ages 18 to 39 yrs) who were diagnosed with PCOS by Rotterdam Criteria, self-reported SDy without severe depression and who did not desire fertility. Vit D 600IU was consumed daily for 6 months. Serum levels of total Vit D were measured at baseline and at study completion (25(OH) Vitamin D

ELISA kit, Abcam). Patients completed the Beck Depression Inventory (BDI) and the Female Sexual Functioning Index (FSFI), which includes domains for desire, arousal, lubrication, orgasm, satisfaction, and pain, at study initiation and at 6 months. Pearson correlation was used to determine associations between total Vit D levels, BDI, and FSFI scores and paired T-Tests were used to determine change over time.

RESULTS: Forty-seven women were initially evaluated; 5 were excluded with severe depression. Of these, 76% (32) with objective SDy on FSFI (< 26.6), had a mean age: 29.2 ± 6.4 yrs (± SD), Body Mass Index (BMI): 38.0 ± 8.5 kg/m2, Ferriman-Gallwey Score: 12.6 ± 7.9, total FSFI: 18.6 ± 6.9; BDI: 15.2 ± 8.8, and Vit D: 41.0 ± 71.2 ng/mL. At baseline, Vit D levels did not correlate with BDI or total FSFI ($p>0.05$), though it was associated with a healthy sexual desire ($r=0.393$, $p=0.032$). Of those that completed the study, 18 of 20 (90%) subjects had improved FSFI scores. Mean FSFI score at baseline was 20.1±5.43 and improved significantly to 25.25 ± 6.38 ($p<.05$). Of the 17 patients that completed both BDI surveys, baseline means changed from 13.8 ± 7.3 to 5.2 ± 4.1 ($p<.001$), and 11/13 (84.6%) with mild to moderate depression had improvement in their BDI scores. At 6 mo, Vit D levels were unchanged from baseline (29.1 ± 21.2 ng/mL) nor were significantly associated with changes in SDy and BDI.

CONCLUSIONS: SDy and BDI scores improved over a 6-mo period after supplementation with Vit D, however this improvement was not correlated with total Vit D levels at baseline and at 6 mo. Correlations with bio-available Vit D levels, the impact of placebo, and identifying a therapeutic dose of Vit D remain to be elucidated.

P-727 4:30 PM Tuesday, October 20, 2020

EVALUATING OVARIAN VOLUME AS A SINGLE MARKER FOR POLYCYSTIC OVARY SYNDROME (PCOS) AND METABOLIC DYSFUNCTION.

Roy G. Handelsman, MD,[1] Sahar Wertheimer, MD,[1] Katherine VanHise, MD,[1] Rae A. Buttle, BA,[1] Erica T. Wang, MD, MAS,[1] Ricardo Azziz, MD, MPH,[2] Margareta D. Pisarska, MD,[1] Jessica L. Chan, MD, MSCE[1] [1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of Alabama at Birmingham, Birmingham, AL.

OBJECTIVE: To determine if ovarian volume alone is an adequate marker for Polycystic ovary syndrome (PCOS) and metabolic dysfunction.

DESIGN: Tertiary-care based cohort study.

MATERIALS AND METHODS: Patients age >14 presented for consultation to 4 academic institutions from 1980 to 2010. Markers of hyperandrogenism (HA) included the modified Ferriman-Gallwey score (mFG), free testosterone (T), and dehydroepiandrosterone sulfate (DHEAS) values. Markers of metabolic dysfunction included body mass index (BMI), waist circumference (WC), high-density lipoprotein (HDL), triglycerides (TG), hypertension (HTN, defined as ≥ 135/85), and insulin and glucose levels during a 2-hour glucose tolerance test. Women were divided into two groups according to ovarian volume (OV): ≥10 mL (OV≥10) and volume <10 mL (OV<10). Categorical variables were compared using χ^2 tests and continuous variables were compared using Student's t-test or Wilcoxon rank-sum, as appropriate. Spearman's rank correlation was calculated to correlate OV with antral follicle count (AFC).

RESULTS: Seven-hundred eighteen women were included, of which OV≥10 was present in 362 women (50.4%) and OV<10 in 356. There was a positive correlation of OV with AFC (r_s =0.54, $p<0.0001$). The mean ages of women (SD) in OV<10 and OV≥10 women were 30.1(7.3) and 29.1(5.8) years, respectively. ($p=0.03$). PCOS by Rotterdam criteria was found in 89.4% of the OV≥10 group and 68.0% of the OV<10 ($p<0.001$). Higher OV was associated with a higher prevalence of HA overall (73.1% vs 58.1%, $p<0.001$), and with an mFG ≥4 (67.5% vs 54.7%, $p=0.001$) and elevated free T (30.1% vs 19.1%, $p=0.002$) specifically. Metabolic parameters including BMI, WC, and 1-hr insulin levels were significantly higher in the OV≥10 group compared to OV<10 women; HTN, HDL, TG and 2-hr glucose values were similar between the groups.

CONCLUSIONS: Ovarian volume of ≥10 mL, as a single marker, is associated with HA and metabolic dysfunction in PCOS. Given that the measurement of AFC is less precise, particularly in less experienced sites, the use of OV alone decreases the complexity of the evaluation and increases the ability to capture patients with risk for PCOS or metabolic dysfunction.

P-728 4:30 PM Tuesday, October 20, 2020

DO POLYCYSTIC OVARIAN SYNDROME PATIENTS WITH LOWER HEMOGLOBIN A1C LEVELS HAVE BETTER IVF OUTCOMES?.

Mary Rossillo, M.S.,[1] Nicole D. Yoder, MD,[1] Jacquelyn Shaw, MD,[2] Jennifer K. Blakemore, MD,[2] David H. McCulloh, Ph.D.,[3] James A. Grifo, MD, PhD,[4] Margaret Nachtigall, M.D.[1] [1]NYU School of Medicine, New York, NY; [2]NYU Langone Prelude Fertility Center, New York, NY; [3]NYU Langone Fertility Center, New York, NY; [4]NYU Langone School of Medicine, New York, NY.

OBJECTIVE: Current data suggests that better blood glucose control contributes to better overall health in women with Polycystic Ovarian Syndrome (PCOS). However, it is unclear whether it directly correlates with better outcomes for *in vitro* fertilization (IVF) in these patients. We hypothesized that Hemoglobin A1C levels, as a measure of long-term blood glucose control, would correlate with IVF outcomes in PCOS patients. The objective was to investigate the relationship between available A1C levels and IVF outcome measures in PCOS patients seen at the NYU Fertility Center.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: PCOS patients who underwent IVF at the NYU Fertility Center from 2012 to 2019 with an available A1C level were identified. Only the first IVF cycle was evaluated for each patient. Outcomes were number of oocytes retrieved, number mature, number fertilized, number blastocysts, number biopsied, and of number euploid, aneuploid, and mosaic embryos. Pearson's correlation was used for analysis, and correlation coefficients with $p<0.05$ were considered significant.

RESULTS: 72 IVF cycles were included for analysis of number of oocytes retrieved, number mature, and number blastocysts. 55 of these patients underwent preimplantation genetic screening (PGS); all of these were analyzed for number of euploid, aneuploid, and mosaic embryos. First, BMI was positively correlated with A1C ($R=0.33$). A1C was negatively correlated with number of oocytes retrieved ($R=-0.26$), number mature ($R=-0.25$), number fertilized ($R=-0.23$), number blastocysts ($R=-0.24$), and percentage blastocysts per mature oocyte ($R=-0.24$).

CONCLUSIONS: Overall, higher A1C level near time of cycle start in PCOS patients is correlated with a lower number of oocytes retrieved, number of mature oocytes, number fertilized, number of blastocysts, and percentage of blastocysts per mature oocyte. Although the correlation between BMI and A1C makes it difficult to dissociate effects of A1C from those of BMI, these results show that overall better metabolic and weight control contribute to better IVF outcomes.

RACIAL AND ETHNIC DIFFERENCES IN THE PREVALENCE OF DIAGNOSED POLYCYSTIC OVARY SYNDROME IN WOMEN RECEIVING AMBULATORY CARE.

Olumayowa M. Dayo, MD, MPH, Nancy P. Gordon, ScD, Malini Chandra, MS, MBA, Miranda L. Weintraub, PhD, MPH, Joan C. Lo, MD Kaiser Permanente, Oakland, CA.

OBJECTIVE: To assess the prevalence of polycystic ovary syndrome (PCOS), a common endocrine disorder among women of reproductive age, according to race and ethnicity, including Asian sub-groups.

DESIGN: Cross-sectional electronic health record (EHR) study conducted within a retrospective observational cohort study of adults who were health plan members in 2016 of a large integrated northern California healthcare delivery system.

MATERIALS AND METHODS: We used EHR data for 405,580 women age 21-44 who had a body weight measured in 2016 and height (in 2015-2016) to calculate body mass index (BMI, kg/m2). We then identified within this population women with one or more ambulatory diagnoses of PCOS (ICD-9 256.4, ICD-10 E28.2) between 1/1/2015 and 12/31/2016. Race/ethnicity was classified as non-Hispanic White, Black, Hispanic, and Asian, with additional identification of Chinese, Filipino, and South Asian ethnicity. The proportion of women with a diagnosis of PCOS was examined by race/ethnicity.

RESULTS: The prevalence of diagnosed PCOS varied by race/ethnicity and was 1.6% among white women but ranged as high as 3.5% among South

Asian women and as low as 1.1% among Chinese women (Table 1). The prevalence among Hispanic and Black women was 1.9% and 1.7%, respectively. When examined by age strata within race/ethnic group, diagnosed PCOS was more prevalent among women age 21-34 years than women age 35-44 years.

Table 1

Race/Ethnicity (Number of women)	White (161,592)	Hispanic (94,607)	Black (33,909)	Chinese (24,366)	Filipino (27,551)	South Asian (24,410)
Mean BMI (SD)	27.9 (7.2)	30.0 (7.2)	31.6 (8.5)	23.6 (4.3)	27.0 (5.8)	25.8 (4.9)
PCOS diagnosis (%)	1.6 %	1.9 %	1.7 %	1.1 %	1.7 %	3.5 %
Age 21-29 years	1.6 %	2.3 %	2.0 %	1.1 %	1.9 %	5.3 %
Age 30-34 years	2.0 %	2.4 %	2.5 %	1.9 %	2.1 %	4.1 %
Age 35-44 years	1.3 %	1.4 %	1.2 %	0.8 %	1.4 %	2.0 %

CONCLUSIONS: The proportion of Northern California women with a diagnosis of PCOS varied by race/ethnicity and was higher during peak reproductive years. Among women of Asian race, the prevalence of PCOS varied by more than 2-fold and was highest for women of South Asian ethnicity. Our study supports the need to further understand ethnic differences in PCOS and reproductive health.

DOES CONTROLLED OVARIAN HYPERSTIMULATION RESPONSE VARIES WITH PCOS PHENOTYPES: A PROSPECTIVE COHORT STUDY AT A TERTIARY INFERTILITY CENTRE IN INDIA.

Kanad Dev Nayar, M.D., DGO., FICOG, Shweta Gupta, MD, MRCOG, Minal Singh, DGO, DNB, Ratnaboli Bhattacharya, MD, DNB, FNB, MRCOG, Eshna Gupta, MS, Gaurav Kant, M.Sc, Rahul Gahlot, M.D., Dip.Clinical Embryology, Kapil Dev Nayar, MBBS Akanksha IVF Centre, Delhi, India.

OBJECTIVE: Polycystic ovarian syndrome(PCOS) is a highly prevalent disorder affecting 15 -25% of infertile women .This disorder has 4 different phenotypes and Controlled ovarian stimulation in these patients represents a task for fertility specialist as response varies from resistance to COH to exaggerated response [1,2]. The present study was undertaken to assess response to controlled ovarian hyperstimulation in various PCOS phenotypes

DESIGN: A prospective cohort study was carried out at a tertiary level infertility centre in India from 1st January 2018 through December 2019. Two hundred and fifty infertile women diagnosed with PCOS according to Rotterdam's criteria were divided into 4 phenotypes. Inclusion criteria were: Age < 40 years, BMI< 30, AMH> 1.5 ng/ml PCOS women undergoing IVF. Other causes of infertility including severe endometriosis, uterine factor, severe male factor, hydrosalpinx were excluded from the study. The primary outcome measured was clinical pregnancy rates. Secondary outcomes measured were doses of gonadotropins used, estradiol levels on the day of trigger and number of oocytes retrieved in different phenotypes.

Four Phenotypes of PCOS are defined as

A. Polycystic Ovaries on USG (PCO) + clinical and/ biochemical hyperandrogenemia (HA) + Oligo/anovulation (OA) (PCOS complete)

B. HA + OA

C. PCO + HA

D. PCO + OA

MATERIALS AND METHODS: The patients underwent controlled ovarian hyperstimulation with recombinant FSH (150 IU-225 IU) from day 2 of cycle with antagonist added from day 6 of stimulation(fixed protocol) and followed up with regular follicular monitoring. Injection ovitrelle 250 mcg was given as trigger routinely except if > 14 follicles of > 11mm size were noted on day of trigger, wherein agonist trigger was given. IVF was done for all patients.

RESULTS: Phenotpye D was the most prevalent phenotype at our sitting (49.60%). Women with phenotype A had significantly higher AMH ($p<0.05$)) and significantly higher estradiol levels on the day of trigger ($p < 0.05$) compared to other 3 groups. Phenotpye B needed highest doses of gonadotropin with respect to all other phenotypes ($p < 0.05$). Phenotype C had significantly higher testosterone levels compared to rest of the phenotypes ($p < 0.05$). Clinical pregnancy rates were significantly higher in phenotype D (50.8%) when compared to other phenotypes (A- 34.48%, B-31.82%, C-30.23%, $p< 0.05$).

CONCLUSIONS: Various PCOS phenotypes show different response to controlled ovarian hyperstimulation. Phenotype A seems to have a highest risk of OHSS and the use of GnRH agonist trigger and freeze all strategy might be beneficial in such cases. Phenotpye B appears to be the most resistant phenotype, hence a higher starting dose of gonadotropin might be needed for optimal response. Phenotype C had highest levels of hyperandrogenism and lowest pregnancy rates. Phenotype D had highest clinical pregnancy rates when compared to other phenotypes, suggesting hyperandrogenism might be responsible for a negative impact on pregnancy rates.

MESENCHYMAL STEM CELLS SECRETOME REGULATES STEROIDOGENESIS AND DECREASES ANDROGEN PRODUCTION IN PCOS CELL MODEL VIA SECRETING BMP-2.

Rishi Man Chugh, PhD, Hang-Soo Park, PhD, Sahar Esfandyari, DVM, Amro Elsharoud, MD, Mara Ulin, MD, Ayman Al-Hendy, MD, PhD The University of Illinois College of Medicine, Chicago, IL.

OBJECTIVE: Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in women with characteristics of inflammation,

hyperandrogenism, and polycystic ovaries. Most available therapies for PCOS aim to regulate the steroidogenesis and decrease ovarian androgen production to enhance fertility. Our previous study shows the ability of human bone marrow mesenchymal stem cells conditioned media (MSC-CM) to inhibit androgen production by human theca-like cell model (H295R cells). Previous studies demonstrated the ability of BMP-2 as a modulator of androgen production and alteration in steroidogenesis pathway enzymes in bovine theca cells. BMP-2 is a prominent member of the TGF-beta family and an important mediator of the regenerative and immune-modulating functions of MSCs. In this study, we analyzed the effect of BMP-2 on steroidogenic pathway enzymes and androgen production using a human PCOS *in-vitro* model.

DESIGN: We hypothesize that BMP-2 secreted by human MSCs is a key factor for regulating steroidogenesis and have the ability to suppress androgen production in a human PCOS cell model.

MATERIALS AND METHODS: The human adreno-carcinoma (H295R) cell line was used as an *in-vitro* PCOS model. Cells were cultured at a density of 1.8 x10^5 cells per well in six-well plates and treated for 48 hours with recombinant human BMP-2 with a dose range of 0 to 100 ng/ml with a negative control. After treatment, cells were washed and serum-free media were added for additional 24 hours. After incubation, cells and media were collected for analysis. The mRNA expression for CYP17A1, CYP11A1, DENND1A genes was quantified by real-time PCR. The testosterone level in media by automated chemiluminescence immunoassay system, BMP-2 level in the MSC-CM by ELISA. To confirm the effect of MSC-CM is due to BMP-2; we neutralized Normal MSC-CM with an anti-human BMP-2 antibody as well as knockdown the BMP-2 gene in MSCs. Student t-test was used for statistical analysis.

RESULTS: H295R cells treated with BMP-2 for 48 hours secreted significantly low level of total testosterone in a dose-dependent manner (0ng/ml: 68.60±10.6 ng/dl, 3.125 ng/ml: 40.17±4.11 ng/dl, 6.25 ng/ml: 28.83±8.2 ng/dl, 12.5 ng/ml: 27.73±3.85 ng/dl, 25 ng/ml: 18.8±1.96 ng/dl ($p<0.05$). BMP2 >25ng/ml suppressed testosterone, which was not detected by the system (detection limit: 10ng/dl). CYP17A1 and DENND1A gene expression were significantly downregulated ($P<0.05$) with all the tested concentrations while there was no change in the expression of CYP11A1 gene ($P>0.05$). The concentration of BMP-2 in MSC-CM was 62 pg/ml. H295R cells treated with Normal MSC-CM neutralized with Anti-human BMP-2 antibody or CM from BMP-2 knockdown MSCs shows nullify the effect of both MSC-CM on steroidogenic pathway genes expression.

CONCLUSIONS: BMP-2 significantly suppressed androgen production and expression of androgen-synthesizing genes in human theca-like H295R cells compared to the control. BMP-2 is a key player in mediating the favorable effects of MSC-CM on the human PCOS cell model. MSCs could provide a novel stem cell therapy for patients with intractable PCOS.

COMPARISONS OF GLUCOSE INTOLERANCE TESTING FOR THE DETECTION AND DIAGNOSIS OF PREDIABETES AND TYPE II DIABETES MELLITUS IN REPRODUCTIVE AGE WOMEN WITH POLYCYSTIC OVARY SYNDROME.

J. Ricardo Loret de Mola, MD, Pamela Bremer, MD, Teresa S. Wilson, BA, Emma V. James, MD, MPH, Kristin Delfino, PhD, Jace Battrell, BS, Kathleen A. Groesch, MS, Paula Diaz-Sylvester, PhD, Katherine Lincoln, BS, Riley Kraus, MD Southern Illinois University School of Medicine, Springfield, IL.

OBJECTIVE: Polycystic Ovary Syndrome (PCOS) is one of the most common metabolic conditions affecting reproductive-age women. Its etiology is not completely understood. PCOS is diagnosed using the 2003 Rotterdam Criteria (ROT), in which patients must meet at least two of the three following criteria: (1) clinical or biochemical evidence of hyperandrogenism, (2) anovulation/oligomenorrhea and (3) polycystic ovarian morphology on ultrasound with the exclusion of other etiologies (e.g., congenital adrenal hyperplasia, androgen-secreting tumors, Cushing's syndrome). Although not included in the Rotterdam criteria, one of the metabolic features of PCOS is glucose intolerance and insulin resistance. PCOS patients have a four to eight-fold increased risk of developing Type II Diabetes Mellitus (DM) making the proper diagnosis imperative in this patient population. Therefore, we sought to determine the most sensitive way to screen for abnormal glucose metabolism in this patient population.

DESIGN: A retrospective chart review (IRB# 19-477) was performed for all women (18-45 years of age) who presented to the Reproductive Endocrinology and Fertility clinic at Southern Illinois University School of Medicine who received glucose testing (2 hour oral glucose tolerance test (OGTT) with a 75gm glucose load, Hemoglobin A1c (Hgb A1c) and insulin levels (fasting and 2-hour post-prandial) at their initial visit as part of their evaluation for PCOS between 07/01/2012 and 07/01/2019.

MATERIALS AND METHODS: Of the 646 charts that were reviewed, 345 women met the eligibility criteria, of which 118 were confirmed to have PCOS based on the 2003 Rotterdam Criteria; however, we removed 17 subjects who were utilizing Metformin/Glucophage at the time of evaluation. Additional criteria such as age, body mass index (BMI), gravity and parity, etc. were also collected. Glucose intolerance was defined by the American Diabetes Association guidelines (fasting glucose: 100-125 mg/dL, normal < 100 mg/dL; 2hr OGTT 140 to 199 mg/dL, normal < 140 mg/dL; Hgb A1C 5.7% to 6.4%, normal < 5.7%.

RESULTS: Of the 101 PCOS subjects, the 2 hour OGTT detected glucose intolerance in 7.5% of the population. Fasting glucose found 14.5% of the subjects to have glucose intolerance and Hgb A1C identified 9.5% of the PCOS patients to have glucose intolerance.

CONCLUSIONS: Based on these preliminary results, fasting glucose tests may be the more sensitive test for women with PCOS. However, these variations in sensitivity prove further investigations are warranted. Furthermore, we aim to determine which characteristics/phenotypes may exacerbate this discordance between diagnostic tests.

SUPPORT: The study was funded by the Department of Obstetrics & Gynecology at Southern Illinois University School of Medicine.

P-733 4:30 PM Tuesday, October 20, 2020

METFORMIN SHOULD BE RECOMMENDED FOR MORE PATIENTS WITH PCOS BASED ON UPDATED GUIDELINES.

Kathryn M. Goldrick, MD, Katherine E. Kostroun, MD, Jessica N. Mondshine, BS, Randal D. Robinson, MD, Erin B. Mankus, MD, Jennifer F. Knudtson, MD University of Texas Health Science Center, San Antonio, TX.

OBJECTIVE: In 2018, the International Evidence-Based Guidelines for the Assessment and Management of PCOS were released to integrate best practices for the diagnosis and treatment of PCOS. Among these guidelines are updated recommendations for the use of metformin in patients with PCOS. These recommendations advise that patients with PCOS and BMI≥25, impaired glucose tolerance, and/or adolescents age <18 should take metformin to prevent metabolic sequelae of PCOS (1). Previously, metformin use was recommended for patients with PCOS who displayed evidence of glucose intolerance and/or hyperinsulinemia (2,3). The objective of this study was to evaluate patients with PCOS who are and should be taking metformin based on these updated recommendations.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: A retrospective chart review of women ages 12-65 who were seen at a university system in 2017 with an ICD code for PCOS were identified and demographic, clinical, laboratory, and ultrasound data were collected in REDCap database. Forty-two women with a self-reported history of diabetes were eliminated to assess patients who were on metformin for PCOS. Patients with PCOS based on updated guidelines were identified with 2 out of 3 of the following criteria met 1) oligo or amenorrhea, 2) clinical and/or laboratory hyperandrogenism, 3) either ovary displaying ≥20 follicles between 2-9mm and/or volume > 10mL (1). It was determined whether the patients with PCOS based on new guidelines were currently taking metformin, and if they should be taking metformin based on updated recommendations as above. Patients with previously diagnosed PCOS were similarly analyzed, and it was determined if they should be taking metformin based on evidence of glucose intolerance and/or hyperinsulinemia. Statistical analysis was performed with SAS 9.4 (Cary, NC) software using Chi-square, and p-value <0.05 was considered significant.

RESULTS: Significantly more women with PCOS by updated guidelines should be taking metformin than women with PCOS by previous guidelines. Using the old guidelines 12% of patients should be taking metformin which increased to 91% using the new guidelines ($p<0.0001$). Ninety-nine percent of patients who should be taking metformin by new guidelines meet criteria by BMI (Table 1).

CONCLUSIONS: Based on updated guidelines, practitioners should prescribe metformin to more patients with PCOS, particularly those patients who are overweight and obese.

	PCOS, should be taking metformin (n=144)
BMI ≥25	142 (98.6%)
Impaired glucose tolerance (A1c >5.7)	22 (15.3%)
Adolescence (age <18)	17 (11.8%)

THE IMPACT OF POLYCYSTIC OVARIAN SYNDROME ON EVALUATION OF REPRODUCTIVE POTENTIAL MEASURED BY ANTI-MUELLERIAN AND FOLLICLE STIMULATING HORMONES.

Evelina Manvelyan, MD,[1] Baruch Abittan, M.D.,[2] Gabriel San Roman, MD[3] [1]Northwell Health at Southside Hospital, Bay Shore, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]North Shore University Hospital, Manhasset, NY.

OBJECTIVE: Our primary objective is to determine the association between BMI and AMH in reproductive age females with and without PCOS that undergo infertility treatment.

DESIGN: Retrospective cohort study in an academic fertility center

MATERIALS AND METHODS: Our study included total of 1937 subjects, 182 with PCOS (9.4%) – PCOS group, and 1755 without PCOS (90.6%) – non-PCOS group. The age, BMI, AMH and FSH levels were analyzed. Multivariable analyses were performed with one way ANOVA and Kruskal-Wallis tests and correlation analyses were performed using Pearson and Spearman tests for normally and lognormally distributed datasets respectively.

RESULTS: As expected, patients with PCOS were significantly younger, with lower FSH levels, higher BMI and AMH than non-PCOS patients (*p<0.001*). There was a mild negative association between BMI and AMH in the non-PCOS group (r=-0.06, p=0.015). FSH was positively associated with age as predicted, and negatively associated with BMI and AMH in the entire cohort, and in the non-PCOS patient population. None of these associations were found in PCOS group (Table).

CONCLUSIONS: Here we demonstrate that the inclusion of PCOS patients in research involving AMH studies results in significant change of AMH levels even in larger samples size and when the PCOS patients make up less than ten percent of the total study subjects.

Based on the results we infer that there is a negative association of AMH and FSH with BMI in infertile patient population in the absence of polycystic ovarian syndrome. The negative correlation of BMI and AMH is no longer found when PCOS subjects are included in the equation, however the correlation of BMI and FSH remains unchanged. This implies that FSH might be a better marker of BMI impact on ovarian reserve when PCOS patient population is included in the studies. Here we demonstrate that the inclusion of PCOS patients in research involving AMH studies results in significant change of AMH levels even in larger samples size and when the PCOS patients make up less than ten percent of the total study subjects.

Correlation Analyses	PCOS group r value	PCOS group P value	Non-PCOS group r value	Non-PCOS group P value	All r value	All P value
AMH vs. BMI	N/A	NS	-0.06	0.015	N/A	NS
AMH vs. FSH	N/A	NS	0.35	< 0.001	0.37	< 0.001
AMH vs. Age	r=0.38	< 0.001	0.36	< 0.001	0.39	< 0.001
FSH vs. Age	N/A	NS	0.23	< 0.001	0.23	< 0.001

INCREASED CERVICAL INSUFFICIENCY RISK IN PCOS WOMEN UNDERGONE ART TREATMENT: A RETROSPECTIVE COHORT STUDY.

Xing Yang, Ph.D., Yao-qiu Wu, M.M The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To explore the correlation between cervical insufficiency (CI) and polycystic ovary syndrome (PCOS) in Chinese women undergone assisted reproductive technology (ART) treatment. The pregnancy outcomes of PCOS women with CI were further analyzed.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: We retrospectively analyzed the CI incidence in women who had an IVF or ICSI treatment at the Six Affiliated Hospital of Sun Yat-sen University between 2010 and 2018.Rotterdam criteria diagnosed PCOS women were randomly matched with non-PCOS cohort based on maternal age, body mass index (BMI), infertility duration and parity history. CI was diagnosed by cervical dilation and/or cervical shortening without contractions or labor, in the absence of other clear causes. The demographic data, clinical characteristics and the prevalence of CI for both groups were analyzed.

RESULTS: In total, 1489 PCOS women and 1489 matched non-PCOS women were included, 34 women were diagnosed with CI (1.14%) overall. Compared with non-PCOS cohort, PCOS women experienced higher prevalence of CI compared with non-PCOS control (1.54% versus 0.74%, P=0.038) , accompanied with a significantly smaller uterus (4.12 ± 0.52cm versus 4.30 ± 0.55cm, P<0.001) and higher serum testosterone (0.59±1.84 nmol/L versus 0.36±0.37 nmol/L, P<0.001). After adjusting for maternal age, BMI, infertility duration, mean uterine diameter, gravidity and parity and basal hormone levels, Logistic regression analysis indicated that PCOS status per se (OR:2.050,95% CI:1.009-4.206), BMI ≥ 25kg/m^2 (OR:3.870,95% CI: 1.833-8.173) and twin pregnancy (OR: 2.401,95%CI: 1.110-5.193) were associated with an increased risk of CI. Among those women diagnosed with CI, PCOS women terminated gestational at 25.35±5.91weeks, which was even earlier than non-PCOS cohort(30.91±6.73 weeks, P= 0.021). The miscarriage rate in PCOS women was 52.17% compared to 18.18% in non-PCOS cohort. PCOS women experienced more undesirable consequences for both maternal and newborn.

CONCLUSIONS: Our study revealed a higher prevalence of CI among PCOS women undergone ART treatment. An even worse maternal and newborn morbidity may incurred.

	PCOS group (n=1489)	Non-PCOS group (n=1489)	P
BMI (kg/m^2, mean ± SD)	22.65±3.01	22.41±2.97	0.652
Testosterone (nmol/L, mean ± SD)	0.59±1.84	0.36±0.37	<0.001*
Mean diameter of the uterus (cm, mean ± SD)	4.12±0.52	4.30±0.55	<0.001*
CI (%)	23 (1.54)	11 (0.74)	0.038 *
Termination gestational age (w) in women with CI	28.55±6.53	25.35±5.91	0.021*
Miscarriage in women with CI	12 (52.17)	2 (18.18)	0.101

P-736 4:30 PM Tuesday, October 20, 2020

EFFECTS OF VITAMIN D ADMINISTRATION IN THE MOUSE MODEL OF POLYCYSTIC OVARIAN SYNDROME. Huiling Xu, master, Shumin Qiu, bachelor, Peiyang Lin, master, Xiuhua Liao, doctor, Beihong Zheng, bachelor Fujian Maternity and Child Health Hospital, Affiliated Hospital of Fujian Medical University, FuZhou, China.

OBJECTIVE: To investigate effects of vitamin .D(Vit.D) administration in patients with polycystic ovary syndrome(PCOS)

DESIGN: Experimental animal study.

MATERIALS AND METHODS: Forty female pre-pubertal mice were randomly divided into 4 groups: the control, PCOS, PCOS+low dose Vit.D and PCOS+high dose Vit.D groups(N=10 per group). The PCOS mouse model was developed by 6mg/kg/day dehydroepiandrosterone(DHEA) administration with subcutaneously injections and high fat diet feeding. After 30 days, Vit.D was administrated by intraperitoneal injection in the following 40 days, 130ng/100g/week 1,25(OH)2D3 in low dose Vit.D group, and 1300ng/100g/week 1,25(OH)2D3 in high dose Vit.D group. Controls were injected with vehicle alone and fed with normal diet. At the end of the 70 days, blood samples were collected and the ovarian and liver tissues were taken.

RESULTS: All the mice in PCOS+high dose Vit.D group died in two weeks after Vit.D administration. In the other three group, the weight of the PCOS mice was significantly higher than the weight of the controls before Vit.D administration(31.10±2.52, 31.76±2.54 VS 28.82±1.83g, PCOS group, PCOS+low dose Vit.D group VS control group, P=0.022). However, at the end of the study, the weight of the mice in PCOS group was significantly higher than those in control group and PCOS+low dose Vit.D group (41.41±3.90 VS 35.50±2.50, 34.55±2.31 g, P=0.000). The serum 25(OH) D concentration was significantly higher in PCOS+low dose Vit.D group than in control group and PCOS group (99.29±18.31 VS 19.55±4.10,18.04±6.51 ng/ml,P=0.000). The testosterone levels in PCOS group were significantly higher than those of control group and PCOS+low dose Vit.D group (1.27±0.27 VS 0.95±0.15 ,0.90±0.17 ng/ml, P=0.001). Furthermore, total cholesterol levels in control group were lower than in PCOS and PCOS+low dose Vit.D group (3.08±0.44 VS 4.55±0.47, 4.42±0.45mmol/L, P=0.011). Moreover, the ratio of liver weight to body weight was significantly different among the three groups (0.045±0.0046 VS 0.036±0.0043 VS 0.041±0.0031, control group VS PCOS group VS PCOS+low dose Vit.D group, P=0.000).

CONCLUSIONS: Our results indicate that low dose Vit.D has positive effects on the hormonal changes and obesity observed in PCOS, maybe through liver metabolism regulation, and high dose Vit.D administration may be harmful.

THE CLINICAL CORRELATION BETWEEN POLYCYSTIC OVARY SYNDROME (PCOS) AND PITUITARY ADENOMA. Sang il Kim, MD St. Vincent's Hospital, The Catholic University of Korea, Suwon, Korea, Republic of (South).

OBJECTIVE: In this study, we investigate the incidence of pituitary adenoma combined with PCOS, cut-off prolactin (PRL) level to detect pituitary adenoma and treatment strategy.

DESIGN: This a retrospective cohort study.

MATERIALS AND METHODS: Medical records from November 2009 to March 2019 were reviewed in our institute, retrospectively. Total of 584 patients was enrolled. According to initial serum PRL level, patients were divided in 5 groups: A (0 ∼25 ng/mL); B (25∼50 ng/mL); C (50∼75 ng/mL); D (75∼100 ng/mL); E (≥ 100 ng/mL). We investigated the frequency of sella MRI and the incidence of pituitary adenomas as each group. Receiver operating characteristic (ROC) curve analysis was performed to determine a cut-off value of serum PRL level that could found pituitary adenoma in hyperprolactinemic PCOS patients.

RESULTS: Of 584 patients diagnosed PCOS, sella MRI was performed in 18 (3.1%, 18/584) patients. Finally, a total of 13 (2.2%, 13/584) patients with pituitary adenoma were identified. The mean value of serum prolactin level of these patients was 73.0 ± 54.5 (range, 20.8 ∼ 211.9) ng/mL. The mean age and follow up period were 26 ± 6.2 (range, 17 ∼38) years and 33.8 ± 27.5 (range, 3∼84) months, respectively. In group A to C, of the 11 patients who underwent sella MRI, 6 had pituitary adenoma (54.5%, 6/11). On the other hand, in Group D to E, of the 7 patients who underwent sella MRI, all of them had pituitary adenoma (100%, 7/7). One patient in group A had observation because PRL level was not as high as 20.8 ng/dL. One patient in group B had a PRL of 26.67 ng/dL and underwent surgery (transsphenoidal approach) because the mass size was 2.9 × 3 × 1.9 cm and there was visual field defect with optic chiasm compression. The remaining patients were treated with bromocriptine or cabergoline and followed-up with OBGY department. Most of all (77%, 10/13) showed a favorable outcome (normalization of PRL level, menstruation and/or success of pregnancy). The results of the ROC curve analysis of the prolactin threshold level for predicting pituitary adenoma in PCOS patients were as follows: The area under the ROC curve (AUC) was 0.831. P-value was 0.001 (95% CI 0.583 to 0.963). Sensitivity and specificity were 69.2 % and 100 %, respectively. The cut-off value was 53.

CONCLUSIONS: PCOS and hyperprolactinemia are common causes of infertility in reproductive women. The PCOS patients with a PRL level of 53 ng/mL or greater may need to consider a sella MRI scan for detecting pituitary adenoma. To expect a favorable clinical course for these patients, a systemic diagnosis, treatment and follow-up plan should be established. Therefore, a multidisciplinary approach between neurosurgery and OBGY is essential.

P-738 4:30 PM Tuesday, October 20, 2020

PCOS AND UTERİNE ABNORMALITY; POSSIBLE CONNECTION AND RELATIONSHIP WITH MATERNAL SERUM AMH LEVELS. Gürkan Uncu, Prof.,[1] Kiper Aslan, M.D.,[1] Ozge Albayrak, M.D.,[2] Aylin Dayan, M.D.,[2] Isıl Kasapoglu, M.D.[2] [1]Bursa Uludag University Faculty of Medicine, Bursa, Turkey; [2]Uludag University School of Medicine, Gynecology and Obstetric ART Center, Bursa, CT, Turkey.

OBJECTIVE: To determine the incidence of uterine abnormalities in PCOS patients higher than normo-ovulatory patients?

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study was conducted at a University Hospital, Department of Obstetrics and Gynecology. Total of 103 women, 51 PCOS, and 52 male factor infertility were included into the study. Hysterosalpingography (HSG) images of all patients were numbered. Six different shapes of the intrauterine cavity were figured. All HSG images were evaluated by ten senior reproductive endocrinologists and surgeons. Seniors were blinded to the research and choose the most appropriate figure for each patient's HSG image. The consensus rate was used to determine the normality of the HSG image.

RESULTS: BMI (27.2 + 6.2 vs. 23.9 + 4.5, p:0.03), Antral follicle count (20 (9-20) vs. 12 (9-18) p:0.05), Anti-Mullerian hormone (4.1 ng/ml (2.5-7.2) vs. 2.3 ng/ml (1.6-3.8), p<0.01) and Serum total testosterone levels (0.59 mcg/l + 0.19 vs. 0.4 mcg/l + 0.16, p:0.02) were significantly higher in PCOS group than the Male factor group. The percentage of the normal uterine cavity (Figure-I) was significantly lower in the PCOS group. (45.9 % and 73.1 %, p<0.01) The abnormal cavities were compared; Arcuate Uterus (Figure-II, ESGE - ESHRE Normal / ASRM VI, 22.18% vs 6.6% p<0.05), Partial Septate Uterus (Figure-III, ESGE - ESHRE U2a / ASRM Va, 5.1% vs 0% p<0.05), Complete Septate Uterus (Figure-IV, ESGE - ESHRE U2b / ASRM Vb, 5.47% vs 1.2% p<0.01) and Y-Shaped Uterus (Figure-VI, ESGE - ESHRE U1c) / ASRM Unclassified, 7.47% vs 0 p<0.05) were significantly higher in PCOS patients. T-Shaped Uterus (Figure V, ESGE - ESHRE U1a / ASRM VII - 13.8% vs. 18.9%) was comparable between the groups. There was no correlation between serum AMH levels and the presence of uterine abnormality.

CONCLUSIONS: This study provides that, compared to the healthy population, the uterine abnormality frequency is clearly higher in PCOS patients. The increased ratio of the abnormal uterine cavity may be related to excessive intrauterine exposure to maternal androgens and AMH.

SUPPORT: None.

INTELLIGENT ALGORITHM COMBINED WITH DEVICE THAT DETECTS LUTEINIZING HORMONE LEVELS CAN IMPROVE THE PREDICTION ACCURACY OF OVULATION DAY. Zheng Yang, PhD, Ning Li, MS, Sylvia M. Kang, MS, MBA. Quanovate Tech Inc., Pleasanton, CA.

OBJECTIVE: Based on daily quantitative luteinizing hormone (LH) measurements, an intelligent algorithm was developed to improve the prediction accuracy of women's ovulation day.

DESIGN: Registry/Database Study. A group of consented Mira products (by Quanovate Tech Inc.) users was asked to provide their menstrual cycle information via the Mira App, and take daily quantitative urine LH measurement by the Mira analyzer and Mira Fertility test wands. The generated data were centralized in a database and analyzed in comparison to the traditional calendar method, which determines the ovulation days as the 14th day before the next menstrual cycle.

MATERIALS AND METHODS: Mira fertility test wands quantitatively detect the LH levels in urine, in conjunction with the Mira analyzer, which reads the immunofluorescent signal generated by the test wand and converts the signal into quantitative concentrations of the LH. Urine samples with LH from Mira users were continuously monitored by the Mira analyzer and Mira Fertility test wands daily for four menstrual cycles. The test data were collected by the Mira app which syncs data from the Mira analyzer via Bluetooth. 327 samples were analyzed.

By analyzing the collected data, we have established an algorithm for the prediction of ovulation day. This system combines the users' hormone test results and cycle information. The ovulation prediction of the users' first cycles was based on the calendar method since no LH tests of a complete cycle were done. As the number of cycles tested and hormone test data increase, it automatically adjusts parameters and learns the users' cycles to improve the accuracy of ovulation day prediction.

The actual ovulation day is obtained by a retrospect analysis of each cycle to find the LH surge day in that given cycle. The deviation between the predicted ovulation day and the actual ovulation day is calculated. If the deviation is within one day, plus or minus, it is defined as an accurate prediction. In the control group where we measured the users' first cycles, the calendar method was used to predict ovulation.

RESULTS: In the control group, the average rate of ovulation prediction accuracy of the users' first cycles using the calendar method is 29%. In the experiment group, the average rate of ovulation prediction accuracy of the users' every later cycle gradually rises. The accuracy rate is 35% for cycle 2, 58% for cycle 3, and 77% for cycle 4.

CONCLUSIONS: Combining the LH hormone measurements, cycle information, and intelligent algorithms, the prediction accuracy of ovulation day can be greatly improved compared with the calendar method. The more cycles a woman tests her LH hormone with this method, the higher accuracy the ovulation day prediction is.

P-740 4:30 PM Tuesday, October 20, 2020

AMH LEVELS MAY PREDICT FOR MULLERIAN ANOMALIES AND PREGNANCY OUTCOMES PATIENTS WITH PCOS. Kiper Aslan, M.D.,[1] Ozge Albayrak, M.D.,[2] Kubra Ozlem Bilgic, M.D.,[2] Isıl Kasapoglu, M.D.,[2] Berrin Avcı, M.D., PhD,[3] Gürkan Uncu, Prof.[1] [1]Bursa Uludag University Faculty of Medicine, Bursa, Turkey; [2]Uludag University School of Medicine, Gynecology and Obstetric ART Center, Bursa, CT, Turkey; [3]Uludag University School of Medicine, Bursa, Turkey.

OBJECTIVE: To investigate the effect of AMH levels on uterine anomaly and adverse pregnancy outcomes in patients with PCOS.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The electronic database of ART Center of a tertiary university hospital was screened between the years 2012-2020. 143 PCOS patients with 336 cycles underwent IVF/ICSI were enrolled in to the study. Uterine abnormality and pregnancy outcomes were evaluated with anti-mullerian hormone (AMH) level per cycle. HSG and 2D-USG used for detection of uterine abnormalities. Demographic parameters, pregnancy outcomes were analyzed. AMH levels were compared between the cycles with normal or abnormal uterus.

RESULTS: Of the 143 patients with 336 ART cycles mean (standard deviation) age and body mass index were 30.7 (4.25) years and 28.3 (5.8), respectively. The median AMH values 6.5 (3.8-10.5) ng/dl. Of the 19 patients (%13.3) with uterine anomalies, arcuate uterus was found in 4, septum uteri in 8, T-shape uterus in 4, unicornus bicollis in 1, unicollis unicollis in 1 and V-shape uterus in 1. Pregnancy rate was %33.1 and livebirth rate was %15. Preterm delivery occurred in 4 of the singleton pregnancies and two of them were because of preeclampsia. The mean AMH value was 7.5 ng / dl in patients without uterine anomaly, whereas the mean AMH value of patients with uterine anomaly was 11.8 ng / dl ($p = 0.056$).

CONCLUSIONS: These results reveal that AMH levels in PCOS patients with uterine anomaly were higher than without uterine anomaly, but there was no statistically significant difference between two group. If the number of cases increases, statistically significant results can be obtained. Contrary to previous studies, preterm birth rates were not increased.

POLYCYSTIC OVARY SYNDROME KNOWLEDGE AMONGST PRIMARY CARE PROVIDERS AND GENERALIST OBSTETRICIAN GYNECOLOGISTS. Micaela J. Stevenson, BS,[1] Yolanda R. Smith, MD,[2] Molly B. Moravek, MD, MPH[2] [1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.

OBJECTIVE: Approximately 6-10% of women in the United States have Polycystic Ovary Syndrome (PCOS). While PCOS is commonly associated with subfertility and infertility, this disorder predisposes patients to several comorbid conditions including metabolic syndrome, hypertension, hyperlipidemia, obstructive sleep apnea, and endometrial cancer. Thus, primary care providers must have an adequate understanding of this diagnosis to manage and screen for these conditions. The objective of this study was to assess primary care provider knowledge of PCOS diagnostic criteria and associated comorbidities.

DESIGN: Cross-sectional survey.

MATERIALS AND METHODS: Adult primary care physicians and general obstetrician gynecologists at an academic institution completed an anonymous, online survey assessing knowledge of PCOS. Response data were processed using R. We fit multilevel logistic regression models to participants' response errors. The models allowed intercepts to vary randomly at the participant and item levels. We report means and standard deviations of error rates, as well as regression coefficients. We also report z-stats and p-values and use an alpha-threshold of 0.001 to infer statistical significance. Our analyses focused on response error rates to different items presented in the questions about diagnostic criteria and comorbidities of PCOS.

RESULTS: Data collection is ongoing. 28 generalist Obstetrician gynecologists (Ob/Gyn), 27 internal medicine physicians, and 20 family medicine physicians participated in this study. For the diagnostic criteria question, the mean error rate across all participants was 25% ($\sigma = 0.43$). Metabolic syndrome was correctly selected as a diagnostic criterion by 77% of respondents. The mean error rate for identification of PCOS associated comorbidities across all participants was 0.15 ($\sigma = 0.36$). 87% of respondents correctly indicated that osteoporosis was not an associated comorbidity of PCOS and 57% of respondents identified hypertension as a comorbidity of PCOS. Overall, Ob/gyn physicians had an error rate of 17%, family medicine physicians had an error rate of 29% and internal medicine physicians had an error rate of 31% all for diagnostic criteria ($p=0.04$). For associated comorbidities, Internal Medicine physicians had error rates of 24%, Ob/gyns had an error rate of 13% and family medicine physicians had an error rate of 7%. ($p= <0.001$)

CONCLUSIONS: Current data suggests that physicians of all primary care specialties incorrectly identified some diagnostic criteria and comorbidities commonly seen with PCOS. Continuing medical education on PCOS diagnostic criteria and associated comorbidities would likely be useful for all of the surveyed specialties.

P-742 4:30 PM Tuesday, October 20, 2020

CHARACTERISTICS OF WOMEN WITH PCOS WHO UNDERGO ENDOMETRIAL BIOPSIES. Kathryn M. Goldrick, MD, Katherine E. Kostroun, MD, Jessica N. Mondshine, BS, Randal D. Robinson, MD, Erin B. Mankus, MD, Jennifer F. Knudtson, MD University of Texas Health Science Center, San Antonio, TX.

OBJECTIVE: In 2018, the International Evidence-Based Guidelines for the Assessment and Management of PCOS were released to integrate best

practices for the diagnosis and treatment of PCOS. These guidelines do not include recommendations about endometrial biopsies for women with PCOS. Although patients with PCOS are at increased risk of endometrial hyperplasia and carcinoma due to unopposed estrogen and oligomenorrhea, no clear guidelines for endometrial biopsy for women with PCOS exist. The objective of this study is to assess characteristics of patients with PCOS who undergo endometrial biopsies.

DESIGN: Retrospective chart review

MATERIALS AND METHODS: A retrospective chart review of women ages 12-65 who were seen at a university hospital system in 2017 with an ICD code for PCOS were identified and demographic, clinical, laboratory, and ultrasound data were collected in REDCap Database. Patient characteristics were compared for women who did and did not undergo endometrial biopsy, and results of endometrial biopsies were analyzed. Statistical analysis was performed with SAS 9.4 (Cary, NC) software with data analysis performed via t-test and Chi-square test, as appropriate, and a p-value <0.05 was considered significant.

RESULTS: Of the 450 patients with PCOS identified, 51 patients had endometrial biopsies. Factors associated with having an endometrial biopsy performed were older age, diabetes, and irregular menses which were significantly different between the groups. Ethnicity, BMI, PCOS by updated guidelines, previous hormone treatment, and metformin use were not different between groups. Of the endometrial biopsies performed, 76% were benign, 20% had hyperplasia, and 2% had malignancy.

CONCLUSIONS: Having diabetes, irregular menses, or older age increased the chance of endometrial biopsy being performed. As expected, a high percentage (22%) of patients with PCOS had endometrial hyperplasia or cancer on endometrial biopsy. Although most endometrial biopsies performed in our study were benign, future research is needed to establish clear guidelines for performing endometrial biopsies for women with PCOS since this group is at increased risk for endometrial hyperplasia and malignancy.

CLINICAL IMPACT OF THE 2017 ASRM EMBRYO TRANSFER GUIDELINES.

Anthony DeAngelis, MD, PhD,[1] Allison A. Eubanks, MD,[1] Mae W. Healy, DO,[1] Rhiana D. Saunders, MD,[1] Saioa Torrealday, MD,[1] Alan H. DeCherney, MD,[2] John M. Csokmay, MD,[1] Micah J. Hill, DO[1]
[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

OBJECTIVE: To evaluate whether implementation of the new ASRM transfer guidelines in our clinical practice resulted in differences in pregnancy outcomes. The American Society of Reproductive Medicine published updated embryo transfer guidelines in March of 2017 in an attempt to decrease twin and higher-order multiple pregnancies. These updated guidelines recommend strong consideration for single embryo transfer for favorable prognosis patients under 38 years of age.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All women < 38 years old who underwent a second embryo transfer, after a prior failed embryo transfer, in the preceding two years or following the national guideline change were included. The primary outcomes assessed were the number of embryos transferred, and whether a clinical pregnancy, live birth, and/or twin live birth resulted. PGT and donor oocyte cycles were excluded. Published SART data was also compared between 2016 and 2017 to assess for national changes in the twin birth rate in patients <38 years of age. Differences in twin clinical pregnancy and live birth rates were compared by chi square test. Statistical significance was set at $P<0.05$.

RESULTS: 2424 transfer cycles from 2015-2018 were analyzed. 325 of these were second cycle transfers with 224 having a prior failed transfer. After implementation of the new transfer guidelines, the number of double embryo transfers was significantly reduced (21.9% vs 1.3% P<0.001). There was no change in clinical pregnancy rate after adaptation of the new guidelines (68.6% vs 67.9%, $P=0.908$); however, there was a significant reduction in the twin live birth rate (18.0% vs 4.3%, $P=0.033$). There were no higher order multiple gestations. The national SART data also showed a reduction in twin live births when comparing 2016 to 2017. In over 90,000 cumulative retrieval cycles in patients <35 years old, the twin rate decreased from 16.5% to 13.3% ($P<0.001$). In over 50,000 cumulative retrieval cycles in patients 35-37 years old, the twin rate decreased from 15.6% to 12% ($P<0.001$). The SART data was less pronounced in the twin reduction, likely because it was not limited to patients with a prior cycle.

Women age < 38	Before Guideline Change	After Guideline Change	*P* Value
Clinical Pregnancy	68.6%	67.9%	0.908
Total Live Birth	42.4%	44.3%	0.767
Twin Live Birth	18.0%	4.3%	0.033

CONCLUSIONS: Implementation of the 2017 ASRM guidelines decreased the twin live birth rate in favorable prognosis women in our institution and at a national level, without impacting the live birth rate. Even after a previous unsuccessful embryo transfer, women <38 can be offered a single embryo and still achieve similar live birth rates but with significantly lower multiple gestation rates.

P-744 4:30 PM Tuesday, October 20, 2020

USE OF MEDROXYPROGESTERONE ACETATE (MPA) IN DONOR CYCLES DECREASES MEDICATION COSTS.

Amber M. Klimczak, MD,[1] Nola S. Herlihy, MD,[1] Julia G. Kim, MD, MPH,[2] Brent M. Hanson, MD,[2] Emily K. Osman, MD,[2] Ashley W. Tiegs, MD,[2] Marie D. Werner, MD,[2] Daniel J. Kaser, MD,[2] Antonio Requena, MD,[3] Richard Thomas Scott, Jr., MD[2] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]IVI RMA New Jersey, Basking Ridge, NJ; [3]IVI RMA Spain, Madrid, NJ, Spain.

OBJECTIVE: Traditionally IVF stimulation protocols have utilized GnRH agonists or antagonists in order to prevent premature LH surge. As progestins can also inhibit the preovulatory rise in LH, medroxyprogesterone acetate (MPA) has recently been used instead of GnRH antagonists/agonists to prevent premature ovulation during IVF cycles. More data is needed in regards to the reliability of MPA in suppressing LH surge, its effects on IVF outcomes, and associated improvement in cost. The aim of this study is to determine whether using MPA instead of GnRH antagonists is associated with a change in medication cost and IVF outcomes.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Prior to February 1, 2019 oocyte donor cycles at our IVF center utilized a GnRH antagonist protocol. After that date a MPA protocol, which consisted of starting 10 mg MPA on the first day of stimulation was introduced. All donor MPA cycles from February 2019 to October 2019 were compared to the antagonist protocol cycles in the preceding year. Additionally a paired analysis was performed on 15 oocyte donors who first underwent a traditional antagonist cycle followed by a MPA cycle. Medication costs gonadotropins, antagonist (Ganirelix), and MPA were obtained from sourcing pharmacy. Statistical analyses were performed using a student's t-test and chi-square test.

RESULTS: A total of 355 antagonist cycles and 31 MPA cycles were included in this analysis. Mean number of stimulation days and mean number of oocytes retrieved did not significantly differ between the two groups (p=0.83; p=0.338). Average number of days of antagonist use was 4 days. Cost per antagonist cycle of Ganirelix was $420.00. MPA cost per cycle was $15.00. The estimated medication cost savings per cycle with MPA was determined to be $405.00. In the paired analysis there was no significant difference in mean total dose of gonadotropins, mean number of MII oocytes, mean number of useable blastocysts or mean number of euploid blastocysts.

CONCLUSIONS: Utilization of MPA in donor cycles may lessen the financial burden of IVF medication costs and does not appear to significantly alter IVF outcomes compared to traditional antagonist cycles.

	MPA Mean, n (%)	St Dev	ANTAG Mean, n (%)	St Dev	P-value

SEPTAL RESECTION IN WOMEN WITH UTERINE SEPTUM SCHEDULED FOR IN-VITRO-FERTILIZATION (IVF); A DECISION ANALYTIC MODEL. Ahmed M. Abdelmagied, MD,[1] Mohammed Khairy Ali, MD,[1] Ali Hassan Hamed, MD, FRANZCOG,[2] Mostafa N. Ibrahim, MD,[1] Amal Y. Zaman, MD,[3] Magdeldin Gaafar Taha, MD,[3] Fawzia Ahmed Habib, MD[3] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Department Of Obstetrics and Gynaecology, Ballarat Health Services, Ballarat, Victoria, VIC, Australia; [3]Department of Obstetrics and Gynecology, Faculty of Medicine, Taibah University, Saudi Arabia.

OBJECTIVE: Evidence is lacking to guide treatment decisions for uterine septum incision prior to IVF. The present work aimed to evaluate the cost-effectiveness and live birth (LB) outcomes of septal resection in the setting of IVF women with septate uterus.

DESIGN: A Decision analytic tree (model)

MATERIALS AND METHODS: A decision-analysis model was constructed to compare four strategies for septal resection in women indicated for IVF. Strategy (1: Res-All) adopts resection for all internal fundal depressions (FD) >1cm, depicting the clinical relevance of defining uterine septum as >1cm FD. Strategy (2: Res-Long) resects FD ≥1.5cm coinciding with ASRM-2016 definition of septate uterus. The third strategy (3: Res-After-failure) resects all FD after 2 failed IVF cycles. The fourth strategy is the reference standard that does not provide any resection (4: No-Res). The 4 strategies were analyzed in 2 models. Model (1) assumed improving LB after resection of any FD more than 1 cm. However, in Model (2) only FD ≥1.5 cm would benefit from resection. Calculations were done for a hypothetical cohort of 100 women undergoing 3 consecutive IVF cycles. Input probabilities were derived from the best available evidence in literature. For cost estimates, we utilized Medicare 2019 national fee rates in US dollars. Analyses were done using TreeAge Pro Healthcare 2020.

RESULTS: In base-case analyses of Model (1), Res-All was the most cost-effective, while in model (2) Res-Long was the most cost effective. Both dominated Res-After-failure and No-Res strategies in models (1) and (2) (Table). In Model (1) sensitivity analysis, both Res-All and Res-Long strategies would result in cost savings if the probability of LB in unresected septum is below 18%, with maximum cost savings of 9500 dollars per LB gained. If the probability was between 18-31%, Res-All and Res-Long strategies remained cost-effective (extra-costs with more effects) at $50,000/QALY willingness-to-pay threshold. Savings were generated through subsequent reduction in failed IVF cycles. In Res-Long strategy, increasing prevalence of FD ≥1.5cm would raise the cost per LB in Model (2), and would lower it in Model (1).

Model (1)	Cumulative Cost	Cumulative LBR	Cost per LB
Res-All indentations	2,489,454	74.1%	33619
Res-Long indentations	2,627,205	52.2%	50370
Res-After-failure	3,247,290	42.7%	76114
No-Res	2,847,217	14.8%	192979
Model (2)			
Res-All indentations	2,506,025	73.2%	34251
Res-Long indentations	2,343,600	73.2%	32031
Res-After failure	2,886,208	53.2%	54210
No-Res	2,563,612	35.8%	71684

CONCLUSIONS: While septal resection initially presents extra-costs, it could potentially save money for both the health care system and infertile couples by preventing reproductive failures of IVF cycles.

EFFICIENCY MARKERS FOR ART CENTERS TO EVALUATE QUALITY AND DELIVERY OF CARE. Bhuchitra Singh, MD, MPH, MS,[1] Mingyu Yan, BBA,[2] Mingqian Wang, MS,[3] Estefania Jordan, BBA,[2] Mindy S. Christianson, MD,[4] Valerie L. Baker, MD,[4] James Segars, MD[1] [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins Carey Business School, Baltimore, MD; [3]Carey Business School, Baltimore, MD; [4]Johns Hopkins Fertility Center, Lutherville, MD.

OBJECTIVE: To identify and develop standardized operational efficiency markers for quality and delivery of care at an ART Center. Efficiency markers combine a quality of care variable, such as patient satisfaction, and the cost required to deliver that degree of satisfaction. They can be used to quantify improvements in healthcare quality.

DESIGN: Quality assessment/improvement study.

MATERIALS AND METHODS: This work was done in two phases; Phase 1 was presented at the ASRM Conference 2018 where we presented a detailed process flow analysis (PFA) of the ART center at Johns Hopkins and identified bottlenecks. Here we report Phase 2, a secondary literature review and development of operational markers for efficiency in quality and delivery of care. The study team developed markers to analyze efficiency of the steps in the flow charts. Markers were reviewed from the other service industries such as hospitality, airlines, and restaurants to align patient-interests of the markers. According to the Donabedian quality of care measurement model, the instruments were categorized into structure, process, and outcome markers.

RESULTS: Our analysis identified 12 major processes from initial intake evaluation, through monitoring, retrieval, and embryo transfer. Within these, there were 42 sub-areas for quality monitoring and improvement efforts at the Hopkins ART center. The study details the instruments developed for comprehensive evaluation of patient-reported measures of satisfaction with care; clinical outcomes such as cumulative live birth rate, complication rates such as OHSS; delivery of general services outcomes like show-up rate, rate of insurance approval; process markers such as number of embryo transfers, average wait time/face time ratio for clinical visits. and structure markers such as IVF nurse/ patient ratio, number of front desk staff/ daily patient visits, number of board-certified certified reproductive endocrinologist. These operational efficiency markers aim to provide metric data to continuously identify the operational efficiency status to serve the reproductive needs of the patients.

CONCLUSIONS: The developed markers measure meaningful patient-centered outcomes, critical structural components, and essential processes that are necessary for continuous monitoring and adaptive changes for an ART center. This comprehensive strategy ultimately can improve the quality and delivery of care while supporting cost-containment at every level by efficient staffing and utilizing existing resources to full capacity.

COST EFFECTIVENESS ANALYSIS OF UNIVERSAL SCREENING FOR SICKLE-CELL TRAIT PRIOR TO IVF IN STATES WITH AND WITHOUT AN IVF INSURANCE MANDATE. Benjamin S. Harris, MD, MPH,[1] Benjamin J. Peipert, MD,[2] Laura J. Havrilesky, MD, MHSc,[3]

Kelly S. Acharya, MD[1] [1]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]Division of Gynecologic Oncology, Duke University Medical Center, Durham, NC, NC.

OBJECTIVE: To evaluate the cost-effectiveness of universal screening for sickle-cell trait (SCT) prior to in-vitro fertilization (IVF). Preliminary studies have shown that in couples known to both carry SCT, IVF with preimplantation genetic testing (IVF-PGT) for selection of embryos unaffected by sickle cell disease (SCD) is a cost-effective strategy[1]. However, it is unknown whether universal SCT screening to identify these dual-carrier couples is cost-effective, or if the value of a specific screening strategy is impacted by the greater number of IVF cycles and resulting higher conception rate afforded by IVF insurance mandates.

DESIGN: Cost-effectiveness analysis

MATERIALS AND METHODS: A simple decision model was designed from a societal perspective with a 1 year horizon, to compare SCT screening to no screening. The primary outcome was cost-effectiveness in US dollars per quality-adjusted life year (QALY) gained. QALY totals were assigned to cases of live offspring based on prior published studies (33 QALYs for HbSS offspring and 67 QALYs for unaffected offspring). We assumed that 50% of dual-positive couples (patient and partner with SCT) would choose IVF-PGT. In states with no insurance mandate, we assumed and that an average of 1.3 cycles of IVF-PGT were employed during the time horizon, with a 70% IVF conception rate. In states with an IVF insurance mandate, we assumed an average of 3 cycles of IVF-PGT were employed due to lower cost constraints on patients, with an 85% IVF conception rate. Rates of natural conception, IVF-PGT, early and late pregnancy loss, amniocentesis, therapeutic abortion, SCD lifetime costs and productivity, and prenatal care were derived from the literature, CPT and APC codes, and our experience at a single suburban academic IVF center. Multiple one-way sensitivity analyses were performed to test model assumptions.

RESULTS: In the base case primary analysis, the mean cost of the SCT screening strategy was lower than for no SCT screening ($322,548 vs. $322,580). No screening resulted in 0.00039 more QALYs than SCT screening, and was cost-effective with an ICER of $83,096/QALY. In the case of an IVF insurance mandate, the mean cost of the SCT screening strategy remained $14 lower than for no SCT screening and also resulted in 0.00048 more QALYS, making SCT screening a dominant strategy. In sensitivity analysis of the base case model, when the IVF conception rate exceeds 76%, SCT screening becomes a dominant strategy.

CONCLUSIONS: Universal SCT screening is cost-effective when compared with no screening if the IVF conception rate exceeds 76%. These conditions would be met if every dual-carrier couple with SCT had the financial resources to pursue the recommended follow-up treatment with maximization of pregnancy rates through multiple IVF-PGT cycles. Ultimately, the cost-effectiveness of this intervention is contingent upon disease prevalence and the cumulative IVF conception rate. Therefore, in states where patients have insurance coverage to undergo multiple IVF-PGT cycles, SCT screening could be considered a value-based strategy.

TOO LITTLE, TOO MUCH, OR JUST RIGHT? HOW PATIENTS FEEL ABOUT THEIR SPENDING ON FAMILY BUILDING. Colin Johnson, MD, Rachel Cusatis, PhD, Kathryn E. Flynn, PhD, Jay I. Sandlow, MD, Judith Myers, MS, Kate D. Schoyer, MD Medical College of Wisconsin, Milwaukee, WI.

OBJECTIVE: To understand how couples and individuals feel about their financial investment in adding a child to their family 6 years after seeking a consultation with a reproductive specialist.

DESIGN: Longitudinal cohort study using prospectively collected patient-reported data and retrospectively collected clinical data.

MATERIALS AND METHODS: 64 couples and 28 individuals seeking initial consultation with a reproductive specialist enrolled in this study. Questionnaires were administered prior to their first consultation, at 1 year, and at 6 years. Participants were asked yes/no questions regarding their thoughts about their financial investment in adding a child to their family (see Table 1). The Decisional Regret Scale was also administered, a 5-item scale assessing regret (0-100), referencing "the decision you made about how to add a child to your family." An additional open-ended question allowed participants to provide detail about their experience. Medical records were used to ascertain whether each participant achieved a live birth using fertility treatments. Chi-squared tests were used for comparisons.

RESULTS: 45 couples and 34 individuals (77 women and 47 men) responded to the 6-year survey. 7% of participants wish they had spent more money and 28% of participants wish they had spent less. There were no gender differences in responses, but there were significant differences between those who had a live birth using fertility treatments and those who did not (Table 1). Additionally, those who expressed moderate or severe regret (score $\geq$25) were more likely to wish they had spent more money on treatments compared to those with no regret or minor regret (p=0.012). Qualitative themes included income limitations, desiring to afford a specific treatment (such as IVF), and the expense of treatments with uncertainty about effectiveness.

CONCLUSIONS: The majority of patients were satisfied with how much money they spent on family-building, though over one-quarter wished they had spent less, and this was more often those who were successful in achieving a live birth through fertility treatments. Additionally, the often onerous financial aspects of fertility treatments in the U.S. may be associated with regret about those treatments over time.

Table 1. Participants who Responded "Yes" to Statements about Money Spent on Family-Building

Statement	Responded "Yes" to Statement		p-value
	Live Birth	No Live Birth	
I wish I had spent more money on trying to add a child to my family	2/69 (3%)	7/55 (13%)	**0.036**
I wish I had spent less money on trying to add a child to my family	26/68 (38%)	9/55 (16%)	**0.008**
I am satisfied with how much money I spent trying to add a child to my family	55/67 (82.1%)	43/55 (78%)	0.589

SUPPORT: Funding came from R21HD071332 from the National Institute of Child Health and Human Development as well as the Department of Obstetrics and Gynecology at the Medical College of Wisconsin

P-749 4:30 PM Tuesday, October 20, 2020

AN ARTIFICIAL INTELLIGENCE PLATFORM TO OPTIMIZE IVF MANAGEMENT DURING OVARIAN STIMULATION: WORKFLOW IMPROVEMENT AND OUTCOME-BASED PREDICTIONS. Gerard Letterie, MD,[1] Andrew MacDonald, MS,[2] Zhan Shi, PhD[3] [1]Seattle Reproductive Medicine, Seattle, WA; [2]Quick Step Analytics, Seattle, WA; [3]University of Washington, Seattle, WA.

OBJECTIVE: to describe and assess the accuracy of an integrated AI platform designed to reduce monitoring during ovarian stimulation to a single day; adjust outcome predictions and enable level loading of oocyte retrievals based on that single day of observations.

DESIGN: descriptive study of a novel AI-based suite of software tools to determine optimal scheduling options and predict outcomes based on clinical profiles at the start of and ongoing data collection during ovarian stimulation and identify options to enable level loading of oocyte retrievals

MATERIALS AND METHODS: Data for the study was in the form of IVF cycles. Our data set included: patient profiles of age, serum concentrations of anti-mullerian hormone, antral follicle counts and BMI; observations during ovarian stimulation to include estradiol (E2) concentrations (in pg/ml);

Table 1. Sensitivity analysis

m-TESE cost ($)	WTP ($)						
	8,000	10,000	12,000	14,000	16,000	18,000	20,000
1,000	**cTESE**	**cTESE**	**cTESE**	**cTESE**	mTESE	mTESE	mTESE
1,200	**cTESE**	**cTESE**	mTESE	mTESE	mTESE	mTESE	mTESE
2,000	mTESE	mTESE	mTESE	mTESE	mTESE	mTESE	mTESE
5,000	mTESE	mTESE	mTESE	mTESE	mTESE	mTESE	mTESE

ultrasound measurements of follicle diameters in 2 dimensions (in mm). Outcomes included number of mature oocytes stratified into 2 groups: 0 to 10 (Group I) and > 10 (Group II)mature oocytes . The database consisted of 2603 total autologous cycles composed of 305,472 clinical data points. There were 1591 complete records encompassing 4731 visits. Eighty percent of the cycles were used for training and validation and 20% for challenge. Predictive algorithms were evaluated and written using Python, NumPy logistic function, Panda and SKLearn. Data was organized using Jupyter Notebook.

RESULTS: The accuracy of the algorithm to predict the single best day for monitoring was 0.95 and identified Day 9 as the single best day. Errors in predicting too early or too late were 0.4 and 0.5 days respectively. Accuracy for prediction for total number of mature oocytes when baseline testing alone or when baseline testing in combination with data during day of observation was 0.76 and 0.80 respectively. In addition, no combination of baseline factors or data observed during stimulation was more influential in the algorithm's predictive power than AMH alone. Sensitivity and positive predictive value for estimating the total number of mature oocytes in Groups I (0 to 10) was 0.78 and 0.79 and for Group II (>10) were 0.73 and 0.72 respectively. After identifying the single day for evaluation, the algorithm identified a range of 3 retrieval days specified by the earliest and the latest day, as options where the number of mature oocytes retrieved was unchanged leaving open the option of a range of 3 days to schedule and level load retrievals.

CONCLUSIONS: We describe a robust suite of integrated management tools encompassing three interrelated nodal points for management, scheduling techniques and decision making during IVF to include reducing monitoring to a single best day during ovarian stimulation; adjustment of outcomes (PR) based on that data and options to level load oocyte retrievals. These tools will enable an improved work flow and reduction in patient care visits without any reduction in the surveillance of response or outcomes during IVF. As such this, algorithm should improve workflow and reduce costs due to reduced need for monitoring and personnel.

P-750 4:30 PM Tuesday, October 20, 2020

FINANCIAL DECISION ANALYSIS FOR SURGICAL SPERM RETRIEVAL APPROACHES. Tracy X. Han, MD, MBA, Ramy Abou Ghayda, MD, MHA, MPH, Brittany D. Berk, MD, John Joseph Ernandez, Jr., BA, Martin Kathrins, MD Brigham and Women's Hospital and Harvard University, Boston, MA.

OBJECTIVE: To determine the most financially optimal surgical approach for testicular sperm retrieval for men with non-obstructive azoospermia (NOA).

DESIGN: A decision tree was created examining five potential surgical approaches for men with NOA pursuing one cycle of ICSI. An expected financial net loss was determined for each surgical option based on couples' willingness to pay (WTP) for one cycle of ICSI resulting in pregnancy. The branch with the lowest expected net loss was defined as the most optimal financial decision (minimizing loss to a couple). Fresh TESE implied TESE was performed in conjunction with programmed ovulation induction. Frozen TESE implied TESE was performed initially, and ovulation induction/ICSI was canceled if sperm retrieval failed. The surgical options included fresh conventional TESE (c-TESE, with and without "back-up" sperm cryopreservation), fresh microsurgical TESE (m-TESE, with and without "back-up" sperm cryopreservation), and frozen m-TESE. Success was defined as pregnancy after one ICSI cycle.

MATERIALS AND METHODS: Probabilities of successful sperm retrieval with c-TESE/m-TESE, post-thaw sperm cellular loss following frozen m-TESE, ovulation induction/ICSI cycle out-of-pocket (OOP) costs, ICSI pregnancy rates for men with NOA, standard c-TESE cost and average WTP for ICSI cycle were gathered from the systematic literature review. Costs were in USD and adjusted to inflation (as of April 2020). Two-way sensitivity analysis was performed on varying couples' WTP for one cycle of ICSI and varying m-TESE OOP costs.

RESULTS: According to our decision tree analysis (assuming minimum m-TESE cost of $1,000 and WTP of $8000), the expected net loss for each branch was as follows: -$17,304 for fresh c-TESE, -$17,282 for fresh m-TESE, -$9,828 for frozen m-TESE, -$17,971 for fresh c-TESE with "backup", and -$18,298 for fresh m-TESE with "backup". Two-way sensitivity analysis with variable WTP values and m-TESE costs confirmed that frozen m-TESE consistently presented the lowest net loss compared to other options. Interestingly, when directly comparing fresh m- and c-TESE with "back-up", scenarios with decreasing WTP and lower m-TESE costs demonstrated c-TESE with "back-up" as more optimal than m-TESE with "back-up" (Table 1).

CONCLUSIONS: Our study suggests that frozen m-TESE is the most financially optimal decision for the surgical management of NOA, regardless of m-TESE cost and couple's WTP.

P-751 4:30 PM Tuesday, October 20, 2020

FROM PEN TO KEYBOARD: TRANSITION TO A SPECIALTY ELECTRONIC MEDICAL RECORD. Baruch Abittan, M.D., Stephanie R. Brownridge, M.D., Randi H. Goldman, M.D., Christine Mullin, M.D. Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: The importance of converting paper medical records to electronic versions has been nationally recognized. There are certain specialties, including Reproductive Endocrinology and Infertility (REI), which have lagged behind the initiative in transitioning to an electronic medical record (EMR). Our objective is to describe the essential steps required for a successful transition to EMR in a large university academic REI clinic, and to report results from an internal survey regarding the perception of transition among multidisciplinary staff members.

DESIGN: Descriptive and Survey study.

MATERIALS AND METHODS: We reviewed the processes executed during our transition from paper to electronic health records. To ensure that the system was designed to match the workflow of the practice, a plan was determined for all fields of the division (andrology, embryology, third party reproduction, clinical services outside of IVF, billing, radiology and laboratory services). The process began with clear goals of implementing an EMR system at 6 ambulatory locations, which was accomplished in a series of 5 rollout periods. Six months following the go live date of EMR implementation, an anonymous survey was administered to staff members regarding the EMR transition and effect of EMR on remote-work during the COVID-19 pandemic.

RESULTS: Patients' safety is of paramount importance, and correct identification of patient, partner, and gametes is a vital objective while transitioning to a paperless system. Challenges recognized during this process were communication, services sharing a single location with differing needs (andrology, embryology, third party reproduction, billing, laboratory, clinical), requirements from multiple regulatory bodies (eg. FDA, CDC, SART), integration of fertility software into existing University health system EMR, complexity of a workflow with multiple providers interacting with patients, and the unique safety procedures involved with fertility care, including witnessing of specimens. Thirty-eight staff members, including physicians, nurses, embryologists, and office staff responded to the survey. Most respondents were between age 31-40y (32%), 21-30y (21%), or 51-60 y (21%). Sixteen percent of respondents did not feel comfortable with EMR use prior to implementation. Almost one third of respondents (29%) had been working in the fertility field for 1-5 y, 27% for 6-10 years, and another 21% for more than 20 years. Seventy percent of staff members felt the education received prior to EMR transition was well organized with attainable goal. Most (90%)

were satisfied with the EMR transition process, 79% identified a positive impact on work patterns since EMR transition, and 87% reported improved communication. Over 90% of staff members believed that the EMR transition prepared them to utilize TeleHealth remotely during the COVID-19 pandemic.

CONCLUSIONS: With proper planning and commitment of administration and staff, a successful transition from paper charts to EMR can be accomplished in a busy REI practice.

P-752 4:30 PM Tuesday, October 20, 2020

PRINCIPLES OF ONLINE DEFAMATION FOR PHYSICIANS. Christopher P. Moutos, MD,[1] Kajal Verma, MD,[2] John Y. Phelps, MD, JD, LLM, MHA[3] [1]University of Texas Medical Branch, Galveston, TX; [2]University of Nevada, Las Vegas, Las Vegas, NV; [3]University of Nevada Las Vegas, Las Vegas, NV.

OBJECTIVE: The goal of this study is to highlight online defamation lawsuits initiated by healthcare providers and discuss situations in which litigation may be an appropriate response to potential claims of online defamation. We also aim to propose solutions for addressing unfavorable online reviews in a way that may avoid the litigation process.

DESIGN: Case law review

MATERIALS AND METHODS: Local county and district court dockets, along with NexisUni, a legal database of appealed court cases, were used to identify relevant lawsuits and legal principles pertaining to online defamation cases. Media coverage was used to further characterize details of specific lawsuits identified. Materials from the American College of Obstetrician and Gynecologists were used to help form recommendations for physicians in handling online interactions.

RESULTS: Successful defamation lawsuits must establish four key elements: (1) presence of a false or defamatory statement; (2) fault, amounting to at a minimum negligence; (3) an unprivileged communication to a third party; (4) harm or damages suffered by the plaintiff due to the statement. The specific lawsuits *Desert Palm Surgical Group v. Petta*, *McKee v. Laurion*, and *Great Wall Medical PC v. Levine* serve as examples of lawsuits that were unsuccessful or have faced significant, ongoing difficulty in the court system due to failure in establishing each of the four principles of a successful defamation case. Successful cases do exist though, as seen in *Austin Eye Clinic v. Hall*. The cases of *Reit v. Yelp Inc* and *Braverman v. Yelp Inc* demonstrate the difficulty in healthcare providers seeking action directly against a website itself, rather than an individual reviewer. Online defamation lawsuits can be resource intensive and harm a practice's reputation due to negative media attention. In addressing patient reviews online, physicians must be mindful to protect patient confidentiality as outlined by the Health Insurance Portability and Accountability Act (HIPAA).

CONCLUSIONS: Physicians considering a lawsuit should weigh the alleged defamatory statement against the four criteria which a defamatory claim must meet. They should also consider the ability to identify the author, the author's ability to pay if damages are awarded, and the opportunity cost of time spent in the legal process. In situations where a physician believes they have sufficient grounds for a case, they should seek professional legal advice. Those choosing to respond online should do so in a professional manner that adheres to HIPAA guidelines. Physicians who are proactive in soliciting evaluations from patients have seen overall positive results. Evidence exists that most online reviews of physicians are positive and having negative reviews is not wholly detrimental to a practice.

P-753 4:30 PM Tuesday, October 20, 2020

IMPACT OF IMPLEMENTATION OF A NEW EMBRYO CULTURE SYSTEM ON EFFICIENCIES OF CLINICAL OPERATIONS IN A MODERN IVF CLINIC. Natalie Hesketh, MSc, Teija Peura, PhD, Andrew Murray, MSc, Sarah Dalati, PhD, Mark Bowman, MB BS PhD, Steven J. McArthur, BSc Genea, Sydney, NSW, Australia.

OBJECTIVE: Although our clinics achieved significant improvements in embryo developmental outcomes and pregnancy rates after the introduction of continuous culture medium and timelapse system, the downstream impact on operational efficiencies remained unknown. In the face of increasing competition these impacts are becoming increasingly important for the clinics, and hence the objective of this study was to examine if implementation of the new system had positive effects also on IVF clinic operational outcomes.

DESIGN: Alongside the change of culture system in a chain of IVF clinics, operational efficiencies were monitored to assess the possible advantages or disadvantages to clinical operations. Overall procedure times per patient and number of cycles per embryologists were tracked. In addition, patient satisfaction regarding monitoring their embryo videos during their cycle was recorded to assess the effect on competitiveness of the clinics' services. The data was collated from 2017-2019.

MATERIALS AND METHODS: Clinical cycles across eight clinics in 2017 to 2019 were included into the study. Cycle procedure and clinical process timings, each broken into 16 separate steps, were captured from clinical records. Average cycle numbers per full-time equivalent embryologists were likewise captured in 8 clinics. 358 patients were surveyed over 8-month period during their cycle about their experiences of accessing their embryo images and videos using a 5-level Likert scale questionnaire.

RESULTS: Average procedure times decreased from 570 to 555 to 490 minutes per patient in 2017, 2018 and 2019, resulting in average savings of 1h 20 min per patient (14% decrease), with biggest relative time savings achieved in embryo assessments and embryo hatching (in-situ) for PGT. Clinical hours per cycle varied from 6.9 to 7.0 to 6.1 hours in 2017, 2018 and 2019, again with biggest time savings gained for embryo checks. Number of cycles per embryologist increased from 107 to 126 to 160 (50% increase) in 2017, 2018 and 2019. Although more flexibility in staffing due to facilitation of remote embryo assessment was the biggest factor, not all efficiency improving factors were directly related to the new culture system.

84.8% of surveyed patients agreed or strongly agreed that their IVF experience was enhanced by access to their images, citing factors such better inclusion of their partner, provision of greater understanding and feeling of being more connected with their treatment. Subsequent surveys showed that even in cycles not leading to pregnancy, majority of patients still felt better connected to and more satisfied with their treatment when having access to their images.

CONCLUSIONS: Implementation of new embryo culture system led to positive trickle-down effects in efficiencies, costs, staffing and patient satisfaction. Rather than looking at laboratory operations and culture systems in isolation, it is hence important to consider the wider picture to ensure IVF clinics' operational and financial success alongside clinical outcome successes.

POSTER SESSION: PREIMPLANTATION GENETIC TESTING

P-754 4:30 PM Tuesday, October 20, 2020

PREIMPLANTATION GENETIC TESTING (PGT) SUCCESS IN THE UNITED STATES (2014-2017): MULTIPLE OUTCOME MEASURES INDICATE SUPERIORITY OF PGT OVER NO PGT. David H. McCulloh, Ph.D.,[1] James A. Grifo, MD, PhD[2] [1]NYU Langone Fertility Center, New York, NY; [2]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: Studies have compared outcomes of transferring embryos tested for Preimplantation Genetic Testing (PGT) with untested embryos (No PGT). Most studies using comprehensive chromosome analysis (CCA: qPCR, array based or sequencing) found benefits for PGT in single centers (1,2,3). One multi-center randomized controlled trial showed benefit only for patients >35 years (4). Data spanning the United States (US) are available; but have not been reviewed since results from 2011 & 2012 (5)(mainly day 3 biopsies with a mix of aCGH and FISH). This study evaluates over 420,000 cycles from 2014-2017 comparing outcomes using PGT (mainly blastocysts using CCA) versus no PGT.

DESIGN: Analysis of Data Collected from the SART Registry (www.sart.org).

MATERIALS AND METHODS: Data for non-banking cycles (years: 2014-2017, inclusive) were segregated by use of PGT biopsy or not. Outcomes included: Livebirth (LB) per cycle (up to 1 transfer), miscarriage, multiple pregnancy and preterm deliveries. The mean number of embryos transferred was determined for each group.

Table 1

Outcome	Group	Female Age (years)[1] <35	35-37	38-40	41-42	>42
LB/cycle (# cycles)	PGT	43.5% (37,903)	37.6% (27,440)	28.0% (29,999)	17.0% (15,120)	6.9% (8,222)
	No PGT	41.8% (134,266)	32.5% (62,944)	20.6% (55,618)	10.1% (28,102)	3.3% (21.395)
# embryos	PGT	1.18	1.18	1.15	1.14	1.19
Xfrd	No PGT	1.56	1.73	2.04	2.44	2.57
LB/cycle dx-adjusted	PGT	44.8%	37.9%	28.0%	16.7%	7.4%
	No PGT	43.0%	33.0%	21.1%	10.3%	2.9%
Miscarriage	PGT	11.4%	12.3%	13.6%	15.0%	16.9%
	No PGT	12.3%	16.6%	25.3%	37.6%	54.3%
Multiple Birth	PGT	10.7%	10.0%	8.6%	7.8%	3.7%
	No PGT	21.4%	20.8%	19.2%	14.4%	9.5%
Premature Birth	PGT	15.0%	14.9%	15.0%	14.8%	13.1%
	No PGT	21.7%	21.2%	21.4%	19.6%	18.2%

[1]In each age group, every outcome was significantly different when comparing between PGT and No PGT (2 x 2 Contingency X^2 with $P < 0.05$)

RESULTS: LB per cycle was significantly greater for PGT in all age groups (see table), despite transfer of more embryos (no PGT). The excess live birth rate (PGT) varied among age groups. Miscarriage, multiple pregnancy and preterm delivery rates were significantly greater with no PGT (all ages). After adjusting for significant differences in reasons for ART in each age group, PGT had greater LB rates (all ages).

CONCLUSIONS: Cycles in the US revealed that PGT provided better rates for all ages: Higher LB, lower miscarriage, lower multiple pregnancy (associated with fewer embryos transferred) and lower preterm birth (associated with lower multiple pregnancy rate). LB rates, adjusted for reasons for ART, indicated that reasons for ART do not account for the significant advantage of PGT over no PGT. Confounders include: cases with PGT intent that had no biopsy (included as No PGT) and cases with PGT for other than PGT-A (included as PGT).

P-755 4:30 PM Tuesday, October 20, 2020

MULTICENTER PROSPECTIVE NON-SELECTION STUDY OF BLASTOCYST TRANSFER WITH LOW-MEDIUM-GRADE MOSAICISM.

Antonio Capalbo, PhD,[1] Maurizio Poli, MSc, D.Phil,[1] Danilo Cimadomo, PhD,[2] Francesca Benini, PhD,[3] Cristina Patassini, MSc,[1] Laura Girardi, PhD,[1] Marco Fabiani, PhD,[1] Silvia Caroselli, MSc,[1] Carmen Rubio, PhD,[4] Elena Albani, MSc,[5] Laura Sacchi, MD,[5] Laura Francesca Rienzi, MSc,[2] Claudia Livi, MD,[3] Paolo Emanuele Levi Setti, MD,[5] Filippo Maria Ubaldi, MD, PhD,[2] Carlos Simon, MD, PhD[6] [1]Igenomix Italy, Marostica, Italy; [2]GENERA, Center for Reproductive Medicine, Rome, Italy; [3]ART Center DEMETRA, Florence, Italy; [4]Igenomix Foundation, INCLIVA, Valencia, Spain; [5]Humanitas Clinical and Research Center- IRCCS, Milan, Italy; [6]Igenomix Foundation, INCLIVA, Valencia, Spain, Department of Obstetrics and Gynecology, Valencia University, valencia, Spain, Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Valencia, Spain.

OBJECTIVE: To investigate the clinical outcome of blastocyst transfer with low-medium-grade mosaicism in a non-selection study

DESIGN: Multicenter prospective non-selection study involving five IVF clinics in Italy. Trophectoderm biopsies showing intermediate chromosome copy number (CN) values consistent with low mosaicism (20-50%) were blindly reported as euploid. The presence of mosaicism did not influence the embryo selection process as unbiased comparison of transfer outcomes between the fully euploid and putative-mosaic groups was performed. Ethical committee approvals were obtained at each site.

MATERIALS AND METHODS: The study involved 783 patients (mean female age 37.50 ± 3.3) undergoing homologous IVF cycles with blastocyst-stage PGT-A and single frozen euploid embryo transfer (SEET) between Sept 2018 and Dec 2019. A total of 845 cycles with at least one embryo available for transfer (euploid or putative mosaic) were included. Main exclusion condition was blastocyst of the worst morphological class. Miscarriage rate and live birth rate (LBR) per transfer were the main outcome measures.

RESULTS: A total of 897 SEET of tested blastocysts were performed in the course of the study, 484 (54%) were euploid, 282 (31,4%) showed low putative-mosaicism (20%-30%), and 131 (14,6%) showed moderate putative-mosaicism (30%-50%). Miscarriage rate was 12% (n=29/241), 11% (n=15/136) and 12.7% (n=8/63) for the three groups respectively; LBR was 43.4% (n=210/484), 42.9% (n=121/282) and 42% (n=55/131), respectively. Logistic regression analysis confirmed the lack of association between the "PGT-A category" and miscarriage risk (P=0.71) and live-birth rate per transfer. Therefore, no differences were observed in the clinical parameters testing across the three categories tested. The only prognostic factor for LBR was blastocyst developmental timing (OR=0.67 for day 6 vs day 5 and OR=0.19 for day 7 vs day 5). Mean mosaicism rate was not increased in biochemical pregnancy losses (BPL) and embryos resulting in miscarriage vs ongoing pregnancies, and in embryos resulting in LB vs embryos failing to implant. Mean number of mosaic chromosomes was also similar between LBR and control. The number of chromosomes with intermediate CN values per embryo was not associated with BPL (OR=1.00; 95%CI:0.85-1.18), miscarriage (OR=1.05; 95%CI=0.89-1.23) or LBR outcome (OR=0.98; 95%CI 0.91-1.07). Our data shows that the exclusion from transfer of all putative mosaics above 20% variability, results in an overall relative reduction in expected cumulative LBR of -36%.

CONCLUSIONS: Intermediate chromosome CN values consistent with low/moderate-grade mosaicism (30-50%) do not provide any clinically useful criteria for defining embryonic reproductive competence and should not be considered for aneuploidy categorization and embryo selection purposes in PGT-A cycles. The previously reported mild association can be explained by a selection bias involving the transfer of putative mosaic embryos to patients that failed previous euploid embryo transfers, thus of lower prognosis.

P-756 4:30 PM Tuesday, October 20, 2020

CONFIRMATION RATE OF WHOLE CHROMOSOME CALLS ON A TARGETED NEXT-GENERATION SEQUENCING PLATFORM ARE HIGHLY CONSISTENT WITH INITIAL TROPHECTODERM BIOPSY.

Julia G. Kim, MD, MPH,[1] Xin Tao, Ph.D,[2] Yiping Zhan, Ph.D,[3] Michael Cheng, MS,[1] Tianhua Zhao, BS,[4] Vanessa Guo, BSc,[1] Brent M. Hanson, MD,[1] Richard Thomas Scott, Jr., MD,[1] Chaim Jalas, N/A[2] [1]IVI RMA New Jersey, Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]The Foundation for Embryonic Competence, Basking Ridge, NJ; [4]IVIRMA, Basking Ridge, NJ.

OBJECTIVE: The ability of preimplantation genetic testing for aneuploidy (PGT-A) based on a single trophectoderm biopsy to reflect the reproductive competence of an entire embryo has been a great source of debate. Some studies have even reported live births after transfer of purportedly aneuploid embryos, and concluded that viable embryos are being discarded due to inaccurate PGT-A results. These studies fail to capture the scope of analytic error in the initial PGT-A result. This study seeks to describe the accuracy of an initial clinical call made by PGT-A by targeted Next Generation Sequencing (NGS) in its ability to reflect the whole embryo by analyzing multiple biopsies from the same embryo.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Donated clinical embryos with prior euploid or whole chromosome aneuploid results determined by a targeted NGS platform were rebiopsied into multiple pieces. To obtain clinical-sized biopsies, embryos were biopsied anywhere from 2 to 12 times depending on blastocyst expansion after warming. NGS was then performed on these rebiopsies, and results were compared to the initial trophectoderm biopsy. All rebiopsies for the study were analyzed by the PGTseq-A platform with calls made by a single reviewer who was blinded to the initial clinical calls.

RESULTS: A total of 106 euploid embryos and 97 aneuploid embryos underwent rebiopsy. In embryos with an initial euploid call, 104 of the 106 embryos had confirmation of euploid status in all subsequent rebiopsied pieces (98.1%). Of the 97 embryos initially called aneuploid, 92 (94.8%) of these were confirmed with the same results in all subsequent rebiopsies.

	Embryos with initial call	Embryos with confirmatory rebiopsy results
Euploid Call	106	104 (98.1%)
Aneuploid Call	97	92 (94.8%)

CONCLUSIONS: This analysis finds a euploid or aneuploid clinical call made by targeted PGTseq-A to be almost always reflective of the entire embryo. The high correlation of subsequent biopsies with an initial biopsy provide reassurance that clinical decisions based off an initial trophectoderm biopsy can be made with confidence.

EFFECTS OF SPERM AGE ON EMBRYO PLOIDY IN PGT-A. Sally A. Rodríguez, ScM, CGC, Sophia Tormasi, BSc, TS(ABB), Catherine Welch, MBA, TS(ABB), Jason Nefalar, BSc, Laura Shin, BSc, Mike M. Moradian, PhD HCLD, Sequence46, Los Angeles, CA.

OBJECTIVE: PGT-A is routinely offered to patients undergoing IVF. Advanced maternal age (AMA), defined as ≥35 years, has a known significant effect on embryo ploidy status. The effects of advanced paternal age (APA), defined as ≥40 years, on ploidy have been studied less. This study assesses euploid and mosaic rates of embryos created with donor sperm (DS), non-APA sperm, and APA sperm, stratified by use of donor egg (DE), non-AMA eggs, and AMA eggs.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: All samples received 5/2018 - 5/2020 were included, except for those sent for PGT-SR or with suspected rearrangements. Samples created with known donor gametes were categorized with their respective age groups. Whole-genome amplification, next generation sequencing, and data analysis was performed using the Ion ReproSeqTM PGS Kit and Ion ReporterTM software (Thermo Fisher Scientific). Results were reported as 1) no abnormal cells detected, 2) abnormal cells detected (with percentages if mosaicism was identified), or 3) did not pass quality control (QC) metrics, leading to embryo categories euploid, aneuploid, mosaic, and QC failure. Results were tallied and chi square analyses were performed to compare euploid and mosaic rates between DS samples and non-APA and APA sperm samples.

RESULTS: A total of 23,239 samples from 4,691 cycles were included. Table 1 displays ploidy rates for each group and corresponding chi square p-values.

CONCLUSIONS: Our data shows that sperm age can have an effect on embryos' ploidy status, as shown by a significantly higher euploid rate in embryos created with DE and DS compared to those created using DE and either non-APA or APA sperm; this effect was noted even with a small sample size. Amongst embryos created with AMA eggs, DS has less of an effect, demonstrating that egg age is still the primary factor affecting embryo ploidy. Clinicians can use this information when counseling patients on the effects of AMA and APA on embryo ploidy.

P-758 4:30 PM Tuesday, October 20, 2020

UNDERLYING RISK FOR A PARENTAL BALANCED CHROMOSOME REARRANGEMENT IDENTIFIED THROUGH PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY USING SNP MICROARRAY ANALYSIS WITH INFORMATICS. Jessica Adsit, MS, Katherine L. Howard, MS, Carrie Chou, MS, Dalar Ratousi, MS, Nina Wemmer, MS, Katrina Merrion, MS Natera, Inc., San Carlos, CA.

OBJECTIVE: To determine the rate of parental balanced chromosome rearrangements identified following preimplantation genetic testing for aneuploidy (PGT-A) with embryo results suggestive of a parental

Table 1. Euploid & Mosaic Rates by Group

Embryo Categories	% Euploid	χ2 p-value (Euploid)	% Mosaic	χ2 p-value (Mosaic)	Average Egg Age (years)	Average Sperm Age (years)
DE + DS	97/146 66.44%	-	19/146 13.01%	-	25.2	28.2
DE + S<40	1770/3146 56.26%	p = 0.015	581/3146 18.47%	NS	25.8	34.6
DE + S≥40	1478/2593 57.00%	p = 0.025	456/2593 17.59%	NS	26	46
E<35 + DS	265/494 53.64%	-	99/494 20.04%	-	31.6	26.3
E<35 + S<40	2662/4808 55.37%	NS	757/4808 15.74%	p = 0.013	31.8	33.7
E<35 + S≥40	455/829 54.89%	NS	129/829 15.56%	p = 0.037	32.1	46.2
E≥35 + DS	396/1145 34.59%	-	129/1145 11.27%	-	39.4	27.4
E≥35 + S<40	2122/5251 40.41%	p = 0.0003	646/5251 12.30%	NS	37.7	36.3
E≥35 + S≥40	1559/4827 32.30%	NS	458/4827 9.49%	NS	39.4	45.1

DE: donor egg; DS: donor sperm; S<40: non-APA sperm; S≥40: APA sperm; E<35: non-AMA egg; E≥35: AMA egg; NS: not significant

rearrangement and to assess any correlation between the number of embryos with an abnormality involving the same chromosomes and the likelihood of confirming a parental rearrangement.

DESIGN: Retrospective study of all trophectoderm (TE) biopsy samples received between April 2014-February 2020 that were suggestive of a parental rearrangement due to a pattern of deletions/duplications and/or aneuploidy involving the same chromosome(s) and parental origin.

MATERIALS AND METHODS: TE biopsies were performed at in vitro fertilization (IVF) centers and shipped to a single reference laboratory for PGT-A using Illumina CytoSNP-12b microarrays and bioinformatics which determine parental origin of each chromosome. For cases with results suggestive of a parental rearrangement, clinics were contacted, and parental chromosome analysis was suggested.

RESULTS: Fifty-seven flagged cases were identified with a total of 228 TE samples. The average number of TE samples tested per case was 7 (range 2-23). Clinics provided follow up on 49 cases, 44 of which pursued chromosome analysis. A chromosome rearrangement was confirmed in 37 patients (84.1%) including 35 translocations and 2 inversions. For all cases, parental origin was consistent with the prediction based on embryo results (29 paternal and 8 maternal). Broken down by the number of TE results suggestive of a parental rearrangement: 16 cases had 5 or more suggestive results with a parental rearrangement confirmed in 13 (81.3%); 14 cases had 3-4 suggestive results with a parental rearrangement confirmed in 13 (92.9%); 14 cases had 1-2 suggestive results with a parental rearrangement confirmed in 11 (78.6%).

CONCLUSIONS: In this study, 84.1% of patients with PGT-A results suggestive of a parental rearrangement were confirmed to carry a translocation or inversion. While having 3 or more embryos with suggestive results correlated to a very high rate of a confirmed parental translocation or inversion (81.3%-92.9%), high confirmation rates (78.6%) were also seen in cases with only 1 or 2. The ability to determine parental origin of abnormalities on PGT-A can be used to identify possible patterns in embryo results, suggest partner-specific karyotype analysis, and may allow for the option of PGT for structural rearrangements in future IVF cycles.

GENDER SELECTION, IS IT TIME TO ABANDON THE ALBUMIN SPERM SEPARATION METHOD?

Irene Woo, MD,[1] Roman James Danielzadeh, BA pnd,[2] Intira Sriprasert, MD,[2] Yulan Zhang, MD, PHD,[3] Peyman Saadat, MD,[4] Eliran Mor, MD[1] [1]California Center for Reproductive Health, Encino, CA; [2]University of Southern California, Los Angeles, CA; [3]California Center for Reproductive Health, West Hollywood, CA; [4]Reproductive Fertility Center, W. Hollywood, CA.

OBJECTIVE: Prior to the advent of preimplantation genetic testing for aneuploidy screening (PGT-A), gender selection has traditionally relied on the Ericsson albumin sperm separation method in which X chromosome bearing sperm are sorted from Y chromosome bearing sperm based on their difference in density. We wished to validate the benefit of the Ericsson sperm separation method against PGT-A results in couples undergoing sperm sorting with the modified Ericsson albumin separation method followed by IVF with PGT-A for gender selection.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients undergoing IVF in 2018 who stated a desired sex preference (gender selection) were offered modified Ericsson sperm separation prior to ICSI. Patients undergoing IVF in the same time period, who did not state a particular sex preference, served as controls. In the gender selection group, after a standard sperm wash via swim up method, the sperm pellet was layered with 0.5cc of 10% synthetic serum substitute and incubated at 37°C for 45minutes. If male sex was desired, the lower 0.25cc was carefully removed. If female sex was desired, the upper 0.25cc was used (Ref 1). The enhanced layer was re-centrifuged and the sperm pellet was re-suspended and used for standard ICSI. In the control group, a standard sperm swim-up was employed followed by ICSI. Blastocysts were biopsied and PGT-A was performed through next generation sequencing platform.

A sample size of 670 embryos was determined to give a 95% confidence interval to identify a 15% difference between the two groups.

RESULTS: 129 couples were identified in the gender selection group and 221 couples served as controls. The demographics between the two groups were similar in terms of woman's age and number of embryos biopsied. The gender selection group was significantly more likely to have advanced paternal age, previous pregnancy and live birth, and prior ART treatment. Of the 129 couples in the gender selection group, 28% desired female and 72% desired male gender.

A total of 2,229 embryos were biopsied and PGT performed (874 embryos in the gender selection group and 1355 blastocysts in the control group).

The percentage of male embryos in the gender selection group desiring male gender was 45.75% versus 49.48% in the control group (P=0.13), while the percentage of female embryos in the gender selection group desiring female gender was 51.72% versus 50.52% in the control group (P=0.71).

The odds ratio for a particular gender was not different between the modified Ericsson method and standard sperm washing technique. Gender selection via the modified Ericsson method did not reveal a specific advantage towards male or female gender.

CONCLUSIONS: While some limited studies have shown separation of sperm on albumin columns can affect the sex ratio at birth, our study is the first to evaluate the modified Ericsson albumin sperm separation method for gender selection in patients undergoing IVF with PGT. We did not find a significant improvement in the likelihood of one desired gender over another. Patients should be counseled that IVF with PGT-A remains the best treatment option for gender selection.

P-760 4:30 PM Tuesday, October 20, 2020

THE UTILITY OF PGT VS NON-PGT FROZEN EMBRYO TRANSFER BY PATIENT AGE GROUP.

Christopher Hibray, BS, Nicole George, BS, Lynn B. Davis, MD, MS, Gerard Letterie, MD, G. David Ball, PhD Seattle Reproductive Medicine, Seattle, WA.

OBJECTIVE: To examine differences in cycle outcomes between patients undergoing autologous frozen embryo transfer (FET) having received embryos that either were euploid by preimplantation genetic testing for aneuploidy (PGT-A) or were untested.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: 3,994 FET cycles from January 2015 through December 2019 were evaluated following transfer of PGT-A euploid embryos using Next-Generation Sequencing (NGS) or single nucleotide polymorphism (SNP) array, versus untested embryos. A total of 4,605 embryos were transferred. Patients were categorized by age based on SART classification. Outcome measures include average number of embryos transferred, implantation rates (IR), clinical pregnancy rates (CPR) and presence of fetal cardiac activity (FCA). Differences between outcomes were calculated (Delta).

RESULTS: FETs without PGT-A had a decline in IR, CPR and FCA with increasing patient age. FETs with PGT-A, the IR, CPR and FCA had similar rates across all age groups. The Delta in IR for patients utilizing PGT-A tested embryos increased as patient age category increased (<35=12%, 35-37=17%, 38-40=24%, 41-42=36% and >42=50%). Likewise, the Delta in CPR and FCA also increased as patient age category increased (CPR <35=5%, 35-37=13%, 38-40=20%, 41-42=29% and >42=37%, and FCA <35=3%, 35-37=18%, 38-40=20%, 41-42=31% and >42= 38%).

2015-2019 FET

FET w/o PGT-A	<35	35-37	38-40	41-42	>42
Transfer n	1177	590	307	110	53
Avg # Transferred	1.23	1.21	1.22	1.37	1.38
IR/Embryo	52%*	50%*	40%*	26%*	17%*
CPR/Transfer	57%	54%*	44%*	33%*	30%*
FCA/Transfer	53%	48%*	41%*	25%	23%*
FET w/PGT-A					
Transfer n	539	574	438	160	46
Avg # Transferred	1.05	1.04	1.05	1.03	1.04
IR/Embryo	64%*	67%*	64%*	62%*	67%*
CPR/Transfer	62%	67%*	64%*	62%*	67%*
FCA/Transfer	56%	66%*	61%*	56%*	61%*
IR Delta	12%	17%	24%	36%	50%
CPR Delta	5%	13%	20%	29%	37%
FCA Delta	3%	18%	20%	31%	38%

CONCLUSIONS: With increasing patient age, there is a steady increase in IR, CPR and FCA per transfer for PGT-A tested embryos versus untested embryos. However, the nonsignificant difference of 3% in FCA in the <35 age group highlights the limitations of PGT-A in younger women. Outcomes per transfer in this analysis, as opposed to outcomes per cycle start, do not reflect other potential pitfalls of PGT-A including fewer eligible embryos for transfer due to false positives or lack of embryo survival at FET. Additionally, patients who received a fresh embryo transfer without PGT-A and became pregnant is not considered in this dataset. PGT-A demonstrates increasing benefit with advancing female age, but it shows no significant advantage in younger women. Further analyses are needed to clarify these issues. * indicates P<.05 within age group and appropriate parameter comparison.

RELATIONSHIP BETWEEN PGT-A & CUMULATIVE LIVE BIRTH RATE IN AUTOLOGOUS & DONOR CYCLES: AN ANALYSIS OF 178,511 PATIENTS REPORTED TO SART CORS.

Alexander Kucherov, MD,[1] Melissa Fazzari, PhD,[2] Harry Lieman, MD,[1] G. David Ball, PhD,[3] Kevin J. Doody, M.D.,[4] Sangita K. Jindal, Ph.D.[1] [1]Albert Einstein College of Medicine / Montefiore Medical Center, Hartsdale, NY; [2]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; [3]Seattle Reproductive Medicine Center, Seattle, WA; [4]CARE Fertility, Bedford, TX.

OBJECTIVE: Cumulative live birth rate (CLBR) outcome prediction models may not account for patient intent at the start of the stimulation cycle, cycle cancellation, or elimination of cycles without transferable embryos. We evaluated & compared the CLBR per cycle start, oocyte retrieval (ER), & embryo transfer (ET) +/- PGT-A across maternal age groups, using autologous or donor oocytes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Autologous & donor oocyte IVF cycles from 2014-2016 reported to SART CORS were evaluated. Inclusion criteria were the first reported ovarian stimulation cycle per patient, combined with the first fresh ET or frozen-thawed embryo transfer (FET) & all subsequent linked FETs. For the PGT-A group, only day 5 & 6 FETs were included. PGT-A cycles without transferable embryos were included in the 'all cycle starts' group. PGT-A cycles without FET and no reason that could be clearly categorized were excluded. Comparisons were stratified by patient age categorically. The primary outcome measure was CLBR per stimulation cycle start. Secondary outcomes were CLBR per ER & per cumulative ET. Chi-square tests were used to assess the association between CLBR across groups. Two-sided p-values <0.05 were considered statistically significant.

RESULTS: 178,511 stimulation cycle starts were analyzed. Increasing age was associated with decreasing CLBR for all stimulation cycle starts (including planned PGT-A cycles) using autologous oocytes. Similarly, the subgroup of cycles which resulted in ER with intention for fresh ET without PGT-A showed inverse CLBR with increasing age (p <0.001 for both analyses).

A subgroup of patients was analyzed per cumulative ET, not per cycle start. In this subgroup, PGT-A FET had higher CLBR vs. fresh ET stratified by age (71.5% vs. 64.2% age <30; 69.7% vs. 59.6% age 30-34; 66.0% vs. 45.5% age 35-39; 57.5% vs. 16.7% age ≥40). FET without PGT-A also had a higher CLBR vs. fresh ET stratified by age (72.3%, 67.9%, 53.9%, & 23.7% for ages ≤30, 30-34, 35-39, ≥40, respectively) (p<0.001 for all comparisons). PGT-A FET had a higher CLBR vs. FET without PGT-A at age >30 (p<0.05), but not at age <30 (p>0.5).

Donor oocyte cycles had higher CLBR per stimulation cycle start for all age groups compared with autologous oocytes (p<0.001). Donor oocyte PGT-A FET resulted in a higher CLBR vs. fresh ET at age 35-39 (p = 0.04) & vs. FET without PGT-A at age ≥40 (p < 0.001), but not at other ages.

CONCLUSIONS: Increasing age is associated with decreasing CLBR in all cycles. For the subset of patients undergoing ET, PGT-A is beneficial at age >30; this improvement is minimal at ages 30-34 & most pronounced at age ≥40. However, it should not be concluded that PGT-A improves CLBR per cycle overall, but rather just in the subset in which ET is done. Under age 30, PGT-A is superior to fresh ET, but not to FET without PGT-A, suggesting limited utility in this age group. Donor oocytes produced the highest CLBR per cycle start & after ET at all ages, but there is no benefit to PGT-A if the recipient is age <35. Patient counseling regarding use of PGT-A & donor oocytes should be age dependent & individualized.

P-762 4:30 PM Tuesday, October 20, 2020

USING UNBALANCED EMBRYOS AS REFERENCES IN DISTINGUISHING CARRIER AND NORMAL EMBRYOS BY SNP ARRAY FOR RECIPROCAL TRANSLOCATIONS.

Rong Li, M.Sc.,[1] Ai-Ling Gu, B.S.,[2] Jing Wang, M.D[3] [1]Medical Genetic, Guangzhou, China; [2]Nursing, Guangzhou, China; [3]medical genetic, guangzhou, China.

OBJECTIVE: To validate the feasibility of using unbalanced embryos as references in the detection of normal euploid embryos by SNP array based preimplantation genetic haplotyping (PGH) in preimplantation genetic testing (PGT) for reciprocal translocations.

DESIGN: The purpose of this study was to compare the consistency of results from using unbalanced embryos as references with family members, thus to evaluate the feasibility of only using unbalanced embryo as a reference to distinguish normal and carrier embryos, for the situation when no family member was available.

MATERIALS AND METHODS: Haplotypes were first established based on SNPs from family members. Blastocysts were biopsied and screened by SNP array based comprehensive chromosome screening (CCS). After CCS, balanced embryos were further tested to identify normal euploidies by haplotyping using either family member as a reference, or unbalanced embryos generated by adjacent-1 or adjacent-2 segregation mode. Karyotypes of transferred embryos were validated by prenatal diagnosis.

RESULTS: A total of 110 couples with reciprocal translocations were analyzed. After CCS, 288 out of 995 embryos were found balanced. Using family members as references, 142 of 288 balanced embryos were tested to be normal, 144 carriers, and the other 2 undetermined. Next, unbalanced embryos were selected as references, and all the results of carrier and normal embryos were consistent with the previous results. A total of 107 embryos were transferred, resulting in 66 clinical pregnancies. Of the 66 clinical pregnancies, 34 received prenatal diagnosis. Karyotypes from prenatal diagnosis were all in accordance with the results of tested embryos.

CONCLUSIONS: PGH based SNP array is a rapid and effective way to identify normal embryos from balanced ones for translocation carriers. In case no family member was available as a reference, unbalanced embryos can be used for distinguishing normal and carrier embryos.

P-763 4:30 PM Tuesday, October 20, 2020

CUMULATIVE LIVE BIRTH RATE IN WOMEN 37 YEARS OF AGE OR LESS WHO UTILIZE PREIMPLANTATION GENETIC TESTING-ANEUPLOIDY (PGT-A) VERSUS UNTESTED EMBRYOS.

Rachel B. Mejia, D.O.,[1] Karen M. Summers, MPH CHES,[1] Abigail C. Mancuso, MD,[2] Emily A. Capper, B.A.,[1] Patrick Ten Eyck, MS PhD,[1] Amy E. Sparks, PhD,[3] Bradley J. Van Voorhis, MD[1] [1]University of Iowa, Iowa City, IA; [2]University of Iowa Hospitals and Clinics, Iowa City, IA; [3]University of Iowa Center for Advanced Reproductive Care, Iowa City, IA.

OBJECTIVE: To determine the effect of PGT-A on the cumulative live birth rate (LBR) in women ≤37 years of age

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Data were collected from Society for Assisted Reproductive Technology (SART) reporting clinics on all 31,900 patients ≤37 years of age undergoing their first retrieval between Jan 2014 and Dec 2015. Subsequent transfer cycles utilizing embryos from the initial retrieval cycle alone were followed through December 2016. The women were grouped based on age, <35 and 35-37 years of age. Generalized linear mixed models were used to control for clinical and demographic variables found to be in the top model selected for by Bayesian Information Criterion. The primary outcome was cumulative live birth, defined as the occurrence of at least one delivery in the follow-up period. Secondary outcomes included multifetal births, miscarriage, and time to pregnancy. Time to pregnancy resulting in delivery was calculated for cycles resulting in a live birth by adding 10 days (standard amount of time from embryo transfer to the pregnancy test) to the number of days between medication start in the retrieval cycle and the embryo transfer that resulted in the live birth.

RESULTS: There were 29,362 patients using untested embryos (91%) and 2,535 patients using PGT-A embryos (7.9%) included. For patients <35, the crude cumulative live birth rate for PGT-A (70.6%) vs untested (71.1%)

embryos was similar. After adjusting for confounding factors, the adjusted odds ratio (aOR) for the LBR with PGT-A was 0.81 (0.72 - 0.92, p< 0.001). For patients 35-37, there was no significant difference in the LBR for PGT-A (66.6%) vs untested embryos (62.5%), aOR 0.98 (0.86 – 1.11). There was a significant decrease in multifetal births in the PGT-A group compared to the untested group for patients <35 (8.6 % vs 23.2%) aOR 0.32 (0.26 - 0.41, p<0.001) and patients 35-37 (10.5% vs 22.8%) OR 0.42 (0.33 - 0.54, p<0.001). There was no significant difference in miscarriage rate between PGT-A and untested groups in either age group, < 35 aOR 1.12 (0.90 – 1.4), 35-37 aOR 0.84 (0.66 – 1.06). The average time from onset of the IVF cycle to a pregnancy resulting in live birth for patients < 35 was 2.17 months (SD 2.86) for untested transfer cycles and 4.10 months (SD 3.12) for PGT-A transfer cycles. For patients 35-37, the average time to pregnancy utilizing untested embryos was 2.14 months (SD 2.86) and for PGT-A cycles was 4.44 months (SD 3.48). All adjusted odds ratios were adjusted for age, BMI, race, length of follow-up, and total 2PN embryos.

CONCLUSIONS: There was a decreased cumulative LBR in women <35 who utilized PGT-A compared to those who did not use PGT-A and no difference in LBR in women 35-37. A strategy utilizing PGT-A for these age groups does not appear to lead to improved LBR or reduced miscarriage rates compared to transferring untested embryos in this national data. Notably, PGT-A was associated with a marked reduction in multiple births although this strategy required a longer time to pregnancy compared to transfer of untested embryos.

P-764 4:30 PM Tuesday, October 20, 2020

IMPACT OF SLIGHT VARIATIONS OF EXTRACELLULAR CULTURE MEDIA pH (PHE) ON EMBRYO QUALITY, EUPLOIDY RATES AND MITOCHONDRIAL DNA (mtDNA). Andrea Abdala, M.Sc., Ibrahim Elkhatib, M.Sc., Aşina Bayram, M.Sc., Ana Arnanz, M.Sc., Ahmed El-Damen, M.Sc., Barbara Lawrenz, M.D., Ph.D., Human M. Fatemi, M.D., Ph.D., Neelke De Munck, M.Sc., Ph.D. IVIRMA Middle East Fertility Clinic, Abu Dhabi, United Arab Emirates.

OBJECTIVE: To determine if variations in pHe affect blastocyst quality, euploidy rates and blastocyst mtDNA content.

DESIGN: A retrospective study was performed between July 2018 and October 2019, including 44 patients with at least 4 fresh autologous mature oocytes and non-male factor infertility. After injection, sibling oocytes were cultured under two different pHe.

MATERIALS AND METHODS: A total of 604 sibling mature oocytes were injected and split: 321 under 6.0% CO_2 and 283 under 7.5% CO_2, cultured in continuous Global® Total® LP media in 5% O_2 and 89% or 87.5% N_2, respectively. The working pH (pHe=7.374±0.003 for 6.0% CO_2 and pHe=7.299±0.004 for 7.5% CO_2) was within the range indicated by the manufacturer (7.20-7.40). Trophectoderm (TE) biopsy for preimplantation genetic testing for aneuploidies (PGT-A) with determination of mtDNA content was performed on day 5, 6 or 7 of embryo development. The primary endpoint was to determine if the pHe has an impact on blastocyst quality classified as excellent (AA or BA), good (AB or BB) and poor (AC, BC, CA, CB, CC), using Gardner scoring for inner cell mass (ICM) and TE, respectively. As a secondary endpoint, the effect of pHe on euploidy rates and mtDNA content of biopsied blastocysts was evaluated.

RESULTS: The mean age of women was 33.0±6.6 years old. Total blastulation rate on day 5 was not significantly different between 6.0% and 7.5% CO_2 (67.8% vs 68.4%, p=0.156). Blastocyst quality did not differ between excellent (OR=0.94, 95% CI: 0.46-1.92, p=0.879), good (OR=1.19, 95% CI: 0.74-1.89, p=0.467) and poor quality (OR=0.87, 95% CI: 0.55-1.36, p=0.542) for embryos cultured under 6.0% compared to 7.5% of CO_2. Additionally, blastocyst biopsy rate per normally fertilized oocyte was not significantly different between 6.0% and 7.5% CO_2 (53.3% vs 59.2%, p=0.335). However, euploidy rate was significantly increased in the 6.0% group (55.7% vs 35.7%, p=0.035). From a linear mixed model, considering non-independence of the data, the mean mtDNA content of biopsied blastocysts cultured under 6.0% was significantly lower than 7.5% CO_2 (30.39±9.1 vs 32.91±10.3, p=0.037).

CONCLUSIONS: Slight variations of pHe do not have an impact on blastocyst quality, however, euploidy rates and mean mtDNA content are significantly affected when embryos are cultured in a lower pHe.

SUPPORT: None.

DOES BODY MASS INDEX INFLUENCE EMBRYO EUPLOIDY RATES? Mohamad Irani, MD,[1] Zev Rosenwaks, M.D.[2] [1]Advanced Fertility Center of Chicago, Chicago, IL; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: Obesity is associated with increased miscarriage rates after natural conception and assisted reproductive technology. However, the underlying mechanism responsible for this association is poorly understood. Here we aim to determine the effect of body mass index (BMI) on embryo euploidy rates.

DESIGN: This is a retrospective cohort study including in vitro fertilization (IVF) with preimplantation genetic testing for aneuploidy (PGT-A) cycles between 2013 and 2017.

MATERIALS AND METHODS: Cycles were divided into three age groups (<35, 35–40, and >40 years old). Embryo euploidy rates were compared between women with a BMI <30 kg/m^2 and those with a BMI ≥30 kg/m^2 (obese) within each age group. χ^2 and Fisher's exact tests were used for categorical variables. Student's *t* test was used for parametric data. Values were expressed as mean ± standard error of mean.

RESULTS: A total of 2,164 IVF/PGT-A cycles were included. In the youngest age group, women with a BMI ≥30 kg/m^2 had comparable numbers of oocytes harvested (14.4 ± 1.1 vs. 16.4 ± 0.4, P=0.1), numbers of biopsied embryos (6.8 ± 0.6 vs. 7 ± 0.2, P=0.7), and euploidy rates (53.2% vs. 55.4%, P=0.6) with those with a BMI <30 kg/m^2 (Table 1). Similarly, euploidy rates were not significantly different between women with a BMI ≥30 kg/m^2 and those with a BMI <30 kg/m^2 in the 35-40-year-old age group (39.9% vs. 37.5%, respectively, P=0.4) as well as in the >40-year-old age group (14.8% vs. 13.9%, respectively, P=0.7) (Table 1).

CONCLUSIONS: Obesity does not significantly affect embryo euploidy rates.

	BMI <30 kg/m^2	BMI ≥30 kg/m^2	*P* value
Age < 35 years old			
# oocytes harvested	16.4	14.4	0.1
# embryos biopsied	7.0	6.8	0.7
Euploidy rate (%)	55.4	53.2	0.6
Age 35–40 years old			
# oocytes harvested	13.4	13.6	0.8
# embryos biopsied	5.6	5.4	0.7
Euploidy rate (%)	37.5	39.9	0.4
Age >40 years old			
# oocytes harvested	11.9	11.6	0.7
# embryos biopsied	4.3	4.2	0.7
Euploidy rate (%)	13.9	14.8	0.7

P-766 4:30 PM Tuesday, October 20, 2020

A COMPARISON OF NON-INVASIVE AND TROPHECTODERM BIOPSY PGT-A. FIRST EXPERIENCE IN ARGENTINA. Francisco Antonio Leocata Nieto, PhD,[1] Jeremías Zubrzycki, PhD,[2] Hernán Dopazo, PhD,[2] Ariel Octavio Ahumada, PhD[1] [1]PROCREARTE, Buenos Aires, Argentina; [2]BIOCÓDICES, San Martín, Argentina.

OBJECTIVE: The discovery of cell-free embryonic DNA (cfDNA) present in the medium in which developing embryos are being cultured in vitro led to the use of this spent culture medium (SCM) as a source of DNA in PGT studies. Different non-invasive PGT (niPGT-A) protocols are in validation and standardization stages worldwide. The objective of this work is to validate a NICS protocol (Yikon Genomics) by comparing the results obtained in PGT-A cycles performed with samples obtained by trophectoderm (TE) biopsies, the current gold standard.

DESIGN: This study evaluates the ploidy state concordance between SCM and embryo biopsies, analyzing the media collected from 30 single D5-D6 blastocysts culture droplets, followed by TE biopsy.

MATERIALS AND METHODS: Embryos were grown in Global Total LP (Life Global) microdrops (37° C, 5% O2, and 6% CO2). On D3, embryos were transferred to a new dish with 30 μl media drops until the moment of

performing the TE biopsies on D5-D6. After biopsy, embryo were transferred to an additional dish, until vitrification. The SCM of the original dish was transferred to PCR tubes containing 5 μl of lysis buffer (Yikon Genomics). The samples were stored at -80°C until processing. Whole-genome amplification (WGA) and subsequent library preparation for TE samples were performed following the Veriseq protocol (Illumina, San Diego, CA, USA), while for medium samples, the NICSInst protocol (Yikon Genomics) was used. All samples (from TE and SCM) were sequenced using the Illumina MiSeq platform according to the recommendations detailed in the mentioned protocols. About 1 million reads were obtained per sample, allowing a resolution of ~10 Mpb. For the subsequent analysis, the BlueFuse Multi (Illumina) and ChromGO (Yikon) software were used for the TE and medium samples, respectively.

RESULTS: WGA was 100% effective for all the samples (TE and SCM). A total of 17 true-positives, 9 true-negatives, 0 false-positive, and 4 false-negatives were obtained after comparisons. These values correspond to 87% concordance, 81% sensitivity, 100% specificity, 100% positive predictive values (PPV), and 69% negative predictive values (NPV). False-negative results correspond to two cases of full autosomal aneuploidies, and two cases of low-level mosaicism detected through the TE biopsy. In the four cases, the culture media showed euploid results.

CONCLUSIONS: niPGT-A starting from cfDNA showed excellent results in comparison to the current gold standard method (TE biopsy). Discordances correspond to four false-negatives, where the non-invasive method showed euploid results while TE biopsy showed aneuploidies. If niPGT-A is a more reliable representation of the whole embryo than TE biopsy, this 13% of discordance, is the kind of result that points out that the non-invasive method is a valuable alternative tool for PGT-A.

P-767 4:30 PM Tuesday, October 20, 2020

LIVE BIRTH RATE FOLLOWING PGT RESULTS IN LOWER LIVE BIRTH RATE COMPARED TO UNTESTED EMBRYOS TRANSFERRED AT DAY 5/6. Kevin J. Doody, M.D., Kathleen M. Doody, MD
CARE Fertility, Bedford, TX.

OBJECTIVE: Embryos progressing through day 5/6 can be transferred fresh or following thaw without biopsy for genetic testing. Alternatively, these embryos may be biopsied, cryopreserved and subsequently thawed and transferred using information obtained from aneuploidy screening. The outcomes of treatments employing these two distinct strategies were compared.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Analysis of publicly available ART outcomes using the 2018 SART National Summary Report was performed. Filters were applied to view the outcomes of the two groups: 1) Autologous IVF cycles without PGT with day 5/6 embryos transferred, and 2) Autologous IVF cycles with PGT. Both groups were compared with respect to their first embryo transfer only.

RESULTS: PGT resulted in a lower chance of live birth in all age groups compared to transfer of day 5/6 embryos without PGT (Table). Although PGT results in higher pregnancy rates following transfer, the majority of PGT procedures done in women over age 38 did not ultimately result in an embryo transfer. Although the rate of miscarriage increased with age in both treatment groups, PGT resulted in a markedly lower risk of pregnancy loss.

CONCLUSIONS: Previous studies have concluded that PGT for aneuploidy improves the success rate for embryo transfers. These studies have generally failed to do appropriately corrected comparisons. Success rates calculated "per transfer" do not reliably approximate "intent to treat". Success rates should be calculated "per PGT cycle". Women in all age groups very frequently will not have euploid embryos available for transfer following biopsy and genetic testing. When the success rate "per PGT cycle" is compared to a similar cohort possessing developing embryos suitable for transfer on day 5/6, the apparent improved success rate obtained by performing PGT is erased. The increased implantation rate following transfer of tested euploid embryos is more than counter-balanced by decreased ET procedures following biopsy and testing. PGT is best viewed as a strategy to decrease the risk of pregnancy loss and does not improve chance of live birth.

P-768 4:30 PM Tuesday, October 20, 2020

THE EFFECT OF MATERNAL AGE ON CHROMOSOMAL MOSAICISM: AN ANALYSIS BY CHROMOSOME TYPE AND MOSAIC RESULT. Jenna Reich, BS,[1] Jennifer K. Blakemore, MD,[2] Andria G. Besser, MS, CGC,[3] Brooke Hodes-Wertz, MD, MPH,[4] James A. Grifo, MD, PhD[3]
[1]NYU School of Medicine, New York, NY; [2]NYU Langone Prelude Fertility Center, New York, NY; [3]New York University Langone Fertility Center, New York, NY; [4]NYU Langone Prelude Fertility Center, New York, NJ.

OBJECTIVE: Previous work by our group (1) showed that the rate of chromosomal mosaicism decreases with maternal age. However, the types of chromosomes involved, as well as the types of chromosomal mosaicism in individual embryos, have not yet been examined. Our objective was to determine whether maternal age was associated with the rate of sex and autosomal chromosome mosaicism and the rates of various types of mosaicism.

DESIGN: Retrospective cohort study of all blastocysts that underwent trophectoderm biopsy for preimplantation genetic testing for aneuploidy (PGT-A) from 1/2015 to 12/2018 at our center.

MATERIALS AND METHODS: All patients with blastocysts that underwent trophectoderm biopsy for PGT-A via Next Generation Sequencing with $\geq$1 chromosome in the mosaic range (20-80%) were included. The primary outcomes were: 1) the rate of sex and autosomal chromosome mosaicism and 2) rates of segmental mosaicism, full chromosome mosaicism and complex ($\geq$3 mosaic chromosomes) stratified by maternal age. Statistical analyses included Kruskal-Wallis (KW) and linear regression (LR) to control for paternal age, with $p<0.05$ considered significant.

RESULTS: 1,670 patients with 10,545 embryos biopsied overall and 3,611 embryos with $\geq$1 mosaic chromosome met inclusion criteria. The number of embryos biopsied decreased with maternal age ($p<0.01$) as expected. 3,366 (93.2%) embryos had only autosomal chromosome mosaics, which was independent of maternal age ($p=0.05$). Alternatively, the percent of embryos with $\geq$1 sex chromosome mosaic (6.8% n=245) was significantly associated with maternal age without clear trend by age group ($p<0.01$). Table 1 shows PGT-A results by type of mosaicism stratified by maternal age. Segmental mosaicism peaked at maternal age 35-37, while complex mosaicism increased

	<35		35-37		38-40		41-42		>42

Complex Mosaicism (%)	9.5	10.7	12.1	22.9	**KW < 0.001** **LR < 0.001**

*LR used to control for paternal age

with maternal age. Full chromosome mosaicism was similar across age groups.

CONCLUSIONS: Among our embryo cohort, rates of segmental mosaicism varied and complex mosaicism increased with maternal age. These results remained significant when controlling for paternal age. The rate of sex chromosome mosaicism was associated with maternal age but may not be sufficiently powered given the low number of chromosomes. Our results provide further data for counseling patients about mosaic embryo results.

PRENATAL AND POSTNATAL GENETIC TESTING AFTER PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A) FOR A NON-SELECTION CLINICAL TRIAL.

Xin Tao, Ph.D,[1] Li Ma, BS,[1] Yiping Zhan, Ph.D,[2] Ashley W. Tiegs, MD,[3] Christine V. Whitehead, BSN, RN,[4] Richard Thomas Scott, Jr., MD,[3] Chaim Jalas, N/A[1] [1]Foundation for Embryonic Competence, Basking Ridge, NJ; [2]The Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA New Jersey, Basking Ridge, NJ; [4]IVI-RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: PGT-A detects whole chromosome aneuploidy before transfer and thus increases live birth rates and decrease early pregnancy failure rates. A prospective and blinded non-selection study using Next Generation Sequencing (NGS) based PGT-A (PGTseq-A) validated the ability of an 'aneuploid' analytical result to predict the failure to deliver. This study was aimed to further validate the accuracy of PGTseq-A. Prenatal genetic testing (through CVS or amniocentesis) or postnatal genetic testing (through newborn buccal DNA) was performed after the non-selected transfer cycles, then karyotypes was compared to the unblinded PGTseq-A results. Products of conception (POC) were tested when the miscarriage happened.

DESIGN: Retrospective

MATERIALS AND METHODS: Fetal tissues (CVS, amniocentesis, or POCs) and newborn buccal swabs were collected for 120 non-selected single embryo transfer cycles. Genomic DNA (gDNA) were isolated using QIAGEN DNA isolation kits. The karyotypes were analyzed by a targeted NGS platform which amplifies~5000 amplicons across the human genome.

RESULTS: Among the 120 transferred embryos, 100 embryos yielded healthy deliveries and 20 embryos resulted in clinical miscarriages. For 5 transferred embryos with deliveries, both prenatal and postnatal samples were tested. PGTseq-A showed that 2 embryos had whole chromosome mosaicism, 2 embryos had segmental mosaicism, and 1 embryo was euploid. The prenatal and postnatal genetic testing showed all the newborns were euploid. For the other 95 transferred embryos with deliveries, only newborn buccal DNA was collected. Based on PGTseq-A, 2 embryos yielded nonconcurrent results, 3 embryos were whole chromosome mosaic, 2 embryos were segmental mosaic, and 88 embryos were euploid. All the newborn gDNA showed normal karyotypes. For the 20 embryos with miscarriages, POCs were collected and tested. PGTseq-A revealed that 1 embryo had nonconcurrent result, 13 embryos were aneuploid, and 6 embryos were euploid. Three POC samples had maternal contamination, and the karyotypes of the remaining 17 POCs were 100% consistent with PGTseq-A results.

CONCLUSIONS: This study demonstrated the accuracy of PGTseq-A. It also showed the reproductive potential of embryos with undetermined safety (whole chromosome mosaicism or segmental mosaicism) based on the limited number of transferred embryos.

P-770 4:30 PM Tuesday, October 20, 2020

RELIABILITY OF THE NEXT-GENERATION SEQUENCING (NGS) DIAGNOSIS OF MOSAICISM TO PREDICT THE CHROMOSOMAL CONSTITUTION OF THE INNER CELL MASS.

Hui He, Msc, Bo Huang, PHD, Li Wu, Msc Huazhong University of Science and Technology, WUHAN, China.

OBJECTIVE: To investigate the reliability of next-generation sequencing (NGS) for diagnosing mosaicism and the predictive diagnostic value of trophectoderm (TE) biopsy for assessing the genetic status of the inner cell mass (ICM) in mosaicism.

DESIGN: Prospective study.

MATERIALS AND METHODS: Sixty-eight human embryos diagnosed clinically as mosaicism were rebiopsied and dissected into three parts: TE, ICM and the remaining parts of embryos (a combination of TE and ICM). All the samples were examined and compared with original clinical diagnosis. Whole genome amplification using the Malbac DNA amplification system followed by NGS via the ThermoFisher DA8600 platform was performed. Statistical analysis was performed using chi square.

RESULTS: Among the 68 blastocysts, the original mosaicism diagnosis was confirmed in at least one additional biopsy in 14 (20.6%) blastocysts; 12 (17.6%) displayed de novo abnormalities; and 42 (61.8%) showed a euploid profile in all segments. Among 59 rebiopsied ICM specimens, the results for 10 (16.9%) were consistent with the original trophectoderm (TE) biopsy; 6 (10.2%) displayed de novo abnormalities; and 43 (72.9%) were euploid. Stratification analysis showed that the type of mosaicism within the original biopsy diagnosis was associated with the concordance across the embryos. The concordance rate with the ICM results was highest for whole-chromosome mosaicism (41.2%), followed by complex mosaicism (20.0%), while that for segmental and mixed mosaicism was lowest (3.3% and 0%, respectively). However, it was not associated with the gain or loss of chromosomes (P=0.138). Closer examination of the level of mosaicism within the original biopsy diagnoses revealed that the concordance rate increased with increasing levels of mosaicism (P<0.001). In addition, the second TE biopsy for mosaicism showed a sensitivity of 68.8% and specificity of 92.9% for predicting abnormalities in the ICM portions.

CONCLUSIONS: This novel study exposes false-positive errors in NGS-based PGT and the limitations of a single TE biopsy for predicting the cytogenetic constitution of the ICM and whole embryos. It also provides suggestions for the transfer of mosaic embryos, indicating that those with segmental mosaicism and a low rate of aneuploidy should be prioritized and that a second TE biopsy is an option for doctors and patients facing a dilemma.

VALIDATION OF PREIMPLANTATION GENETIC TESTS FOR ANEUPLOIDY WITH CELL-FREE DNA FROM SPENT CULTURE MEDIA (SCM): CONCORDANCE ASSESSMENT AND IMPLICATION.

Li Meng, Ph.D; HCLD, Baoli Yin, PHD, Cuilian Zhang, MD; Ph.D Henan Provincial People's Hospital, Zhengzhou, CA, China.

OBJECTIVE: Preclinical validation of cell-free DNA in SCM represents ploidy status of the chromosomal constitution of a blastocyst.

DESIGN: Validation study

MATERIALS AND METHODS: Seventy-five vitrified blastocysts with known karyotypes were donated for research, under informed consent, by patients undergoing IVF for treatment of infertility at Henan Provincial People's Hospital in China. All blastocysts were warmed and cultured individually at 37 °C in an atmosphere of 5% O_2 and 6 –7% CO_2, balanced with N_2. The SCM drops, TE biopsied cells, and the corresponding whole blastocysts samples are stored at -80 °C for library preparation. Multiple annealing and looping-based amplification cycle (MALBAC) techniques are utilized for whole genome amplification to ensure increasing amplification uniformity and less amplification biases. Next generation sequencing (NGS) was performed on the Illumina Hiseq 2500 platform with 2.0 Mb raw reads generated for each sample. All analyses have been incorporated into a pipeline and can be automatically generated.

RESULTS: To conduct a valid comparison of ploidy concordance assessment, we evaluated the full concordance rates between SCM and WB (SCM-to WB), and between TE and WB (TE-to-WB) as well as sensitivity, specificity and overall diagnostic accuracy. In addition, we comparatively adjusted the thresholds aimed at removing DNA amplification noise to more accurately distinguish aneuploid from euploid blastocysts. Interpretable NGS results in the SCM group are 78.67% (59/75) under Threshold 1 and 74.67% (56/75) under Threshold 2, respectively, and are significantly lower than their corresponding TE and WB groups. This manifests intrinsic low quantity/abundance and poor integrity in nature in DNA from SCM. Subsequently, remarkable differences in full concordance rates (including mosaicism, and segmental aneuploidies) are seen: 32.2% (SCM-to-WB, 19/59) and 69.33% (TE-to-WB, 52/75), ($P<0.001$) under threshold 1. Using the same approach, the full concordance rates show a similar trend when threshold 2 is adjusted as an alternative diagnostic threshold. In such a case, full concordance rates were 27.27% (15/55) in SCM-to-WB, and, 76% (57/75) in TE-to-WB ($P<0.001$). Collectively, the NGS data from SCM also translated into lower sensitivities, Positive Predictive Value (PPV), Negative Predictive Value (NPV), and overall diagnostic accuracies and to higher Negative Likelihood Ratio (NLR).

CONCLUSIONS: Cell free DNA is detectable in majority of SCM samples during blastocyst culture, but suboptimal and likely linked to degraded DNA in nature. The full ploidy concordance assessment further demonstrates that TE-to-WB is more accurate representation of the chromosomal constitution of the whole blastocyst in comparison with that of SCM-to-WB. Before PGT-A with the use of DNA from SCM for clinical implementation, new WGA techniques must be custom-tailor designed to overcome the nature of low DNA quantity and quality associated with DNA in SCM.

P-772 4:30 PM Tuesday, October 20, 2020

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A) AND TIME TO PREGNANCY.

Marissa Palmor, MD, MBE,[1] Dan W. Duvall, Jr., BA,[2] Alan S. Penzias, M.D.,[3] Denny Sakkas, PhD,[2] Denis A. Vaughan, MD[1] [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Boston IVF, Waltham, MA; [3]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

OBJECTIVE: The utilization of PGT-A as an adjunct to IVF remains controversial. The objective of this study was to evaluate whether PGT-A decreases time to pregnancy for patients undergoing a single oocyte retrieval cycle.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: 18,143 women undergoing autologous IVF with and without PGT-A at an academically-affiliated infertility practice between January 2015-December 2018 were included. Ovarian stimulation protocols were performed per provider preference and both natural and programmed frozen embryo transfer (FET) protocols were utilized. For patients undergoing PGT-A, only those with a FET within three months of oocyte retrieval were included. Outcomes were compared according to age at oocyte retrieval (<38, ≥38 years). The primary outcome was time to pregnancy. This was defined as the time (days) from oocyte retrieval to the first positive serum hCG in a cycle resulting in a live birth. Live birth rates per transfer and cumulative live birth rate per retrieval were also calculated. Outcomes were compared using a chi square test.

RESULTS: 12,740 women underwent oocyte retrieval during the study period, with 16,215 transfers performed. All PGT-A patients underwent cryo-all cycles. 2378 (69.9%) control patients underwent a fresh embryo transfer. 5403 retrievals (42.4%) resulted in a live birth (43.7% in the PGT-A and 41.9% in the control group, $p=0.07$). In women <38 years (7689), a total of 11,217 transfers were performed that resulted in 4173 live births (37.2%). Live birth rates per transfer were significantly different (48.1% in the PGT-A and 34.6% in the control group, $p<0.05$). Live birth rates per retrieval in this group were 54.5% in the PGT-A and 54.2% in the control group ($p=0.84$). In women ≥38 years (5051 retrievals), a total of 4998 transfers were performed that resulted in 1230 live births. Live birth rates per transfer were significantly different (52.3% in the PGT-A and 17.5% in the control group, $p<0.05$). Live birth rates per retrieval were also significantly different (31.5% in the PGT-A and 20.7% in the control group, $p<0.05$).

Of those <38 years who had a live birth, mean time to pregnancy (TTP, mean (SD)) was 71.9 (109.2) days and differed between groups. TTP in the PGT-A group was 104.3 (88.0) and for controls was 62.9 (112.8) ($p<0.05$). In women ≥38 years, mean TTP was 67.1 (103.5), with TTP in the PGT-A group 90.1 (71.4) and in the control group 53.2 (116.7) ($p<0.05$). Excluding fresh transfer cycles from the control cohort, mean TTP was 168.2 (162.6); 165.0 (156.7) for those <38 and 189.5 (196.5) for those ≥38.

CONCLUSIONS: As has been previously reported, PGT-A patients benefit in relation to live birth rates per transfer. However, for those who achieved live birth within this cohort, utilizing PGT-A did not decrease time to pregnancy. This is largely influenced by the use of fresh transfers. PGT-A without a prior indication, in particular for younger patients, may add both time and cost without significant benefit. Clinicians should consider time to pregnancy as a critical factor when providing counseling to patients regarding this method.

P-773 4:30 PM Tuesday, October 20, 2020

RNA FOR PGT-A AND IDENTIFICATION OF NEW BIOMARKERS OF CLINICAL OUTCOME IN IVF.

Julie Laliberte, PhD,[1] Manuel Viotti, PhD,[2] Andrea Victor, MS,[3] Alan Brake, MS,[3] Isabel Gonzalez, Ph.D,[3] Christo Zouves, MD,[3] Frank Barnes, PhD,[3] Andrew Farmer, Ph.D[1] [1]Takara Bio USA, Mountain View, CA; [2]Zouves Foundation for Reproductive Medicine, Foster City, CA; [3]Zouves Fertility Center, Foster City, CA.

OBJECTIVE: Preimplantation genetic testing for Aneuploidies (PGT-A) has been performed to screen embryos for nearly three decades. For certain patient populations, the selection of genetically fit embryos increases the chances of a healthy pregnancy in IVF. However, euploid embryos do not always lead to successful pregnancies. The discovery of new biomarkers is important to improve IVF success rates. Here we aim to evaluate the dual utility of RNA-Seq from trophectoderm biopsies to report ploidy of the embryos accurately and identify new biomarkers to distinguish unhealthy embryos.

DESIGN: Comparing results from conventional PGT-A to RNA for chromosomal copy number evaluation, and differential expression analysis between euploids and aneuploids.

MATERIALS AND METHODS: PGT-A was previously performed on twenty-four embryos using Illumina® VeriSeq PGS at the Zouves Fertility Center (ZFC). Eight embryos were euploids and sixteen showed diverse aneuploidies. The embryos were donated to research by signed informed consent. For each embryo, a second trophectoderm biopsy was collected, cDNA was generated using Takara SMART-Seq® v4 Ultra Low Input RNA Kit for Sequencing at ZFC, libraries were created using Illumina® Nextera XT and sequenced on a NextSeq 500 at TBUSA. Data were analyzed using custom pipelines. Briefly, copy number alterations were detected using reads count and B-minor allele frequencies. Differential expression analysis was performed using DESeq2.

RESULTS: The RNA-Seq method showed high concordance in reporting chromosomal aneuploidies compared to VeriSeq PGS. The eight euploids samples characterized by VeriSeq PGS showed no chromosomal alteration when using the RNA-Seq method. Perfect karyotype concordance was also observed in fifteen of the sixteen previously identified aneuploid embryos. For the sex chromosomes, the concordance between the RNA-Seq method and VeriSeq PGS was 100% (24/24). Interestingly, we observed that exclusively the male embryos invariably expressed three genes located on chromosome Y: *EIF1AY, RPS4Y1*, *DDX3Y.* Differential expression analysis between the euploid and aneuploid groups was used to identify potential new biomarkers. One candidate is *NMI* (encoding N-myc and STAT interactor), which showed higher expression in aneuploid samples. The expression of *NMI* has also been reported to be dysregulated in cancer cells.

CONCLUSIONS: In this proof-of-concept study, we show that RNA analysis can potentially replace DNA analysis for the purpose of PGT-A, with the added advantage of providing biomarkers of clinical outcome.

P-774 4:30 PM Tuesday, October 20, 2020

ASSESSMENT OF CELL-FREE DNA FROM EMBRYO SPENT MEDIA AND ITS EFFECT ON NON-INVASIVE PGT-A CONCORDANCE TO CONVENTIONAL PGT-A AND CALCULATED COPY NUMBER NOISE.

Jacob Meyers, PhD,[1] Julie Laliberte, PhD,[1] Kajal Choudhary, PhD,[1] Nao Yasuyama, MS,[1] Christopher J. Sifuentes, PhD,[1] Wenwen Xiang, Master,[1] Karthikeyan Swaminathan, PhD,[1] Manuel Viotti, PhD,[2] Frank Barnes, PhD,[2] Andrea Victor, PhD,[2] Isabel Gonzalez, Ph.D,[3] Christo Zouves, MD,[3] Patrick Martin, PhD,[1] Andrew Farmer, Ph.D[1] [1]Takara Bio USA, Mountain View, CA; [2]Zouves Foundation for Reproductive Medicine, Foster City, CA; [3]Zouves Fertility Center, Foster City, CA.

OBJECTIVE: Recent advances in PGT-A have explored the use of embryo spent media as an alternative sample input to trophectoderm (TE) biopsy. Multiple groups have shown that spent media can be used to determine calculated copy number (CCN) for non-invasive PGT-A (niPGT-A). However, several knowledge gaps remain on the state of cfDNA in spent media and its effect on niPGT-A. The objective of this study was to assess the DNA concentration and fragmentation of cfDNA in spent media and evaluate how cfDNA input affects niPGT-A results and CCN noise.

DESIGN: Prospective study. DNA concentration and fragmentation were compared between samples cultured for 24hr vs 48hr and euploid vs aneuploid embryos. Spent media samples were subjected to niPGT-A and analyzed for clinical concordance to PGT-A on TE biopsy. CCN noise was evaluated in niPGT-A results in relation to sample DNA quantity and fragmentation.

MATERIALS AND METHODS: Embryos were group cultured until day 4 when they were transferred into fresh culture media. Embryos were cultured for 24 or 48hr before media extraction and storage at -80°C. Importantly, no zona breach or invasive embryo manipulation was performed prior to media collection. Media samples were tested by the DNA Quantification and Quality Assessment Kit developed in-house to assess DNA concentration and fragmentation. Media samples were also tested by the niPGT-A kit and analyzed on a CNV Analysis Software developed by Takara Bio. In parallel, TE biopsy samples were tested by VeriSeq and analyzed on BlueFuse software. The clinical concordance of the niPGT-A vs PGT-A was analyzed for each sample and compared to DNA concentration and fragmentation, as well as CCN noise in the niPGT-A.

RESULTS: DNA concentration ranged from negligible to 2.53 pg/μL. There was no statistical difference in DNA concentration between media from euploid and aneuploid embryos. There was a trend suggesting 48hr incubation increased DNA concentration compared to 24hr (24hr: 0.449 pg/μL $\pm$ 0.675; 48hr: 1.076 pg/μL $\pm$ 0.648, p-value = 0.056, n=23). DNA fragmentation analysis showed that DNA was not highly fragmented across samples.

niPGT-A was performed on samples ranging in input DNA quantities from 0.49-12.67 pg. All samples successfully amplified. Concordance compared to TE biopsy was 80% for samples with an input above 1 pg, while samples below 1 pg had 0% concordance (n=12). There was no relationship between DNA fragmentation and clinical concordance to TE biopsy. CCN noise also decreased with increasing input DNA quantity ($R^2 = 0.9197$) and decreasing DNA fragmentation ($R^2 = 0.7065$).

CONCLUSIONS: Our results show that spent media cultured with minimal embryo manipulation results in relatively large DNA fragments occurring across a wide range of DNA concentrations. Our data suggest that longer embryo culture periods increases the cfDNA found in the media. We discovered that input DNA quantity is critical for accurate niPGT-A results, with a minimum threshold of 1pg DNA to achieve highly concordant results with TE biopsy. Additionally, higher input DNA samples had reduced CCN noise, allowing higher confidence and resolution in calling abnormalities.

P-775 4:30 PM Tuesday, October 20, 2020

PRE-IMPLANTATION TESTING WITH COMPREHENSIVE CHROMOSOME SCREENING: WHAT VALUE DOES IT ADD TO IVF SUCCESS? A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED STUDIES.

Omur Taskin, MD,[1] Justin Tan, MD, MPH,[1] Lauren Adye-White, BSc,[1] Arianne Y. K. Albert, PhD,[2] Timothy C. Rowe, MD,[1] Michael H. Dahan, M.D.,[3] Mohamed Ali Bedaiwy, M.D., Ph.D.[1] [1]University of British Columbia, Vancouver, BC, Canada; [2]Women's Health Research Institute, Vancouver, BC, Canada; [3]McGill University, Montreal, QC, Canada.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) has the capacity to improve selection of competent embryos for transfer in IVF cycles. Previous meta-analyses found lower miscarriage and higher clinical and ongoing pregnancy rates from euploid embryos identified by PGT-A compared to those selected by morphology alone. However, results from randomized control studies (RCTs) have been inconsistent with a recent large study demonstrating benefit in only a select group, thereby calling into question the indications for PGT-A. Hence, the purpose of this meta-analysis is to investigate the age-stratified pregnancy outcomes of embryo selection by PGT-A compared to traditional morphologic grading.

DESIGN: Meta-analysis of RCTs.

MATERIALS AND METHODS: Electronic databases were searched from their inception to December 2019. RCTs comparing pregnancy outcomes in PGT-A and unbiopsied embryo transfer cycles were identified and random effects meta-analysis employed to calculate average odds ratios (OR) for clinical pregnancy rate (CPR), ongoing pregnancy rate (OPR), and spontaneous abortion (SA) rate. Heterogeneity of exposure effects were evaluated using Forest plots and I^2 statistic while publication bias was assessed using Egger's test.

RESULTS: Among 1251 citations identified, 467 articles met eligibility criteria and seven RCTs were included for statistical analysis comparing pregnancy outcomes from PGT-A cycles versus routine IVF based on embryo morphology selection. Among a pooled cohort of 1851 cycles (905 PGT-A, 946 control), no significant difference in CPR (OR 1.16, 95%CI 0.63–2.13; 4 studies, n=624) and OPR (OR 1.40, 95%CI 0.86-2.29; 5 studies, n=1212) was observed. Stratified analysis by maternal age demonstrated similar OPRs among women <35-years-old (OR 1.24, 95%CI 0.56-2.76; 3 studies, n=615) while a small but significant increase was observed in PGT-A cycles among women 35-43 years-old (OR 1.49, 95%CI 1.00-2.22; 3 studies, n=868). SA rates were also significantly lower in PGT-A cycles across all maternal age groups (OR 0.58, 95%CI 0.34-0.97; 4 studies, n=455). There was no evidence of systematic bias in the funnel plots and Egger's test was non-significant for all analyses.

CONCLUSIONS: Our meta-analysis of RCTs found no overall difference in CPR and OPR with PGT-A compared to embryo selection by morphologic grading. However, SA rates were lower in PGT-A cycles and subgroup analyses suggest an increase in pregnancy outcomes in women 35-43 years-old. Significant heterogeneity was observed between studies (I^2=43.5-81.5%), likely owing to differences in patient population, day of biopsy, and sequencing techniques. Hence, the use of PGT-A should be individualized based patient and provider characteristics, while future prospective trials should evaluate the benefit of PGT-A in specific populations (e.g. recurrent implantation failure) and report clinically important outcomes of interest such as cumulative live birth rate, time-to-live birth, cost-effectiveness, and implications of mosaic results.

P-776 4:30 PM Tuesday, October 20, 2020

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY CONFERS GREATER BENEFIT TO YOUNG PATIENTS WITH POLYCYSTIC OVARIAN SYNDROME.

Hillary Pearson, M.D.,[1] Baruch Abittan, M.D.,[2] Randi H. Goldman, M.D.,[2] Christine Mullin, M.D.[2] [1]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: We have previously shown that there is no difference in pregnancy outcomes between patients with and without polycystic ovarian syndrome (PCOS) undergoing their first single frozen euploid blastocyst transfer, despite patients with PCOS having an increased risk of miscarriage. This suggests that aneuploidy contributes to pregnancy failure in patients with PCOS. The aim of this study is to determine whether PGT-A improves pregnancy outcomes among young patients <35 years (y) with and without PCOS.

DESIGN: Retrospective cohort study at an academic medical center.

MATERIALS AND METHODS: Patients with and without PCOS who underwent their first single embryo transfer of a blastocyst with or without PGT-A from 2015-2018 were included. The primary outcome was live birth

rate (LBR) per embryo transfer. Group 1 consisted of patients with PCOS <35y of age and was further sub-divided into Group 1A and 1B based on utilization of PGT-A (yes vs. no, respectively). Group 2 consisted of patients without PCOS <35y and was further sub-divided into Group 2A and 2B, based on utilization of PGT-A. Student's t-tests and chi-square tests were used to compare patient characteristics and clinical outcomes, as appropriate.

RESULTS: Of the 191 patients with PCOS under 35y, 113 patients underwent PGT-A (Group 1A) and 78 did not (Group 1B). The LBR for Group 1A was significantly higher than Group 1B (59.3%, vs. 42.3%; p=0.03), representing an increase in the LBR by 17 percentage points with utilization of PGT-A (Table 1). Of the 773 patients without PCOS <35y (Group 2), 462 patients underwent PGT-A (Group 2A) and 311 patients did not (Group 2B). The LBR for Group 2A was significantly higher than Group 2B (50.8%, vs. 38.5%; p<0.01), representing an increase in the LBR by 12 percentage points with utilization of PGT-A. The miscarriage rate was significantly lower for patients with and without PCOS with utilization of PGT-A (8.0% vs. 19.2% and 7.1% vs. 12.9%, respectively; p<0.05 for both).

Table 1. Clinical Outcomes in Women <35y of Age With and Without PCOS Undergoing a Euploid Embryo Transfer vs. Non-Diagnosed Blastocyst Transfer

	PCOS			Non-PCOS		
	+PGT n=113	-PGT n=78	p value	+PGT n=462	-PGT n=311	p value
Avg. Age	30.5	30.7	0.59	31.6	31.4	0.14
Avg. BMI	25.8	27.8	0.04	24.7	25.1	0.45
Avg. Parity	0.42	0.5	0.72	0.55	0.59	0.47
%Biochemical	7.1	10.2	0.18	9.1	11.3	0.39
%Spontaneous Abortion	8.0	19.2	**0.04**	7.1	12.9	**0.01**
%Live birth	59.3	42.3	**0.03**	51.1	38.9	**<0.01**

CONCLUSIONS: In our population, while PGT-A confers an increase in LBR per transfer for all patients younger than 35y, we demonstrated a greater increase in live birth rate by 17 vs. 12 percentage points for patients with PCOS vs. patients without PCOS. This data may aid in counseling patients with PCOS regarding the utility of genetic testing for aneuploidy.

P-777 4:30 PM Tuesday, October 20, 2020

EFFECTS OF DIFFERENT BIOPSY PROTOCOL ON RATE OF MOSAICISM AFTER NEXT-GENERATION SEQUENCING (NGS) IN PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A) CYCLES.

Shun Xiong, Master,[1] Jiang Wang, Master,[2] Jun Xia Liu, Master,[2] Wei Han, Master,[2] Jing Yu Li, PhD,[3] Guoning Huang, M.D[2] [1]Chongqing, China; [2]ChongQing Health Center for Women and Children; [3]Chongqing Key Laboratory of Human Embryo Engineering,Chongqing Reproductive and Genetics Institute, Chong Qing, China.

OBJECTIVE: The incidence of mosaicism at blastocyst stage using next generation sequencing (NGS) method is highly variable between clinics, ranging from as low as 2% to as high as 40%. A consistent high incidence of mosaic embryos in some clinics may be indicative of clinical treatment, embryology, analysis approach or in some cases be patient-related factors (Fragouli et al., 2019). However, little is known about the influence of biopsy protocol on the rate of mosaicism in preimplantation genetic testing for aneuploidy (PGT-A) cycles.

DESIGN: This was a retrospective analysis.

MATERIALS AND METHODS: Women undergoing PGT-A at a single fertility center from July 2018 to December 2019 were included. Cycles with abnormal sperm parameters were excluded. Intracytoplasmic sperm injection (ICSI) was applied in all PGT cycles. PGT-A was performed via trophectoderm biopsy on day5 or 6 and analyzed using NGS at a single reference lab. Two different biopsy protocols were used. For method one, a 5-10 μm opening was made by laser before transferring the embryos into extended culture on the afternoon of day 3. This allowed some trophectoderm cells to herniate through the hole before biopsy on day 5 or 6. For method two, the zona pellucida was opened immediately before biopsy on day 5 or 6. Approximately 3–5 trophoblast cells were sucked and removed from biopsied blastocysts. The rates of mosaicism at the blastocyst stage were compared between two protocols.

RESULTS: Fifty seven PGT-A cycles were included for analysis: 37 from method one and 20 from method two, resulting in 143 and 73 biopsied blastocysts. There was no difference in two groups regarding the female age, number of blastocysts biopsied, euploid and aneuploid blastocyst rates. However, the rates of mosaic blastocyst in method one group was 14.69%, significantly higher than that in method two group (5.48%, P=0.045).

CONCLUSIONS: Different biopsy protocols may influence the rate of mosaicism at blastocyst stage. Method two, namely, the zona pellucida was opened immediately before biopsy on day 5 or 6, may be preferable to method one, to minimize the rate of mosaicism in NGS PGT-A cycles.

SUPPORT: no

P-778 4:30 PM Tuesday, October 20, 2020

INCREASED INCIDENCE OF ECTOPIC PREGNANCY IN IN VITRO (IVF) PREIMPLANTATION GENETIC SCREENED EUPLOID EMBRYOS.

Evelina Tuers, CNM, WHNP-BC, Thomas Molinaro, MD, MSCE, Paul A. Bergh, MD, Meghan K. Pierce, MSN, Mckenna Wilson, BA, PA-S IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Determine whether there is an increased rate of sustained ectopic pregnancies following the transfer of PGT-A tested euploid embryos compared to untested embryos.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: An analysis was performed on 27,348 patients who were treated from November 22, 1999 to October 31, 2019. All patients underwent in vitro fertilization with day 5 blastocyst single or double embryo transfers. The study group comprised patients who underwent transfer of PGT-A tested euploid embryos. Control patients were those undergoing transfer of untested embryos. The primary outcome was the rate of sustained ectopic pregnancy which was defined as absence of chorionic villi after D&C, visualization of an adnexal mass consistent with ectopic pregnancy on ultrasound or an ectopic pregnancy that was surgically removed. If the above criteria were not met it was categorized as a pregnancy of undetermined location (PUL) and was not included in this analysis. Chi-square and t-tests were performed on our normally distributed population. Logistic regression was performed to control for confounders.

RESULTS: Patients using PGT-A were older and more likely to have a frozen embryo transfer (Table 1). The rate of sustained ectopic pregnancy was higher in the PGT tested group (0.79% vs 0.44%). After performing logistic regression, sustained ectopic pregnancies were found to be 1.63 more likely to result from a PGT tested embryo.

Table 1

	NO PGT-A	PGT-A	p-value
Number	14,229	13,119	
Age	32.5 (4.6)	34.4 (4.5)	<0.001
Frozen Transfer	7,579 (53.3%)	11,883 (90.6%)	0.000
Ectopic	63 (0.44%)	103 (0.79%)	<0.001
PUL	227 (1.6%)	104 (0.79%)	<0.001

CONCLUSIONS: This data suggests that there is an increased likelihood of persistent ectopic pregnancy in PGT-A tested euploid embryos than in untested embryos. This finding is likely due to euploid embryos being more likely to sustain implantation in both intrauterine and extra-uterine locations. More studies are warranted to determine whether this finding is also seen in other IVF facilities.

P-779 4:30 PM Tuesday, October 20, 2020

EVALUATION OF THE INHERITANCE OF COPY NUMBER VARIATIONS (CNVS) IN THE EMBRYOS WHEN THE SAME CNV PRESENTS IN MORE THAN ONE EMBRYO AFTER PGT-A FROM IVF CYCLES. Heather Garnsey, BS, MPS,[1] Yiping Zhan, Ph.D,[2] Chaim Jalas, N/A,[1] Vaidehi Jobanputra, PhD,[1] Richard Thomas Scott, Jr., MD,[3] Xin Tao, Ph.D[1] [1]Foundation for Embryonic Competence, Basking Ridge, NJ; [2]The Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: CNV involves both duplications and deletions of DNA sequences, which may cause human diseases. Some CNVs can be identified using targeted next generation sequencing-based preimplantation genetic testing for aneuploidy (PGTseqA). When the same patterns of CNVs are observed in multiple embryos, one of the parents may carry the CNV. In this study, we requested follow-up parental testing to confirm whether the same CNVs presenting in more than one embryo are inherited.

DESIGN: Retrospective observational

MATERIALS AND METHODS: PGTseqA amplifies ~5000 amplicons across the human genome and evaluates the copy number of the amplicons. Validations for CNVs were performed using 5-cell samples from cell lines with known CNVs, and trophectoderm (TE) biopsies from embryos with a previously diagnosed parental structural rearrangement. Microarray testing of the couples was requested when multiple embryos from their cohorts showed the same CNV.

RESULTS: Among 6782 PGTseqA cycles, 51 cycles from 42 patients showed the same CNVs in more than one embryo and 43 CNVs were observed. The size of deletions or duplications involved in CNVs ranged from 3.5 kb to 8.6 Mb, and included from 2 to 17 amplicons. Microarray results were received from 36 couples, and 94% (34 out of 36) confirmed that one of parents carried the CNVs, including one couple where one parent carried two CNVs. For the ClinVar pathogenic category, 11 out of 35 CNVs were classified as benign or not reportable, and the euploid embryos carrying the CNVs were available for transfer. Five were likely benign and 15 had uncertain significance. Finally, 2 were possibly pathogenic, 1 was likely pathogenic, and 1 was pathogenic.

CONCLUSIONS: The confirmation of parental CNVs further validated the diagnostic accuracy of deletions or duplications in embryo biopsies. Genetic counseling about the PGTseqA and parental CNV results will help patients to decide whether they will transfer the embryos with parentally-inherited CNVs.

P-780 4:30 PM Tuesday, October 20, 2020

ENDOMETRIAL RECEPTIVITY ANALYSIS (ERA) FOR PATIENTS WITH PGT-A NORMAL FROZEN EMBRYO TRANSFERS (FET): A RETROSPECTIVE ANALYSIS. Joshua C. Combs, MD,[1] Jeanne E. O'Brien, MD, MSc,[2] Kate Devine, MD,[2] Mae W. Healy, DO,[1] Samad Jahandideh, PhD,[2] Alan H. DeCherney, MD,[3] Micah J. Hill, DO,[1] Nicole Doyle, MD, PhD[2] [1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Shady Grove Fertility Center, Rockville, MD; [3]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

OBJECTIVE: Determine implantation rate (IR) and live birth rate (LBR) for patients undergoing a single PGT-A normal frozen embryo transfer according to standard progesterone timing versus ERA timed transfer.

DESIGN: Retrospective cohort study at a large reproductive center from 2018 and 2019.

MATERIALS AND METHODS: Patients with or without a history of prior unsuccessful FET with PGT-A normal vitrified embryos completed ERA prior to analysis. The outcome of the first FET following ERA was assessed for all patients classified as receptive (FET according to standard protocol) and non-receptive (ERA adjusted FET). Outcomes were compared between PGT-A normal embryo transfer in patients with versus without ERA testing. Exclusion criteria were vaginal progesterone only, uterine factor and PGT-A untested embryos. Descriptive statistics were used to characterize outcomes. Chi square was used to compare dichotomous outcomes.

RESULTS: The clinical outcomes of 307 ERA patients were compared to 1937 control FET cycles. For patients who underwent ERA testing, results were classified as receptive for 194 patients and non-receptive for 113 patients. A single PGT-A normal FET in the receptive group resulted in 67.5% and 43.2% IR and LBR, respectively. In comparison, the IR and LBR in the non-receptive and therefore ERA timed FET group were 74.3% and 46.9%, respectively. This difference was not statistically significant ($p > 0.05$). Patients without ERA testing had an IR and LBR of 62.2% and 50.2% for their last recorded transfer cycle. Compared to the ERA adjusted FET groups this was not statistically significantly different.

CONCLUSIONS: There was no significant difference in IR or LBR for patients who did undergo ERA testing prior to PGT-A normal embryo FET compared to those whose endometrial receptivity status was unknown and therefore included both receptive and non-receptive patients. We recognize that a randomized controlled trial is needed to sufficiently assess the clinical utility of ERA testing.

	Frequency	Percentage
ERA Receptive – FET According To Standard Protocol		
HCG +	131/194	67.50%
HCG -	63/194	32.50%
Live Birth	84/194	43.20%
ERA Non-Receptive – ERA Adjusted FET		
HCG +	84/113	74.30%
HCG -	29/113	25.70%
Live Birth	53/113	46.90%
FET For ERA Untested Patients		
HCG +	1205/1937	62.20%
HCG -	732/1937	37.80%
Live Birth	972/1937	50.20%

*No comparisons between the 3 groups were statistically significant.

SUPPORT: None

P-781 4:30 PM Tuesday, October 20, 2020

A NOVEL METHOD TO ATTENUATE EMBRYO ANEUPLOIDY DUE TO PATERNAL INHERITANCE. Alessandra Parrella, M.Sc., Danielle Rebecca Tavares, B.A., Mounia Haddad, M.D., June Wang, B.A., Derek Keating, B.A., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To test the efficacy of a sperm-selection method to generate genetically healthy embryos in couples with recurrent embryo aneuploidy.

DESIGN: Consenting men with high sperm DNA fragmentation (SCF) in their spermatozoa who were treated at our center during the last three years were included. Spermatozoa were selected by density gradient centrifugation (DGC) for ICSI cycles, which frequently yielded aneuploid embryos, resulting in no embryo transfer or failed implantation. In subsequent ICSI cycles, their spermatozoa were processed by microfluidics sperm selection (MFSS). SCF, including the assessment of double-stranded DNA breaks (DSBs), was performed before and after each selection method. SCF, embryo aneuploidy, and clinical outcomes were assessed and compared.

MATERIALS AND METHODS: A total of 29 men underwent semen analysis according to WHO 2010 criteria. SCF was carried out by TUNEL on at least 500 spermatozoa with an established threshold of 15%. DSBs were measured by a neutral Comet test using a modified in-house protocol. A threshold of $\leq$3% was considered normal, with at least 200 spermatozoa assessed per patient. Clinical outcomes were compared between ICSI cycles performed with the DGC and MFSS methods. Preimplantation genetic testing for aneuploidy (PGT-A) was carried out on the resulting blastocysts. Euploid embryos were replaced into the uterine cavity, and implantation and clinical pregnancy rates (CPR) were recorded.

RESULTS: A total of 29 men (40±7 years) had the following semen parameters: a concentration of 38.7 ± 39 x10^6/mL, 31 ± 17% motility, and 2.1 ± 1% morphology. After DGC and MFSS, the sperm concentration was 18±29 and 7.3±11 x10^6/mL, with 55.2±30% and 98.3±2% motility, respectively (P<0.0001). The average SCF decreased from 22±9% in the raw samples to 16±3% following DGC, and dropped to 1.8±1% after MFSS processing (P<0.0001). The DSB rate was 3.8±2% in the raw samples, 2.8±1% after DGC, and only 0.3±0.1% after MFSS. These couples (female partner, 37.2±5 years) underwent 42 ICSI cycles with DGC-selected spermatozoa and achieved a fertilization rate of 61.8% (254/411) with 23.8% (26/109) of the embryos identified as euploid. The replacement of

these euploid embryos yielded an implantation rate of only 4.3% (1/23) and a CPR of 8.3% (1/12), with 8.3% (1/12) resulting in a pregnancy loss. When these couples underwent subsequent ICSI cycles with MFSS, a fertilization rate of 80.2% (334/416) ($P<0.00001$) was achieved, with 48.9% (90/184) of the embryos identified as euploid ($P<0.0001$). A total of 29 embryos were replaced, resulting in an implantation rate of 65.5% (19/29; $P<0.0001$) and a CPR of 73% (19/26) ($P<0.001$), resulting in 5.2% (1/19) pregnancy loss and 69.2% (18/26) ongoing pregnancy or deliveries ($P<0.0001$).

CONCLUSIONS: Spermatozoa with DNA damage, particularly double-stranded nicks/breaks, may impair the ability of the oocyte to repair the male genome. Because the male genome contributes to embryo aneuploidy, selecting spermatozoa with the highest motility and chromatin integrity may enhance the chances of obtaining a euploid embryo for transfer and boost embryo implantation.

THE VALUE OF NONINVASIVE PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY ON HUMAN CELL-FREE DNA FROM BLASTOCOELE FLUID WITH GENOME SEQUENCING: A PROSPECTIVE COHORT STUDY.

Dao W. Wang, MD, PhD, Lingbo Cai, PHD, Qiao Zeng, MD, PhD, Chao Gao, BSc, Wei Wu, MD, PhD, Jiandong Shen, MD, PhD, Yugui Cui, MD, PhD, Jiayin Liu, MD PhD
The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.

OBJECTIVE: Noninvasive preimplantation genetic testing for aneuploidy (niPGT-A) on cell-free DNA in blastocoele fluid (BF) is a promising but controversial method for selecting euploid embryos in assisted reproductive technologies.

DESIGN: Examine whether niPGT-A of BF can predict clinical outcomes and identify fetal ploidy for clinical use.

MATERIALS AND METHODS: In this prospective cohort study performed in a single IVF center, 182 blastocysts from patients undergoing their first in vitro fertilization and embryo transfer (IVF-ET) cycle in 2017 were analyzed (one blastocyst per patient). There were 33 withdrawals from the study. BF was collected prior to blastocyst vitrification. Clinical pregnancy outcomes were followed up till baby was born and karyotyping. Cell-free DNA from the BF was amplified (WGA) for next generation sequencing (NGS) -based comprehensive chromosome screening (CCS). The results were compared with clinical outcomes from newborn baby karyotyping, Chorionic Villus Sampling (CVS) results from miscarriages, or fetal Noninvasive Prenatal Test (NIPT) results from ongoing pregnancies.

RESULTS: A total of 139 BF samples produced CCS results for analysis (76.37%). Balanced euploidy was observed in 34 samples (24.46%) and aneuploidy in 92 samples (75.54%). A total of 113 patients (76.87%) achieved clinical pregnancy. Of those, 14 (11.38%) miscarried in their first trimester. CVS analysis results revealed a weak correlation between miscarriage tissue DNA samples and BF DNA samples. All 97 live-born babies showed normal phenotype and almost matched their NIPT results from pregnancies, even though some of the results of BF tests indicated abnormal genotypes. When compared all the testing results of BF, NIPT and CVS, there were about 30% consistencies.

CONCLUSIONS: When compared with PGS, niPGT-A is a lower risk method for the preimplantation screening of embryos, but currently can only identify weak correlations between clinical outcomes and BF ploidy analysis results. The future of niPGT-A is promising but the technology is not yet ready for clinical use.

SUPPORT: This work was supported by the China National 973 program (2012CB944902); National Key R&D Program of China (2016YFC1000207); Jiangsu Provincial Science and Technology Project (BL20122009 and BE2011798); and the Priority Academic Program Development of Jiangsu Higher Education Institutions (PAPD).

ANALYSIS OF 3,967 EMBRYOS USING A USING A NOVEL NON-INVASIVE PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (NIPGT-A) PLATFORM.

Meir Olcha, MD,[1] Manar Elzaky, BS, MS,[1] Malgorzata Jaremko, PhD,[1] Zaher Merhi, MD, HCLD,[2] John J. Zhang, MD, PhD[3] [1]New Hope Fertility Center, New York, NY; [2]SUNY Downstate University and New Hope Fertility Center, New York, NY; [3]Darwin Life INC, New York City, NY.

OBJECTIVE: Preimplantation Genetic Testing for Aneuploidy (PGT-A) has been widely used around the world to identify ploidy status of embryos. The primary modality for obtaining DNA from blastocysts has been trophectoderm (TE) biopsy, which requires removal of embryonic cells. A validated niPGT-A platform, termed Non-Invasive Chromosomal Screening (NICS™, Yikon Genomics, Lewes, DE), has been developed which allows embryonic DNA to be amplified by analysis of embryo culture media only and has been shown to have an approximate 90% positive correlation with TE biopsy PGT-A [1]. The purpose of this study to report the outcome analysis of a large sample of embryos tested using this novel niPGT-A platform.

DESIGN: Retrospective data analysis at a fertility center with university-based affiliation.

MATERIALS AND METHODS: Patients electing to have their embryos undergo PGT-A were offered to utilize the novel non-invasive platform instead of conventional TE biopsy after appropriate informed consent. Spent media was collected on Day 5, 6, or 7 of embryo culture per NICS™ protocol and processed on site using multiple annealing and looping-based amplification cycles followed by next-generation sequencing to obtain ploidy information on all chromosomes. Chi-square test was used to compare the percentage of euploid versus mosaic embryos.

RESULTS: There were 3,967 embryos tested with niPGT-A obtained from 845 patients (mean age = 39.0 ± 5.3) between July 1st, 2019 and May 17th, 2020. 96.2% of embryos had results with the proportion of reported euploid, mosaic, and aneuploid at 27.3%, 18.1%, and 54.6%, respectively. 3.8% (n=150) of all tested embryos had "no result" reported. 114 embryos with "no result" were retested, all of which resulted in usable ploidy data: 39.8% were euploid, 18.6% were mosaic, and 41.6% were aneuploid. Compared to embryos that initially had a reportable result, retested embryos had a significantly higher rate of euploidy (p=0.003), lower rate of aneuploidy (p=0.006), and similar rate of mosaicism (p=0.89). Data was further stratified based on established Society for Assisted Reproductive Technology (SART) age groups. Excluding mosaic results, rate of euploidy decreased with age: 87.5%, 68.8%, 34.7%, 23.0%, and 11.9% in patients under 35, 35-37, 38-40, 41-42, and over 42 years old, respectively ($p<0.001$). The ratio of female to male embryos was 1.03.

CONCLUSIONS: The novel niPGT-A platform, NICS™, can be safely implemented and can effectively distinguish mosaic embryos from aneuploid or euploid ones. Embryos resulting as "no result" initially can be successfully retested and have higher likelihood of being euploid. These data are very helpful in counseling patients desiring niPGT-A, rather than the traditional TE biopsy testing on their embryos. Caution in counseling patients should be taken when generalizing results as certain clinical and embryologic practice parameters could affect DNA capture and successful amplification.

P-784 4:30 PM Tuesday, October 20, 2020

CLINICAL OUTCOME COMPARISON BETWEEN TRANSFER OF EUPLOID AND MOSAIC BLASTOCYSTS IDENTIFIED USING A NOVEL NON-INVASIVE PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (NIPGT-A) PLATFORM.

Meir Olcha, MD,[1] Manar Elzaky, BS, MS,[1] Malgorzata Jaremko, PhD,[1] Zaher Merhi, MD, HCLD,[2] John J. Zhang, MD, PhD[3] [1]New Hope Fertility Center, New York, NY; [2]SUNY Downstate University and New Hope Fertility Center, New York, NY; [3]New Hope Fertility Center, New York City, NY.

OBJECTIVE: The primary modality for obtaining DNA from blastocysts for Preimplantation Genetic Testing for Aneuploidy (PGT-A) has been trophectoderm biopsy, which requires removal of embryonic cells that could potentially damage the embryos. Recently, the advent of a validated niPGT-A platform has been developed which allows embryonic DNA to be amplified by analysis of embryo culture media only and has been shown to have an approximate 90% positive correlation with traditional biopsy based PGT-A [1]. The purpose of this study was to evaluate the clinical outcome after single embryo transfer (SET) of euploid or mosaic embryos identified via niPGT-A.

DESIGN: Retrospective data analysis at a fertility center with university-based affiliation

MATERIALS AND METHODS: Biochemical and clinical (CPR) pregnancy rates were evaluated after SET of 132 euploid and 14 mosaic embryos between November 1st 2019 to April 20th 2020 at a single fertility center. All embryos had assisted hatching prior to media collection. Spent media was collected on Day 5, 6, or 7 of embryo culture per niPGT-A protocol [2]. Ploidy information on all chromosomes was derived on site using the NICS™ (Yikon Genomics, Lewes, DE) niPGT-A platform that utilizes multiple annealing and looping-based amplification cycles followed by next-generation sequencing. Initial ß-hCG levels were analyzed 7 days after SET. Biochemical pregnancy was defined by the absence of identifiable pregnancy on ultrasound despite positive serum ß-hCG. CPR was defined by the presence of a fetal heartbeat at 6-7 weeks of pregnancy. In all cycles, oral estradiol and vaginal progesterone were used for endometrial lining preparation and a minimum thickness of 7 mm was required for all SETs. Embryo transfers performed by physicians in training were excluded from the analysis. Chi-square test was used to calculate pregnancy rates and compare outcome between euploid and mosaic embryos transferred.

RESULTS: 146 patients with a mean age of 36.5 years were included in the study. A total of 91 out of 132 (68.9%) euploid embryos and 5 out of 14 (35.7%) mosaic embryos transferred resulted in a ß-hCG >5 mIU/ml. The CPR was 51.1% for euploid embryos and 28.6% for mosaic ones (p=0.01). The biochemical pregnancy rate was 26.3% for euploid embryos and 24% for mosaic embryos (p=0.7). The ratio of male to female embryos was 0.91 for Euploid and 1.0 for mosaic embryos (p=0.8).

CONCLUSIONS: These novel data show that niPGT-A, performed on the NICS™ platform, can be utilized successfully with comparable pregnancy rates to traditional PGT-A. Whether the use of NICS reduces embryo damage compared to conventional biopsy based PGT-A will be determined in our future studies.

CREB1 INTEGRATES THE METABOLIC AND GROWTH NETWORKS ASSOCIATED WITH THE AGING OF HUMAN GRANULAR CELLS. Kuan-Hao Tsui, M.D; Ph.D, Chia-Jung Li, Ph.D Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan.

OBJECTIVE: This study investigated whether changes in metabolism occur during granulosa cells (GCs) senescence and the mechanisms that regulate these changes.

DESIGN: Experimental laboratory study.

MATERIALS AND METHODS: We used excessive oxidative stress to induce cell senescence and examined the phenotype of aging. Protein and gene expression of different enzymes related to metabolism in senescent granulosa cells were analyzed by qPCR, protein array or immunofluorescence. Further, we applied bioinformatics methods and integrated publicly available resources to study the role of CREB1 gene expression in reproduction.

RESULTS: Here, we show that mitochondrial regulator CREB1 is induced by excessive oxidative stress (OS) in human HGL5 granulosa cells, and at the cellular level, OS-like activation of CREB1 impacts a network that integrates mitochondrial status with metabolism and growth parameters. Proteomics profiling reveals that diverse functions, including biogenesis pathways, growth, structure, and macromolecule homeostasis, are responsive to CREB1. Delayed cellular proliferation, altered cytoskeleton, and attenuated growth signaling through post-transcriptional and post-translational mechanisms were also identified as outcomes of CREB1-directed mitochondrial activation. Furthermore, endogenous CREB1 expression was correlated with this same metabolism and growth network. These data show that small changes in metabolism have broad consequences that arguably would profoundly alter cell function.

CONCLUSIONS: We suggest that this CREB1 sensitive network may be the basis for the association between mitochondrial function and aging where small deficiencies precipitate loss of function across a spectrum of cellular activities.

P-786 4:30 PM Tuesday, October 20, 2020

IMPACT OF BLASTOCYST RE-BIOPSY AND RE-FREEZE ON PREGNANCY OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS. Chelsea N. Fortin, MD, Molly B. Moravek, MD, MPH, Min Xu, Ph.D, Nicholas Henderson, PhD, MA University of Michigan, Ann Arbor, MI.

OBJECTIVE: While blastocyst vitrification and biopsy are generally considered safe, it is unclear if multiple biopsies and vitrification-warming procedures negatively impact clinical outcomes. This situation arises when patients request preimplantation genetic testing (PGT) on already cryopreserved embryos. Another scenario necessitating additional vitrification-warming procedures is failure to obtain a result from the initial trophectoderm biopsy, in which case a second biopsy would also be necessary. There is very limited information on the clinical outcomes following transfers of blastocysts twice biopsied and vitrified-warmed. The objective of this study was to compile the available literature on the clinical pregnancy (CP) rates of blastocysts transferred after undergoing multiple vitrification-warming and/or biopsy procedures.

DESIGN: Systematic review and meta-analysis.

MATERIALS AND METHODS: A systematic search of the literature was conducted using the PubMed database. Studies were selected for inclusion if they compared blastocysts 1) biopsied and vitrified-warmed once (1Bx + 1V/W), 2) biopsied once but vitrified-warmed twice (1Bx + 2V/W), and/or 3) biopsied and vitrified-warmed twice (2Bx + 2V/W). A total of six retrospective cohort studies met inclusion criteria. Data involving patient and blastocyst characteristics, PGT results, and clinical outcomes were extracted. Study quality was assessed using the Newcastle Ottawa scale for non-randomized comparative cohort studies. The studies were evaluated independently by two of the authors and any discrepancies were settled by a third author. From the six studies included, a multiple-treatments random-effects meta-analysis comparing the risk difference in CP rate for the three groups identified above was performed.

RESULTS: A total of 9437 single euploid blastocyst transfers were included in the analysis. The pooled CP rate was significantly lower in the 2Bx + 2V/W group compared to the 1Bx + 1V/W group, with an estimated difference of 13%, 95% CI [4.3-21.6%]. No significant differences in CP rate were observed between the 1Bx + 1V/W and 1Bx + 2V/W groups (risk difference, 4.5%; 95% CI [-2.1-11.1%]) or between the 1Bx + 2V/W and 2Bx + 2V/W groups (risk difference, 8.5%; 95% CI [-2.3-19.3%]).

CONCLUSIONS: These findings indicate that CP rates are significantly reduced when blastocysts are biopsied and vitrified-warmed twice compared with blastocysts biopsied and vitrified-warmed once. For patients who receive an inconclusive diagnosis from the initial biopsy, this risk should be weighed against the risk of transferring a possible aneuploid embryo. However, given the retrospective nature of the limited number of studies available, further research is needed to confirm this finding.

P-787 4:30 PM Tuesday, October 20, 2020

PREIMPLANTATION GENETIC TESTING (PGT) WAS NOT ASSOCIATED TO ADVERSE MATERNAL AND NEONATAL OUTCOMES. Mauro Cozzolino, MD,[1] Juan A. Garcia-Velasco, MD, PhD,[2] Antonio Pellicer, MD[1] [1]IVIRMA Foundation, Valencia, Spain; [2]IVI-RMA Madrid,Universidad Rey Juan Carlos, Madrid, Spain.

OBJECTIVE: To assess whether trophectoderm biopsy for preimplantation genetic testing (PGT) has increased the risk of maternal and neonatal outcomes compared with pregnancies achieved with IVF without PGT.

DESIGN: Retrospective observational cohort study.

MATERIALS AND METHODS: Women receiving fertility care at IVIRMA with PGT-A or without PGT-A were enrolled in study from January 2016 to April 2019. Patients between 18 and 45 year, in whom at least one embryo was transferred after blastocyst stage biopsy were considered. Cases of no embryo survival after vitrification or pregnancies with oocyte donation was excluded. Patients with missed information about maternal and neonatal outcomes were excluded. Primary outcomes was preeclampsia defined by the presence of hypertension (persistent systolic blood pressure (BP) 140 mm Hg or higher and/or diastolic BP 90 mm Hg or higher) after 20 weeks of gestation in a previously normotensive woman with proteinuria. The incidence of gestational diabetes and small for gestational age was considered secondary outcomes.

Neonatal outcomes such as preterm birth (<37 weeks), birth weight, birth defects, Apgar score at 5 minutes, neonatal intensive care unit (NICU) admission, were considered as secondary outcomes. The study was approved by the Ethics Committee of the IVIRMA (identification code #1910-FIVI-096-MC). Statistical analysis was performed using Fisher's Exact Test, $p<0.05$. Statistical analyses were conducted using the R statistical software 3.1.0.

RESULTS: The study included 544 pregnancies with PGT-A and 2051 without PGT-A. There was not a statistically significant increase in the risk of preeclampsia among PGT-A pregnancies compared with pregnancies without PGT-A, with an incidence of 4.4% versus 4.1%, OR 1.03, 95% CI (0.61-1.67) p=0.94. The incidence of preterm birth (<37 weeks) was 15% in patients with PGT-A versus 14.1% in pregnancies without PGT-A, OR 1.08, 95% CI (0.82-1.40), p=0.54. Similar incidence in small for gestational age (SGA) was observed in pregnancies with PGT-A compared to without PGT-A OR 0.99, 95% CI (0.75-1.22), p=1.Conversly, in pregnancies with trophectoderm biopsy the rate of gestational diabetes was increased 10.1 % versus 7.4%, OR 1.40, 95% CI (0.99-1.96), p=0.05. No statistically, difference were observed for neonatal intensive care unit admission, Apgar punctuation and birth defects.

CONCLUSIONS: The pregnancies with PGT-A have not increased the rate of preeclampsia, preterm birth, SGA, while PGT-A increase the risk of gestational diabetes. Trophectoderm biopsy was not associated with adverse neonatal outcomes. Although in pregnancies with PGT-A gestational diabetes was increased, the sample size is a limitation of the study. Thus, larger studies including patients by different infertility centres are needed to add more insight into the safety of PGT.

P-788 4:30 PM Tuesday, October 20, 2020

IMPACT OF BLASTOCYST BIOPSY TECHNIQUE ON DNA QUALITY AND PGT-A RESULTS. Michael J. Abeyta, BS,[1] Chaochun Lin, BS,[1] David M. Pardo, PhD,[1] William B. Schoolcraft, MD,[2] Jason E. Swain, PhD, HCLD[3] [1]CCRM San Francisco, San Francisco, CA; [2]CCRM Colorado, Lone Tree, CO; [3]CCRM IVF Network, Lone Tree, CO.

OBJECTIVE: Blastocyst biopsy is an invasive procedure with a technical signature. Improper biopsy technique, such as taking too many cells, can impair blastocyst quality. It is thought that biopsy technique may also impact quality of the biopsied cells and resulting genetic content, which may influence results called/reported by the genetics lab. Two blastocyst biopsy techniques were compared to determine the impact on PGT-A results.

DESIGN: Prospective trial

MATERIALS AND METHODS: To control for technician and lab variation, all biopsy procedures were conducted at a single IVF center by a single embryologist over an approximate 1 month period of time. All PGTA testing was performed at a single genetics lab. Only high quality blastocysts (HQB) >=3BB were biopsied. All embryos were breached on Day 3 of culture to create a small opening for subsequent herniation. Resulting HQBs were biopsied by either the "Standard" approach or the "Flick" technique. Standard biopsy entailed gentle suction by a holding and biopsy pipet, with several laser pulses (~3-6) and simultaneous stretching to biopsy trophectoderm cells. The Flick approach used the same biopsy setup and laser settings, but utilized 2 laser pulses at the top and bottom of the herniated cells and then a gentle flick using a finger to tap the side of the biopsy pipet to shear trophectoderm cells from the rest of the blastocyst. 4-6 cells were taken from all blastocysts and subjected to PGT-A testing using an NGS platform. Data were analyzed using Chi Square analysis.

RESULTS: The Standard biopsy technique was utilized on 73 blastocysts while the Flick technique was used on 67. All samples yielded DNA for amplification. A "no result" is given when the genetic material from the biopsied cells is of insufficient quality to make a reliable call. The Standard approach yielded results on 98.6% of samples, which not significantly different than the Flick technique at 94.0%. However, the 6% no result rate using the Flick approach was higher than our established acceptable threshold for internal quality control. Both Standard and Flick biopsy approaches yielded similar blastocyst euploid rates (54.8% vs. 54.2%).

CONCLUSIONS: Prior reports suggest that biopsy technique may significantly impact PGT-A results, likely via impact on the quality of the biopsied genetic material. While the Standard biopsy technique used in this study used more laser pulses, this was done in a controlled fashion. By contrast, the Flick used fewer laser pulses but a less controlled motion to shear the cells via vibration. Though both approach appeared equally effective, this vibration from the Flick technique may have caused further damage to the cells and enclosed DNA resulting in the slight increase in the observed "no result" rate, Future studies with a larger data set will help further assess efficacy of these techniques and determine if one approach appears superior compared to another when biopsying specific stages of blastocysts.

P-789 4:30 PM Tuesday, October 20, 2020

COMPARISON OF THE STRUCTURE OF CHROMOSOMAL ABNORMALITIES IN THE EMBRYOS OBTAINED AFTER REPRODUCTIVE NUCLEAR TRANSFER VERSUS IVF-ICSI-PGT-A. Dmytro O. Mykytenko, MD, DSc, Kateryna Lavrova, PhD, Tetiana Cherneha, MSc, Pavlo Mazur, MSc, Lada Diachenko, MSc., Valery Zukin, MD, PhD Clinic of Reproductive Medicine "Nadiya", Kyiv, Ukraine.

OBJECTIVE: The safety of reproductive nuclear transfer (or mitochondrial replacement therapy) in cases of IVF in patients with severe forms of infertility or a family history of mitochondrial diseases causes lively debate worldwide. Meanwhile, births of 13 children following this technique have already been announced. However, while the safety of the artificially created mitochondrial heteroplasmy is being discussed, the issue of possible induction of chromosomal abnormalities in the embryos caused by the manipulations with the nuclei at the stage of reconstruction is not addressed. This particular issue is the subject of this study.

DESIGN: The study included a comparison of chromosomal abnormalities in the embryos obtained following reproductive nuclear transfer (259 blastocysts) and IVF-ICSI-PGT-A (3236 blastocysts).

MATERIALS AND METHODS: Obtained TE biopsy samples were 3 times washed in the separate 1xPBS-1%PVP drops followed by WGA procedure (SurePlex DNA Amplification System, Illumina). Samples were analyzed by NSG method for preimplantation genetic testing for aneuploidies (PGT-A). NGS: analysis was performed using VeriSeq PGS Kit, RH-101-1001, Illumina. Interpretation of the chromosomal NGS-patterns was performed in accordance to manufacturer's recommendations. Standard statistical methods were used for analysis.

RESULTS: In the embryos obtained after reproductive nuclear transfer, more frequent involvement of chromosomes 8, 10, 12, 14, 18 and 20 (complete and structural abnormalities) and less frequent involvement of chromosomes 1, 2, 9, 13, 16 were observed.

A significant change in the monosomy/trisomy ratio for chromosomes 1, 2, 3, 4, 6, 7, 8, 17 was also observed.

The distribution of the embryos obtained after reproductive nuclear transfer according to the patient's age at the time of oocyte retrieval showed an abnormally high proportion of the embryos with abnormalities in chromosomes 10 and 11, as well as a shift to more frequent involvement of the chromosomes from groups A, B and C in patients aged $\geq$37 years (164 blastocysts, aneuploidy level 91%). In the younger age group, a more frequent involvement of the chromosomes from groups D, E, F and G was observed (94 blastocysts, aneuploidy level 44%).

CONCLUSIONS: The analysis showed a significant change in the structure of chromosomal abnormalities in the embryos obtained after reproductive nuclear transfer. Further research is required to identify through what mechanisms the reproductive nuclear transfer causes changes in the structure of chromosomal abnormalities and whether this phenomenon may have any prognostic value in the assessment of the effectiveness of manipulations with the cell nuclei or in clinical efficacy.

P-790 4:30 PM Tuesday, October 20, 2020

THE EFFECT OF GERMLINE MUTATIONS ON THE ABILITY OF SURGICALLY RETRIEVED SPERMATOZOA FROM AZOOSPERMIC MEN TO SUPPORT EMBRYONIC DEVELOPMENT. Stephanie Cheung, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To identify eventual germline mutations involved in spermatogenesis and the ability of spermatozoa retrieved from azoospermic men to support embryonic development.

DESIGN: For over 20 months, we recruited infertile men undergoing epididymal aspiration for obstructive (OA; n=17) and testicular retrieval for nonobstructive (NOA; n=10) origins. Three men functioned as fertile controls. Gene mutations were compared according to the etiology of the azoospermia and in relation to whether they were able to generate a pregnancy (fertile) or not (infertile).

MATERIALS AND METHODS: Specimens were provided by consenting men, who were being treated at our center for infertility. DNA was extracted and amplified from at least 500 spermatozoa (DNA concentration, 705±562 ng/ul; quality, 1.7±0.1 nm). Following NGS, gene mutations, duplications, and deletions were detected using the CLC Genomic Server 9.0. Genes were considered duplicated or deleted when the read depth was >1.5 or <0.5 times the median read depth in the control. Common gene mutations in the OA and NOA cohorts were assessed according to the couples' clinical outcomes.

RESULTS: Of the 27 couples (paternal age, 41.3±5yrs) included, 17 OA men underwent epididymal sperm retrieval with an average concentration of $1.3\pm3x10^6$/ml and 7±14% motility, while 10 NOA men yielded twitching spermatozoa with a concentration of $0.03\pm0.2x10^6$/ml and 0.5±1% motility. Whole genome karyotype assessment showed an overall sperm aneuploidy rate below only 2%, specifically 1.7% in the OA and 1.9% in the NOA cohort.

In the OA group overall, only 3 housekeeping genes were mutated (ATP4A, SLC17A7, and OR1D4). However, in the NOA cohort, 5 genes involved in RNA transcription (POLR2L), apoptosis (AP5M1), and basic spermiogenic function (AP1S2, AP1G2, and APOE) were deleted.

The OA men and their partners (maternal age, 34.8±3yrs) underwent 17 ICSI cycles, resulting in a pregnancy and delivery rate of 47.1% (8/17). For those able to reproduce (n=8), all shared a mutation in ZNF749, which is mainly responsible for spermatogenesis. Those who remained infertile had a common mutation in PRB1, a gene involved in DNA replication.

When NOA men were treated in 10 ICSI cycles with their partners (maternal age, 38.2±2yrs), the pregnancy rate was 70% (7/10). Of those 7 men, 1 mutation (MPIG6B) related to stem cell lineage differentiation was in common. The remaining 6 who remained childless had mutations in genes associated with spermatogenesis (6 genes), apoptosis (4 genes), acrosomal function (2 genes), and, most importantly, in early embryonic development (MBD5, CCAR1, PMEPA1, POLK, REC9, REPIN1, MAPRE3, and ARL4C).

CONCLUSIONS: Screening infertile men for germline mutations can help characterize spermatogenic function in relation to the etiology of their azoospermia and provide valuable information on their reproductive potential. In men capable of reproducing, gene mutations were limited to those associated with spermatogenic function. For men unable to reproduce, particularly the NOA cohort, the mutated genes were mostly related to multiorgan functions and embryo development.

P-791 4:30 PM Tuesday, October 20, 2020

ANOTHER CHANCE FOR SUCCESS: THE LIKELIHOOD OF OBTAINING A EUPLOID EMBRYO FOR TRANSFER AFTER AN IVF CYCLE WITH NO EUPLOID EMBRYOS. Nola S. Herlihy, MD,[1] Amber M. Klimczak, MD,[2] Brent M. Hanson, MD,[2] Julia G. Kim, MD, MPH,[2] Ashley W. Tiegs, MD,[2] Emily K. Osman, MD,[2] Emre Seli, MD,[2] Richard Thomas Scott, Jr., MD[2] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Although most patients achieve at least one euploid blastocyst with their first IVF cycle using preimplantation genetic testing for aneuploidy (PGT-A), a minority will not have any suitable embryos for transfer and need to be counseled about the utility of attempting another cycle. The objective of this study was to determine the likelihood that those patients achieve a euploid embryo in their subsequent IVF cycle.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: This was a retrospective review of all patients who underwent IVF with PGT-A using Next Generation Sequencing (NGS) from July 2016 to October 2019 at a University-affiliated clinical practice. Patients were included if their first IVF cycle resulted in no euploid embryos for transfer and they underwent at least one more IVF cycle using PGT-A. Patients using donor eggs and those who did PGT for monogenic diseases or structural rearrangements were excluded.

RESULTS: A total of 438 patients were identified who underwent PGT-A resulting in no euploid embryos. Of those patients, 223 (51%) had at least one euploid embryo for transfer in their second IVF cycle. Results by SART age group and number of blasts tested in the initial cycle are presented in Table 1. Overall, euploidy rates in the second cycle are not diminished compared to expected rates per age group

CONCLUSIONS: Patients undergoing PGT-A who achieve no euploid blastocysts in their first cycle may be reassured that this outcome is not indicative of an inherent defect in embryo quality. They should be offered the opportunity to attempt another IVF cycle and should be counseled that they retain a high likelihood of achieving a euploid blastocyst in their second attempt.

TABLE 1. Likelihood of obtaining a euploid blastocyst in a subsequent IVF cycle according to number of blastocysts initially tested. n : the number of patients in that group; first % number: corresponds to percentage of patients with a euploid blastocyst to transfer in their second cycle; second % number: corresponds to overall euploidy rates in the second cycle.

	Number of tested blastocysts in first cycle

AGE-RELATED PREGNANCY LOSS IS LARGELY OVERCOME WITH SINGLE EUPLOID EMBRYO TRANSFER. Mandy G. Katz-Jaffe, PhD, Susanna McReynolds, PhD, Lauren Henry, BS, Nathan McCubbin, BS, Rachel S. Mann, BS, MS, Rachel Tucci, BS, Sue McCormick, BS, William B. Schoolcraft, MD Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Oocyte aneuploidy is significantly associated with increasing maternal age and is the primary cause of reproductive failure including pregnancy loss for women of advanced maternal age (AMA; ≥38 years). Preimplantation genetic testing for aneuploidy (PGT-A) has been shown to improve IVF live birth outcomes from embryo transfer for AMA infertility patients. The aim of this study was to evaluate the efficacy of single euploid embryo transfers to reduce the impact of AMA on pregnancy loss.

DESIGN: Retrospective large cohort study

MATERIALS AND METHODS: A total of 3,773 single euploid transfers (SET) from 2010-2019 at a large IVF clinic, which underwent PGT-A at a single Genetics laboratory, were included in this cohort analysis. Donor oocyte and gestational carrier cycles were excluded. Groups were defined based on maternal age at the time of oocyte retrieval: <35 years (n=1,261 SETs), 35-37 years (n=1,074 SETs), 38-40 years (n=950 SETs), 41-42 years (n=397 SETs) and >43 years (n=91 SETs). Outcome measures included clinical pregnancy (visualized gestational sac and fetal pole), miscarriage (visualized fetal heart tone followed by loss) and live birth. Statistical analysis was performed where appropriate with Fisher's exact, Kruskal-Wallis and Benjamini-Hochberg adjustment, significance at $p < 0.05$.

RESULTS: Clinical pregnancy and live birth rates significantly decreased with AMA of ≥38 years (Table 1; *P<0.001). In contrast, miscarriage was not significantly different across the maternal age groups, including for AMA women (≥38 years). Only 2.4% of sustained implantations resulted in monozygotic twinning with monozygotic twinning 2.5x more likely to result in a pregnancy loss ($p < 0.05$).

CONCLUSIONS: This large cohort analysis of SETs has revealed that the age-related increase in pregnancy loss associated with aneuploidy has been largely overcome with PGT-A and the selection of euploid embryos for transfer. A small but significant decrease in live birth outcomes still remains for AMA women undergoing infertility treatment and represents the additional embryonic and maternal factors associated with reproductive success.

GENERALIST PHYSICIANS' REFERRAL BEHAVIOR ON PRE-IMPLANTATION GENETIC TESTING (PGT) FOR SINGLE GENE DISORDERS: DO WE NEED TO PLAY CATCH UP? Sarah M. Capelouto, MD,[1] Melanie Evans, MS, MD,[2] Jennifer Shannon, MD,[1] Katelyn Jetelina, PhD, MPH,[3] Orhan Bukulmez, MD,[1] Bruce R. Carr, MD[1] [1]UT Southwestern Medical Center, Dallas, TX; [2]The University of Texas, Southwestern Medical Center, Dallas, TX; [3]University of Texas Health Science Center at Houston, Dallas, TX.

OBJECTIVE: Pre-implantation genetic testing is a growing aspect of fertility treatment. However, prior national analyses reveal that the majority of cycles are for aneuploidy screening, while only about 15% are for monogenic disease, PGT-M [1]. To explore why so few PGT-M cycles are performed, we aimed to study physicians on the front lines of such referrals. Specifically, we evaluated the knowledge, barriers, and referral behaviors regarding PGT-M across generalist groups, comprised of internists, pediatricians and Ob/Gyns, in hopes of advancing PGT-M utilization.

DESIGN: Cross-sectional survey.

MATERIALS AND METHODS: We distributed an anonymous survey on PGT-M among generalists at our academic medical campus from March-May 2020 at grand rounds or online via REDCap. The survey included constructs on demographics, PGT-M knowledge (definition, success rates, who performs, does our institution offer), and referral/practice behavior. Bivariate analyses evaluated associations between physician specialty and demographics with their PGT knowledge and practice behavior.

RESULTS: A total of 145 respondents participated in our survey: 65 Ob/Gyns, 36 internists, and 44 pediatricians. Overall, 88% of physicians believed patients at risk of passing on genetic disorders should be provided PGT-M information. Despite this belief, few reported discussing PGT-M with their patients (24%) or referring for testing (23%). Moreover, most physicians only discussed (54%) or referred (79%) once a year. Objective PGT knowledge had a major effect on practice behavior. Among physicians that got 2 of 4 knowledge questions correct (compared to 1 of 4), the odds of discussing PGT were eight times higher and the odds of placing a referral five times higher ($p < 0.001$). Compared to internists and pediatricians, Ob/Gyns answered significantly more knowledge questions correctly. With this in mind, the odds of referring for PGT-M were eight times higher for Ob/Gyns compared to pediatricians, and ten times higher compared to internists ($p<0.001$). Subjective knowledge of PGT also correlated with practice behavior. Compared to Ob/Gyns, internists and pediatricians had lower odds of feeling they had enough basic PGT knowledge to adequately answer patient questions on the topic. Those odds were significantly lower for internists (OR 0.06, 95% CI 0.01-0.46) but non-significantly lower for pediatricians (OR 0.41, 95% CI 0.16-1.07). Lastly, demographics played a role. Internists, and physicians who graduated medical school before 1980, more likely believed that lack of physician knowledge was a barrier to PGT-M use.

CONCLUSIONS: While the majority of generalists surveyed believed patients at risk of passing on genetic disorders should be provided PGT-M information, less than 1 in 4 discussed PGT with their patients or placed testing referrals. Our study shows there is opportunity to promote a greater understanding of PGT among generalists. Follow-up interventions to advance knowledge could take the form of grand rounds lectures or continuing medical education courses led by fertility specialists, in turn expanding the use of PGT-M for all patients.

ADVANCED PATERNAL AGE DOES NOT INFLUENCE BLASTOCYST EUPLOIDY RATES IN DONOR EGG CYCLES. Daniel Skora, M.D., Jennifer A. Rodriguez, B.Sc., Rebecca A. Chilvers, M.D., Satin S. Patel, M.D., Jerald S. Goldstein, M.D., Carlos A. Guerrero, Ph.D. Fertility Specialists of Texas, Frisco, TX.

OBJECTIVE: The average age of parentage has been increasing over the last decades. Research has suggested that advanced paternal age (APA) may play a role in increased risk of several disorders in offspring, including: schizophrenia, musculo-skeletal syndromes, and autism spectrum disorders[1]. The question remains whether there are changes in euploidy rates associated solely with APA. Most studies assessing APA effects are confounded by concomitant advanced maternal age. To avoid this confounder, we looked at euploidy rates in our donor egg population assessed by PGT-A to assess rate of aneuploidy by paternal age.

DESIGN: Retrospective analysis of data collected from January 2017 through January 2020. Donor egg cycles were divided into 4 treatment groups based on paternal age. Clinical end points and laboratory parameters were analyzed using Fisher's exact test and t-test as appropriate.

MATERIALS AND METHODS: A total of 210 donor egg cycles and 1410 blastocyst biopsies were included in this study. Blastocysts were biopsied on Day 5/6 and aneuploidy testing was performed via NextGen Sequencing. Males with epididymal or testicular sperm and oocyte donors >30 years of age were excluded.

RESULTS: Euploidy rates remained within the margin of error for all paternal age groups; around 70% euploid (Table 1). No difference was noted in euploidy rate between groups. Furthermore, there was no difference between treatment groups for semen quality parameters, blastocyst quality, number of oocytes retrieved and egg donor age.

Table 1. Effect of paternal age on blastocyst euploidy rate.

Paternal Age Group	# of Cycles	# of Blastocysts Biopsied	Euploidy Rate (%)
<35	53	353	254/353 (71.9%) [a]
35-40	70	464	326/464 (70.2%) [a]
41-45	47	313	217/313 (69.3%) [a]
>45	40	280	196/280 (70.0%) [a]

[a] Different superscripts within columns indicate significant differences ($P<0.05$)

CONCLUSIONS: These findings suggest that the euploidy rate of blastocysts determined by PGT-A is not associated with paternal age. Other disorders associated with APA are more likely a result of imprinting or epigenetic changes not detected by PGT-A.

OUTCOMES FOLLOWING TRANSFER OF EMBRYOS WHOSE PGT-A RESULTS WERE INDETERMINATE AND THAT WERE NOT RE-BIOPSIED. Tamar Alkon-Meadows, MD,[1] Carlos Hernandez-Nieto, MD,[1] Joseph A. Lee, BA,[1] Rose Marie Roth, MSc, TS(ABB), CLT (NYS),[1] Richard Slifkin, BA, TS(ABB), CLT(NYS),[1] Deborah Cassis-Bendeck, MD,[1] Martha Luna-Rojas, MD,[1] Alan B. Copperman, MD,[2]

Benjamin Sandler, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: PGT-A with *NGS* is broadly utilized by reproductive specialists at modern ART treatment centers to improve embryo transfer selection. However, there are technical limitations to PGT which might prevent formal designation of the embryo as euploid or aneuploid. While re-biopsy of the embryo is possible, some studies suggesting that the selection of twice biopsied embryos at time of transfer might compromise overall implantation[1]. Hence, patients have been known to electively select embryos with indeterminate results for transfer. The aim of this study is to evaluate clinical outcomes following transfer of indeterminate embryos compared to re-biopsied euploid embryos.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: The study included patients who underwent a single FET of blastocysts that underwent a trophectoderm biopsy from 2016 to 2020. Cohorts were separated into 2 groups: (Group 1: single biopsy embryos with an indeterminate result; Group 2: initial embryo biopsy with indeterminate result that underwent a secondary biopsy and was diagnosed as euploid). Patients whose PGT-A results were indeterminate had extensive clinical and genetic counseling and signed informed consent prior to re-biopsy and/or ET. Demographic characteristics, embryology parameters and clinical outcomes were compared. Comparative statistics and an adjusted multivariate regression were used for analysis.

RESULTS: 61 FET cases were included in the analysis: indeterminate PGT results embryos (n= 21); double biopsied euploid embryos (n=40). Patients that elected to transfer indeterminate result embryos had higher age at oocyte retrieval (39.0 vs 36.9, p=0.02) and at ET (39.3 vs 37.2, p=0.01) than patients in group 2. All other demographic variables, embryonic quality at ET, implantation, clinical pregnancy (CPR), ongoing pregnancy (OPR) and clinical pregnancy loss (CPL) rates were statistically comparable among groups. After adjusting for BMI, age, AMH, and embryo quality at FET, transfer of an indeterminate embryo was not associated with lower odds of implantation (OR 1.03 CI95% 0.2-4.3, p=0.96), CPR (OR 1.02 CI95% 0.2-3.8, p=0.40), OPR (OR 1.4 CI95% 0.3-4.9, p=0.60) when compared with double biopsied embryos. Also, there was no association with higher CPL rates (OR 0.4 CI95% 0.3-5.2, p=0.50).

CONCLUSIONS: This is the first study to describe outcomes when embryos biopsied for PGT-A were indeterminate and selected for transfer without re-biopsy. Our study suggests that implantation and ongoing pregnancy rates are lower when indeterminate embryos are selected for transfer compared to the selection of embryos that underwent a second biopsy and were found to be euploid, albeit the differences were not statistically significant. We recommend re-biopsy of embryos upon an initial indeterminate result to allow for enhanced transfer selection and greatest reproductive potential. However, for patients that have frozen indeterminate embryos and are unable to undergo another IVF cycle, comparable reproductive outcomes are achievable, especially in younger patients who have a higher prevalence of embryonic euploidy.

OBSTETRIC AND NEONATAL OUTCOMES OF PREGNANCIES RESULTING FROM PREIMPLANTATION GENETIC TESTING: A SYSTEMATIC REVIEW AND META-ANALYSIS. Wei Zheng, MD, Yichun Guan, MD, PhD, Chen Yang, MD, Shuheng Yang, MD, Simin Sun, MD, Mingkun Mu, MD, Ruowen Zu, MD, Junfang Yan, MD, Bingnan Ren, MD The Third Affiliated Hospital of Zhengzhou University, Zhengzhou, China.

OBJECTIVE: This study aims to investigate whether preimplantation genetic testing (PGT) pregnancies increase the risks of adverse obstetric and neonatal outcomes compared to IVF/ICSI pregnancies or spontaneous conceptions (SC).

DESIGN: a systematic review and meta-analysis.

MATERIALS AND METHODS: PubMed, EMBASE, Web of Science and Cochrane Library from January 1990 to November 2019 were searched. Published studies were included if they reported data on obstetric and neonatal outcomes for PGT and IVF/ICSI or SC. The primary outcomes were low birth weight (LBW) and congenital malformations (CMs), whereas secondary outcomes were preterm delivery (PTD), birth weight (BW), very low birth weight (VLBW), very preterm delivery (VPTD), Neonatal Intensive Care Unit (NICU) admission, placenta previa (PP), gestational age, preterm premature rupture of membranes, gestational diabetes and pre-eclampsia. Besides, we pooled results of PGT singleton pregnancies, and subgroup analyses included preimplantation genetic diagnosis (PGD) and preimplantation genetic screening (PGS) singleton pregnancies.

RESULTS: Thirteen studies were included in this meta-analysis. The relative risks of having LBW (RR = 4.08, 95% CI: 2.83–5.89), CMs (RR = 2.24, 95% CI: 1.48–3.37) and PTD (RR = 3.30, 95% CI: 2.37–4.58) were significantly higher in PGT pregnancies, when compared with SC; and the BW significantly reduced in PGT pregnancies (RR = –91.66, 95% CI: –161.09 to –22.23). Furthermore, The risks of LBW [relative risk (RR) = 0.90, 95% confidence interval (CI) : 0.80–1.00], VPTD (RR = 0.61, 95% CI: 0.41–0.93) and VLBW (RR = 0.70, 95% CI: 0.50–0.98) were significantly lower when PGT pregnancies compared with IVF/ICSI pregnancies (both single and multiple pregnancies), but the risk of PP (RR = 2.97, 95% CI: 1.37–6.42) was significantly higher in PGT pregnancies than IVF/ICSI pregnancies. We further found that PGT singleton pregnancies significantly decreased the risks of LBW (RR = 0.68, 95% CI: 0.49–0.94), VPTD (RR = 0.51, 95% CI: 0.25–1.00) and VLBW (RR = 0.52, 95% CI: 0.28–0.97) compared with IVF/ICSI singleton pregnancies. The subgroup analysis indicated there was a significantly lower risk of LBW (RR = 0.66, 95% CI: 0.48–0.92) in PGD singleton pregnancies compared with IVF/ICSI singleton pregnancies, but the results of PGS singleton pregnancies were comparable with those of IVF/ICSI singleton pregnancies. No statistical differences were noted in the remaining outcomes.

CONCLUSIONS: This systematic review and meta-analysis revealed that PGT pregnancies might increase the risks of adverse neonatal outcomes when PGT pregnancies compared with SC. However, the other factor, like infertility background may have a greater impact on neonatal outcomes because PGT pregnancies reduced the risk of adverse neonatal outcomes when compared with IVF/ICSI pregnancies. The overall obstetric outcomes are reassuring, but embryo biopsy of PGT, especially trophectoderm biopsy, may affect the development of placental and increases the risk of PP.

OBESITY AND MITOSCORE: DETERMINANT OF ART SUCCESS? Maria Bustillo, M.D,[1] Ineabelle Collazo, BS,[2] Katherine L. Palmerola, BS, MD,[2] Sabrina A. Gerkowicz, MD,[2] Juergen Eisermann, M.D,[1] Nicholas Hendon, BS,[2] Himanshu Arora, PhD[3] [1]IVFMD, South Florida Institute for Reproductive Medicine, MIAMI, FL; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [3]University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: Mitochondrial gene copy number (mtDNA or "MitoScore") may reflect embryo stress and energy supply, which may impact implantation. In assisted reproductive technology (ART), multiple factors affect outcome, with emerging evidence suggesting that patient body mass index (BMI) and body fat are critical players. However, little is known regarding the impact of BMI or percent body fat on an embryo's MitoScore.. In the present study we compared MitoScore, BMI and percent body fat in ART outcomes, as this information may be important to maximizing the success rate of single embryo transfer in ART

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Data from 166 women (2016-2017), who underwent ART with pre-implantation genetic testing for aneuploidy (PGT-A) was analysed. PGT-A and MitoScore testing on euploid embryos were performed by Igenomix. Body fat was measured with Tanita body composition analyser (Model TBF-410). MitoScore, BMI and percent body fat were compared between pregnant and nonpregnant cohorts following ART. Additionally, Mitoscore, BMI, and percent body fat were compared in subgroups of the pregnant cohort (live birth, biochemical, spontaneous abortion). GraphPad Prism (GraphPad Software) was used for statistical analysis. All data are presented as the means ± SEM. The statistical significance between two groups was estimated by unpaired one-tailed t test. In all cases, $p < 0.05$ was considered statistically significant.

RESULTS: Data from 166 women was analysed, including 130 with positive beta human chorionic gonadotropin (bhCG): 104 live births, 15

biochemical pregnancies, and 11 spontaneous abortions. MitoScore, BMI and percent body fat were significantly lower in pregnant compared to non-pregnant women (MitoScore- p=0.04, BMI- p=0.05, percent body fat- p=0.03). Correlation studies between MitoScore, BMI and percent body fat in subgroups of the pregnant cohort showed that MitoScore was positively correlated with BMI in patients with biochemical pregnancies (p=0.04) and not correlated in patients with live births (p=0.63) or with spontaneous abortions (p=0.48). MitoScore was not correlated with percent body fat in any of the pregnant subgroups.

CONCLUSIONS: Our findings suggest that MitoScore, BMI and percent body fat could act as critical parameters in determining the success of ART in regards pregnant or non-pregnant outcomes. Many factors need to be considered to reliably establish and clarify this correlation. Further analyses of other determinants such as age and infertility diagnosis and inflammatory markers are underway to establish the significance of MitoScore.

EFFICACY OF PGT-A WITH A SINGLE BLASTOCYST. Alexis Gadson, MD,[1] Wendy Kuohung, MD,[1] Denny Sakkas, PhD[2] [1]Boston University School of Medicine, Boston, MA; [2]Boston IVF, Waltham, MA.

OBJECTIVE: Pre-implantation genetic testing for aneuploidy (PGT-A) has been used to allow the transfer of a euploid embryo to achieve a higher chance of pregnancy. Currently, PGT-A is offered to IVF patients on a self-pay basis, even in states with a legislative mandate to cover infertility treatment. It is unclear if PGT-A improves clinical pregnancy rates if the cycle yields only one blastocyst of sufficient quality to biopsy and cryopreserve. The objective of this study was to determine if there is any difference in clinical pregnancy rates between patients with a single freezable blastocyst who undergo PGT-A compared to those who undergo transfer of a single untested blastocyst.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: We reviewed deidentified cycles of women undergoing a frozen embryo transfer cycle between January 1, 2014 and March 31, 2020, and whose prior IVF cycle yielded a single high-quality blastocyst for transfer at Boston IVF. Criteria for PGT-A cycle was the presence of only one blastocyst available for biopsy and cryopreservation. Non PGT-A patients included the cycle being a frozen embryo transfer cycle with transfer of a single thawed blastocyst. Exclusion criteria included cycles utilizing donated eggs. Patient data including age at cycle start, pre-implantation testing type, cycle data (cycle number, trophectoderm and inner cell mass grade, dates of treatment), and outcomes (presence of fetal heart rate in a clinical pregnancy) were collected for each cycle. Chi square analysis was used to determine differences between the single blastocyst patients utilizing PGT-A and the group that did not (control).

RESULTS: A total of 13,293 charts were included in the initial analysis. Patients who had a single blastocyst and underwent PGT-A were extracted from the database and analyzed separately. Clinical pregnancy rates in patients who had a single embryo transfer and did not undergo PGT-A were 50.4% in patients less than 35 years old, 47.5% in patients 35-37 years old, 37.7% in patients 38-40 years old, and 26.2% in patients over 40 years old. In patients with a single blastocyst who elected to undergo PGT-A, the clinical pregnancy rate was found to be 60.4% in patients under 35 years old (p=0.15), 61.0 % in patients age 35-37 (p=0.02), 62.3% in patients age 38-40 (p<0.0001), and 55.6% in patients older than 40 (p <0.001). The rate of aneuploidy amongst patients with a single blastocyst undergoing PGT-A was 54.7%; those patients did not undergo embryo transfer and thus were not included in this analysis.

CONCLUSIONS: Use of PGT-A for a single blastocyst was associated with a statistically significant increase in clinical pregnancy rate in women over age 35 who elected to undergo PGT-A prior to frozen single embryo transfer. Despite the retained risk of an aneuploid diagnosis, PGT-A still allows these older than 35 patients to achieve improved pregnancy rates with frozen embryo transfer. Although out-of-pocket costs may be higher and patients should be aware of the high likelihood of embryo aneuploidy, patients with only one blastocyst available still benefit from PGT-A.

SUPPORT: Internally funded.

P-799 4:30 PM Tuesday, October 20, 2020

THE IMPACT OF USING ARTIFICIAL INTELLIGENCE IN REPORTING HIGH RESOLUTION NGS RESULTS UPON PRIORITIZATION OF EMBRYOS SELECTED FOR TRANSFER. Nawal Mohamed Saad, Sr., BSc, Nada Elmegharbel, Ashrakat Abdeltawab, Mona Ashraf, Hanaa Alkhader, Hosam Zaki. Elfostat new city, Cairo, Egypt.

OBJECTIVE: There are many factors that influence the interpretation of the plots of high resolution NGS (hr-NGS) in PGT A examination of the embryos, such as the Genetist experience, cut-off points, and the chromosomal number. The PGT A results differentiate between euploidy embryos that are given first priority for embryo transfer (ET), second priority for low mosaic, and aneuploidy or high level mosaic those who are not transferred . This study compares between manual calling of the results versus using artificial intelligence platform.

DESIGN: This is a prospective ongoing study.

MATERIALS AND METHODS: A total of 720 biopsied sample from 280 patients processed according to Miseq Illumina protocol. Results are manually called subjective methodology (SM) using Bluefuse software and also uploaded up to **PGTai^{SM}** platform Coopersurgical.

RESULTS: The mean age of the female partners is 34 years. There was a difference in 138 results out of 720 (19%) comparing between the "SM" and **PGTai^{SM}** platform interpretation. The following table shows the differences between four categories in both SM and PGTai results:

	SM	PGTai^{SM}
categories	No. of embryos	
Euploid	31	14 low level mosaic 11 high level mosaic 5 aneuploid 1 QA fail
Aneuploid	27	1 low level mosaic 15 high level mosaic 1 euploid 10 QA fail
High level mosaic	29	2 low level mosaic 14 euploid 12 aneuploid 1 QA fail
Low level mosaic	46	12 high level mosaic 28 euploid 5 aneuploid 1 QA fail

The PGTai platform changes some of the results in all reported categories. That would change the prioritization of embryos for transfer. There were 16 embryos that were reported euploidy by SM, while they are deemed "untransferable" by PGTai, being 5 aneuploidy and 11 being of high level mosaic. Again, in the same group 14 embryos were of low mosaic level which would have been given a second priority. In the aneuploidy group only 2 embryos (1 euploid and 1 low level mosaic) would have been possibly transferred according to PGTai.

In the high level mosaic group 16 embryos would have been given priority for embryo transfer as 14 were found euploidy while 2 were of low mosaic level. In the low level mosaic group 28 embryos would have been given first priority as found to be euploid, while 17 embryos would have must been considered to be as 12 of high level mosaic and 5 were aneuploidy.

CONCLUSIONS: PGTai is thought to be more valid than manual subjective calling of results as based upon true data set of live births and sustained pregnancy outcomes. This study shows a strong difference of 19% in results that changes how embryos are prioritized for ET. Moreover, same embryos would have been not transferred as being aneuploidy as of high mosaic level. Further studies are needed to evaluate if using PGTai would improve live birth rate and decrease miscarriage by better selection of embryos.

P-800 4:30 PM Tuesday, October 20, 2020

BATCHING OF BLASTOCYSTS TOGETHER WITH PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A) IS A HIGHLY SUCCESSFUL STRATEGY FOR ADVANCED MATERNAL AGE AND YOUNGER WOMEN WITH DIMINISHED OVARIAN RESERVE. Lilach Marom Haham, MD,[1] Michal Dviri, MD,[2] Adi Kuperman, M.D, MHA,[1] Anjila Roumia, MD,[3] Svetlana Madjunkova, MD, PhD,[1] Clifford Lawrence Librach, MD[1] [1]CReATe Fertility Centre, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]CReATe fertility centre, Toronto, ON, Canada.

OBJECTIVE: In the recent years the number of women at the advanced maternal age (AMA, ≥ 38 years) undergoing fertility treatments is growing, owing to many women delaying childbearing. The increased rate of chromosomal aneuploidy in the AMA population, as well as the low oocyte and embryo yield in women with decreased ovarian reserve (DOR), are leading factors contributing to poor in vitro fertilization (IVF) treatment outcomes. A strategy of accumulating embryos throughout several stimulation cycles, often called batching, increases the number of embryos available for PGT-A, reduces the cost of multiple testing runs, and increases the likelihood of having normal embryos for transfer now and for future pregnancies. However, data regarding the outcomes of this strategy are lacking. The aim of our study was to evaluate the outcomes of batching for PGT-A.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: The study had institutional REB approval. Infertile women performing consecutive IVF cycles for accumulation of blastocysts for PGT-A at the CReATe Fertility Centre (Toronto, Canada) between 2017-2019 were included. Patients were divided to three main groups according to age and ovarian reserve: [1] AMA [2] AMA and DOR [3] DOR. DOR was defined according to POSEIDON groups 3 and 4 or retrieving ≤ 4 oocytes with conventional stimulation protocol. Patients using donor oocytes were excluded. The primary outcomes were number of euploid embryos accumulated per patient, clinical pregnancy rate (CPR), and the number of euploid and mosaic embryos for future usage. T-test and ANOVA were used to compare continuous and dependent variables between the groups. P <0.05 was statistically significant.

RESULTS: A total of 61 patients performed embryo pooling for PGT-A in this cohort. The mean age was 38.9±3.2. The mean number of cycles per patient was 3.4±1.2 (range 2-7). The mean number of total blastocysts, euploid and mosaic embryos accumulated per patient was 6±3 (range 1-17), 2.1±1.7 (range 0-7) and 0.4±0.6 (range 0-2) respectively. 43 of these patients (70.5%) used their embryos and underwent FET cycles yielding a clinical pregnancy rate of 58.9% and a miscarriage rate of only 3.4%. The mean time to pregnancy was 5.8±3 months. The mean number of remaining euploid and mosaic embryos for future usage was 1.5±1.5 (range 0-6) and 0.5±0.7 (range 0-2), respectively. When comparing the three main study groups: 1. AMA (n=21), 2. AMA and DOR (n=20) and 3. DOR (n=13), no significant difference in CPR was observed (48.6%, 64.7%, 50%, respectively; p=0.6), the mean number of remaining euploid (1.6, 1, 1.3, respectively; p=0.3) and mosaic embryos (0.6, 0.3, 0.3, respectively; p=0.2) for future usage.

CONCLUSIONS: To our knowledge, this is the largest series to date of blastocysts batching for PGT-A. This strategy increases the likelihood of having a normal embryo for transfer and may optimize treatment outcomes by exploiting the short "window of opportunity" to preserve normal embryos for future use, for both older women with, or without, DOR, as well as younger women with DOR.

P-801 4:30 PM Tuesday, October 20, 2020

THE ASSOCIATION BETWEEN THE GENDER OF PATIENTS WITH ROBERTSONIAN TRANSLOCATION AND EUPLOID RATE. Jing Wang, M.D,[1] Baomin Lubachela.[2] [1]medical genetic, guangzhou, China; [2]medical examination, guangzhou, China.

OBJECTIVE: To give a better counseling on the chances of available embryos to the robertsonian translocation carriers.

DESIGN: A single center, retrospective, observational study.

MATERIALS AND METHODS: Patients who were robertsonian translocation carriers without other gene or chromosomal diseases were chosen for the study. On the day of occyte retrieval, the semen sample will be tested routinely. Biopsy was performed when the trothectoderm was suitable for the manipulation either on day5 or day6. Six to eight cells were taken routinely for NGS analysis. The patients were divided into two groups based on the gender of robertsonian translocation carries, the male patients group and the female patients group. Moreover, the embryos were divided into euploid group and aneuploidy group according to the NGS results.

RESULTS: A total of 1253 embryos from 156 PGT cycles of 146 couples were enrolled in the study, during July 2017 to September 2019. The male and female patients were 87 and 69, respectively. There were 53 male patients with the known robertsonian translocation suffering poor semen parameters, the abnormal rate was 60.92% compared with 21.74% in the companions of the female patients. Out of 1253 analysed embryos, 1242 had a chromosomal result, indicating that the detection rate was 99.12%. The euploid rate was statistically higher in the male patients group which was 49.26% than the female patients group that was 28.65%(P<0.05). Logistic regression analysis adjusted for male and female ages suggested that the gender of patients had a positive impact on the euploid rate(OR=2.497, 95% CI 1.965-3.173, P<0.001).

CONCLUSIONS: Although the robertsonian translocation has an negative influence on the semen quality which may lead to male infertility, the euploid rate is still acceptable if the patients undergo PGT. This study shows that the male patients have a more bright future when considering the euploid rate, however, the mechanism is still uncertain. We need more fundamental researches to tackle this problem.

P-802 4:30 PM Tuesday, October 20, 2020

ASSOCIATION BETWEEN STANDARD MORPHOLOGY ASSESSMENT AND CHROMOSOME CONSTITUTION AFTER NGS ANALYSIS. Pamela Villanueva, MD, PhD,[1] Huayhua Julio, BSc,[2] Luis Noriega-Hoces, MD,[1] Javier Noriega, MD,[1] Luis Guzman, PhD.[1] [1]Laboratorios de Reproduccion Asistida PRANOR, Lima, Peru; [2]ADN Diagnostico, Lima, Peru.

OBJECTIVE: To determine the correlation between standard morphology assessment and chromosome constitution in blastocyst analyzed by NGS.

DESIGN: Retrospective observational study

Table 1. Association between chromosome constitution and embryo morphology

	Good	Fair	Poor
Euploid	1092 (53.06%)	880 (42.76%)	86 (4.18%)
OR	1	0.74 (0.65-0.84)**	0.70 (0.52-0.94)*
Aneuploid	301 (44.93%)	331 (49.40%)	38 (5.67%)
OR	1	0.99 (0.82-1.19)	0.94 (0.64-1.39)
Mosaic	290 (43.81%)	339 (51.21%)	33 (4.98%)
OR	1	1.25 (1.03-1.51)*	1.25 (0.82-1.89)
Double Aneuploid	86 (39.09%)	109 (49.55%)	25 (11.36%)
OR	1	1.04 (0.75-1.44)	1.94 (1.15-3.26)*
Complex Mix	79 (31.60%)	147 (58.80%)	24 (9.60%)
OR	1	1.54 (1.13-2.10)**	2.03 (1.24-3.33)**

OR (IC 95%): Odds Ratio (Confident Interval 95%),* p<0.05, ** p<0.001.

MATERIALS AND METHODS: Data was collected retrospectively from June 2016 to October 2019. In 1221 IVF cycles, 4719 blastocysts were biopsied and analyzed by NGS. DNA from trophectoderm cells were amplified by using Sureplex, hr-NGS was performed with VeriSeq PGS assay, (MiSeq-Ilumina). NGS data was analyzed with Bluefuse sofware (Ilumina). Chromosome constitution was classified according to the genetic results as: euploid, single aneuploid, double aneuploid, complex aneuploidy (>3 chromosomes are aneuploid), (single, double and complex) mosaic, complex mix and mix (aneuploid and mosaic). Embryo morphology was classified as good, fair, or poor based on SART. Descriptive statistics and multilevel model for logistic regression considering a patient as second level and blastocyst as first level were used to evaluate the association between chromosome constitution and embryo morphology which was adjusted by levels of trophectoderm and inner cell mass, maternal age, fertilization technique and day of embryo biopsy. $p<0.05$ as significant level. All analyses were performed by Stata.

RESULTS: For all blastocyst analyzed the frequency was euploid (43.6%), single aneuploid (14.2%), double aneuploid (4.7%), complex aneuploid (2.4%), single mosaic (14%), double mosaic (4.9%), complex mosaic (7.3%), mix (2.9%) and complex mix (5.3%). Most of the embryos biopsied have a good (46.8%) and fair (47.9%) quality and 5.3% were poor quality.

Euploidy embryos were associated to have good morphology as is shown in table 1. Interestingly, poor embryo quality have a significantly increased frequency of double aneuploidy ($p=0.013$). On the contrary, any associations were found for double mosaic, complex aneuploid and mix.

CONCLUSIONS: NGS results confirmed the association between embryonic morphology and euploidy. Mosaicism was reported more frequently in fair embryos, while double aneuploidy and mixed complex are more associated with embryos with low embryo quality.

P-803 4:30 PM Tuesday, October 20, 2020

BIPARENTAL INHERITANCE OF MITOCHONDRIAL DNA IN RHESUS MACAQUES. Hong Ma, PhD,[1] Hayley Darby, MS,[1] Crystal Van Dyken, BS,[1] Aleksei Mikhalchenko, PhD,[1] Nuria Marti-Gutierrez, PhD,[1] Amy Koski, BA,[1] Dan Liang, PhD,[1] Ying Li, MS,[1] Yeonmi Lee, PhD,[2] Eunju Kang, PhD,[2] Paula Amato, MD,[1] Shoukhrat Mitalipov, PhD[1] [1]Oregon Health & Science University, Portland, OR; [2]ASAN Medical Center, Seoul, Korea, Republic of (South).

OBJECTIVE: It is generally believed that the mitochondrial genome (mtDNA) is inherited exclusively through the maternal lineage from oocytes. We investigated fate of paternal mtDNA in rhesus macaque (*Macaca mulatta*) offspring generated by natural breeding or Assisted Reproductive Technologies (ART).

DESIGN: Live offspring were produced by ART employing intracytoplasmic sperm injection of oocytes with sperm from geographically isolated subpopulations of *Macaca mulatta*. In addition, offspring were generated by natural breeding.

MATERIALS AND METHODS: DNA samples from 28 organs/tissues were collected from monkeys post necropsy and high-depth whole mtDNA sequencing (MiSeq) was used to evaluate contribution of maternal and paternal mtDNA.

RESULTS: Sequencing analyses showed no detectable paternal mtDNA contribution in five of the six tested monkeys. However, mtDNA variants of one monkey produced by natural mating matched to both maternal and paternal mtDNA haplotypes in twenty organs/tissues, with paternal mtDNA heteroplasmy levels ranging from 5% to 33%. Interestingly, paternal mtDNA was absent in eight other organs of this animal, suggesting tissue specific segregation of paternal mtDNA. Analyses of blood samples from additional 10 offspring fathered by this male revealed that one monkey carried variants matched to the paternal mtDNA at 31% heteroplasmy.

CONCLUSIONS: Our results demonstrate paternal mtDNA contribution from one particular male.

P-804 4:30 PM Tuesday, October 20, 2020

TROPHECTODERM BIOPSY PRIOR TO AUTOLOGOUS FROZEN BLASTOCYST TRANSFER IS NOT ASSOCIATED WITH ADVERSE OBSTETRICAL OUTCOMES. Michael S. Awadalla, MD, Kristen E. Park, BA, Kyle R. Latack, BA, Lynda K. McGinnis, PhD, Ali Ahmady, PhD, Richard J. Paulson, MD, MS Keck School of Medicine, University of Southern California, Los Angeles, CA.

OBJECTIVE: To determine if trophectoderm biopsy prior to autologous frozen blastocyst transfer is associated with gestational age at delivery, birth weight, or cesarean rate in ongoing singleton gestations.

DESIGN: retrospective cohort study

MATERIALS AND METHODS: We identified all patients at a university-affiliated center that had viable singleton gestations after autologous frozen blastocyst transfers from January 2016 through December 2018. Obstetrical outcomes of 67 viable singleton pregnancies after blastocyst trophectoderm biopsy for preimplantation genetic testing (PGT) with next generation sequencing were compared to 78 viable singleton pregnancies from unbiopsied frozen blastocysts. All transfers occurred in programmed frozen transfer cycles. Cycles that utilized a gestational carrier, donor oocytes, or frozen oocytes were excluded. Primary outcomes included gestational age at delivery, birth weight, and cesarean rate. The study had 80% power at a significance level of 0.05 to detect a 4-day difference in median gestational age at delivery, 300-gram difference in median birth weight, and 20% difference in cesarean rate. Secondary outcomes included preterm delivery, low birth weight, and birth weight over 4000 grams.

RESULTS: There were no significant differences between the two groups in terms of maternal age, BMI, or ethnicity. There were no differences in the PGT cohort compared to the reference cohort for median gestational age at delivery, median birth weight, cesarean rate, preterm delivery rate, rate of low birth weight, or rate of birth weight over 4000 grams (Table). There were no differences in the primary outcomes for subgroup analysis based on fetal sex, single embryo transfer, nulligravid, and no history of prior term birth.

CONCLUSIONS: Trophectoderm biopsy prior to frozen blastocyst transfer is not associated with adverse obstetrical outcomes related to gestational age at delivery, birth weight, or cesarean rate.

	No PGT (ref) n = 78	PGT n = 67	RR (95% CI)	P value
Demographics and baseline characteristics				
Maternal age (SD)	35.6 (4.3)	35.8 (3.7)		0.77
Maternal BMI kg/m^2 (SD)	24.5 (5.4)	24.0 (5.2)		0.59
Number of embryos transferred	1.6 (0.6)	1.2 (0.4)		< 0.01

P-805 4:30 PM Tuesday, October 20, 2020

MUTATION ANALYSIS AND CHARACTERIZATION OF COL7A1 C.4531_4564-42DEL FROM TROPHECTODERM (TE) BIOPSIES USING NEXT GENERATION SEQUENCING (NGS) SIMULTANEOUSLY WITH PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A). Xin Tao, Ph.D,[1] Li Ma, BS,[1] Yiping Zhan, Ph.D,[2] Heather Garnsey, BS, MPS,[1] Richard Thomas Scott, Jr., MD,[3] Chaim Jalas, N/A[1] [1]Foundation for Embryonic Competence, Basking Ridge, NJ; [2]The Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: The COL7A1 gene encodes a protein called pro-α1(VII) chain that is used to assemble a larger protein called type VII collagen. Type VII collagen plays an essential role in strengthening and stabilizing the skin. Mutations in *COL7A1* can cause Dystrophic epidermolysis bullosa (DEB). Each of the couple undergoing IVF carries a recessive mutation in COL7A1. The patient carries a point mutation (c.266+2T>C), which can be detected by mutation direct Taqman qPCR genotyping assay. The partner carries an 87 base pair (bp) deletion (c.4531_4564-42del), which can't be detected by Taqman genotyping assay, or informative SNPs within the deletion region. No partner's parental DNA is available to set up linkage analysis. In this study, we developed an NGS assay to detect the 87bp deletion from TE biopsies. The PGT-A by NGS was performed simultaneously.

DESIGN: Experimental study.

MATERIALS AND METHODS: A primer pair amplifying 214bp amplicon which covered the 87bp deletion was designed and added to the primer pool for PGT-A and c.266+2T>C point mutation. c.266+2T>C point mutation was detected by Taqman assay. Sequencing was performed on Illumina NextSeq 550 using single 150bp reads. Reads were aligned to a human referenc genome (GRCh37/hg19) with the Burrows-Wheeler Aligner (BWA). PGT-A was analyzed using an in-house clinical established bioinformatics workflow. c.4531_4564-42del was evaluated using Integrative Genomics Viewer (IGV) 2.3.

RESULTS: The workflow was validated on parental DNA and 5-cell samples. Eight TEs from usable blastocysts were tested for PGT-A and COL7A1 PGT-M. All the embryos were euploid. One embryo inherited maternal c.266+2T>C point mutation, three embryos had paternal c.4531_4564-42del variant, and one embryo showed compound heterozygous, which would not be suitable for transferring. The remining three embryos were negative for both mutations. There were four carrier embryos and three wild type embryos available for transfer.

CONCLUSIONS: This study provided a new strategy to access the microdeletion for PGT-M when there is no linkage analysis available.

P-806 4:30 PM Tuesday, October 20, 2020

HOW EFFECTIVE IS TARGET SEQUENCE ENRICHMENT DURING WHOLE GENOME AMPLIFICATION ON THE IMPROVEMENT OF PGT-M RESULTS? Evrim Unsal, Assoc Prof,[1] Leyla Ozer, MD, PhD,[2] Merve Polat, PhD,[2] Suleyman Aktuna, PhD,[2] Volkan Baltaci, MD, PhD[3] [1]cinnah caddesi 47/1, ankara, Turkey; [2]Yuksek Ihtisas University, Ankara, Turkey; [3]Yozgat Bozok University, Yozgat, Turkey.

OBJECTIVE: PGT-M has been applied for many years for any genetic disease that can be diagnosed. Development of Whole Genome Amplification (WGA) technologies enabled simultaneous monogenic disease testing and euploid embryo selection (combined PGT). As a result of widespread use of whole exome/genome sequencing technologies, variety of single gene diseases referred for PGT-M has started to increase thus leading to a considerable elevation in the number of setup studies conducted for rare diseases.

DESIGN: In this context, a steady test setup and uniform WGA unaffected by the Alel Drop Out (ADO) trap, has become a necessity. For this purpose, here we demonstrate that ADO ratio is reduced for a wide range of PGT-M conditions using target sequence enrichment (TSE), which also allows sequential aneuploidy screening.

MATERIALS AND METHODS: 739 biopsy samples from 118 PGT-M patients were classified in three groups: PGT-M only (group 1; 389 biopsy samples/56 patients), combined PGT (group 2; 108 biopsy samples/23 patients), combined PGT with TSE (group 3; 242 biopsy samples/39 patients). Doplify Kit (PerkinElmer) and in house designed target sequence specific primers were used for WGA. Initially, routine STR based PGT-M protocol using biopsies directly (group 1), WGA products without TSE (group 2) or with TSE (group 3) was followed. After the selection of eligible embryos, WGA samples were further processed using PG-Seq Kit (PerkinElmer), with (10 samples) or without further mutation specific enrichment for direct mutation analysis and aneuploidy screening.

RESULTS: According to our findings, ADO ratio was 2% and 7.1% for group 1 and 2 respectively. On the other hand, ADO ratio for group 3 was 3% showing that TSE protocol dramatically reduces ADO ratio compared to similar patient gropus without TSE. Eventhough blastomere use for WGA is contradictory, blastomere biopsies were included in this study. ADO ratio was unquestionably high for blastomere; 8.1% in group 1 and 13.3% in group 2. Only 7 blastomere biopsies from 2 patients were included in group 3 and ADO was not observed. In order to prove this result, additional data for blastomere cell type are needed. Moreover, we further processed 30 WGA products obtained from group 3 for both mutation confirmation and aneuplody screening. This methodology allows us to detect mutation regions with high read depth (500X-4000X) together with aneuploidy screening for 24 chromosomes.

CONCLUSIONS: In combined PGT applications, WGA is the most critical stage and TSE increases the accuracy of the test. Eventhough a potential saturation in STR markers is expected , the number of new designs for novel conditions is still increasing annually. Most patients referred to our center carries a rare disease thus STR markers are designed almost solely for that patient. This creates an extensive STR bank which is seldomly used for a couple of cases due to this high variability in PGT demand. TSE method is valuable especially for such laboratorie,since it allows combination of PGT-M and PGT-A by using existing STR markers and primers thus enables efficient use for primers for rare disorders.

P-807 4:30 PM Tuesday, October 20, 2020

COMPARISON OF ETHICAL PERSPECTIVES OF INDIVIDUALS CONSIDERING PREIMPLANTATION EMBRYO GENETIC TESTING FOR ANEUPLOIDY (PGT-A) VS. MONOGENIC DISORDERS (PGT-M). Jiahui Zhang, BA,[1] Lisa M. Pastore, PhD,[2] Lisa R. Rubin, PhD[3] [1]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY; [2]Stony Brook Medicine, Stony Brook, NY; [3]The New School, New York, NY.

OBJECTIVE: To identify and compare patient perspectives toward the ethics of preimplantation genetic testing among patients considering using PGT to screen for aneuploidy (PGT-A) and monogenic disorders (PGT-M).

DESIGN: A cross-sectional study of patient perspectives using an online questionnaire.

MATERIALS AND METHODS: A 17-item questionnaire was created to assess various ethical concerns regarding the use of PGT, including clinical indications for PGT, the greater implications of PGT for society, and unused embryo disposition. A total of n=152 patients from 31 US states who recently considered using PGT-A (n=80) or PGT-M (n=72) completed the questionnaire. Chi-square and Fishers' exact tests were run in STATA with α=0.05.

RESULTS: The majority of respondents in both PGT-A and PGT-M groups were female (92%), married (91%), white non-Hispanic (80%), and educated at or beyond a college level (89%). The majority of both PGT-A and PGT-M considerers supported using PGT to screen for diseases fatal in childhood (86-89%), those causing lifelong disabilities (76-79%), and those arising in adulthood and have no treatment (60-67%). Similar proportions of PGT-A and PGT-M considerers opposed using PGT to screen for physical (80-87%) or intellectual traits (74-86.0%). More PGT-M than PGT-A considerers opposed the implantation of genetically abnormal embryos when requested by parents (29% PGT-A vs. 56% PGT-M, $p = 0.007$). Respondents in both groups agreed that PGT aids in parental decision-making, although some expressed concern over its potential to further socioeconomic inequalities or lead to unforeseen consequences. Regarding the disposition of embryos without known genetic defects, more PGT-A considerers favored freezing (95% PGTA vs. 82% PGT-M, $p = 0.018$) or donating to research (73% PGT-A vs. 57% PGT-M, $p = 0.044$) than PGT-M considerers. For embryos with known genetic abnormalities, more PGT-M considerers supported donating to research than PGT-A considerers (56% PGT-A vs. 81% PGT-M, $p = 0.001$).

CONCLUSIONS: PGT-A and PGT-M considerers agreed on the clinical indications for PGT by supporting its use in screening for disease conditions and opposing its use in trait selection. PGT-A and PGT-M considerers also agreed that PGT aids in parental decision-making. More PGT-M considerers opposed the implantation of a genetically abnormal embryo when requested

by parents. More PGT-A considerers supported freezing embryos without known genetic defects or donating them to research, while more PGT-M considerers supported donating embryos with known genetic defects to research.

P-808 4:30 PM Tuesday, October 20, 2020

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDIES (PGT-A) IS NOT ASSOCIATED WITH IMPROVED LIVE BIRTH RATES IN PATIENTS UNDER 35 YEARS OLD. Elnur Babayev, MD, MSc,[1] John X. Zhang, PhD,[2] Marymllen Pavone, MD[1] [1]Northwestern University, Chicago, IL; [2]Northwestern Medicine, chicago, IL.

OBJECTIVE: Preimplantation genetic testing for aneuploidies (PGT-A) is being widely used in ART practice. Although the rate of aneuploidy is significantly lower in younger patients, the availability of PGT-A has led to significant utilization of this technology in this group. The goal of this study was to analyze the association of PGT-A with live birth rates (LBR) in patients under 35 years old.

DESIGN: This was a retrospective observational study

MATERIALS AND METHODS: We analyzed single blastocyst transfer outcomes in patients <35yo in our institution from Jan/1/2015 to Jun/1/2018. Only the first embryo transfers in each group were evaluated. Outcomes of first fresh blastocyst transfer was compared to first frozen blastocyst transfer with or without PGT-A. Live birth rates were compared using Odds Ratio. Chi-Square test was used for statistical analysis. $p < 0.05$ was considered statistically significant. We also compared clinical pregnancy rate (CPR), miscarriage, biochemical and ectopic pregnancy rates among groups.

RESULTS: 264 fresh single blastocyst and 228 frozen single blastocyst transfers were performed, which included 158 untested (FET) and 70 euploid embryos (FET-euploid). 65% of all biopsied embryos were euploid. Overall, live birth rate was 52.5%. LBR following fresh ET was 48.5%. Euploid transfers had 58.6% LBR, and for untested FETs this number was 56.3%. FET alone or FET with euploid blastocysts was not associated with increased live birth rates when compared to fresh transfers in patients <35yo, OR 1.39 (95% CI 0.93-2.07) and 1.5 (95% CI 0.88-2.55), respectively. This analysis showed a non-significant trend of increased LBR in FET and FET-euploid groups compared to fresh transfers. However, LBR was not different between FET and FET with euploid groups, OR 1.08 (95% CI 0.61-1.91). CPR showed a similar trend, but was not significantly different between fresh, FET and FET-euploid groups. Miscarriage rates were also not significantly different; 16%, 14%, and 13% for fresh, FET and FET-euploid cycles, respectively. We had 4 ectopic pregnancies in fresh transfer group and one in FET group. Biochemical pregnancy rate was significantly lower in FET group 0.25 (CI 95% 0.11-0.58) compared to fresh transfers, but not significantly different between FET and FET-euploid groups.

CONCLUSIONS: PGT-A is not associated with improved live birth rates in patients <35yo. The trend of increased LBR observed in this age group with FET cycles, both untested and FET-euploid, is likely secondary to cryopreservation and subsequent embryo transfer in frozen cycle, which points to the role of endometrial factors. Prospective studies examining the role of PGT-A in younger patients should compare euploid embryo transfers to frozen untested embryo transfers, instead of fresh transfers, given potential benefit of cryopreservation in this age group. Decreased biochemical pregnancy rate in FET cycles at least partially explains the trend of increased LBR compared to fresh cycles in our study.

P-809 4:30 PM Tuesday, October 20, 2020

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY: IS IT REALLY COST EFFECTIVE? Michael Saad-Naguib, MD, Douglas Timmons, MD, MPH, George R. Attia, MD, MBA University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) is increasingly used in patients undergoing in vitro fertilization (IVF).[1] However, this is not without debate.[2] Physicians must also factor in additional costs for aneuploidy testing. Neal et al. created a decision analytic model showing IVF with PGT-A can reduce costs when compared to IVF alone in patients with more than 1 embryo.[1] However, the multi-center STAR trial by Munne et al. concluded PGT-A did not improve overall pregnancy outcomes in all women.[2] With this new finding, we question the cost efficacy of PGT-A. To our knowledge, no cost efficacy studies have been done with the findings of the STAR trial. We plan to demonstrate a theoretical model using the new findings from the STAR trial in which we will determine if PGT-A is cost effective.

DESIGN: An IRB exempt hypothetical cost-analysis study.

MATERIALS AND METHODS: In this hypothetical study, we created a comparison model with 100 patients undergoing single frozen embryo transfer in a PGT-A group and 100 control IVF patients. We performed an analysis between patients less than 35 years old and a subsequent analysis looking at patients 35-40 years old. Procedural costs were based on those used in our clinic. All costs up to the point of embryo biopsy were assumed to be equal. Pregnancy and live birth rates in the non-PGT group were based on SART data. The percentage of euploid embryos in the PGT-A group were obtained from the STAR trial. Each group of patients was then taken thru 2 frozen embryo transfer cycles. After this, the cost per live birth in each cycle and the average cost per live birth over two cycles was determined.

RESULTS: In patients less than 35 years old undergoing IVF without PGT, the cost per live birth in the 1st cycle was $12,500, while the cost per live birth after the second cycle was $26,785. In women under 35 undergoing IVF with PGT-A, the cost per live birth after one cycle was $21,250, and the cost after two cycles was $31,250. In patients 35-40 years old using IVF without PGT-A, the cost per live birth was $18,518 after one cycle and $42,800 after the second cycle. In the 35-40 year old PGT-A group, the cost per live birth after one cycle was $26,176. After two cycles, the cost was $36,176. The average cost per live birth over 2 cycles in patients under 35 with and without PGT-A was $24,583 and $17,417, respectively. The average cost per live birth over 2 cycles in patients 35-40 years old with and without PGT-A was $29,637 and $27,190, respectively.

CONCLUSIONS: This data further demonstrates PGT-A is not cost effective in patients under 35 years old. In light of the new data from the STAR trial, in patients 35-40 years old, PGT-A is cost neutral if a patient requires two cycles of frozen embryo transfer.

THE INCIDENCE AND PARENTAL ORIGIN OF WHOLE AND SEGMENTAL ANEUPLOIDIES IN HUMAN IMPLANTATION EMBRYOS. Jing Wang, M.D,[1] Baomin Lu bachela.[2] [1]Medical genetic, Guangzhou, China; [2]medical examination, guangzhou, China.

OBJECTIVE: To investigate the incidence and parental origin of whole and segmental aneuploidies in human early embryos and identify the relationship between the aneuploidies and parental origin and age.

DESIGN: This is a retrospective observational study. A total of 2232 trophectoderm biopsies from 235 couples who underwent 278 PGT-M cycles from 2015 to February 2020 were identified.

MATERIALS AND METHODS: The average age of the female was 31.76±4.075 years, while that of the male was 34.26±5.137 years. All couples had normal karyotypes, due to monogenetic disease to perform with preimplantation genetic testing. Aneuploidy screening was performed by quantitative analysis by SNP array. Meanwhile, haplotypes were constructed using the genotypes of the parent and the reference. Then, the parental origin of aneuploidy was determined by the haplotype results of the embryo.

RESULTS: In 2232 biopsy samples, the incidence of chromosomal aneuploidy (both whole and segment) was 27.2% (608/2232). Only one chromosomal aneuploidy was detected in 462(76.0%) of the TE samples, of which 437 involved autosomal chromosomes. 73.7% (322/437) were the whole chromosome aneuploidies, and 26.3% (115/437) were segmental aneuploidies. The trisomy accounted for 39.8%, and the monosomy accounted for 60.2%. The whole chromosome abnormally was mainly caused by the maternal chromosome abnormality. On the contrary, the segmental aneuploidy was mainly caused by the paternal chromosome abnormality. The incidence of whole chromosome aneuploidy from maternal chromosome errors was higher in the group of women over the age of 35 years, comparing with the group of women under the age of 35 years (trisomy, 9.0% *vs* 3.2%, *p=0.000*; monosomy, 12.5% *vs* 5.3%, *p=0.000*). There was no significant difference in segmental aneuploidy between mother and father ages.

CONCLUSIONS: Only single autosomal abnormalities were analyzed. The whole chromosome abnormally was mostly caused by the abnormality of maternal origin, and the haplotype analysis of trisomy showed that it was mostly caused by the error of MI. The incidence of trisomy and monosomy was increased with the increase in maternal age. For segmental aneuploidy, especially the loss, it seems that paternal abnormalities were more common. Neither paternal segment loss nor maternal segment loss was associated with age.

PGT-A DOESN'T SEEM TO BENEFIT RECURRENT IMPLANTATION FAILURE COUPLES TO OPTIMIZE LIVE BIRTHS. Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology, Shankhadeep Debnath, MSC Molecular Biology and Biotechnology, Nandita Relekar Sanjay Relekar, Master in Clinical embryology, Durga Gedela Rao, Sr., MRCOG Oasis fertility, Hyderabad, India.

OBJECTIVE: To assess the role of Pre-Implantation Genetic Testing for Aneuploidy (PGT-A) in couples with Recurrent Implantation failure (RIF) to optimize Live Birth Rates (LBR).

DESIGN: This is retrospective data of couples at our private fertility teaching clinic, with RIF and undergoing PGT-A (n=54) during January 2014 to July 2019. Women with RIF and no PGT-A acted as control (n=189) for this study. Women with at least two fresh/frozen embryos transfers with minimum 4 blastocysts transferred in total and never conceived were considered as RIF and offered PGT-A.Only women with one euploid embryo, who underwent frozen embryo transfers (FET) were recruited in this study.Women of all age groups who had Blastocysts available for transfer were included in the study.Only self-gamete cycles were considered in this study.

MATERIALS AND METHODS: All the women with RIF underwent controlled ovarian stimulation and oocyte retrieval as per our clinic's standard operating protocol (SOP). ICSI was the choice of insemination considering history of failed implantation, fertilized oocytes were cultured till blastocysts and freeze all policy was adopted. Blastocysts were biopsied and trophectoderm tissue was subjected to genetic testing through Next-Generation Sequencing (NGS). Study group women underwent elective Single Euploid Blastocyst transfer (eSET) and control group women underwent transfer with un-screened double Blastocyst Transfer (DET) in a frozen cycle. Primary Outcome was LBR and secondary outcomes – Miscarriage Rates (MR), Multiple Pregnancy Rates (MPR), Implantation Rates (IR) and Time To Pregnancy (TTP) (from Oocyte retrieval to clinically viable pregnancy)

RESULTS: Mean of Reproductive outcomes in Study Vs Control Group were as follows:

IR - 47.50 % vs. 41.50% (p value 0.45)
MR - 9.25% vs. 17.89% (p value 0.18)
MPR- 0% Vs 17% (p value 0.0012)
LBR - 46.8% vs 45 % (p value 0.82)
TTP was 6.5 months vs. 9.5 month.

Outcomes in Study and Control Group are comparable in this study. eSET of Euploid embryo and Un-Screened DET seem to be offering similar pregnancy outcomes in RIF patients, except for higher MPR in control group.

Data from this study is questioning the role of PGT-A in RIF patients to improve LBR. Transferring a Euploid eSET only seems to offer lower MPR and shorter TTP in RIF couples.

CONCLUSIONS: PGT-A for RIF couples doesn't seem to improve take home baby rates. Couples need to be counselled appropriately while offering PGT-A for RIF.

P-812 4:30 PM Tuesday, October 20, 2020

DOES POOR BLASTOCYST MORPHOLOGY IMLPY LOWER EUPLOIDY RATE IN PATIENTS UNDERGOING PGT-A? Shujing He, MM,[1] Lei Jia, Master,[2] Wenlong Su, MS,[3] Cong Fang, PHD, MD[4] [1]The Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [3]Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [4]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: The aim of this study is to figure out whether poor blastocyst morphology implies lower euploidy rate and whether blastocysts of low morphological scores deserve to be performed trophectoderm (TE) biopsy.

DESIGN: This is a single center retrospective observational study performed between June 2018 and April 2020.

MATERIALS AND METHODS: The study included the data analysis of 798 blastocysts from 197 couples undergoing preimplantation genetic testing for aneuploidies (PGT-A) via next generation sequencing. According to the patients' chromosome karyotype, blastocysts were divided into two groups: preimplantation genetic screening (PGS, patients with normal chromosome karyotype) and preimplantation genetic diagnosis (PGD, patients with chromosomal rearrangements). According to the Gardner grading system, the morphological score of good quality blastocyst was $\geq$3BB, and that of poor quality blastocyst was <3BB (including 3BC, 3AC, 4BC, 4CB, 4CA and 4AC). We also analyzed the impact of maternal age by dividing female into young group (age<35) and old group (age$\geq$35). Chi-square test was used to assess differences. All statistical analysis was performed using SPSS 22.0. P <0.05 were considered to be statistically significant.

RESULTS: Euploidy rate in total PGT-A was 41.2% (259/628) and 28.2% (48/170) in good and poor quality blastocyst groups, respectively (P<0.01). In PGD group, euploidy rate was 37.1% (159/429) and 18.9% (18/95) in good and poor quality blastocyst groups (P<0.01), which indicated that blastocyst morphology was significantly associated with genetic condition (euploidy or aneuploidy). Whereas, there was no statistical differences in PGS group. For patients undergoing PGS, euploidy rate was 50.3% (100/199) and 40.0% (30/75) in good and poor quality blastocyst groups, respectively (P>0.05). When considering maternal age, in young group, there was strong association between blastocyst morphology and euploidy rate. Euploidy rate was 42.5% (211/497) and 29.8% (39/131) in good and poor quality blastocyst groups, respectively in young group (P<0.01). But in old group, euploidy rate was36.6% (48/131) and 23.1% (9/39) in good and poor quality blastocyst groups (P>0.05).

CONCLUSIONS: Poor blastocyst morphology implied lower euploidy rate in patients undergoing PGD. For patients undergoing PGS, it is worthy to perform trophectoderm (TE) biopsy of blastocysts of low morphological scores. And TE biopsy of poor quality blastocysts may benefit the patients with advanced maternal age.

NON-INVASIVE CHROMOSOME SCREENING AND ITS CORRELATION AGAINST RANKING PREDICTION MADE BY ERICA, A DEEP-LEARNING EMBRYO RANKING ALGORITHM. Alejandro Chavez-Badiola, MD,[1] John J. Zhang, MD, PhD,[2] Adolfo Flores-Saiffe Farias, Sr., MSc, PhD,[1] Gerardo mendizabal-Ruiz, PhD,[3] Meir Olcha, MD,[4] Andrew J. Drakeley, MD FRCOG,[5] IVF 2.0[1]IVF 2.0 LTD, Maghull, United Kingdom; [2]New Hope Fertility Center, New York City, NY; [3]Universidad de Guadalajara, Guadalajara, Mexico; [4]New Hope Fertility Center, New York, NY; [5]Liverpool Women's Hospital, Liverpool, United Kingdom.

OBJECTIVE: to compare euploidy predictions made by ERICA, a deep-learning embryo-ranking tool, against the results of a non-invasive chromosomal screening (NICS)

DESIGN: prospective, comparative study at a single New Hope Fertility Center

MATERIALS AND METHODS: blastocyst images aimed for NICS were collected through the erica.embryoranking.com platform over six consecutive months (September 2019 to March 2020). Inclusion criteria were i) NICS performed on all the embryos at blastocyst stage in the given cycle; ii) woman's age <45 years old. Exclusion criteria included: i) Genetics' report of mosaics; ii) insufficient DNA report or mosaicism; iii) unclassifiable embryos due to low quality images. ERICA's generated prognoses were retrieved from the platform, and compared against the NICS report using confusion matrix analysis. True euploid proportion Z test was performed between the good/bad prognosis groups in relation to ERICA's predictions.

RESULTS: a total of 595 embryo images (218 cycles), were considered for this study. After applying inclusion and exclusion criteria, only 109 embryo images were included for analysis (29 euploid). 46 images were excluded due to age constraints; 410 due to poor quality in the image; 5 due to insufficient DNA; and 34 due to a report of mosaics. ERICA had a 0.75 specificity and an overall accuracy of 0.66 against NICS report. Euploid proportion of poor prognosis embryos according to ERICA (score < 0.5) was 17/77 (22%); euploid proportion of good prognosis embryos (ERICA score >0.5) was

12/32 (37.5%). We computed the Z-score for two population proportions and obtained Z= -1.66, for a p-value of 0.0485.

CONCLUSIONS: on the one hand, predicting ploidy has proven challenging even for well stablished although controversial tests (i.e. T-biopsy PGT-A). On the other hand, ERICA has previously shown a good correlation against PGT-A. Since both NICS, and ERICA are non-invasive studies aimed at classifying embryos in accordance to their ploidy status, we wondered if the previous correlation shown against PGT-A were to be maintained in this feasability study. Results suggest ERICA was better than chance at predicting ploidy, although it didn't achieve the previously reported accuracy against PGT-A, we expect further training, and a larger testing sample might improve ERICA's predicting capabilities. NICS still has to prove its value as a replacement for the classic PGT-A, which lends an opportunity to test, in a future study, the outcome of the combination of both technologies as a comprehensive non-invasive embryo assessment. Although reporting on DNA amplification during NICS is beyond the reach and objective of this study, we found the low rate of tested embryos with failed DNA amplification noteworthy (<1%). Further studies testing ERICA against NICS should increase the sample size.

P-814 4:30 PM Tuesday, October 20, 2020

DOES PRE-IMPLANTATION GENETIC TESTING FOR ANEUPLOIDY OPTIMISE THE REPRODUCTIVE OUTCOMES INWOMEN WITH IDIOPATHIC RECURRENT PREGNANCY LOSS? Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[1] Sherin Mathew, MSc,[1] Shivanand Soorve, Sr., BSc,[1] Durga Gedela Rao, Sr., MRCOG,[1] Sandeep Karunakaran, Sr., M.B.B.S, MS, PGDHM, PGDMLE[2] [1]Oasis fertility, Hyderabad, India; [2]oasis fertility, Hyderabad, India.

OBJECTIVE: To evaluate the role of Pre-Implantation Genetic Testing for Aneuploidy (PGT-A) for improving live birth and reducing miscarriage in patients with Idiopathic Recurrent Pregnancy Loss (RPL).

DESIGN: This is a retrospective study where patients with previous two or more pregnancy loss (idiopathic) who underwent IVF cycles in the period of January 2014 to June 2019 were considered. A total of 112 patients were analysed for the study. Out of which 82 patients underwent PGT-A (n=82) and 30 patients did not underwent PGT-A (n=30), but had history of RPL considered as the control group.

MATERIALS AND METHODS: All the women underwent controlled ovarian stimulation and oocyte retrieval as per our clinic's standard operating protocol (SOP). ICSI was the choice of insemination considering history of multiple pregnancy loss, fertilized oocytes were cultured till blastocysts. Day 5, day 6 biopsy was done in study group and freeze all policy was adopted. Trophectoderm biopsy and Next-Generation Sequencing (NGS) were used for PGT-A. Study group underwent elective Euploid Single Embryo Transfer (eSET) in a Frozen Embryo Replacement cycle (FET). Control group underwent transfer of two blastocysts (DET) in FET cycle. Live Birth Rate (LBR), Multiple Pregnancy Rates (MPR) and Miscarriage Rate (MR) were considered as primary outcomes. Aneuploidy rates were evaluated in the study group.

RESULTS: Mean reproductive outcomes in Study Vs Control group were as follows: MR - 9.68% vs 23.33% (p value 0.0610) MPR – 0% Vs 10% (p value 0.0039) LBR- 32.32% vs 30.00% (p value 0.8160) Aneuploidy in Study group - 55.74% No difference in LBR was observed when PGT-A was introduced in RPL patients. However a marked reduction in MR was observed with PGT-A in RPL patients. In Idiopathic RPL women, though the incidence of miscarriage comes down with transfer of an Euploid embryo, take home baby rates doesn't seem to improve. Role of PGT-A for RPL women needs further research through well designed randomized control trials.

CONCLUSIONS: PGT-A as an intervention for Idiopathic RPL women doesn't seem to improve Live Birth.

P-815 4:30 PM Tuesday, October 20, 2020

IS IT POSSIBLE TO DETECT ALL SEGMENTAL CHROMOSOMAL IMBALANCES WITH NGS USING CUSTOM ANALYSIS ALGORITHMS? Merve Polat, PhD,[1] Volkan Baltaci, MD, PhD,[2] Leyla Ozer, MD, PhD,[1] Evrim Unsal, Assoc Prof,[3] Suleyman Aktuna, PhD[1] [1]Yuksek Ihtisas University, Ankara, Turkey; [2]Yozgat Bozok University, Yozgat, Turkey; [3]cinnah caddesi 47/1, ankara, Turkey.

OBJECTIVE: Next Generation Sequencing (NGS) has been used for PGT of chromosome rearrangements with a resolution of ≥ 5-20 Mb, which is declared detection limit of available commercial kits. However, many patients carry a chromosome rearrangement below these detection limit values thus a customized analysis approach enables effective use of this method for a broad range of chromosomal imbalances.

DESIGN: In this study we aimed to detect small unbalanced chromosome segments (≥1 MB) below manufacturer's recommended resolution limits.

MATERIALS AND METHODS: NGS library of genomic DNA from 4 patients with unbalanced segmental imbalances were prepared using PG-Seq Kit 2.0 (PerkinElmer), 48 samples were sequenced with MiSeq (Illumina) and analysed with PG-Find Analysis Software. Six small unbalanced chromosome segments previously detected with Microarray were evaluated with the sizes of 0.5 MB to 4.5 MB. Three of patients included in the study had products of familial subtelomeric translocations and one of them had a product of familial paracentric inversion. Reanalysis was performed for samples, where standard analysis fails to detect target rearrangements with specific analysis algorithm to focus on target regions by altering filtering paramateres. Each sample was assessed for the size of the segmental gain/loss (Mb), copy number for each segment, concordance with Microarray results and was compared in terms of different algorithms we used.

RESULTS: NGS was capable of detecting 7/8 (87.5%) unbalanced segments previously identified using Microarray. 6/8 (75%) of variants were ≤4.5 Mb. The rest of variants were 8.6 MB and 17.9 MB respectively (Table 1). One of the variants was very small (0.5MB) that we couldn't detect by NGS. According to assessment of individual data quality, optimum number of reads was 500000 per sample to detect segmental gains/losses ≥1 MB.

CONCLUSIONS: This study has shown that analysis with different filtering algorithms makes NGS qualified to detect unbalanced chromosome rearrangements ≥1 Mb. Further studies can be designed with lower sample size (24) in order to increase read/sample, which may enable detection of chromosomal imbalances bellow 1 MB. Further studies with PGT samples should be required to define the detection limit of NGS method.

Table 1. True positive detection of CNV's with customized analysis algorithm is presented.

CNV Size	Standard Algorithm	Customized Algorithm
1,4 MB	NO	YES
17,9 MB	YES	YES
2,6 MB	NO	YES
1,15 MB	NO	YES
1,2 MB	NO	YES
4,5 MB	NO	YES
8,6 MB	YES	YES
0,5 MB	NO	NO

POSTER SESSION: REGENERATIVE MEDICINE AND STEM CELLS

P-816 4:30 PM Tuesday, October 20, 2020

EXOSOMES DERIVED FROM MENSTRUAL BLOOD-DERIVED STROMAL CELLS RESTORED OVARIAN FUNCTION IN RAT MODEL OF PREMATURE OVARIAN INSUFFICIENCY. Siwen Zhang, Master, Jichun Tan, PhD, Pingping Li, PhD Shengjing Hospital of China Medical University, shenyang, China.

OBJECTIVE: Premature ovarian insufficiency (POI) is one of the major causes of infertility. We previously demonstrated that transplantation of menstrual blood-derived stromal cells (MenSCs) effectively improved ovarian function in POI murine model. Recent studies indicated that MSC-derived exosomes were important components in tissue repair and enhanced oocyte activity in vitro. In this study, we investigated the therapeutic effects of exosomes derived from MenSCs (MenSCs-Exos) in POI model and its mechanism in restoring ovulation.

DESIGN: MenSCs-Exos was prepared from serum-free culture media of MenSCs by ultra-centrifugating. Rat POI models were established and we

evaluated the therapeutic effect of MenSCs-Exos on ovarian restoration *in vivo* and its mechanism.

MATERIALS AND METHODS: Rat POI models were established by intraperitoneally injection of VCD. 48 POI model rats were randomly assigned to four groups received different treatment: PBS, MenSCs, MenSCs-Exos and exosome-free MenSCs culture supernatant. Estrous cycle, ovarian morphology, follicular composition, serum hormones, fertility and molecular changes were investigated.

RESULTS: MenSCs-Exos significantly promoted the proliferation and development of primordial and primary follicles. MenSCs and MenSCs-Exos were stromal tropism in POI ovaries. Both MenSCs and MenSCs-Exos application effectively restored the estrous cycle, regulated the serum level of E2 and AMH and FSH, markedly improved the live birth outcome in POI rats. MenSCs and MenSCs-Exos treatment regulated the compositions of follicular extracellular matrix and up-regulated the expressions of Dazl and Foxl2 in ovary cortex.

CONCLUSIONS: Overall, MenSCs-Exos markedly improved ovarian reserve and promoted fertility in POI rats, suggesting an ovarian restorative effect. The therapeutic effect of repeated application of MenSCs-Exos was sustainable, which was consistent with that of MenSCs transplantation. Our results indicated MenSCs-Exos is a promising cell-free bioresource in the treatment of POI.

P-817 4:30 PM Tuesday, October 20, 2020

LONG-TERM ENGRAFTMENT AND SAFETY OF HUMAN BONE MARROW DERIVED CD133+ CELLS IN A RAT MODEL OF ASHERMAN'S SYNDROME. Xavier Santamaria, MD, PhD,[1] Nanda Kumar, PhD,[2] Carlos Simon, MD, PhD[3] [1]Asherman Therapy, Paterna, Spain; [2]Universitat de Valencia, Paterna, Spain; [3]Igenomix Foundation, INCLIVA, Valencia, Spain, Department of Obstetrics and Gynecology, Valencia University, valencia, Spain, Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Valencia, Spain.

OBJECTIVE: Asherman Syndrome (AS) is defined by presence of intrauterine adhesions, due to the loss of endometrial stem cells. CD133+ bone marrow-derived stem cells (BMDSCs) contribute to human endometrium regeneration and represent an advanced cell therapy to treat this disease. Our aim is to describe the short-term and long term engraftment as well as safety and Mechanisms of Action (MoA) of pure and stable population of human CD133+ cells in a model of AS with athymic rats.

DESIGN: Prospective randomized controlled trial in AS athymic rats conducted in Good Laboratory Practice (GLP) and Good Manufacturing Practices (GMP) conditions.Human cells were obtained from voluntary donors from the study PreENTIRE (NCT03665649)

MATERIALS AND METHODS: CD133+ BMDSCs were mobilized after injecting Granulocyte Colony Stimulating Factor in three healthy donors with a mean age of 34,4 years-old (range 22-43), and isolated with CliniMACS. Potency, stability and viability was assessed as well as FACS analysis for peripheral blood markers (CD56, CD66b, CD14,CD19, CD3, CD45 and CD34) and endothelial markers (CD31, VE-Cadherin, VEGFR-2, CXCR4 and CD133).In vitro exosome secretion and trasdifferentiation was confirmed. A total of 2mL with a mean of 1,72x106 cells/mL (range 1,26-2,36 x106 cells/mL) CD133+ BMDSCs were intra-arterially injected into athymic female nude rats (n=33) distributed into two experimental groups: group A treated with vehicle and group B with CD133+ cells throughout a catheter implanted in the carotid artery towards the heart. AS was previously induced in the left uterine horn 2 weeks prior to administration and each of these groups were assessed 24 hours, 14 days and 6 months after instillation. Uterine cell engraftment was assessed by Immunohystochemistry of both horns (damaged and non damaged) of the mice with the specific human nuclear protein Ku80. Additional markers such as human specific CD133 were assessed. Finally, safety assessment relied on mortality, local and systemic clinical signs, body weight and food consumption recorded throughout the study period, in addition to clinical pathology determinations and histopathological evaluation of 21 tissues performed at sacrifice.

RESULTS: The results of this experimental study showed that human CD133+ BMDSCs remain in the endometrial tissue up to six month after stem cell instillation.However, engrafted cells express Cd133 marker 48h hours after instillation but this maker progressively disappeared at 14 days and 6 months. Moreover, a higher engraftment was observed in damaged horns and human cells seem to be aggregated in a clonal manner, specially in the group of 6 months after stem delivery.Regarding safety, the administration of these cells didn't display significant side effects representing a long-term safe treatment in this animal model.Hystopathologically, not pathological findings were associated with this treatment in none of the 21 different tissues assessed.

CONCLUSIONS: CD133+BMDSCs represent a safe therapy with engraftment potential up to six months after stem cell therapy. CD133 expression decreases in engrafted cells after 6 months.

miRNA-144 INCREASES ESTROGEN-PRODUCING GENES EXPRESSION AND SUPPRESS APOPTOSIS IN HUMAN GRANULOSA CELL LINE. Sahar Esfandyari, DVM The University of Illinois College of Medicine, Chicago, IL.

OBJECTIVE: Primary ovarian insufficiency (POI) — also called premature ovarian failure — occurs when the ovaries stop functioning normally before age 40 and often leads to infertility. POI is frequently caused by chemotherapy in cancer patients. Chemotherapy reagents are Gonadotoxic and destruction granulosa cells, which are vital for oocyte maturation and follicular development. The incidence of POF is growing and the underlying molecular mechanisms are not still clear. However, women with POF exhibited downregulation of miRNA-144 in their plasma compared with normal women. miRNA-144-5p also has been shown to be downregulated in the POF tissues of animal models compared with that in normal ovarian tissues. Recently published reports have described that intraovarian transplantation of human mesenchymal stem cells (hMSCs) can restore fertility in a chemotherapy-induced POI mouse model. A previous study demonstrated that various growth factors, cytokines, and miRNAs (including miRNA-144), both free and in exosomes are secreted by Bone marrow mesenchymal stem cells. In this study, we evaluated the effects of miRNA-144 mimic on estrogen synthesis such as CYP19A1, StAR and also apoptosis genes expression and secreted estrogen level using human non-luteinized granulosa cell line (HGrC1).

DESIGN: We hypothesize that HGrC1 cells transfected with miRNA-144 mimic will exhibit an increase in the estrogen synthesize gene expression and estrogen level.

MATERIALS AND METHODS: HGrC1 were seeded on 6-well plates at a density of 3×10^5 cells per well and cultured for 24 hours. Cells were transfected with different concentrations 25 and 50 pM of mirVana has-miR-144-5p mimic or negative control-1 mimic using manufacturer protocol. After 24 hours of transfection the medium changed with regular media and after 24 h HGrC1 cells and conditioned media were collected for analysis. The mRNA and protein expression of CYP19A1, StAR, AKT-I, Bax and Caspase3 were quantified by RT-PCR and Western blot, while estrogen level in media was measured by Automated chemilumenescence immunoassay system.

RESULTS: Human HGrC1 cells transfected with 50pM of miRNA-144-5p mimic secreted significantly higher level of estrogen (9.28 $\pm$ 0.5 pg/ml) compared to control C (7.335 $\pm$ 0.1 pg/ml) ($P<0.05$). the expression level of estrogen synthesizing genes CYP19A1 and StAR was significantly increased ($p<0.05$). The expression of anti-apoptosis gene AKTI increased significantly at mRNA and protein level ($p<0.05$) while the expression of apoptotic genes Bax and caspase3 was significantly decreased ($p<0.01$) at RNA level.

CONCLUSIONS: The miR-144-5p mimic induced a significant upregulation in estrogen-producing pathway genes and decrease apoptosis in human non-luteinized granulosa cell line (HGrC1). Mesenchymal stem cell therapy may be a viable novel treatment option for POI patients.

P-819 4:30 PM Tuesday, October 20, 2020

THE USE OF SEMIPERMEABLE SPHERES ENGULFED WITH MOUSE EMBRYONIC STEM CELLS TO GENERATE MALE GERM CELLS. Sherina Lawrence, B.S., Mounia Haddad, M.D., Philip Xie, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To test the efficiency of direct spherification in supporting differentiation of mouse embryonic stem cells (mESCs) into meiotic male germ cells.

DESIGN: Biological 3D scaffolding was utilized to culture and differentiate mESCs. Two main methods were investigated: 1) mESCs were injected into pre-formed spheres (IN), and 2) a suspension of mESCs was directly encapsulated (DE) into spheres. To coax differentiation, spheres were bathed in a growth factor cocktail. After mechanical breaching of the spheres, serial isolation at different time intervals was carried out. These isolated cells were analyzed with germ cell stage–specific markers.

MATERIALS AND METHODS: MESCs were initially cultured on a 6-well dish, trypsinized, and resuspended in stem cell medium. For the IN method, the suspension was injected by using a 1 mL syringe into pre-formed spheres. For the DE method, spheres were formed by suspending mESCs in a base spherification solution and encapsulated by exposure to sodium alginate. Four spheres were bathed in EpiLC differentiating medium containing Activin A, bFGF, and KSR for 3 days, and then submerged in spermatogonial stem cell (SSC) medium composed of DMEM, GDNF, FGF2, 2-mercaptoethanol, L-glutamine, B27 supplement, and 1 μM retinoic acid (RA) for 7 days. Each sphere measured at a diameter of 8 to 10 mm, containing approximately $6.3x10^5$ cells per sphere. Cells were isolated and analyzed after 3 days for OCT4 and Nanog, and DAZL and VASA at day 10.

RESULTS: Both IN and DE proved successful in supporting the growth of mESCs. However, optic visualization through the membrane of the IN sphere showed a lower concentration compared to the DE approach. Embryoid body formation was first observed in the DE group at day 4, indicating greater efficiency with this approach. Confident with the sustainability and efficiency of DE, we attempted differentiation solely by this method, by bathing the spheres in EpiLC medium. After 3 days of culture, two spheres were breached and their cellular content was analyzed, showing OCT4 expression in about 85% of cells and a more conspicuous decrease in Nanog expression (<40%), indicating successful progression to EpiLCs. The remaining two spheres cultured in SSC medium with RA from day 4 to 10 showed an increase in embryoid body size that even extruded through the sphere wall. At day 10, the spheres were mechanically breached, and isolated cells showed positivity for VASA (~5%) and DAZL (~5%), confirming meiotic differentiation into germ cells.

CONCLUSIONS: Successful sustenance and propagation of mESCs using direct spherification indicates the feasibility of this 3D culture system to promote differentiation towards the male germ line. The ability to support differentiation to post-meiotic stages confirmed by biological proof would render this culture method sustainable for *in vitro* neogametogenesis.

P-820 4:30 PM Tuesday, October 20, 2020

SENSITIVE TOXICITY TESTING OF ART DISPOSABLES USING HUMAN PLURIPOTENT STEM CELLS. Ye Yuan, PhD,[1] Courtney Grimm, MS,[1] Rachel C. West, PhD,[1] William B. Schoolcraft, MD,[1] Rebecca L. Krisher, PhD[2] [1]Colorado Center for Reproductive Medicine, Lone Tree, CO; [2]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: To develop a novel assay to sensitively detect toxicity using human pluripotent stem cells (hPSC) for human IVF clinic quality control (QC) testing.

DESIGN: Prospective research study

MATERIALS AND METHODS: To determine the sensitivity of hPSC culture to Triton X100 (TX100), cells were cultured for 48 h in StemFlex medium containing various dilutions of TX100 (10^{-5}, 5×10^{-6},10^{-6}, 10^{-7}) and compared with non-treated control cells. To compare the hPSC QC assay with known MEA results, StemFlex medium was exposed to previously tested plastics for 12 h at 37ºC prior to hPSC culture. Medium incubated at 37 ºC for 12 h without plastic exposure was used as the control. Media was refreshed daily for each treatment group. Colonies were digested with TrypLE and the resulting single cell suspensions were stained with Trypan blue to count the number of live cells.

RESULTS: After 48h, TX100 at higher concentrations (10^{-5}, 5×10^{-6}) triggered complete hPSC death. The number of viable hPSC was significantly decreased when exposed to TX100 at 10^{-6} ($1.1 \pm 0.2 \times10^5$ cell/well vs. $5.2 \pm 0.2\times10^5$ cell/well in control, n=3, p=0.002) and 10^{-7} ($1.9 \pm 0.2 \times10^5$ cell/well vs. $5.2 \pm 0.2\times10^5$ cell/well in control, n=3, p=0.003). Medium exposed to plasticware that had passed the MEA yielded a similar number of viable cells compared to control ($5.7 \pm 0.7 \times10^5$ cell/well vs. $5.2 \pm 0.2\times10^5$ cell/well in control, n=3, p=0.7). However, culture in medium exposed to plastics that had failed the IVM MEA resulted in fewer viable cells compared to the control ($2.9 \pm 0.4 \times10^5$, $1.5 \pm 0.4 \times10^5$, and $4.5 \pm 0.02 \times10^5$ cell/well for three independent plasticware vs. $5.2 \pm 0.2\times10^5$ cell/well in control. n=3, P=0.05, 0.01, and 0.08, respectively).

CONCLUSIONS: Our hPSC culture system was able to detect the known contaminant, TX100, at a lower concentration than the IVM MEA, and demonstrated the ability to replicate known MEA results for QC testing for commonly used plasticware. We are currently working on simplifying the procedures and performing the assay in a high throughput capacity. This QC assay has the potential to provide a sensitive, consistent, cost-effective, and less time-consuming platform for human ART QC.

INSULIN RESISTANCE & INFERTILITY: ASSESSING THE SIGNIFICANCE OF INSULIN RESISTANCE AMONG WOMEN SEEKING FERTILITY CARE. Rachel Ruderman, MD, MPH, Lydia Hughes, MD, Sedona Speedy, MD, Christina E. Boots, MD, MSCI Northwestern University, Chicago, IL.

OBJECTIVE: To assess prevalence and significance of insulin resistance (IR) among women seeking fertility care

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: A database query was performed on patients aged 18 to 47 of the Reproductive Endocrinology and Infertility division from 2014 to 2020 who had a hemoglobin A1c (A1c) value. All women

	Normal (A1c < 5.7)	Insulin Resistance (A1c 5.7-6.4)	Diabetes (A1c 6.5+)	*p-value*
Age	34.33 (+/- 4.40)	34.86 (+/- 5.11)	35.16 (+/- 5.51)	0.02
BMI	26.18(+/- 6.18)	32.39(+/- 8.12)	34.32(+/- 9.77)	<0.001
Normal (18.5-24.9)	1238 (90.6%)	117(8.6%)	12(0.9%)	
Overweight (25-29.9)	662(82.9%)	116(14.5%)	21(2.6%)	
Obese (30+)	514 (58.2%)	319(36.1%)	50(5.7%)	
Race				0.00
White	1488(85.9%)	214(12.4%)	30(1.7%)	
Non-White	629(66.7%)	265(28.1%)	49(5.2%)	
AMH	4.00(+/- 4.28)	3.89(+/- 3.88)	2.90(+/- 2.74)	NS
TSH	1.88(+/- 1.20)	2.09(+/- 3.55)	2.25(+/- 2.01)	0.02
Total Gonadotropins	2661.92(+/- 1279.42)	2898.40(+/- 1337.10)	3359.09(+/- 1446.60)	0.02
Total Oocytes	14.91(+/- 9.57)	14.65(+/- 9.66)	13.60(+/- 7.91)	NS
Frozen Blasts	4.21(+/- 3.44)	4.01(+/- 3.18)	3.20(+/- 2.78)	NS

NS = non-significant

who present to this office are screened with a A1c if their BMI is >25kg/m2. Data was correlated to in vitro fertilization (IVF) data. Insulin resistance was defined per the American Diabetes Association. Statistical analysis was performed using student's T test, ANOVA, or chi square. Linear and logistic regression were used to adjust for confounding variables.

RESULTS: 3170 women were included in the study. The prevalence of IR was 17.9% and diabetes was 2.7%. Mean A1c value was 5.4 +/- 0.58. After adjusting for age, a higher body mass index (BMI) (OR 1.12, 95% CI 1.11-1.14, $P<.001$) and a non-white race (OR 2.38 95% CI 1.97-2.89, $P<.001$) were predictive of an elevated A1c. IR was significantly associated with increased total gonadotropin dose ($P = 0.02$), but was not associated with worse IVF outcomes, such as number of oocytes retrieved, pregnancy or live birth rate after adjusting for age and anti-Mullerian hormone (AMH). IR was not associated with any particular diagnosis of infertility. Of the 464 women with IR who conceived and received care in our hospital system, 18% (102) developed gestational diabetes (GDM), compared to 6.9% (173/2345) of women without IR.

CONCLUSIONS: Insulin resistance is a common finding among women seeking fertility treatment, especially when BMI is >30kg/m2, and should be considered during preconception evaluation. While IR was not associated with worse IVF outcomes, patients with IR may require higher doses of gonadotropins and have a higher risk of GDM. Preconception evaluation and lifestyle counseling provide a unique and motivational opportunity to improve pregnancy and long term health outcomes.

P-822 4:30 PM Tuesday, October 20, 2020

OOCYTE SECRETED FACTORS REGULATE *FSHR* AND *AMH* mRNA LEVELS IN CUMULUS CELLS.

Jose Buratini, DVM, PHD,[1] Thaisy Tino Dellaqua, Ms.,[2] Mariabeatrice Dal Canto, BSci, PHD,[1] Mario Mignini Renzini, MD[1] [1]Biogenesi Reproductive Medicine Centre, Monza, Italy; [2]Sao Paulo State University, Botucatu, Brazil.

OBJECTIVE: Considering that (1) FSH activity decreases cumulus-oocyte communication via retraction of transzonal processes (TZP), (2) AMH inhibits FSH signalling by decreasing *FSHR* expression and adenylyl cyclase activation, and (3) the oocyte is an active player in the cumulus-oocyte complex (COC) regulating cumulus cell metabolism and gene expression via oocyte-secreted factors (OSF), we tested the hypothesis that the oocyte decreases mRNA abundance of *FSHR* while increasing that of *AMH* in cumulus cells through OSF, as part of an effort to preserve its communication with cumulus cells thus safeguarding its developmental competence.

DESIGN: The relative mRNA abundance of *FSHR and AMH* in cumulus cell was compared among 3 treatment-groups: (1) Intact COC subjected to *in vitro* maturation (IVM); (2) oocytectomized COC (OOX) subjected to IVM and (3) OOX subjected to IVM with the addition of denuded oocytes (OOX+DO; 1 DO/μL). Four culture replicates including all three treatment-groups were performed.

MATERIALS AND METHODS: COC were aspirated from 3-8mm follicles of bovine ovaries. Oocytectomy was achieved by aspiration of the ooplasm with a micromanipulator while preserving the structure of the COC. COC and OOX underwent IVM in pools of 20 for 22 hours. IVM was performed in 100 μL of TCM199 with Earl's salts supplemented with 1μg/mL FSH, 0.4% BSA, 22 μg/mL sodium pyruvate, 75 μg/mL of amikacin at 38,5°C and 5.5% CO_2 in humid atmosphere. Abundance of mRNA encoding *FSHR* and *AMH* in cumulus cells was assessed by real-time RT-PCR using Power SybrGreen (LifeTech®) and *RPL15* (ribosomal protein 15) as the reference gene. Effects of treatments were tested by ANOVA and groups were compared with the Tukey test. Statistically significant differences were those with $p<0.05$, while p values >0.05 and <0.1 were considered as tendency of difference.

RESULTS: Oocytectomy decreased *AMH* mRNA levels ($p=0.005$) while tended to increase *FSHR* mRNA abundance ($p=0.077$) in cumulus cells. The addition of denuded oocytes (DO) reversed the effects of oocytectomy on both genes. Relative *AMH* mRNA levels (*AMH/RPL15* mRNA abundance, mean ± EPM) were 0.875 ± 0.1, 0.3675 ± 0.02 and 0.7825 ± 0.1 for COC, OOX and OOX+DO, respectively. For *FSHR*, the respective values (*FSHR/RPL15* mRNA abundance) were 1.495 ± 0.54, 2.575 ± 0.52 and 0.875 ± 0.29.

CONCLUSIONS: Oocyte secreted factors seem to reduce *FSHR expression* while enhancing *AMH* expression in cumulus cells. We speculate that this is part of an effort of the oocyte to restrain FSH activity in the COC in order to preserve its communication with cumulus cells thus favouring developmental competence.

P-823 4:30 PM Tuesday, October 20, 2020

CONTRASTING TOXICITY OF D-GALACTOSE ON OOCYTES AND EMBRYOS.

Mili Thakur, MD, David Bai, BS, Neha Nayak, student, Husam M. Abu-Soud, PhD Wayne State University, C.S. Mott Center for Human Growth and Development, Detroit, MI.

OBJECTIVE: A rare mutation in galactose-1-phosphate uridyltransferase, an enzyme in the Leloir pathway of galactose metabolism, causes classic galactosemia (CG), a metabolic disorder characterized by harmful accumulation of D-galactose and its metabolites galactose 1-phosphate (gal 1-P) and galactitol in physiological systems. One especially susceptible system is the female reproductive tract, specifically the ovaries, which often leads to primary ovarian insufficiency (POI) even with careful monitoring of diet. However, some number of pregnancies in CG patients has been reported even though the general perception is that they are infertile. Previous studies have delineated a mechanism of D-galactose toxicity in oocytes associated with apoptosis and excessive reactive oxygen species, but considering the incidence of pregnancy in CG patients, embryos could be less affected by D-galactose toxicity. Therefore, the aim of this study is to explicate the effects of D-galactose and its metabolites on embryos and subsequent development.

DESIGN: This was an experimental case-control design.

MATERIALS AND METHODS: D-galactose (2 mM), galactitol (11 mM) and gal 1-P (0.1 mM), with concentrations corresponding to those typically found in plasma of CG patients under dietary restrictions, were used to treat one-cell mouse embryos (n = 31) for 4 h. After exposure, the embryos were then incubated in culture for 120 h. Similar procedures were used to treat metaphase II mouse oocytes (n = 120), which were then fertilized *in vitro*, and then cultured for 120 h. Cells were analyzed for development at 24, 48, and 96 h. Cleavage stage embryos were assessed for nuclear fragments, morphology, and blastomere count. Blastocyte stage embryos were assessed for blastocoel expansion, trophectoderm morphology, and inner cell mass quality.

RESULTS: No differences were found between directly treated embryos and untreated controls. Conversely, there was significant decline in cleavage and blastocyst development in embryos derived from treated, fertilized oocytes compared to untreated controls.

CONCLUSIONS: Considering the relatively high pregnancy rate observed in women with CG-associated POI compared to all women with POI, D-galactose exposure does not appear to be embryotoxic. Thus, oocytes that avoid the harmful effects of D-galactose or its metabolites have the potential for a normal developmental course even if they are then later exposed to D-galactose or its metabolites. These results should encourage women with CG to maintain optimism for childbearing and childbirth.

P-824 4:30 PM Tuesday, October 20, 2020

NOVEL ANTI-MÜLLERIAN HORMONE RECEPTOR 2 BINDING PEPTIDE (AMHR2BP) STALLS GRANULOSA CELLS PROLIFERATION.

Laura Detti, MD,[1] Ghassan M. Saed, PhD[2] [1]Cleveland Clinic, Cleveland, OH; [2]Wayne State University School of Medicine, Detroit, MI.

OBJECTIVE: Anti-Müllerian hormone decreases hormone production, and cellular proliferation/apoptosis, in in both, *in vitro* and *in vivo*, ovarian cortex [1-3], and in luteinized granulosa cells (GCs) [4]. We sought to investigate whether a novel AMHR2BP could perform similarly to native AMH in a primary luteinized GC culture.

DESIGN: Experimental study

MATERIALS AND METHODS: A primary culture of GCs isolated from follicular fluid was used. Cells were seeded in well cell culture plates at a density of 100,000 cells/well in medium. Following an overnight incubation (37°C, 5% CO2), cells were treated with AMHR2BP 10 ng/ml (AMHR2BP group), or Phosphate-buffered saline (PBS, control group), for an additional 24 hours. After incubation, real-time RT-PCR was performed to quantify GCs expression of AMH, AMH-R2, FSH-R, Inhibin B, cell proliferation (Ki67) and apoptosis (Caspase 3).

RESULTS: Cellular expression of AMH, AMH-R2, FSH-R and Inhibin B, were significantly reduced by AMHR2BP-treated cells compared to a Negative peptide and control groups ($p \leq 0.005$ for all). In addition, AMHR2BP-

Variable Groups	AMH pg/μg RNA	AMH-R2 pg/μg RNA	FSH-R pg/μg RNA	Inhibin B pg/μg RNA	Ki67 pg/μg RNA	Caspase3 pg/μg RNA
Control	3.05±0.1	9.88±0.3	4.43±0.3	101.8±5.9	425.1±16.6	1101.6±91.4
Negative BP	2.91±0.2	9.95±0.1	4.42±0.4	94.0±2.7	428.3±6.8	1140.4±16.8
AMHR2BP	1.60±0.1	4.17±0.2	1.65±0.1	46.9±1.1	229.5±6.7	207.3±4.7
p-value	0.005	<0.001	<0.001	0.001	<0.001	<0.001

treated cells showed decreased cell proliferation, as well as decreased apoptosis by greater than 50%. The Table shows the cellular mRNA expression of (A) AMH, its receptor AMH-R2, FSH-R, and inhibin B, and (B) Ki67 and Caspase3, in granulosa cells cultured for 24 hours in plain medium (control), 10 mcg novel AMHR2BP (AMHR2BP), and a negative peptide.

CONCLUSIONS: Binding to AMHR2, the novel AMHR2BP reproduced native AMH's effects [5], with inhibition of cell proliferation and apoptosis in luteinized GCs. AMHR2BP also downregulated cellular expression of the major regulatory hormones and receptors. AMHR2BP could be used in place of AMH in AMH-regulated functions.

THE INCIDENCE OF UNDETECTABLE AMH LEVELS IN WOMEN SEEKING PROACTIVE FERTILITY HORMONE TESTING. Sharon Briggs, PhD, Avner Hershlag, MD Modern Fertility, San Francisco, CA.

OBJECTIVE: To determine the frequency of undetectable anti-mullerian hormone (AMH) among women not currently seeking fertility treatment.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: Our cohort consists of over 11,000 participants who represent a subset of people who used an at-home fertility hormone test between May 2018 and March 20th, 2020. To be included, participants must have consented to research and not reported a previous diagnosis of polycystic ovary syndrome or primary ovarian insufficiency (POI). Participants were subset by age and whether they were currently using contraceptives.

RESULTS: Undetectable levels of AMH were found in 0.9% of our cohort, representing 102 women. In our age-restricted analysis, the frequency ranged from 0.2% in women under 35, 1.98% in women 35-39, and 6.85% in women 40 and older. 63 women (0.74%) in this cohort meet the definition of primary ovarian insufficiency: under the age of 40 with undetectable AMH levels.

Results were similar when restricting the analysis to women who were not using contraceptives at the time of testing (Table 1).

CONCLUSIONS: AMH has become the most common test used in reproductive medicine to evaluate ovarian reserve. While it is hotly debated in the literature whether AMH can be used to predict fecundity in general, undetectable AMH clearly represents a decrease in the number of eggs available to create a viable pregnancy either naturally or with assistance.

Undetectable AMH was found with notable frequency in our cohort — nearly 2% of women between ages 35 and 39 had undiagnosed POI. Given the association with various health conditions and a decreased chance of natural pregnancy, identification of undiagnosed POI should prompt followup with a physician and fertility specialist.

It is important to note that this is a cohort of women seeking proactive fertility hormone information; they are unlikely to be seeing a fertility specialist. Without fertility testing and identification of undetectable AMH levels, these women may have tried to achieve pregnancy at home for months, potentially years, before seeking help. Measuring AMH at-home can help women identify an issue and see a fertility center or physician. This can give them valuable time and opportunity to optimize their chances for a child.

Table 1. Frequency of undetectable AMH by age and contraceptive status.

Cohort	Age	% Undetectable (<0.08 ng/ml)
All customers (n=11277)	All ages	0.9%
Mean (SD) Age: 31.8 (4.3)	<35 (n=8481)	0.22%
	35-39 (n=2226)	1.98%
	40+ (n=569)	6.85%
Customers not on contraceptives (n=7387)	All ages	1.03%
	<35 (n=5114)	0.2%
Mean (SD) Age: 32.5 (4.5)	35-39 (n=1762)	1.76%
	40+ (n=511)	6.85%

P-826 4:30 PM Tuesday, October 20, 2020

SLEEP DURATION AND TIMING ARE NOT ASSOCIATED WITH ANTIMULLERIAN HORMONE LEVELS. Caitlin Elizabeth Martin, MD, MS,[1] Allison P. Schelble, MD,[2] Ashley Eskew, MD, MSCI,[3] Joan Riley, PhD, HCLD,[2] Emily S. Jungheim, MD, MSCI[4] [1]Washington University School of Medicine, St. Louis, MO; [2]Washinton University School of Medicine, St. Louis, MO; [3]Atrium Health, Charlotte, NC; [4]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: Many women who consider future family building seek advice regarding modifiable behaviors and reproductive health. To determine if sleep duration and timing are associated with AMH levels in a reproductive aged, Midwestern cohort of women.

DESIGN: Cross sectional study.

MATERIALS AND METHODS: 200 women aged 18-44 years with regular menstrual cycles were enrolled into the LORE study, a cross-sectional cohort study designed to investigate associations between lifestyle factors and ovarian reserve. Women who were currently pregnant or who had history of major chronic illness, infertility or ovarian surgery were excluded. Fasting blood was drawn and stored at -80 degrees for batched analysis. Samples were run on the Roche Elecsys analyzer for AMH levels. Participants also completed a survey that included questions regarding typical bedtime and wake time on work and non-work days. Sleep measures included duration of sleep, midsleep point (defined as the midpoint time between bedtime and wake time, also known as chronotype), and social jetlag (the difference in midsleep point on workdays and non-work days of >1 hour). Standard bivariate statistics were run to determine associations between sleep duration, timing of sleep and AMH levels. SPSS v.25 was used for analysis.

RESULTS: Participants had an average age of 30.9 ± 6.7 years and an average body mass index of 28.3 ±7.1. The majority of the participants were white (n=136, 68%); thirty percent were black (n=60). The average AMH level was 2.9 ±2.0 ng/mL. Average duration of sleep was 7.2 hours (Range 4.0 to 11.0 hours). Average mid sleep point on work nights was 2:51 AM and on non-work nights was 3:54 AM. Average social jet lag was 1:31 hours (range 0 to 14:30 hours). None of these measures were associated with AMH.

CONCLUSIONS: This data suggests that for healthy, reproductive aged women in the Midwest, modifying sleep duration and timing is unlikely to improve or adversely affect AMH.

COMPARISON OF CONTROLLED OVARY STIMULATION PROTOCOLS FOR *IN VITRO* FERTILISATION: A META-ANALYSIS.

Rong Li, MD, PhD,[1] Yichun Guan, MD, PhD,[2] Rui Yang, MD, PhD,[1] Valerie Perrot, Master,[3] M. A. Juan, Master[4] [1]Peking University Third Hospital, Beijing, China; [2]The Third Affiliated Hospital of Zhengzhou University, Zhengzhou, MN, China; [3]Ipsen Pharma, Boulogne-Billancourt, France; [4]Ipsen Pharma (Beijing), Beijing, China.

OBJECTIVE: The purpose present of meta-analysis is to compare the effectiveness of different types of GnRH agonist (GnRH-a) protocols (long-acting follicular, long-acting luteal and short-acting luteal protocols) and GnRH antagonist (GnRH-ant) protocol for IVF.

DESIGN: Meta-analysis.

MATERIALS AND METHODS: In this meta-analysis, a literature search was performed in both English and Chinese databases (PubMed, Embase, Cochrane, CNKI and Wanfang) using pre-defined search strings till 1st March 2019. The methodology adhered to Preferred Reporting Items for Systematic Reviews and Meta-analysis guidelines and registered in PROSPERO (CRD42019139396). RCTs and observational studies that compared GnRH-a protocols (long-acting follicular, long-acting luteal and short-acting luteal) and GnRH-ant protocols were included. The primary outcome was live birth rate (LBR); the secondary outcomes were clinical pregnancy rate (CPR), implantation rate (IR) and safety in terms of miscarriage rate (MR) and ovarian hyperstimulation syndrome (OHSS) rates. 'R software' was used for statistical analysis. Outcomes were reported in terms of relative risk (RR) and 95% confidence interval (CI) with P value <0.05 considered statistically significant.

RESULTS: Literature search retrieved 5331 studies of which 111 were included. Long-acting follicular agonist protocol (13 studies) consisted of 1878 and 2342 women in agonist and antagonist arms respectively. No significant difference was observed in LBR (RR=1.38, 95%CI: 0.79-2.39, *P*=0.2542) and MR (RR=0.97, 95%CI: 0.63-1.49, *P*=0.8833). CPR (RR=1.48, 95%CI: 1.37-1.59, *P*<.0001) and IR (RR=1.39, 95%CI: 1.10-1.76, *P*=0.0062) were significantly higher in agonist group whereas OHSS was significantly lower in GnRH-ant group (RR=1.35, 95%CI: 1.06-1.72, *P*=0.015).The long-acting luteal agonist protocol included 24 studies: 6579 and 2900 women in agonist and antagonist arms, respectively. There was no significant difference in LBR (RR=1.02, 95%CI: 0.91-1.14, *P*=0.75), CPR (RR=1.48, 95%CI 0.80-2.76, *P*=0.21) and MR (RR=0.90, 95%CI: 0.64-1.26, *P*=0.536). CPR/transfer (RR=1.07, 95%CI: 1.01-1.14, *P*=0.0194) and IR (RR=1.17, 95%CI: 1.03-1.32, *P*=0.0161) were significantly higher in agonist group but OHSS was significantly lower in GnRH-ant group (RR=1.29, 95% CI 1.02-1.63, *P*=0.0311).The short-acting luteal agonist protocol included 74 studies:7385 and 11881 women in agonist and antagonist arms, respectively. LBR (RR=1.34, 95% CI 1.22-1.48, *P*<.0001) was significantly higher in the short-acting luteal agonist group. There was no significant difference in CPR (RR=1.01, 95%CI 0.93-1.09, *P*<.834), CPR/cycle (RR=1.05, 95%CI 0.93-1.18, *P*=0.415), CPR/transfer (RR=1.06, 95%CI 0.88-1.27, *P*=0.548), IR (RR=1.02, 95%CI 0.95-1.10, *P*=.563) and MR (RR=0.92, 95%CI 0.74-1.15, *P*=0.473). However, a significantly lower OHSS rate was observed in GnRH-ant group (RR=1.61, 95% CI 1.33-1.94, *P*<0.0001).

CONCLUSIONS: GnRH-a long protocols were found to have potential benefit over the GnRH-ant protocol in terms of live birth rate, clinical pregnancy rate and implantation rate.

HIF1-ALPHA INDUCED ADRENOMEDULLIN EXPRESSION SUPPORTS ANGIOGENESIS IN 3D LEIOMYOMA XENOGRAFTS. Joy L. Britten, MD,[1] Minnie Malik, Ph.D.,[2] Anthony DeAngelis, MD, PhD,[2] William Catherino, M.D., Ph.D.[1] [1]Uniformed Services University for the Health Sciences, Bethesda, MD; [2]Uniformed Services University of the Health Sciences, Bethesda, MD.

OBJECTIVE: Cellular responses to hypoxia are critical to homeostasis. In eukaryotes, the primary regulator of angiogenesis is the transcription factor hypoxia inducible factor-1 alpha (HIF-1α). Hormonally-stimulated human leiomyoma 3D xenografts express HIF1-α protein and undergo *in vivo* neovascularization. Our objective was to characterize hypoxia regulated genes and HIF-1α regulated angiogenesis in our human leiomyoma cell lines and xenograft model.

DESIGN: Laboratory study

MATERIALS AND METHODS: Leiomyoma and myometrial cells exposed to normal O_2 (21%) and low O_2 (1%) levels and chemically induced hypoxia with cobalt chloride ($CoCl_2$) for 6 and 24 hours; leiomyoma and myometrial cell protein; 3D leiomyoma and myometrial xenograft tissue from placebo-, estrogen- and progesterone-treated groups; Immunohistochemistry and Western blot analyses

RESULTS: Quantitative WB analysis of myometrial cells exposed to hypoxia demonstrate a greater than 3-fold increase (3.35$\pm$0.01-fold **p<0.05) in HIF-1α expression at 24 hours in myometrial cells under hypoxic conditions. Conversely, leiomyoma cells show up regulation of HIF-1α expression (1.16$\pm$0.004-fold **p<0.01) at 6 hours and 24 hours (1.44$\pm$0.05-fold *p=0.05) under normoxic conditions. Adrenomedullin (ADM), a pro-angiogenic protein under HIF-1α transcriptional control, was upregulated in hypoxic myometrial cells at 6 (1.76+/-0.5-fold) and 24 hours (1.28+/- 0.3-fold), compared to normoxic myometrium. Leiomyoma cells show an almost 1.5-fold increased ADM expression under both normoxia and hypoxic conditions at the 6 hour time point. Exposure of myometrial cells to $CoCl_2$ for 24 hours demonstrate a >1.5-fold increase in ADM and a >2-fold increase in the stress inducible protein, sestrin 2. After 24 hours of exposure to $CoCl_2$, leiomyoma cells show a similar increase in ADM expression to that of myometrium at 6 hours, and a >7-fold increase in sestrin 2. IHC results for ADM expression in 3D xenografts show that the estrogen-, estrogen+progesterone and progesterone-treated groups demonstrate intense cytoplasmic/matrix staining for ADM compared to placebo treated groups, particularly under the growth-stimulatory influence of gonadal hormones.

CONCLUSIONS: Angiogenesis is supported by hypoxia induced, HIF-1α facilitated ADM expression in 3D leiomyoma xenografts.

P-829 4:30 PM Tuesday, October 20, 2020

DETERIORATION IN BASELINE REPRODUCTIVE HORMONE PROFILE IS ASSOCIATED WITH INCREASE IN REPRODUCTIVE ENDOCRINE DISORDERS: DATA EVALUATION IN INDIAN WOMEN OVER A 15-YEAR DURATION. Bindu N. Chimote, M.Sc., M.Phil, Ph.D.(Biochemistry); M.Sc. Clinical Embryology (Leeds-UK),[1] Natchandra Manoharrao Chimote, M.Sc., Ph.D[2] [1]Consultant Clinical Embryologist, Nagpur, India; [2]Scientific Director, Vaunshdhara Fertility Centre, Nagpur, India.

OBJECTIVE: To validate if deterioration in reproductive hormone profile of women reporting for fertility treatment may be responsible for increased endocrine anomalies and stagnant success rates post-IVF despite clinical, embryological and technical advances.

DESIGN: Retrospective analysis of anthropometric parameters and baseline hormones in reproductive age (21-44 years) women reporting for fertility consultation over a 15-year duration, phased out into Group A: 2005-2009 (n=814), Group B: 2010-2014 (n=1264), Group C: 2015-2019 (n=1222).

MATERIALS AND METHODS: Baseline reproductive hormones Oestradiol E2, LH, FSH, TSH, Testosterone, Prolactin, Insulin, DHEAS, AMH were estimated by RIA/ELISA using diagnostic kits in women on day2/3 of menstrual cycle. Study population comprised of all women including eumenorrhic normal (non-PCOS), PCOS and POI/F women. We designated women as PCOS (AFC >20, AMH >4ng/ml, LH >FSH, Testosterone >60ng/dL) and POF/POI (AFC <4, AMH <0.43ng/ml, FSH>25mIU/ml, LH= 20-25mIU/ml, Testosterone <20ng/dl) as per standards established in Indian women by our endocrine laboratory. Statistical analysis was done using Graph-pad prism VI software.

RESULTS: A significant rise in age (29.93$\pm$0.17 vs. 31.41$\pm$0.17 vs. 32.19$\pm$0.15 years; p<0.0001), ovarian age (15.83$\pm$0.23 vs. 17.46$\pm$0.20 vs. 17.68$\pm$0.18years;p<0.0001), BMI (23.65$\pm$0.19 vs. 24.39$\pm$0.20 vs. 24.66$\pm$0.15;p=0.0002) and WHR (0.87 vs. 0.89 vs. 0.91;p=0.04) of women reporting for fertility treatment was observed among the study groups A, B, C respectively. The steroid hormones Estradiol (71.03$\pm$1.96 vs. 83.98$\pm$1.23 vs. 96.42$\pm$1.98 pg/ml; p<0.0001) and Testosterone (62$\pm$1.5 vs. 79$\pm$1.4 vs. 105$\pm$2.1; p<0.0001) were significantly higher, displaying correlation of raised androgen with concurrently raised peripheral estrogen levels. Insulin (7.9$\pm$0.3 vs. 8.2$\pm$0.17 vs. 8.5$\pm$0.18μM/L; p<0.0001) and TSH (2.96$\pm$0.18 vs. 3.34$\pm$0.08 vs. 4.01$\pm$0.5mIU/L;p<0.0001) levels also depicted a significant rise whereas Prolactin levels did not differ significantly. Disconcertingly, results showed an increased tendency towards two extremes of Polycystic Ovarian Syndrome (PCOS) (19 vs. 25 vs. 33%; p<0.0001) and Premature Ovarian Insufficiency/failure (POI/F) (11 vs. 13 vs. 15%;p<0.0001) while rates of 'normal' eumenorrhic non-PCOS females declined (69 vs. 62 vs. 52%;p<0.0001) over the years between the 3 study groups respectively. Among PCOS, there was a rise in incidence of obese (BMI >30 kg/m^2) PCOS (9.37 vs. 12.61 vs. 14.37%; p=0.0004) whereas rates of lean-thin (BMI<19 kg/m^2) PCOS declined (16.61 vs. 13.53 vs. 11.49%; p<0.0001) between the three study groups respectively. DHEAS levels were high in young PCOS whereas low in elderly PCOS and women with POI/F condition. AMH levels also displayed increasing tendency towards significant extremes based on PCOS and POI/F status.

CONCLUSIONS: A progressive decadence in baseline reproductive endocrine profile of women reporting for fertility treatment warrants re-establishing ethnicity based normal control values, redefining endocrine anomalies and redesigning of protocols for enhanced IVF outcomes.

NOMOGRAM TO PREDICT CERVICAL INSUFFICIENCY INCIDENCE IN PATIENTS UNDERGOING IVF/ICSI TREATMENT. Xing Yang, Ph.D., Yao-qiu Wu, M.M The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: This study aimed to identify the risk factors for Cervical insufficiency (CI) occurrence after in vitro fertilization (IVF) or intracytoplasmic sperm injection (ICSI) treatment, and set up a predictive model providing personalized and clinically specific information related to CI incident.

DESIGN: A retrospective observational cohort study.

MATERIALS AND METHODS: This retrospective study included 4710 women pregnant after IVF/ICSI treatment from Jan 2011 to Dec 2018 at The Six Affiliated Hospital of Sun Yat-sen University. CI was first diagnosed during pregnancy based on cervical dilation and/or cervical shortening. Univariate and multivariate logistic regression were used to analysis the correlation of pre-pregnancy clinical covariates with CI occurrence. Nomogram model for CI incidence rate prediction was built from a training cohort of 3108 patients and tested on an independent validation cohort of 1602 patients. A bootstrapping technique was used for external validation.

RESULTS: A total of 109 patients (2.31%) were diagnosed with CI among all the enrolled patients. In multivariable analysis of the training cohort, CI occurrence was significantly related to serum Testosterone (odds ratio [OR], 7.103; 95% confidence interval [CI], 3.451 - 8.987; p <0.001), BMI (OR, 2.382; 95% CI, 1.186 - 5.786; p = 0.009) , uterine length (OR, 0.261; 95% CI, 0.132 - 0.525; p = 0.005) and gravidity (P = 0.031). Testosterone over 0.7ng/ml, uterine shorter than 45mm, increased BMI and gravidity were highly risky for CI occurrence . The nomogram model was built based on BMI, serum T, gravidity and uterine length, the area under the curve (AUC) was 0.839 (95% CI: 0.763 - 0.900) for the training cohort, the AUC for the validation cohort was 0.708 (95% CI: 0.685 - 0.832). The model showed a satisfactory goodness-of-fit and discrimination ability. No significant difference was detected between the predicted probability obtained from the bootstrap correction and the actual probabilities of CI occurrence (P = 0.261), which means the model is well calibrated.

CONCLUSIONS: The user-friendly nomogram graphically presented with pre-pregnancy predicted tool for CI incidence in patients undergoing IVF/ICSI treatment. It is of great importance to monitor highly risk women have polycystic ovary syndrome and take preventive measures prior to IVF/ICSI treatment and subsequent pregnancy as well.

HMG DIMINISH THE AVAILABLE OOCYTES UTILIZATION IN FRESH CYCLES. Peiyang Lin, master, Beihong Zheng, bcahelor, Rongshan Li, bachelor, Huiling Xu, master, Suqin Zhu, master Fujian Maternity and Child Health HospitalAffiliated Hospital of Fujian Medical University, FuZhou, China.

OBJECTIVE: During assisted reproductive therapy, both controlled ovarian stimulation(COS) and embryo culture have important effects on the development and maturation of oocytes. We aim to figure out how to evaluate the effect of ovulation promotion on oocyte development and the final embryonic development outcome.

DESIGN: Univariate analysis, multivariate analysis and case-control matching were used in this retrospective research.

MATERIALS AND METHODS: In this article, we introduced the concept of available oocytes utilization(AOU) to evaluate the effect of COS on oocyte development. A total of 460 fresh cycles with AOU lower than 50% were enrolled in our present study between January 2015 to December 2019, including 106 pregnancy cycles and 354 non-pregnancy cycles.

RESULTS: Univariate analysis and multivariate analysis revealed that basal E2(OR=0.98, p=0.04), endometrial thickness on HCG day (OR=1.25, p<0.01), number of follicular punctured(OR=1.58, p<0.01), number of oocytes retrieved(OR=0.80, p=0.04), number of available oocytes(OR=0.48, p=0.04) and AOU(OR=1.18, p<0.01) were contributed to clinical pregnancy. ROC analysis for fertilization rates showed a possible cutoff for AOU(AUC=0.788, cutoff=34.13%). Based on the ROC results, all 103 cycles with AOU less than 34% were included in the case group, and 103 cycles were selected as the control group according to the 1: 1 case control matching. The dosage of HMG was significantly different between the case group and control group(1064.00±1042.01U VS 675.00±691.67U , respectively,p=0.006). The duration of HMG usage were 7.88±4.73day and 5.79±3.59day in case group and control group(p=0.014).

CONCLUSIONS: Our results indicated that in the low AOU assisted pregnancy cycle, larger dose of HMG will reduce the proportion of available oocytes, which ultimately affects pregnancy outcomes.

P-832 4:30 PM Tuesday, October 20, 2020

SERUM FOLIC ACID, VITAMIN B12 AND VITAMIN D3 LEVELS ARE NOT ASSOCIATED WITH ANTIMULLERIAN HORMONE LEVELS. Caitlin Elizabeth Martin, MD, MS,[1] Joan Riley, PhD, HCLD,[2] Emily S. Jungheim, MD, MSCI[3] [1]Washington University School of Medicine, St. Louis, MO; [2]Washinton University School of Medicine, St. Louis, MO; [3]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: Reproductive aged women often seek advice regarding modifiable behaviors that may improve their future reproductive health. We aimed to determine if serum levels of vitamin B12, vitamin D3 or folic acid were associated with antimullerian hormones (AMH) levels in a reproductive aged, Midwestern cohort of women.

DESIGN: Cross-sectional cohort study.

MATERIALS AND METHODS: There were 200 women aged 18-44 years with regular menstrual cycles who were enrolled into the LORE study, which was designed to investigate associations between lifestyle factors and ovarian reserve. Women who were currently pregnant or who had history of major chronic illness, infertility or ovarian surgery were excluded. Fasting blood was drawn and stored at -80 degrees for batched analysis. Samples were run on the Roche Elecsys analyzer for AMH, vitamin B12, vitamin D3 and folic acid levels. Standard bivariate statistics were run to determine associations between vitamin B12, vitamin D3 and folic acid with AMH levels. SPSS v25 was used for analysis.

RESULTS: Participants had an average age of 30.9 ± 6.7 years and body mass index of 28.3 ±7.1 kg/m^2. About two thirds of the participants were white (n=136, 68%) and one third were black (n=60, 30%). The average AMH level was 2.9 ±2.0 ng/mL. The average vitamin B12 level was 604.2 pg/mL (Range 230.6-2000.0 pg/ML), vitamin D3 level was 22.3 ng/mL(range 6.8-94.9 ng/mL) and folic acid level was 14.9 ng/mL (range 2.2 - 20.0 ng/mL). None of these serum analytes were associated with AMH levels.

CONCLUSIONS: This data suggests that for healthy, reproductive aged women from the Midwest, modifying levels of vitamin B12, folic acid, or vitamin D through supplementation is unlikely to improve or adversely affect AMH.

SUPPORT: Financial Support: UL1TR000448.

ATYPICAL CORE BODY TEMPERATURE PATTERNS AND THE WIDER IMPLICATIONS FOR CONDITIONS RELATED TO PREGNANCY, INFERTILITY, AND MISCARRIAGE RISK. Bradley S. Hurst, MD Atrium Health Carolinas Medical Center, Charlotte, NC.

OBJECTIVE: To determine if pregnancy complications, ovulatory abnormalities and miscarriage risk were associated with atypical Patterns of vaginal core body temperature (CBT) measurements from the OvuSense (OS) system.

DESIGN: Retrospective, longitudinal, comparative, observational study.

MATERIALS AND METHODS: Participants used OS vaginally at night to monitor CBT when not menstruating. Three atypical CBT Patterns published previously, confirmed in updated Total Study Population (TSP) 20,067 ovulatory cycles from 8,177 OS users recorded March 2016 to March 2020: (A) "Crash To Baseline" = first nightly averaged CBT falls by >0.2 degrees Celsius (oC) to lowest cycle CBT point (baseline), (B) "False Start" = rise of >0.1oC did not result in ovulation but instead a return to baseline CBT followed by ovulation two or more days later in the cycle, (C) "Crash After Ovulation" = final CBT >0.2oC lower than the post ovulatory peak CBT.

A detailed medical questionnaire was then issued to study participants and the answers from 382 respondents accounting for 1,534 of the TSP cycles was used for further assessment. TSP used to confirm prevalence of cycle Patterns (A)-(C); and questionnaire assessed per respondent for each following historic 'Diagnosis':

1. Any infertility related diagnosis
2. PCOS
3. PCOS and regular cycles
4. Previous miscarriage = gravida >0, number miscarriages >0.
5. Gestational Diabetes in any previous pregnancy
6. Gestational Hypertension in any previous pregnancy

Diagnostic Odds Ratio (OR) calculated as (w/x)/(y/z) for each Pattern + Diagnosis combination together with their Lower (LCI) and Upper (UCI) 95% Confidence Interval: w. Positive Diagnosis (+D), Pattern >1 cycle for respondent (+P); x. -D+P; y. +D-P; z. -D-P.

RESULTS: Prevalence of Patterns: (A) 61.0%: 282 cycles in 172 respondents; (B) 66.3%: 205 cycles in 136 respondents; (C) 59.8%: 229 cycles in 137 respondents

Pattern	A			B			C		
Diagnosis	*LCI*	*OR*	*UCI*	*LCI*	*OR*	*UCI*	*LCI*	*OR*	*UCI*
Any infertility diagnosis	0.96	**1.43**	2.15	1.48	**1.72**	2.65	0.88	**1.09**	1.67
PCOS	1.19	**1.79**	2.69	1.83	**2.80**	4.29	1.03	**1.57**	2.39
PCOS + Regular Cycles	1.00	**1.76**	3.11	0.79	**1.14**	2.51	0.85	**1.51**	2.69
Previous Miscarriage	3.52	**5.94**	10.03	3.82	**6.84**	12.25	3.80	**6.88**	12.46
Gestational Diabetes	0.69	**2.15**	6.68	0.26	**0.85**	2.81	0.07	**0.34**	1.54
Gestational Hypertension	0.57	**1.50**	3.97	0.18	**0.58**	1.81	0.11	**0.39**	1.39

CONCLUSIONS: Results confirm previous research [1] that atypical CBT Patterns may aid infertility diagnosis, and elevated risk of miscarriage. Pattern A. may also provide a warning for elevated risk of pregnancy issues. It should be noted that the absence of an existing Diagnosis does not necessarily render the results with positive Patterns "false", and the existence of a Pattern could anyway indicate investigation for ovulatory abnormalities.

ERYTHROPOIETIN-PRODUCING HEPATOCELLULAR A7 RESTRAINS ESTROGEN-NEGATIVE FEEDBACK OF LUTEINIZING HORMONE VIA EPHRIN A5 IN THE HYPOTHALAMUS OF FEMALE RATS. Shang Li, M.D.,[1] Junyu Zhai, M.D. Ph.D.,[2] Yanzhi Du, M.D. Ph.D.[1] [1]Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [2]University of California, San Francisco, San Francisco, CA.

OBJECTIVE: We have previously shown that systemic injection of exogenous erythropoietin-producing hepatocellular (EPH) A7-Fc raises serum luteinizing hormone (LH) levels before ovulation in female rats, indicating the induction of EPHA7 in ovulation. In this study, we aimed to identify the mechanism and hypothalamus–pituitary–ovary (HPO) axis level underlying the promotion of LH secretion by EPHA7.

DESIGN: A study based on various rat models.

MATERIALS AND METHODS: Using an ovariectomized (OVX) rat model, in conjunction with low-dose estradiol (E_2) treatment, we investigated the association between EPHA7–ephrin (EFN) A5 signaling and E_2-negative feedback. Various rat models (OVX, E_2-treated OVX, and abarelix-treated) were injected with the recombinant EPHA7-Fc protein through the caudal vein to investigate the molecular mechanism underlying the promotion of LH secretion by EPHA7.

RESULTS: *Efna5* was observed strongly expressed in the arcuate nucleus of the female rat using RNAscope in situ hybridization. Our results indicated that E_2, combined with estrogen receptor (ER) α, but not ERβ, inhibited *Efna5* and *gonadotrophin-releasing hormone 1* (*Gnrh1*) expression in the hypothalamus. In addition, the systemic administration of EPHA7-Fc restrained the inhibition of *Efna5* and *Gnrh1* by E_2, resulting in increased *Efna5* and *Gnrh1* expression in the hypothalamus, as well as increased serum LH levels.

CONCLUSIONS: Our findings demonstrated the involvement of EPHA7–EFNA5 signaling in the regulation of LH and the E_2-negative feedback pathway in the hypothalamus, highlighting the functional role of EPHA7 in female reproduction.

SUPPORT: This work was supported by grants from the National Key Research and Development Program of China (No. 2018YFC1003202 and 2017YFC1001002), the National Natural Science Foundation (No. 81971343, 81671413, 81671414, and 81901549), and Shanghai Commission of Science and Technology (No. 19410760300 and 17DZ2271100).

P-835 4:30 PM Tuesday, October 20, 2020

EFFECT OF GROWTH HORMONE ON BLASTOCYST FORMATION AND IMPLANTATION RATES IN WOMEN UNDERGOING IN VITRO FERTILIZATION. Larissa Matsumoto, MD,[1] Ekaterini koutsantonis Pires, MD,[1] Michelle Nagai, MD,[1] Fernanda Imperial Granjo, MD,[1] Carolina Rebello Costa, MD,[1] Edson G. Lo Turco, PhD,[2] Lucas Yamakami, MD,[3] Renato Tomioka, MD,[3] Orcar Duarte, MD[4] [1]MD, São Paulo, Brazil; [2]IonMedicine - Precision Medicine, Sao Paulo, Brazil; [3]Clinical Chief, São Paulo, Brazil; [4]Clinical Chief in Lab For Life Laboratory, São Paulo, Brazil.

OBJECTIVE: Evaluate the adjuvant effect of human growth hormone (hGH) on blastulation, implantation, and pregnancy rates in women undergoing IVF cycles.

DESIGN: Retrospective chart review at a private infertility center

MATERIALS AND METHODS: This analysis uses data from a total of 293 IVF treatments from jan/2015 to april/2020. Patients with the poor ovarian response or who did not obtain blastocysts in previous cycles were selected and were split into two groups IVF with 2,66mg/day of hGH starting at the beginning of the stimulation until the trigger and without hGH protocol. The data analysis we have performed the T-test to assess the comparisons between groups, with a confidence interval of 95% and a statistical significance of p< 0,05.

RESULTS: A total of 293 cases, with 100 IVF stimulation cycles without hGH, classified as Controls (CG), and 193 with hGH protocol, classified as Study group (SG), didn't show the average age, (38,67+- 3,46 (CG) and 38,67 +- 3,00 (SG), p= 0,322). No differences between groups with AMH, basal FSH, and basal LH were observed. The number of oocyte retrieved showed no statistical difference, but we observed better results, with a blastulation rate (46% +- 0,37) into the SG when compared with, controls (29% +- 0,31), p= 0,001. The SG shows a better implantation rate (42,6% +- 0,5) and controls was (28,1% +- 044), p= 0,029. The OR for pregnancy rate with GH is 3,098 (IC 1,324-7,247, 95%).

CONCLUSIONS: Different strategies were used to attempt to improve oocyte and embryo quality in IVF cycles, particularly in older, POR, and women with diminished ovarian reserve. In our findings, the use of hGH was related to improvement in embryo quality, implantation rate, and pregnancy rate, as shown in prior studies. Consequently, the use of hGH as adjuvant therapy should be considered to optimize the results of IVF cycles. Large-scale randomized controlled trials are needed to determine the adequate dose and duration of the treatment, as well as to establish which populations would benefit most.

EXAMINING THE ASSOCIATION BETWEEN INFERTILITY, PREGNANCY INTENTION, AND POSTPARTUM DEPRESSION. Gabriela A. Barber, M.S., Julia R. Steinberg, Ph.D. University of Maryland, College Park, MD.

OBJECTIVE: To examine whether symptoms of postpartum depression differ between women who conceived naturally and intentionally, women who used fertility treatments, and women who had unintended pregnancies.

DESIGN: Cross-Sectional Survey

MATERIALS AND METHODS: Using data from the Pregnancy Risk Assessment Monitoring System (from 2009-2015; 36 states and NYC), we examined whether postpartum depressive symptoms differed between three pregnancy groups: women who reported conceiving naturally and intentionally (n = 91,064), women who reported conceiving naturally and unintentionally (n = 96,284), and women who reported conceiving with fertility treatments (n=5,535). We created two postpartum depressive symptom measures: 1) a continuous standardized measure of postpartum depressive symptoms, and 2) a dichotomous measure (called elevated postpartum depressive symptoms) that differentiated those who were at least one standard deviation above from those who were less than one standard deviation from the mean of postpartum depressive symptoms. We examined unadjusted and adjusted means of the continuous measure and predicted probabilities of the dichotomous measure. We adjusted for sociodemographics, relationship context, birth context, psychological health, and general health.

RESULTS: Women who conceived unintentionally (unadjusted M = 0.07, 95% CI: 0.06 – 0.08; adjusted M = 0.14, 95% CI: 0.09 – 0.20) had more postpartum depressive symptoms than women who conceived naturally and intentionally (unadjusted M = -0.17, 95% CI: -0.18 - -0.16; adjusted M = -0.0004, 95% CI: -0.05 – 0.05) and than women who used fertility treatments (unadjusted M = -0.14, 95% CI: -0.17 - -0.11; adjusted M = 0.01, 95% CI: -0.05 – 0.07), p-values <0.0005. The unadjusted and adjusted predicted probability of having elevated postpartum depressive symptoms was higher for the unintended pregnancy group (unadjusted predicted probability = 20.5%, 95% CI: 20.2% – 20.9%; adjusted predicted probability = 12.9%, 95% CI: 11.9% – 13.9%) compared to those who conceived naturally and intentionally (unadjusted predicted probability = 12.4%, 95% CI: 12.1%-12.7%; adjusted predicted probability = 9.9%, 95% CI: 9.1%-10.6%) and those who conceived using fertility treatments (unadjusted predicted probability = 11.2%, 95% CI: 10.0%-12.3%; adjusted predicted probability = 9.5%, 95% CI: 8.3%-10.8%), p-values < .0005.

CONCLUSIONS: Results suggest that the utilization of fertility treatments in order to conceive does not place women at a differential risk for PPD, whereas having an unintended pregnancy does. These results add to the small existing body of literature that has sought to characterize and examine postpartum mental health outcomes for women that have conceived through the use of fertility treatments. While undergoing fertility treatments may be a stressful experience, our

data do not provide evidence that undergoing such treatments increases women's risk of experiencing PPD relative to women who conceived naturally and intentionally. Instead, having an unintended birth increases risk of experiencing more postpartum depressive symptoms.

P-837 3:30 PM Wednesday, October 21, 2020

ASSOCIATION OF PSYCHOSOCIAL STRESS WITH OVARIAN FUNCTION IN YOUNG CANCER SURVIVORS. Jayeon Kim, MD, MPH,[1] Brian W. Whitcomb, PhD,[2] Brian Kwan, PhDc,[3] Sally A. D. Romero, PhD, MPH,[3] H. Irene Su, M.D., M.S.C.E.[3] [1]CHA Fertility Center Seoul Station, Obstetrics and Gynecology, Seoul, Korea, Republic of (South); [2]University of Massachusetts, Amherst, Amherst, MA; [3]University of California San Diego, La Jolla, CA.

OBJECTIVE: To investigate the association between psychosocial stress and ovarian function in adolescent and young adult cancer survivors (AYA survivors)

DESIGN: A cross-sectional study was conducted estimating the association between perceived stress, measured by self-report and saliva cortisol, and ovarian function, measured by bleeding pattern, dried blood spot (DBS) FSH and LH and saliva estradiol. We included 377 AYA survivor participants.

MATERIALS AND METHODS: AYA survivor participants were ages 15-35 at cancer diagnosis and ages 18 to 40 at study enrollment, had completed primary cancer treatment, had a uterus and at least one ovary, did not have uncontrolled endocrinopathy, and were not on hormone therapy. Recruited from cancer registries, physician referrals and cancer advocacy groups, participants provided self-reported information on psychosocial stress (Perceived Stress Scale-10) and on cancer, reproductive (fertility, contraception, menstrual pattern) characteristics. DBS samples were collected timed to the early follicular phase (cycle days 3-7) for menstruating individuals and on a random day for amenorrheic individuals; saliva samples were collected 3 time points within one day. FSH and LH were measured by ELISA's, cortisol and estradiol were measured by LC/MS.

RESULTS: The median age of participants was 34.0 years (range 19-41) at a median of 6.0 years since cancer diagnosis. The most common cancer was breast (32.1%). Median PSS-10 score was 15 (range 0-36), with 5.3% scoring $\geq$ 26, the cut point suggestive of severe stress. Cortisol levels followed a diurnal pattern and cortisol area under the curve (AUC) was negatively correlated with PSS-10 scores ($P = 0.03$). Neither PSS-10 scores nor cortisol AUC were associated with FSH, LH, estradiol levels or menstrual pattern. Waking cortisol and the cortisol awakening response also were not related to ovarian function measures.

CONCLUSIONS: We observed no association between self-reported and biomarkers of psychosocial stress and ovarian function measures in AYA survivors. The lack of association between psychosocial stress and a variety of ovarian function measures in female AYA cancer survivors suggests that psychosocial stress does not have a significant impact on the reproductive axis of AYA survivors. This finding is important in counseling this population on their menstrual pattern and family building plans.

ASSOCIATIONS BETWEEN QUALITY OF LIFE, SOCIODEMOGRAPHICS AND MILITARY CHARACTERISTICS IN A US VETERAN POPULATION WITH INFERTILITY. Mary K. Skalitzky, BA,[1] Michelle A. Mengeling, MS, PhD,[2] Andrea Holcombe, MS, PhD,[2] Amy M. J. O'Shea, PhD,[2] Karen M. Summers, MPH CHES,[3] Ginny L. Ryan, MD, MA[4] [1]University of Iowa Carver College of Medicine, Iowa City, IA; [2]Iowa City VA Health Care System, Iowa City, IA; [3]University of Iowa, Iowa City, IA; [4]University of Iowa Hospitals and Clinics, Iowa City, IA.

OBJECTIVE: To identify sociodemographic and military characteristics associated with quality of life for male and female US Veterans with infertility.

DESIGN: A cross-sectional survey of a national sample of military Veterans aged 20-45.

MATERIALS AND METHODS: Data were collected using a computer assisted telephone interview which included socio-demographics, reproductive health, and military exposures. Participants completed the Fertility Quality of Life (FertiQoL) tool if the Veteran and/or a current or previous partner had been diagnosed with infertility. The FertiQol tool is a validated instrument providing a summative Core FertiQoL score made up of 4 subscales (Emotional, Mind-Body, Relational, and Social) specific to patients with infertility. Higher subscale and resulting Core scores indicate higher quality of life. PTSD was measured in two ways: Veterans could self-report a past diagnosis or screen positive during the interview via the PCL-5 checklist. Bivariate analyses were completed to evaluate factors associated with the FertiQol scores.

RESULTS: 303 participants completed the FertiQoL: 166 females and 137 males. There were no statistically significant differences between male and female Veterans with regards to marital status, age, education level, household income, history of biological parenting, or PTSD diagnosis or screening. Female Veterans were more likely to report a history of any parenting, including parenting beyond the biological such as adoption (77.7% vs. 67.9%, p=0.05). Male Veterans reported significantly longer deployments, with 57.0% of men vs. 32.7% of women deployed more than 12 months (p=0.0001), and greater exposure to combat arms (53.3% vs. 15.1%, p=0.0001) and experience under enemy fire if deployed (81.3% vs. 59.3%; p=0.0008). Male Veterans also tended to have higher rank (p=0.003).

The mean Core FertiQol score for all 303 Veterans was 68.9 (SD=17.6). Higher total Core FertiQoL scores in male compared to female Veterans (mean 73.4 vs. 65.2, p<0.0001) resulted from higher Emotional, Mind-Body, and Social but not Relational subscale scores. Core FertiQol scores were positively associated with a history of biological parenting (mean = 70.8 vs. 65.2, p= 0.01) and age (p=0.006). Veterans with PTSD were found to have significantly lower Core FertiQoL scores compared to Veterans without PTSD (mean=65.3 vs. 74.0, p<0.0001). There were no differences in scores by marital status, race, income, education, or combat exposure.

CONCLUSIONS: This is the first known study of infertility-related quality of life in the Veteran population using the FertiQoL. Our study demonstrates that among Veterans with infertility, those with PTSD have poorer quality of life as measured by the FertiQol. Results show higher FertiQol Core and certain subscale scores in male Veterans, consistent with prior studies suggesting men experience less distress following an infertility diagnosis. Our findings support prior work showing age and biological parenthood, though not other parenting, mitigate the negative quality of life effects of infertility.

SUPPORT: The research reported here was supported by the Department of Veterans Affairs, Veterans Health Administration, Health Services Research and Development (HSR&D) Service grantÂ IIR 13-294. HEALING ENVIRONMENT IN THE FERTILITY CLINIC. Hoa T. Nguyen, MD, Emily A. Evans-Hoeker, MD Carilion Clinic, Roanoke, VA.

OBJECTIVE: The purpose of our study was to determine if alterations in the ambient environment have an impact on the anxiety level and/or satisfaction of patients undergoing fertility evaluation and treatment.

DESIGN: Cross-sectional survey study administered pre and post implementation of a "healing environment" in the fertility clinic.

MATERIALS AND METHODS: The healing environment intervention included: a cooperative coloring activity in the waiting room, lowering and warming lights in exam and waiting rooms, maintaining a low noise level and using sound machines in exam rooms, utilizing a mild calming natural aroma, and maintaining a comfortable temperature for equipment. The primary outcome was psychological well-being as measured by the validated State-Trait Anxiety Inventory (STAI) 6-Y survey which was self-administered at the time of the patient visit. A lower composite score in the STAI survey indicates a lower current level of anxiety. The STAI 6-Y survey was also made available to staff. The secondary outcome of patient satisfaction was evaluated using the Press-Ganey Survey in follow up to the patient visit as per institutional protocol, with a higher score indicating higher satisfaction. T-test and fisher exact tests were used for statistical analyses. Power analysis demonstrated a need for 35 surveys from each phase of the study to achieve 80% power to detect an effect size of .40 in STAI scores.

RESULTS: A total of 37 and 48 STAI surveys were conducted pre and post intervention, respectfully. The average scores during the pre and post "healing environment" intervention were 35 and 32, respectively (p = .26). Assessing individual components of the STAI, only the component assessing "feeling upset" demonstrated a statistically significant difference between the groups (p = .0396). In the pre intervention group, 21.62% reported feeling "somewhat upset" as compared to 6.25% in the post intervention group. Whereas, 0% reported feeling "moderately upset" in the pre intervention group compared to 6.25% in the post intervention group. Although not

powered, the staff STAI composite score was 38 (medium anxiety state) versus 27.5 (low anxiety state) pre and post intervention respectfully. The Press-Ganey surveys have been completed and are requested.

CONCLUSIONS: Though there was no significant difference in overall STAI scores pre and post intervention, patients rated feeling upset significantly more after implementation of the healing environment. The reason for this is currently unclear. Differences in patient satisfaction scores are yet to be determined.

EMOTIONAL WELL-BEING DURING FERTILITY TREATMENT: A RANDOMIZED CONTROLLED TRIAL TO EVALUATE THE USE OF AN ONLINE LEARNING PLATFORM AS A RESOURCE.

Abigail L. Bernard, MD,[1] Ashley K. Barbour, MPhys,[2] Jody L. Madeira, Ph.D., J.D.,[3] Steven R. Lindheim, M.D.,[4] Linnea R. Goodman, MD[1] [1]University of North Carolina, Raleigh, NC; [2]Brody School of Medicine at East Carolina University, Greenville, NC; [3]Professor of Law, Bloomington, IN; [4]Wright State University, Dayton, OH.

OBJECTIVE: Infertility and associated therapies have been characterized as anxiety-provoking. As emotional states can be triggered by stimuli, we assessed the impact of a visual multimedia electronic (e)-learning and e-consent platform on patients' anxiety states prior, during, and upon completion of infertility treatment cycles.

DESIGN: Prospective randomized controlled trial

MATERIALS AND METHODS: Patients aged 18-43 years undergoing their first intrauterine insemination (IUI) or in-vitro fertilization (IVF) cycle were randomized to two groups receiving either: 1) standard fertility counseling with their physician and nurse team (conventional group); or 2) standard counseling plus access to an interactive multimedia e-learning platform (EngagedMD) before and during their treatment cycle (EMD group). Patients completed surveys including a modified 19-question State-Trait Anxiety Inventory (STAI) at three time points to quantitively assess their treatment experience: T1 (prior to treatment), T2 (after the MD/RN teaching session at the start of their cycle), and T3 (after cycle completion). Each STAI item is given a weighted score of 1 to 4, the instrument has a possible score from 19 to 76, and the 50th percentile for an anxious state in women aged 19-39 is 34. Student's t-test and Chi-squared test were used as appropriate.

RESULTS: To date, a total of 77 patients (IUI=35 and IVF=42) with a mean age of 35.2 +/- 4.4 years have been enrolled with no differences in baseline demographics (age, duration of infertility, infertility diagnosis, and education level) for both IUI and IVF and conventional and EMD groups. Overall, STAI scores at T1, T2, and T3 were 37.8 +/- 11.3, 37.0 +/- 10.6, and 37.0 +/- 11.6 respectively, with no difference in IUI and IVF patients at T1 (p=0.51). However, IVF patients scored significantly higher at T2 (40.3 +/- 9.3 vs. 33.7 +/- 11.1, p=0.03) and T3 (41.3 +/- 12.1. vs. 32.7 +/- 9.5, p=0.01) compared to IUI patients at the same timepoints. IUI patients had a significant decrease in their anxiety from T1 to T2 (mean delta -3.1; p=0.05) and T1 to T3 (mean delta -3.9 p=0.01), while patients undergoing IVF treatments had no significant change in their anxiety scores throughout. With respect to conventional and EMD groups, there were no differences in STAI scores in IUI and IVF cycles from T1 to T3. Of the patients undergoing IUI, there was a significant decrease in patients' anxiety levels from T1 to T2 in the EMD group (35.8 +/- 9.3 vs. 31.6 +/- 10.2; p=0.02), while this difference was not seen in the conventional group (37.4 +/- 11.5 vs. 35.5 +/- 12.0; p=0.46).

CONCLUSIONS: Anxiety levels were significantly elevated in first-time IVF patients during and after treatments compared to those undergoing IUI. The addition of an e-learning platform did not alter the level of anxiety compared to traditional teaching methods in IVF patients. In contrast to standard counseling, patients undergoing IUI experienced a decrease in their immediate anxiety level after exposure to EngagedMD. Overall, anxiety levels in this cohort of patients were high, indicating that added psychological resources may be beneficial to this population.

PERINATAL EXPOSURE TO HIGH DIETARY AGES DELAYS PUBERTY ONSET AND DISRUPTS FOLLICULOGENESIS IN FEMALE OFFSPRING. Zaher Merhi, MD, HCLD,[1] Xiu-Quan Du, N/A,[2] Maureen Charron, Ph.D.[2] [1]SUNY Downstate University and New Hope Fertility Center, New York, NY; [2]Albert Einstein College of Medicine, Bronx, NY.

OBJECTIVE: Nutrition is an important source of exogenous advanced glycation end-products (AGEs) where thermally processed foods present in western-style diets contain large amounts of these pro-inflammatory molecules. Maternal nutrition and the intrauterine environment are important in determining susceptibility to reproductive and metabolic disturbances. The objective of this study was to determine whether perinatal exposure to high amounts of dietary AGEs affect metabolic and the reproductive parameters in female mice offspring.

DESIGN: Animal experiments in a university setting.

MATERIALS AND METHODS: 7 week old female CD1 mice were placed on either a diet low (L-AGE) or high (H-AGE) in AGEs for 2 weeks before mating and then for additional 6 weeks throughout pregnancy and lactation. Offspring from L-AGE dams (n=10) and H-AGE dams (n=13) were all weaned onto the L-AGE diet and studied through 16 weeks of age. Offspring were counted and weighed at birth then weekly. Body weight, growth curve, pubertal onset (age at vaginal opening), estrus cyclicity (vaginal smear), serum levels of anti-Mullerian hormone (AMH), leptin and adiponectin as well as insulin tolerance test (ITT) and glucose tolerance test (GTT) were performed. Ovaries were harvested for follicular count and gene expression by RT-PCR. Data were reported as mean ± SEM. For GTT and ITT, the total area under the curve (AUC) for 120 minutes for glucose concentrations in mg/dL was calculated. Mann-Whitney U test and repeated measures ANOVA were performed as appropriate.

RESULTS: Pups exposed to perinatal H-AGE diet had significantly lower body weight at birth compared to pups exposed to perinatal L-AGE diet (1.38 ± 0.1 vs. 1.58 ± 0.16 grams, $p<0.05$; respectively). Adult offspring exposed to perinatal H-AGE diet exhibited delayed growth and lower serum levels of leptin and AMH ($p<0.05$ for all). There was no significant difference in AUC for GTT ($p=0.7$) or ITT ($p=0.2$) between both groups. Perinatal exposure to H-AGE diet affected the reproductive potential in the adult female offspring by exhibiting delayed vaginal opening and irregular estrus cycles by spending less time in the proestrus phase and more time in the metestrus phase ($p=0.04$). Adult offspring exposed to perinatal H-AGE diet had significantly fewer corpora lutea (CL) in their ovarian sections, exhibited arrested folliculogenesis with most follicles in the secondary follicle stage, and had significantly lower ovarian mRNA expression levels of *Amh* ($p=0.005$), *Amhr2* ($p=0.02$), and *Cyp19a1* ($p=0.03$) compared to adult offspring exposed to perinatal L-AGE diet.

CONCLUSIONS: These results indicate that perinatal exposure to a diet elevated in AGEs causes deficits in perinatal growth, pubertal onset, and reproductive organ development in female mice. Whether these findings translate to humans remains to be determined in future studies.

SUPPORT: This research was supported by a grant from the American Society for Reproductive Medicine and a grant from the Society for Reproductive Investigation.

P-842 3:30 PM Wednesday, October 21, 2020

GETTING STRAIGHT TO THE POINT: DOES INDIVIDUALIZED PRE- AND POST-EMBRYO TRANSFER ACUPUNCTURE INCREASE PREGNANCY RATES? Lauren Grimm, M.A., Kate Phillippi, L. Ac, Lamya Kamel L.Ac, Dipl. OM, DAOM, Roohi Jeelani, MD Vios Fertility Institute, Chicago, IL.

OBJECTIVE: To examine the pregnancy and clinical pregnancy rates of those patients undergoing elective individualized pre- and post-embryo transfer acupuncture compared to receiving no acupuncture on day of frozen embryo transfer (FET).

DESIGN: Retrospective chart review at a private fertility center.

MATERIALS AND METHODS: All patients undergoing FET between the months of May 2018 – April 2020 were included. All patients meeting internal clinic standards for having a frozen embryo transfer can elect to have individualized pre- and post-embryo transfer acupuncture performed on-site 30 minutes before and immediately after embryo transfer. Patients were divided into two groups: those that received acupuncture therapy pre- and post- FET, and those that did not. Patients' past medical and cycle history were reviewed, and pregnancy outcomes recorded. Pregnancy was defined as having received a serum bHCG >5mIUmL, while clinical pregnancy was defined as receiving confirmation of gestational sac on transvaginal ultrasound 14 days following transfer. Two sample t-tests and chi square analysis were used to analyze the data using SPSS (SPSS Inc., Chicago, IL, USA).

RESULTS: A total of 654 cycles were analyzed. Baseline characteristics, including age and BMI, were similar between the two groups ($p>0.05$). There was a statistically significant difference in pregnancy rates between the Acupuncture FET and non-Acupuncture FET groups of 66.8% and 56.65% respectively ($p=0.003$). Similarly, the clinical pregnancy rate between the two groups was also statistically significant, with the acupuncture group having a clinical pregnancy rate of 60.6% compared to 46.95% in the control group ($p=0.017$). Additionally, of the patients that underwent PGT and transferred known euploid embryos, those that received acupuncture had a significantly higher pregnancy rate of 73.93% compared to 63.29% for those that did not ($p=0.042$). For those patients that did not undergo PGT, both pregnancy rates and clinical pregnancy rates were similar, with the acupuncture group having a pregnancy rate of 56.41% and clinical pregnancy rate of 52.56%, compared to 52.63% ($p=0.55$)and 41.4% ($p=0.11$) respectively for the non-acupuncture group. Although not statistically significant it is clinically relevant.

CONCLUSIONS: Previous studies have shown that acupuncture promotes blood flow and regulates the nervous system; therefore, it is thought to be helpful on the day of embryo transfer to promote relaxation and decrease stress while encouraging blood flow to the uterus. Inherent to Chinese Medicine is creating individualized treatments and although the standard diagnostics were not utilized, the past medical and cycle history were used to draw diagnostic conclusions and inform the unique treatments. Overall, individualized acupuncture performed on the day of embryo transfer was associated with statistically significantly higher pregnancy and clinical pregnancy rates. Follow-up research will investigate the difference in live birth rates and the cost-effectiveness of adding an acupuncture regimen to FET treatment protocols.

IMPACT OF ACUPUNCTURE AND TRADITIONAL CHINESE MEDICINE (TCM) ON FROZEN EMBRYO TRANSFERS (FET) OF AUTOLOGOUS EMBRYOS WITH COMPREHENSIVE CHROMOSOMAL SCREENING (CCS): A RETROSPECTIVE COHORT STUDY. Lee Hullender Rubin, DAOM,[1] Carmelo S. Sgarlata, M.D.,[2] Morgan Hogue, MAcOM,[2] Lisa Pate, MAcOM,[2] Elizabeth Richards, MAcOM,[2] Lisa K. Tongel, MAcOM,[2] Hong Jin, DAOM, MD(PRC)[3] [1]Osher Center for Integrative Medicine University of California San Francisco, San Francisco, CA; [2]ORM Fertility, Portland, OR; [3]Oregon College of Oriental Medicine, Portland, OR.

OBJECTIVE: We aimed to assess birth outcomes from Frozen Embryo Transfer (FET) cycles of autologous embryos with Complete Chromosomal Screening (CCS) between patients with no known additional therapies compared with the addition of two distinct acupuncture approaches varying in dose (2 sessions or ≥3 sessions) and treatment (standardized or individualized).

DESIGN: Retrospective cohort study of patient charts from a single, private clinic matched with charts from affiliated acupuncturists' clinics.

MATERIALS AND METHODS: The fertility clinic contracted with six acupuncture associates to perform day of embryo transfer acupuncture (ET Acu) onsite. Charts were reviewed of women who completed an FET cycle with chromosomally screened, euploid, autologous embryos with or without ET Acu between July 2016 and December 2018. The acupuncturists also extracted data from charts from their community clinics of shared fertility clinic patients who added acupuncture therapy prior to embryo transfer (ET). Data was matched by name and ET date then merged with the fertility clinic database for analysis. Cycles with gestational carriers, donor eggs, no transfer, or embryos without chromosomal screening were excluded. Patient groups were categorized as 1) usual care for women who completed FET alone (UC group); 2) UC and ET Acu of two standardized acupuncture sessions before and after ET (ET Acu group); and 3) UC, ET Acu and acupuncture therapy received in the community prior to ET that included Traditional Chinese Medicine (TCM group) therapies such as diet and lifestyle modifications, warming therapy, or if appropriate, Chinese herbal therapy. Comparability between groups was assessed by age and number of embryos transferred. Differences in means were assessed using

one-way analysis of variance and proportions by Chi-square analysis. Main outcome measure was live birth.

RESULTS: We identified 1,035 FET-CCS cycles, of which 526 were UC, 150 were ET Acu, and 359 were TCM. The mean age of women in ET Acu (36.5 ± 3.8) and TCM (36.5 ± 3.7) groups was older than the UC group (35.9 ± 4.3, *p=0.05*) and not comparable. The mean number of embryos transferred in the ET Acu (1.29 ± 0.5) and TCM (1.25 ± 0.4) groups was also more than UC (1.20 ± 0.4), but not significantly (*p=0.095*). There was no difference in live births between UC (67.7%) and TCM (64.6%, *p=0.35*), but both groups were associated with significantly more live births over ET Acu (55.3%, *p=0.005* and *0.05*, respectively). The rate of miscarriage was also similar between UC (6.6%) and TCM (8.9%, *p=0.20*), but again, both were associated with significantly less than ET Acu (15.3%, *p=0.001* and *0.03*, respectively).

CONCLUSIONS: In autologous FET-CCS cycles, individualized acupuncture therapy with three or more visits and FET alone were associated with significantly more live births and fewer miscarriages when compared with ET Acu. In this observational study, patients who chose ET Acu and TCM differed on important variables that may predict birth outcomes thereby limiting interpretation. Future study should determine the ideal acupuncture dose and approach to support FET cycles with screened embryos.

SUPPORT: No financial support to disclose.

P-844 3:30 PM Wednesday, October 21, 2020

SUNNY SIDE UP? THE ROLE OF VITAMIN D IN FOLLICULAR DEVELOPMENT IN WOMEN OF ADVANCED MATERNAL AGE UNDERGOING INTRAUTERINE INSEMINATION.

Christy Oso, B.A.,[1] Nepheli Raptis, B.A., M.A.,[1] Emma Radley, M.A.,[1] Hanna Mandell, M.A.,[1] Lauren Grimm, M.A.,[1] Jessi Anderson, MPH,[1] Zoran J. Pavlovic, M.D.,[2] Angeline Beltsos, MD,[1] Roohi Jeelani, MD[1] [1]Vios Fertility Institute, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.

OBJECTIVE: This study sought to determine whether vitamin D levels influenced follicular development in women of advanced maternal age undergoing intrauterine insemination (IUI).

DESIGN: Retrospective chart review at a private, multi-site fertility clinic.

MATERIALS AND METHODS: All patients over the age of 35 who underwent IUI between January 2017 - August 2019 were included. All patients received a basic fertility work up, including serum vitamin D and estradiol levels, as well as ultrasound evaluations. Sufficient serum vitamin D levels were defined as > 20 ng/mL at baseline while deficient patients were defined as <20 ng/mL. Maximum estradiol and follicle size as determined by ultrasound were used to measure follicular development. T-tests and chi square analysis were used to analyze the data using SPSS (SPSS Inc., Chicago, IL, USA).

RESULTS: A total of 163 patients were analyzed. Baseline characteristics between the two groups, including age and BMI were insignificant. The average baseline vitamin D level for deficient patients was 15.53 ng/mL while the average for sufficient patients was 35.83 ng/nL. For both vitamin D deficient and sufficient patients, no statistically significant relationship between vitamin D and dominant follicle size was found (p=0.249 and p=0.932, respectively). There was also no significant relationship found between vitamin D and maximum estradiol levels (p=0.910 and p=0.234, respectively).

CONCLUSIONS: Much attention has recently been given to the potential role of vitamin D in fertility treatments as its replenishment has been shown to improve IVF success rates. Vitamin D, believed to play an integral role in human reproduction, has receptors located throughout the endometrium and on the granulosa cells of growing follicles. Some in vitro studies demonstrated that treatment of follicles with vitamin D enhanced granulosa cell proliferation, and others found that vitamin D may counteract the inhibitory actions of AMH on the recruitment of primordial follicles, allowing for follicular maturation.The results of previous studies investigating the relationship between vitamin D and fertility treatment have been conflicting. While some studies have shown vitamin D to play a role in IUI success as measured by pregnancy outcomes, others have shown the opposite. The results of this study demonstrate that vitamin D may not play a role in follicular development. Future research is needed to determine whether vitamin D should be replenished for patients pursuing IUI.

EFFECTS OF DAIRY INTAKE TO PREGNANCY OUTCOME AMONG WOMEN IN THE UNITED STATES.

Liang Yu, PhD,[1] Tina Duong Cunningham, PhD[2] [1]Eastern Virginia Medical School; [2]Eastern Virginia Medical School, Norfolk, VA.

OBJECTIVE: Dairy intake has been considered as a source of calcium and protein to keep bones and muscles functioning properly. Recent studies suggested that dairy intake has also related to reproductive health due to its influence on hormone level. However, no past studies have examined the association between the dairy intake and pregnancy outcome. This study investigated this association in women of reproductive age in the U.S.

DESIGN: The retrospective study utilized the National Health and Nutrition Examination Surveys (NHANES) 2015-2016 public data, including data from biospecimen collection and health questionnaires on diet and pregnancy.

MATERIALS AND METHODS: The sample was consisted of 1366 women between 18-44 years extracted from this data. Simple Logistic regression was used first to examine the bivariate association between dairy intake and pregnancy outcome alone. After that, multiple logistic regression models were fitted to examine the same association, with the presence of confounding factors such as dairy intake, age, estradiol level, education and race.

RESULTS: A majority of women became pregnant trying within a year was 1055 (89.94%), and those who tried a year to become pregnant but still failed were 118 (10.06%). The population who regularly intake dairy (dairy use 5 time per week) was close to non-regularly dairy intake group (27.50% vs. 28.87%). Dairy intake was found not significantly associated with pregnancy with an odds ratio of 0.980 [95%CI = (0.585, 1.641)]. The Multiple logistic regression model showed that age was significantly associated with pregnancy with a p-value at 0.0044, and an odds ratio of 1.061 [95%CI = (1.019, 1.105)]. The odds of pregnancy failure in Mexican American women significantly higher than White women with a p-value at 0.0306, and the odds ratio was 2.542 [95%CI = (1.091, 5.921)].

CONCLUSIONS: This retrospective analysis showed that dairy intake frequency was not associated with pregnancy outcome among women in the United States during 2015-2016. The association did not differ when considering dairy intake alone as an individual factor or taking multiple factors into account including age, estradiol, race or education level.

P-846 3:30 PM Wednesday, October 21, 2020

VITAMIN D SUPPLEMENTATION PROTOCOLS AND BASELINE CHARACTERISTICS IN WOMEN SEEKING FERTILITY CARE.

Alex Finlinson, MD,■ Oluwafunmilayo Ogunremi, MD,[2] Andrea Goldstein, BS,[2] Brittany N. Carson, BS,[2] Sadeq Quraishi, MD,[3] Albert L. Hsu, MD[4] [1]University of Missouri, Columbia, MO; [2]Tufts Medical Center, Boston, MA; [3]Department of Reproductive Endocrinology and Infertility; University of Missouri, Columbia, MO; [4]■ ■ ■.

OBJECTIVE: In women of reproductive age, low serum 25-hydroxyvitamin D (25OHD) levels are associated with lower pregnancy rates. However, guidance on optimal vitamin D supplementation regimens during preconception are sparse. Our goal was to assess the efficacy of two vitamin D supplementation protocols in a cohort of women presenting for preconception or infertility.

DESIGN: We performed a retrospective analysis of 185 patients who presented for preconception or infertility at the University of Missouri between 2017 to 2018. Women who had 25OHD levels ≤20 ng/ml received 50,000 IU of oral vitamin D weekly for 8 weeks, while women with 25OHD 21-29 ng/ml received 50,000 IU of oral vitamin D weekly for 4 weeks. All women were also encouraged to take an extra 1000 IU of oral vitamin D daily, per Endocrine Society recommendations; 25OHD levels were re-assessed after the supplementation period.

MATERIALS AND METHODS: Pregnancy status was assessed as of 12/31/19 for all patients. Means were compared with two-sample t-tests. SAS version 9.4 (SAS Institute, Cary, NC) was used for all analyses.

RESULTS: In an initial comparison of the three groups (normal, insufficient, and deficient vitamin D levels), there was a statistically-significant difference in median BMI. There were differences in pregnancy rates between the three groups (31.7% in deficient group, 56.9% in insufficient group, 44.2% in normal vitamin D group) that will require further analysis. This comparison did not account for differences in fertility diagnoses or treatments. Intriguingly, while also likely not statistically significant, the mean number of days to pregnancy was quite different: 159 days in the deficient group, 234 days in the insufficient group, and 426 days in the normal vitamin D group.

Variable	Group 1 = deficient	Group 2 = insufficient	p-value	Group 3 = normal
# of women	63	68		53
Age (median, range)	31.1 (21-43 y/o)	30.0 (17-43 y/o)	0.254	33 (21-45 y/o)
Calculated age	31.6 (21.4-43.4)	31.4 (18.0-43.2)		33.1 (21.1-45.3)
BMI	**36.6 (17-65)**	**31.0 (17-52)**	**0.01**	26 (18-57)
AMH	6.1 (0.2-23)	3.12 (0.5-16)		2.3 (0.1-37)
FSH	7.9 (2-53.3)	5.95 (2.7-15.5)		7.0 (0.4-16.2)
Initial Vit D level	14.9 (4-20)	26.0 (21-29)	< 0.0001	36 (30-84)
Repeat vit D level	36.2 (11-86)	43.0 (21.9-87)	0.0252	n/a
Pregnant	= 13	= 33		= 19
Not pregnant	= 28	= 25		= 24
%	= 13/41 = 31.7%	= 33/58 = 56.9%		= 19/43 = 44.2%
Days to achieve pregnancy	159 (43-511 days)	234 (35-606 days)		426 (98-537 days)

CONCLUSIONS: Both vitamin D supplementation strategies were successful in improving median vitamin D levels. There are intriguing differences in baseline characteristics (BMI, AMH levels) and pregnancy results (percent pregnant, time to pregnancy), which need to be explored further in subsequent studies.

POSTER SESSION: OVARIAN RESERVE

P-847 3:30 PM Wednesday, October 21, 2020

DIFFERENCES IN FOLLICULAR FLUID CYTOKINE PROFILE IN WOMEN WITH DIMINISHED OVARIAN RESERVE. Sina Abhari, MD,[1] Heather S. Hipp, MD,[1] Sabrina A. Gerkowicz, MD,[2] Quinton S. Katler, MD,[1] Laurie J. McKenzie, M.D.,[3] Shang Weirong, PhD,[1] Alicia K. Smith, PhD,[1] Anna K. Knight, PhD[1] [1]Emory University School of Medicine, Atlanta, GA; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [3]Baylor College of Medicine, Houston, TX.

OBJECTIVE: To investigate the expression of cytokines in follicular fluid (FF) of women with diminished ovarian reserve (DOR) undergoing in vitro fertilization (IVF) and explore correlated functional pathways.

DESIGN: Nested case-control study

MATERIALS AND METHODS: Women undergoing ovarian stimulation and planned oocyte retrieval were recruited from the Emory Reproductive Center. We included 51 women with DOR and 30 controls, defined as women undergoing IVF for male factor, tubal factor due to tubal ligation, or oocyte cryopreservation for planned fertility delay (non-oncologic). Follicular fluid samples were collected from each participant at the time of oocyte retrieval and stored for later use. The follicular fluid samples were then assessed using multiplexed sandwich ELISA-based quantitative array platform (RayBiotech). Quantile regression was used to assess the association of DOR diagnosis and cytokine concentrations. The false detection rate was controlled at 5%.

RESULTS: A total of 357 cytokines were investigated in both women with DOR and controls. Expression of 26 cytokines was found to be significantly different in the follicular fluid between the DOR and the control group (*FDR<0.05),* following adjustment for age and BMI. Differentially expressed cytokines belong to diverse functional groups involved in follicular development and maturation including growth factor and related proteins, receptor signaling, apoptosis and inflammation. Among the most significant differentially expressed cytokines were sonic hedgehog ligand (SHH) and Amphiregulin (AR), both of which were lower in women with DOR. SHH is involved in granulosa and theca cell communication and promotes cellular proliferation in mouse ovary. AR has a significant role in oocyte maturation. We also detected a lower level of soluble Fas in women with DOR comparted to controls. The soluble form of Fas has anti-apoptotic activity, and our finding suggests down regulation of this pathway in women with DOR,

CONCLUSIONS: We found 26 cytokines differentially expressed between women with DOR and controls with normal ovarian reserve. Our data suggest feasibility of identifying biomarkers that illuminate how the ovarian follicle microenvironment is altered in the DOR population and identification of pathways playing a role in pathophysiology of DOR.

P-848 3:30 PM Wednesday, October 21, 2020

TUMOR NECROSIS FACTOR-ALPHA (TNFA) INHIBITORS DO NOT IMPACT OVARIAN RESERVE. Pamela B. Parker, M.D., M.P.H., Sacha A. Krieg, M.D., Ph.D., David Lee, MD, Thomas O'Leary, PhD, Diana Wu, MD, Bharti Garg, MBBS, MPH, Paula Amato, MD Oregon Health & Science University, Portland, OR.

OBJECTIVE: Increasing numbers of women are prescribed immunosuppressive and biologic medications for rheumatologic disorders and inflammatory bowel disease. TNFa is a potent cytokine with proinflammatory, cytotoxic, angiogenic, and growth modulatory effects of various target cells. While evidence on the safety of certain biologic medications has led to recommendations for use in pregnancy, few studies have assessed the impact of this immunotherapy on fertility in the preconception period. The purpose of this study is to analyze the impact of anti-tumor necrosis factor-alpha (TNFa) inhibitors on markers of ovarian reserve specifically, anti-mullerian hormone (AMH) level and antral follicle count (AFC).

DESIGN: IRB-approved retrospective cohort study

MATERIALS AND METHODS: We analyzed data from infertility patients seen at a single tertiary academic institution from 2008-2019 who reported taking any of the following anti-TNFa medications: infliximab, adalimumab, golimumab, certolizumab, etanercept, anakinra. AMH levels and AFC were compared to those of age-matched controls undergoing in-vitro-fertilization (IVF) during the same time period. Comparisons were done using two-sample t-tests (continuous variables) and Fisher Exact tests (categorical variables). In addition, we assessed ovarian response and IVF outcomes in a subset of patients taking TNFa-inhibitors who underwent IVF.

RESULTS: A total of 54 subjects were included (18 in study group; 36 controls). There were no differences in baseline characteristics such as age or parity. The most common indications for use of TNFa inhibitors were rheumatoid arthritis (38.9%), ulcerative colitis (22.2%), and Crohn's disease (22.2%). The most common TNFa inhibitors taken were infliximab (44.4%), etanercept (27.8%), and adalimumab (22.2%). There was no statistically significant difference in AMH level (2.07 vs 2.82 ng/mL, p = 0.29) nor AFC (17.95 vs 18.86, p=0.17) between the study group and controls, respectively. Analysis of IVF outcomes revealed no differences between groups in etiology of infertility, gonadotropin dose, duration of ovarian stimulation, cycle cancellation rates, number of oocytes retrieved, fertilization rate, number of embryos, number of embryos transferred, day of embryo transfer, or clinical pregnancy rate.

CONCLUSIONS: We conclude that anti-TNFa medications do not have a significant impact on ovarian reserve or ovarian response to stimulation. The information from this study can assist providers when counseling infertility patients regarding the impact of immunomodulators on fertility. Larger studies are needed to further assess the impact of immunomodulators on ovarian reserve and pregnancy outcomes in the general population.

P-849 3:30 PM Wednesday, October 21, 2020

OVARIAN AUTOLOGOUS PLATELET-RICH PLASMA (PRP) TREATMENT IMPROVES OOCYTE AND EMBRYO QUALITY IN WOMEN WITH POOR OVARIAN RESPONSE. Dimitar Parvanov, PhD,[1] Rumiana Ganeva, MSc,[1] Nina Vidolova, MSc,[1] Kristina Nikolova, MSc,[1] Magdalena Vasileva, MSc,[1] Ivaylo Stoykov, MSc,[1] Fabio Scarpellini, MD,[2] Georgi Stamenov, MD/PhD[1] [1]Nadezhda Women's Health Hospital, Sofia, Bulgaria; [2]Centre for Endocrinology and Reproductive Medicine, Rome, Italy.

OBJECTIVE: The application of platelet rich plasma (PRP) as a non-operative treatment is an innovative approach, introduced only recently in reproductive medicine. A few case studies have shown that intraovarian injection of PRP in women with poor ovarian reserve resulted in an increased number of MII oocytes and cleavage-stage embryos. However, little is known about the effect of autologous ovarian PRP treatment on oocyte and embryo quality. The objective of the present study was to evaluate the role of ovarian PRP treatment on the number and quality of oocytes and embryos in women with poor ovarian response undergoing IVF cycles.

DESIGN: Prospective cohort study

MATERIALS AND METHODS: A total of 132 women with a history of poor ovarian response (according to the Bologna criteria) in the previous cycle(s) were included in this prospective study between June 2019 and February 2020. They were treated with ovarian autologous PRP injection in two subsequent menstrual cycles. Approximately 21 ml autologous blood obtained from peripheral vein was obtained and used to prepare PRP following standard protocols. PRP injection was performed using a 21Gx11.8 inch needle under transvaginal ultrasound guidance. Antral follicle counts (AFC) and FSH levels were determined at baseline. Biomarkers of ovarian reserve (AFC and FSH) and IVF outcome variables (fertilization rate, number and quality of MII oocytes, and the number and quality of blastocysts) were recorded and compared between the cycle before and after PRP treatment. All collected oocytes and obtained Day 5 embryos were graded morphologically (Grades 1–3; Grade 1 being highest relative quality and Grade 3 being the lowest quality of the three grades) based on the standard methods. The results were analysed using Student's paired t-test. $P<0.05$ was considered statistically significant.

RESULTS: Ovarian PRP treatment resulted in insignificantly lower FSH (12.6±1.46 vs. 13.8±1.55, P=0.37) and slightly higher number of mature follicles (3.4±1.8 vs. 2.8±1.5, P=0.56). There were also insignificant increases in the number of retrieved oocytes (4.71±2.6 vs. 4.63±2.8, P=0.34, respectively), fertilization rate (81 vs. 79, P = 0.81) and, consequently the total number of Day 5 embryos (3.93±0.43 vs. 3.29±0.39, P=0.23). However, the percentage of high-quality MII oocytes (67.2% vs. 40.7%, P=0.03) and the percentage of grade-I blastocysts (65.56% vs. 45.89%, P=0.05) were significantly higher after PRP treatment in comparison to the pretreatment period. In addition, the mean MII oocyte quality (1.76±0.61 vs. 2.03±0.73, P=0.05) and blastocyst quality (1.49±0.57 vs. 2.11±0.92, P=0.03) were significantly improved in the post-treatment period.

CONCLUSIONS: The applied autologous ovarian PRP treatment is an effective approach in improving oocyte and embryo quality in poor responders. This approach may contribute to increased pregnancy rates.

P-850 3:30 PM Wednesday, October 21, 2020

BIOAVAILABLE INHIBIN B (INHB) MAY BE A BETTER MARKER OF OOCYTE YIELD THAN CURRENTLY USED MARKERS OF OVARIAN RESERVE.

Rachel Blair Danis, MD,[1] Intira Sriprasert, MD,[1] Jacqueline Ho, MD MS,[1] Ajay Kumar, PhD,[2] Lynda K. McGinnis, PhD,[3] Frank Z. Stanczyk, PhD[1] [1]University of Southern California, Los Angeles, CA; [2]Ansh Labs, Webster, TX; [3]Keck School of Medicine, University of Southern California, Los Angeles, CA.

OBJECTIVE: InhB is a dimeric protein secreted by granulosa cells. Its concentration rises at two points in the follicular phase, corresponding to preantral follicular growth and rising follicle-stimulation hormone (FSH). Despite its relationship with folliculogenesis, inhB has shown inter-cycle variability and cross-reactivity with other proteins, making it an inaccurate marker of ovarian reserve or predictor of oocyte yield. However, a new ELISA that specifically measures the β_B and α units detects the true biologically active, or bioavailable, inhB (bio-inhB). We hypothesized that selective measurement of bio-inhB may predict oocyte yield in controlled ovarian stimulation (COS).

DESIGN: Prospective cohort study

MATERIALS AND METHODS: Serum from women undergoing COS was obtained at the: 1) start, 2) middle ("mid"), and 3) end ("final") of COS. A new ELISA (Ansh Labs, Webster, TX) measured bio-inhB in these samples. The trend of bio-inhB ("delta") was calculated. Spearman tests evaluated correlations between bio-inhB and other ovarian reserve markers, such as age, antral follicle count (AFC), FSH, anti-Müllerian hormone (AMH), and oocyte yield. Participants were then stratified by diminished ovarian reserve (DOR) parameters.

RESULTS: Participants (n=64) had an average age of 34.5 years. 45.3% of women had an AMH <2ng/mL, but only 10.5% of women had an FSH >10mIU/mL and 8.2% had an AFC <7. Consistent with prior studies, bio-inhB at the start did not correlate with other ovarian reserve markers. However, mid, final, and delta bio-inhB were positively associated with AFC and AMH and negatively associated with age and FSH, reflecting DOR status (Table).

TABLE. Bio-inhB correlations with other ovarian reserve markers and oocyte yield

	Age	FSH	AFC	AMH	Total oocytes
Bio-inhB, baseline	-0.10	0.24	0.08	0.04	0.12
Bio-inhB, mid	-0.57*	-0.22	0.64*	0.60*	0.71*
Bio-inhB, final	-0.52*	-0.36*	0.89*	0.81*	0.88*
Bio-inhB, delta	-0.51*	-0.38*	0.88*	0.80*	0.87*
Total oocytes	-0.55*	-0.37*	0.86*	0.82*	

*p-value <0.05, Spearman tests used

When examining COS outcome, final and delta bio-inhB correlated strongly with oocyte yield (r= 0.87-0.88, p<0.05, Table). These correlations were stronger than those for age, FSH, and AMH, and similar to that of AFC. Correlations between bio-inhB and oocyte yield strengthened when stratified by age >35 years, AMH <2 ng/mL, and FSH >10mIU/mL.

CONCLUSIONS: When using this specific assay, bio-inhB values reflected ovarian activity in COS and correlated with other ovarian reserve markers. Correlations between bio-inhB and oocyte yield were stronger than those between most markers of ovarian reserve and oocyte yield. In contrast to prior data, bio-inhB may be a valuable tool in predicting oocyte yield, particularly in women with DOR.

EFFECT OF NIGHT SHIFT WORK ON ANTI-MULLERIAN HORMONE (AMH) LEVELS IN REPRODUCTIVE-AGED AFRICAN AMERICAN WOMEN (AAW).

Chelsea N. Fortin, MD,[1] Emma Giuliani, MD,[1] Anne Waldo, MS,[1] Lia Bernardi, MD,[2] Mercedes Carnethon, PhD,[2] Erica E. Marsh, MD, MSCI, FACOG[1] [1]University of Michigan, Ann Arbor, MI; [2]Northwestern University, Chicago, IL.

OBJECTIVE: Circadian disruption, as commonly occurs in night shift workers, has been associated with adverse reproductive outcomes. Very few studies have examined the association between night shift work and ovarian reserve, and no prior studies have investigated this association in African American women (AAW). The objective of this study was to determine whether levels of AMH, a widely used serum biomarker of ovarian reserve, are associated with working night shift in a cohort of reproductive-aged AAW.

DESIGN: Cross-sectional study

MATERIALS AND METHODS: This study utilized an established cohort of AAW from Detroit, MI aged 25 to 35 years old, who had been recruited as a part of the NIEHS Study of the Environment, Lifestyle and Fibroids. Anthropometric measurements, self-reported medical history, and serum AMH levels (picoAMH assay, Ansh Labs, Webster, TX) were analyzed. Multivariable linear regression models were used to estimate the impact of night shift work on AMH levels (SAS 9.4- Cary, NC). Models were adjusted for age, age^2, body mass index, recent or current hormonal contraception use, and irregular menses (>35 days). AMH was log transformed for inclusion in the linear regression model.

RESULTS: A total of 1,646 women were included in this analysis with an average age of 29.2±3.4 years old and a median AMH of 4.1 ng/mL (IQR

2.3-6.7). Of these women, 236 (14%) reported working night shifts, with an average of 113±97 night shifts worked per year, and a median AMH value of 3.74 (IQR 1.90-5.91). Adjusted models demonstrated that working night shift was significantly associated with lower AMH levels (-13.5%, 95% CI -23.9% to -1.7%, p=0.02).

CONCLUSIONS: These findings suggest that ovarian reserve, as measured by serum AMH levels, is lower in reproductive-aged AAW who work night shifts than in those who do not work night shifts. Further research is needed to establish the mechanistic link between disruptions in circadian rhythm and decreased ovarian reserve. Providers should have an understanding of the factors that impact ovarian reserve in a diverse cross-section of women, as this will improve our ability to provide personalized recommendations and empowers all patients to make informed reproductive choices.

SUPPORT: This study was supported by NIH grant R01HD088638, the Evergreen Invitational Women's Health Grants Initiative and by the Intramural Research Program of the NIH, National Institute of Environmental Health Sciences.

P-852 3:30 PM Wednesday, October 21, 2020

REPEATED APPLICATION OF LUTEAL PHASE ESTRADIOL / GnRH ANTAGONIST PRIMING INCREASES IVF SUCCESS FOR POOR OVARION RESERVE PATIENTS.

Temel Ceyhan, M.D., Professor, Mustafa Ozturk, Associate Professor, Ummü Gül Yıldız, MD, Ulas Fidan, Associate Professor, Elif Agacayak, Associate Professor, Cem Korkmaz, Professor Helth Science Universty Gulhane Medical Faculty, Ankara, Turkey.

OBJECTIVE: The aim of this study is to compare the results of repeated luteal phase estradiol patch / GnRH antagonist protocol (LPP) in patients with poor ovarian response (POR) with other protocols.

DESIGN: 226 patients and 293 cycles were applied to POR patients who underwent luteal estradiol patch / GnRH antagonists priming protocol (LPP), microdose flare up protocol or antagonist protocol in the Gulhane training and research hospital between January 2013 and March 2019.

MATERIALS AND METHODS: Among these, 38 patients underwent LPP protocol in the first cycle and LPP protocol in the second cycle. In 29 patients, LPP protocol was applied in second cycle after microdose flare up or antagonist protocol. 128 patients who underwent LPP only once and 31 patients who received only microdose flare up were also evaluated.

RESULTS: The clinical pregnancy rate was higher in the group that had repeated LPP protocol compared to the group applied with LPP after different protocol (p: 0.035). In this group, b hcg positivity and clinical pregnancy rate per embryo were also significantly higher (p: 0.000, p: 0.001).

CONCLUSIONS: Recurrent LPP protocol seems to be a suitable option in POR patients

POSTER SESSION: OVARIAN STIMULATION

P-853 3:30 PM Wednesday, October 21, 2020

PROGNOSTIC VALUE OF LOW ANTI-MULLERIAN HORMONE LEVEL DURING IVF AMONG YOUNG WOMEN: A SART CORS STUDY.

Papri Sarkar, MD,[1] Erika P. New, MD, MPH,[1] Rachel Grimes Sprague, MD,[2] Jean Tanner, PhD,[1] Anthony N. Imudia, MD[3] [1]University of South Florida, Tampa, FL; [2]Shady Grove Fertility, Washington D.C., DC; [3]Department of Obstetrics and Gynecology, Morsani College of Medicine, University of South Florida, Tampa, FL.

OBJECTIVE: Diminished ovarian reserve (DOR) describes women of reproductive age whose response to ovarian stimulation or fecundity is reduced as compared to women of similar age group. Lower anti-mullerian hormone (AMH) level has been associated with, but not necessarily predict, poor responses to ovarian stimulation, poor embryo quality, an poor pregnancy outcome in IVF. However, there are no useful threshold for critical clinical decision making. Studies have shown that lower AMH in combination with advanced maternal age indicates poor IVF outcome. However little is known about the prognostic value of lower AMH in young IVF population. The goal of the study was to determine association between low AMH level and IVF pregnancy outcomes among women who are < 35 years old.

DESIGN: Retrospective analysis of Society of Assisted Reproductive Technology Clinic Outcome Reporting System Database (SART CORS) from 2012-2016.

MATERIALS AND METHODS: All fresh autologous IVF cycles in women <35 years old were included (n=113,643). Based on AMH level, cycles were stratified into 4 groups; Normal (≥1.05 ng/mL), Low (0.4-<1.05 ng/mL), Very low (0.16-<0.4 ng/mL) and Ultra-low (<0.16 ng/mL). Multivariable logistic regression was used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI) representing the association between AMH and each pregnancy outcome. Models were adjusted for patient's age, body mass index (BMI), gravidity, infertility diagnosis, FSH dose used for stimulation, stimulation protocol used, total 2 pronuclei zygote (2PN), and embryo grade.

RESULTS: A total of 83,556 cycles had embryo transfer and were included in the analysis. Live birth rates (LBR) were 48.4%, 40.2%, 35.9% and 32.8% per transfer in women with normal, low, very low and ultra-low AMH level, respectively. After adjusting for potential confounders, compared to women with normal AMH, women with low, very low and ultra-low AMH have a significantly lower risk of live birth (aOR: 0.95, 95% CI: 0.91-0.99; aOR: 0.91, 95% CI: 0.83-0.99; aOR: 0.81, 95% CI: 0.66-0.99, respectively). Maternal BMI, embryo grade and of total 2PN were independently associated with live birth. Overweight and obese women less likely to have a livebirth compared to normal BMI patients (aOR: 0.91, 95% CI: 0.88-0.94; aOR: 0.76, 95% CI: 0.73-0.79). For every 10 unit increase in the total number of 2 PN, we observed a 1.38 increase in the odds of live birth (95% CI: 1.34-1.43). Embryos graded as "fair" and "poor" embryos were less likely to lead to live birth as compared to "good".

CONCLUSIONS: Serum AMH level is an independent predictor of live birth in women who are < 35 years old and seeking IVF treatment for infertility.

P-854 3:30 PM Wednesday, October 21, 2020

RESVERATROL FOR PREVENTING OVARIAN HYPERSTIMULATION SYNDROME IN WOMEN AT RISK UNDERGOING EGG DONATION: A RANDOMIZED CONTROLLED STUDY.

Israel Ortega, M.D., Ph.D.,[1] Abigail Alvarez de la Fuente, B.S,[2] Sonia Matey, B.S,[3] Elizabet Henzenn, M.D,[3] María Cruz, PhD,[4] Alberto Pacheco, PhD,[3] Antoni Duleba, M.D.,[5] Juan A. Garcia-Velasco, MD, PhD[2] [1]IVI-RMA Madrid, MADRID, Spain; [2]IVI-RMA Madrid, Rey Juan Carlos University, Madrid, Spain; [3]IVIRMA Madrid, Madrid, Spain; [4]IVIRMA Global Headquarters, Madrid, Spain; [5]University of California San Diego, La Jolla, CA.

OBJECTIVE: Ovarian Hyperstimulation Syndrome (OHSS) is the most serious and potentially life-threatening iatrogenic complication associated with ovarian stimulation protocols, being partially mediated by vascular endothelial growth factor A (VEGF). Previously, our group has reported that resveratrol, a natural polyphenol with anti-proliferative and anti-oxidant properties, exerts anti-angiogenic actions mediated by decreased VEGF in rat granulosa cells *in vitro*. The present study evaluated the role of resveratrol as a potential preventive strategy of OHSS in egg donors at high risk undergoing ovarian stimulation protocols.

DESIGN: A randomized controlled study.

MATERIALS AND METHODS: Fifty-six egg donors at risk to develop OHSS (21 follicles greater than 12 mm and/or estradiol levels ≥ 3000 pg/ml on the day of oocyte maturation trigger) undergoing ovarian stimulation were included. The study group (n=29) received a daily dose of 2 g of resveratrol orally for nine days from the day of GnRH administration as the trigger of oocyte maturation, whereas the control group (n=27) received a daily dose of 2 g of placebo. All participants were monitored every three days with vaginal ultrasound scans and blood tests, evaluating the amount of ascitic fluid, VEGF levels, estradiol concentration and hemoconcentration. The reduction of VEGF concentration was the primary outcome.

RESULTS: Baseline characteristics were comparable between both groups. Resveratrol treatment did not significantly reduce VEGF concentration compared to placebo at any time point (281.72 ± 133.57 vs 224.73 ± 107.28 on Day 9, P=0.08). Similarly, resveratrol did not affect either estradiol concentration (56.41 ± 29.99 vs 53.16 ± 28.44, P>0.05), hemoconcentration (40.03 ± 2.92 vs 40.48 ±2.57, P>0.05) or the amount of ascitic fluid (11.29 ± 7.3 vs 8.61 ± 6.07, P>0.05) in the pouch of Douglas.

CONCLUSIONS: Prophylactic treatment with resveratrol did not reduce either the incidence of OHSS or the VEGF concentration in egg donors at high risk undergoing ovarian stimulation protocols. Higher doses and/or longer exposure periods may be needed to elucidate whether resveratrol can reduce the risk of OHSS as suggested by in in vitro studies.

P-855 3:30 PM Wednesday, October 21, 2020

IMPACT OF BODY HABITUS ON INCIDENCE OF COMPLICATIONS IN PATIENTS HOSPITALIZED WITH OVARIAN HYPERSTIMULATION SYNDROME. Liat Bainvoll, BS,[1] Rachel S. Mandelbaum, MD,[2] Meghan B. Smith, MD,[2] Caroline Violette, MD,[2] Shinya Matsuzaki, MD, PhD,[2] Jacqueline Ho, MD MS,[2] Kristen Bendikson, MD,[2] Richard J. Paulson, MD, MS,[2] Koji Matsuo, MD, PhD[2] [1]Keck School of Medicine at USC, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.

OBJECTIVE: The impact of body habitus on risk of complications resulting from ovarian hyperstimulation syndrome (OHSS) has not been well-elucidated. This study aimed to evaluate the association between body habitus and complications resulting from OHSS in hospitalized patients.

DESIGN: A retrospective analysis of the National inpatient Sample, a U.S. population-based database, between 2012-2015

MATERIALS AND METHODS: Women <50 years of age with a diagnosis of OHSS were identified and classified as normal weight, class I-II obesity, or class III obesity. ICD-9 codes were used to evaluate the incidence of OHSS-related complications. Multinomial logistic regression was used to identify factors associated with obese body habitus, and binary logistic regression was used to evaluate independent risk factors for incidence of *i)* any or *ii)* multiple complication(s) that occurred during hospitalization.

RESULTS: Of 2,745 women hospitalized with OHSS during the study period, 2,440 (88.9%) were of normal weight, 155 (5.6%) had class I-II obesity, and 150 (5.5%) had class III obesity. There were a total of 270 (9.8%) pregnant women, 20 (7.4%) of which were obese. Obese women (either class I-II or III) had a higher degree of comorbidity, had lower incomes, and were less likely to have private insurance than non-obese women (all, $P<0.001$). Non-obese women had higher rates of OHSS-related complications than women with class I-II obesity or class III obesity (any complication: non-obese 65.2%, class I-II obesity 54.8%, and class III obesity 46.7%, $P<0.001$; and multiple complications: non-obese 38.5%, class I-II obesity 32.3%, and class III obesity 20.0%, $P<0.001$). In the multivariable model, obesity remained independently associated with lower risk of complications (class I-II odds ratio [OR] 0.57, 95% confidence interval [CI] 0.39-0.83, $P=0.003$; class III OR 0.30, 95%CI 0.20-0.44, $P<0.001$). Obese women were also less likely to require paracentesis (non-obese 32.8%, class I-II obesity 9.7%, and class III obesity 13.3%, $P<0.001$).

CONCLUSIONS: Larger body habitus is associated with decreased OHSS-related complication rates in hospitalized patients. Body habitus may therefore be used in risk stratification of patients to identify those at risk of major complications from OHSS.

P-856 3:30 PM Wednesday, October 21, 2020

RELUGOLIX, A NOVEL ORALLY ACTIVE GnRH ANTAGONIST IS EFFECTIVE IN IVF PROTOCOL. Hideki Igarashi, M.D., Ph.D.,[1] Jin Kumagai, M.D., Ph.D.,[2] Mayumi Toya, M.D., Ph.D.,[1] Tomoko Hashimoto, M.D., Ph.D.,[3] Yuya Takeshige, Ph.D.,[3] Nobuya Aono, Ph.D.,[1] Yukiko Nakajo, AS,[2] Hiromitsu Hattori, Ph.D.,[1] Tomomi Tosa, MT,[1] Koichi Kyono, M.D., Ph.D.[3] [1]Kyono ART Clinic Sendai, Sendai, Miyagi, Japan; [2]Kyono ART Clinic Morioka, Morioka, Iwate, Japan; [3]Kyono ART Clinic Takanawa, Tokyo, Japan.

OBJECTIVE: The aim of this study was to clarify the effectiveness of relugolix, a novel orally active GnRH (GnRH) antagonist in in vitro fertilization (IVF) protocol.

DESIGN: This study was prospective, without randomization study which was conducted at Kyono ART clinic Sendai, Morioka, and Takanawa in Japan from December 2019 to March 2020. This study was approved by the Ladies Clinic Kyono Ethics Committee.

MATERIALS AND METHODS: This study includes a total of 113 controlled ovarian hyperstimulation (COH) cycles with GnRH antagonist protocol in IVF. 63 cycles were in daily injection of ganirelix (0.25mg) or cetrorelix (0.25mg) group (Ga/Ce group), and 70 cycles were in every 36 hours oral administration of relugolix (40mg) group (Rel group). GnRH antagonist (ANT) was administrated by fixed day 6 protocol or flexible protocol. Hormonal profiling (LH, FSH, E2 and P4) was assessed in the previous or the day of GnRH antagonist administration (ANT start day), and the decision day of oocyte pick-up (Trigger day). Number of retrieved oocyte and MII oocyte, fertilization rate, Day3 good embryo rate and good blastocyst rate were compared between each group. The statistical analyses were done by Welch T test and Chi square test. $P<0.05$ was considered statistically significant.

RESULTS: Patient characteristics including age, BMI and AMH level in each group were similarly. There were no significant differences in hormonal profiling in the ANT start day (Ga/Ce group vs. Rel group: LH; 4.2±5.6 vs. 4.2±5.6, E2; 720.8±544.4 vs. 795.8±443.8, P4; 0.3±0.3 vs. 0.3±0.3, respectively) and the Trigger day (Ga/Ce group vs. Rel group: LH; 3.0±3.9 vs. 2.8±1.7, E2; 1659.3±1044.4 vs. 1606.4±872.8, P4; 0.5±0.7 vs. 0.5±0.3, respectively) between each group. A total number of GnRH antagonist administration in Rel group was significantly fewer than that of Ga/Ce group (2.4±0.7 vs. 3.7±0.9, $p<0.01$). A total dose of HMG/FSH administration was considerably higher in Rel group, though the difference was not statistically significant (2346.3±748.8 vs. 2136.1±634.2, $p=0.08$). Despite no significant difference in average number of retrieved oocyte (Ga/Ce group vs. Rel group: 9.9±5.8 vs. 9.7±5.5) and MII oocyte (Ga/Ce group vs. Rel group: 7.8±4.5 vs. 7.2±4.0), maturation rate in Rel group was significantly lower than that in Ga/Ce group (73.7% vs. 81.7%, $p<0.05$). There were no significant differences in fertilization rate (79.1% vs. 80.0%), good day3 embryo rate (22.6% vs. 24.9%), blastocyst rate (47.0% vs. 49.9%) and good blastocyst rate (26.2% vs. 29.7%) between Ga/Ce group and Rel group. Premature LH surge was observed in one patient in Ga/Ce group, but not in Rel group.

CONCLUSIONS: Our results suggested that relugolix, a novel orally active GnRH antagonist was effective in COH with GnRH antagonist protocol in IVF. As clinical effectiveness of relugolix is expected by less expensive and few times administration compared with ganirelix and cetrorelix, relugolix is useful for patients in cost-benefit.

P-857 3:30 PM Wednesday, October 21, 2020

TYPE OF FOLLITROPIN ALFA FOR OVARIAN STIMULATION WITH MEDROXYPROGESTERONE ACETATE DOES NOT AFFECT CLINICAL OUTCOMES IN A DONOR-RECIPIENT PROGRAM. María Cruz, PhD,[1] Vanessa Vergara, MD,[2] Antonio Requena, PhD, MD[2] [1]IVIRMA Global Headquarters, Madrid, Spain; [2]Reproductive Medicine Specialist, Madrid, Spain.

OBJECTIVE: To assess stimulation and clinical outcomes using different follitropin alfa preparations, in order to provide important educational and clinical insights on recently introduced stimulation agents in new emerging protocols.

DESIGN: Multicenter (n=11), retrospective, analysis to determine the efficacy of different follitropin alfa preparations with MPA during 2019.

MATERIALS AND METHODS: The study population included women accepted as oocyte donors and undergoing ovarian stimulation (OS) with 3

	Bemfola (n=2810)	Gonal (n=389)	Ovaleap (n=1558)	p-value
Days of stimulation	10.2 ± 0.7	9.6 ± 0.5	10.0 ± 0.1	0.003
Estradiol_hCG (pg/ml)	3026 ± 125	3754 ± 515	3218 ± 155	0.021
Doses FSH (IU)	1909 ± 20	1993 ± 50	1887 ± 25	0.002
Oocytes retrieved	23.3 ± 0.5	26.0 ± 1.2	23.7 ± 0.6	<0.001
Oocytes metaphase II	19.1 ± 0.6	21.1 ± 0.9	18.6 ± 1.5	0.325
Fertilization rate (%)	77.4%	78.6%	78.7%	0.789
Implantation rate (%)	62.1%	60.8%	63.8%	0.223
Pregnancy rate (%)	60.8%	58.8%	62.1%	0.363
Miscarriage rate (%)	6.3%	5.9%	6.9%	0.210
Ongoing pregnancy rate (%)	53.1%	53.7%	55.7%	0.451

different follitropin alfa preparations Ovaleap n=1558; Bemfola n=2810; or Gonal-F n=389. Ovaleap and Bemfola are both biosimilars to the originally approved biological product, Gonal-F. All donors underwent OS in a MPA protocol. On day cycle 2 or 3, donors started to administer daily 150-225 IU of one of the 3 different follitropin alfa preparations. On the first FSH stimulation day, 10 mg MPA was administered daily and then continued until GnRH agonist trigger. Finally, a single dose of 0.1 mg GnRH agonist was administered to trigger final oocyte maturation.

RESULTS: There were some age related significant differences in stimulation characteristics, which were higher in the Gonal-F-stimulated donor group, however, regarding clinical variables analysed, there were no significant differences found between the three study groups (Table 1).

This was further confirmed on applying a linear regression model, which used the clinical pregnancy rate as the explanatory variable. Neither age, the number of oocytes retrieved or the type of follitropin alfa administered significantly affected the chances of achieving a clinical pregnancy The results were as follows: age 1.001 (0-987-1.014, p=0.930); retrieved oocytes 0.998 (0.992-1.003, p=0.414); and type of follitropin alfa 1.034 (0.967-1.107, p=0.327)

CONCLUSIONS: MPA as a substitute for GnRH analogues with OS in a donor-recipient program is effective. Minor differences in FSH isoforms present in follitropin alfa biosimilars versus the originator FSH molecule used for OS with MPA, had no impact on clinical outcomes or stimulation characteristics. Therapeutic equivalence has been established.

SUPPORT: Not apply

BASELINE PROGESTERONE ELEVATION AT THE ONSET OF OVARIAN STIMULATION IS NEITHER CORRELATED WITH EMBRYO QUALITY NOR EUPLOIDY RATE.

Carlos Hernandez-Nieto, MD,[1] Tamar Alkon-Meadows, MD,[1] Joseph A. Lee, BA,[1] Daniel E. Stein, MD,[2] Alan B. Copperman, MD,[2] Benjamin Sandler, MD,[2] Erkan Buyuk, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: Elevation of progesterone (P) during day 3 of a menstrual cycle is an uncommon phenomenon during ovarian stimulation cycles. Incomplete luteolysis, endogenous P production by the adrenals and ovarian aging have been described as potential causes of baseline progesterone elevation (BPE). Some authors have postulated that BPE predicts decreased implantation in fresh IVF cycles [1] However, to date, there is no published evidence clarifying a correlation with embryonic morphological appearance and genomic competence. The objective of this study is to asses the association of BPE on ovarian stimulation outcomes and embryonic quality of IVF/PGT cycles.

DESIGN: Retrospective cohort analysis.

MATERIALS AND METHODS: The study included infertile couples who underwent IVF with GnRH antagonist stimulation from 2016-2020. PGT-A with NGS were performed in all cases. Cohorts were segregated in two groups: Group 1: cycles with normal P levels (P $<$1.5 ng/mL) on day 3 of the cycle; Group 2: cycles with BPE (P $\geq$1.5 ng/mL). Patients with OCP pre-treatment, an active follicle on day 3, or oocyte recipients were excluded. Demographics, COH parameters, blastulation, and euploidy rates were evaluated. Comparative statistics and an adjusted mixed model with a GEE framework was utilized for analysis. A sample size of 163 blasts per group was calculated to have an 80% power to detect a 15% difference on euploidy rates (α=0.05).

RESULTS: 16892 blastocysts from 3527 cycles with normal P were compared to 202 blasts from 46 cycles with BPE. A BPE prevalence of 1.2% was found. On an unadjusted analysis, significant differences were found in AMH, baseline estradiol, day of ovulation trigger and estradiol on triggerday between cohorts. No significant differences were found in mean number of oocytes retrieved, maturity, fertilization, blastulation, and utilizable blastocyst rates among cohorts. The average of good, moderate and fair grading blastocysts were comparable among groups. Aneuploidy rates differed between groups (Group 1= 44.2%, BPE= 32.9%;p=0.02), however euploidy and inconclusive embryo rates were comparable between groups. After adjusting for age, BMI, AMH, days of stimulation and number of fertilized oocytes per cycle, no association was found between BPE and blastulation rates (OR 0.98, CI95% 0.5-1.7, p=0.97); euploidy rates (OR 1.05, CI95% 0.6-1.8, p=0.84), or aneuploidy rates (OR 0.86, CI95% 0.5-1.4, p=0.58).

CONCLUSIONS: For patients who undergo ART treatment, BPE at the beginning of the menstrual cycle during does not appear to compromise embryonic quality in freeze all/PGT cycles. Our study demonstrated that BPE is not associated with impaired number of oocytes retrieved, oocyte maturity rates, embryonic quality or euploidy rates when compared with cycles with normal P on day 3. The clinical significance of BPE and success rates following an embryo transfer has yet to be established. Further research, including detailed endocrine monitoring, is necessary to better understand if BPE represents a normal variation within menstrual cycles or if it embodies a measurable consequence derived from a subtle ovarian dysfunction.

COMPARISON OF PROGESTIN-PRIMED OVARIAN STIMULATION AND GNRH ANTAGONIST PROTOCOL IN CLINICAL OUTCOME FOR PCOS PATIENTS.

Yujie Li, Doctor Sixth Affiliated Hospital of Sun Yat-sen university.

OBJECTIVE: To investigate whether progestin-primed ovarian stimulation (PPOS) can be an alternative as gonadotrophin-releasing hormone antagonist (GnRH-ant) protocol for infertile women with polycystic ovary syndrome (PCOS) during IVF/ICSI.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: This retrospective cohort study included 260 PCOS patients who underwent their first IVF/ICSI procedure with PPOS (n=65) or GnRH-ant protocol (n=195) followed by cryopreservation of all embryos from January 2016 to July 2019. Baseline characteristics of the two groups were balanced with propensity score matching using the nearest neighbor random matching algorithm in a ratio of 1:3. The primary outcome measure was the number of oocytes retrieved. The embryological and clinical outcomes were measured and only the first embryo transfer cycle was followed-up.

RESULTS: Basic characteristics such as infertility duration, age, and body mass index (BMI) were comparable in both groups. No significant difference was found in the number (mean $\pm$ SE) oocytes retrieved (20.2 $\pm$ 1.4 for PPOS vs 20.7 $\pm$ 0.6 for GnRH-ant protocol) or high quality embryos (7.5 $\pm$ 0.8 for PPOS vs 7.6 $\pm$ 0.4 for GnRH-ant protocol) between the groups. The FSH dosage, ovarian stimulation duration, ovarian hyperstimulation syndrome incidence were comparable between the groups. There was no significant difference in the clinical pregnancy rate (57.1% for PPOS vs 60.7% for GnRH-ant protocol) or live birth rate (42.9% for PPOS vs 46.4% for GnRH-ant protocol) of the first embryos transfer cycle between the two groups. In the cost-effectiveness analysis, the PPOS protocol was strongly dominant over the antagonist protocol.

CONCLUSIONS: Our results showed that the application of PPOS protocol in PCOS patients could achieve comparable oocyte retrieval and pregnancy outcomes to GnRH-ant protocol, but the medico-economic analysis was in favor of PPOS protocol.

P-860 3:30 PM Wednesday, October 21, 2020

THE ASSOCIATION OF AMH WITH ENDOMETRIAL THICKNESS IN GONADOTROPIN STIMULATION/INTRAUTERINE INSEMINATION CYCLES.

Stylianos Vagios, MD, Karissa C. Hammer, MD, Caitlin Sacha, MD, Irene Dimitriadis, MD, Charles L. Bormann, PhD, Irene Souter, MD Massachusetts General Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: The role of *anti-Müllerian hormone* (AMH) and its receptor (AMH-R) on endometrial function and development is not well known. However, endometrial production of AMH has been reported, and endometrial expression of both AMH and AMH-R has shown cyclic variation with unclear significance. Our objective was to evaluate the association, if any, between AMH and pre-ovulatory endometrial thickness (ET) in gonadotropin induction (Gn)/intrauterine insemination (IUI) cycles.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All Gn/IUI cycles (n=11,383) taking place at a large academic fertility center between 11/2007 and 12/2019, were retrospectively reviewed. 1,856 Gn/IUI cycles (from 912 patients) with a recorded pre-treatment serum AMH level and information available on endometrial thickness (ET) (measured by transvaginal ultrasound on either the day of or the day prior to HCG-trigger) were identified and included in the current analysis. Uterine factor infertility patients were excluded.

Statistical analysis: Parametric and non-parametric tests were used as appropriate. Linear regression models, adjusted for potential confounders,

were used to evaluate the effect of AMH on ET (b_{AMH} stands for the regression coefficient of AMH). $P < 0.05$ was considered significant.

RESULTS: Mean (SD) age, BMI, and AMH were: 35.9 (4.0) years, 25.1 (5.1) kg/m^2, and 3.5 (4.2) ng/ml, respectively. Idiopathic infertility was the most common diagnosis (32.0%), and PCOS accounted for 8.7% of the population. Mean (SD) and median (IQR) ET (mm) were: 9.1 (2.3) and 9.0 (7.5, 10.4), respectively, when measured on HCG-trigger day, and 8.4 (2.3) and 8.0 (7.0, 10.0), respectively, when measured the day prior to it.

Unadjusted regression models, showed a positive, albeit weak, correlation between AMH and ET (as measured on both HCG-trigger day and day prior to it) [r: 0.1, b_{AMH} (95%CI): 0.03 (-0.003, 0.06), p: 0.08, and r: 0.1, b_{AMH} (95%CI): 0.04 (0.01, 0.08), p: 0.02, respectively]. When models were adjusted for BMI, prior parity, and peak estradiol (E_2) levels, the positive correlation between AMH and ET became stronger, [r: 0.2, b_{AMH} (95%CI): 0.04 (0.03, 0.11), p: 0.009; r: 0.3, b_{AMH} (95%CI): 0.07 (0.03, 0.11), p<0.001, for HCG-trigger day and day prior to HCG, respectively]. When models were further adjusted for PCOs diagnosis, the results remained significant [r: 0.2, b_{AMH} (95%CI): 0.04 (0.001, 0.08), p: 0.045; r: 0.3, b_{AMH} (95%CI): 0.05 (0.01, 0.10), p:0.03; for HCG-trigger day and day prior to HCG, respectively].

CONCLUSIONS: Pre-treatment, circulating serum AMH levels correlated positively with endometrial thickness in the pre-ovulatory phase of Gn/IUI cycles. Our data suggests a possible independent effect of AMH on endometrial development among patients undergoing Gn/IUI treatments.

P-861 3:30 PM Wednesday, October 21, 2020

REDUCTION IN OHSS INCIDENCE IN JAPANESE IVF/ICSI PATIENTS WHEN APPLYING INDIVIDUALIZED DOSING WITH FOLLITROPIN DELTA. Osamu Ishihara, MD, PhD,[1] Joan-Carles Arce, MD, PhD[2] [1]Saitama Medical University, Saitama, Japan; [2]Ferring Pharmaceuticals, Copenhagen, Denmark.

OBJECTIVE: To compare the impact of the individualized follitropin delta dosing regimen based on AMH and body weight with regard to OHSS incidence and severity compared to conventional standard dosing regimen in Japanese IVF/ICSI patients.

DESIGN: Randomized, assessor-blind, controlled trial conducted in 347 Japanese women undergoing their first IVF/ICSI cycle (NCT03228680).

MATERIALS AND METHODS: Patients were randomized to controlled ovarian stimulation with follitropin delta (Rekovelle, Ferring Pharmaceuticals) or follitropin beta (Follistim / Puregon, Merck). The dose of follitropin delta was individualized based on serum AMH and body weight, and was fixed throughout stimulation – AMH <15 pmol/L [<2.1 ng/mL]: daily dose of 12 μg, AMH ≥15 pmol/L [≥2.1 ng/mL]: daily dose decreasing from 0.19 to 0.10 μg/kg body weight by increasing AMH (min-max 6-12 μg). Elecsys® AMH, Roche Diagnostics was used. The follitropin beta dose was 150 IU/day for the first five days and could thereafter be adjusted as per the investigator's discretion. A GnRH antagonist protocol was applied. OHSS was classified using Golan's system. Early OHSS was defined as onset ≤9 days after triggering of final follicular maturation, and late OHSS as onset >9 days after triggering. Pre-defined preventive interventions for early OHSS included cycle cancellation due to excessive ovarian response, triggering with GnRH agonist and administration of dopamine agonist. Clinical pregnancy was assessed 5-6 weeks after single blastocyst transfer.

RESULTS: The frequency of early OHSS was significantly (p<0.05) reduced from 18.6% in the follitropin beta group with conventional dosing to 10.0% in the follitropin delta group with individualized dosing. A similar observation was made for moderate/severe early OHSS which was significantly (p<0.05) reduced from 13.0% with follitropin beta to 6.5% with follitropin delta. Preventive interventions for early OHSS occurred for 3.4% and 1.2% for patients in the follitropin beta and delta groups, respectively. Late OHSS occurred at a low and similar frequency of 1.1-1.2% in the two groups. Overall, the frequency of OHSS was significantly (p<0.05) reduced from an incidence of 19.8% with conventional follitropin beta dosing to 11.2% with individualized follitropin delta dosing for OHSS of any grade, and from 14.1% with follitropin beta to 7.1% with follitropin delta for moderate/severe OHSS. The proportion of patients with at least one blastocyst on day 5 was not significantly different between groups with 89.3% for follitropin beta and 82.9% for follitropin delta. The clinical pregnancy rate for all patients who started stimulation was 23.7% for follitropin beta and 25.3% for follitropin delta.

CONCLUSIONS: The individualized follitropin delta dosing regimen based on AMH and body weight resulted in a statistically significant and clinically relevant reduction in OHSS frequency in Japanese IVF/ICSI patients when compared to follitropin beta in a conventional dosing regimen using a 150 IU/day starting dose. This improvement in patient safety with follitropin delta does not compromise efficacy outcomes.

ORAL VERSUS INJECTABLE OVARIAN STIMULATION AGENTS FOR INTRAUTERINE INSEMINATION (IUI) IN WOMEN ≥38 YEARS OF AGE WITH DECREASED OVARIAN RESERVE. Russell Frank, M.D.,[1] Naama Steiner, M.D.,[1] Maryam Al-Shatti, M.D.,[1] Jacob Ruiter-Ligeti, M.D,[1] Michael H. Dahan, M.D.[2] [1]McGill University Health Centre, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada.

OBJECTIVE: To compare effectiveness of oral versus injectable stimulation agents in women ≥38 years of age with decreased ovarian reserve undergoing IUI

DESIGN: Retrospective cohort study from a university health center

MATERIALS AND METHODS: A database was created of all women aged 38-42 years old who underwent IUI with stimulation at the McGill University Reproductive Centre between 2009-2018. The database contains 1597 IUIs from 944 women. A comparison of outcomes of oral (clomiphene citrate or letrozole) versus injectable (gonadotropins) agents was performed for those with antral follicle count (AFC) ≤6. ANOVA, chi square tests, and stepwise multivariate logistic regression were performed. The primary outcome was clinical pregnancy rate per cycle (intrauterine sac with fetal pole and heartbeat), and secondary outcomes were rate of multiple gestation. Data presented are mean ±SD. Power analysis required 196 cycles for an effect size of 0.2, alpha 0.05 and power 0.80.

RESULTS: 335 IUI cycles in 210 patients met inclusion criteria. Stimulation was with clomiphene citrate in 38 (11.3%), letrozole in 33 (9.8%), and gonadotropins in 264 (78.8%) of cycles. Most common co-etiologies of infertility (excluding age and decreased ovarian reserve as factors) were male factor (34.3%) and tubal factor (8.4%). Among the three stimulation agent groups, there was no significant difference in mean: age of females (p=0.41) or of males (p=0.28), gravidity (p=0.11), parity (p=0.55), or AFC (p=0.98) (see table). Number of stimulated follicles (p=0.21) and follicles (≥14mm) (p=0.10) at trigger also did not differ. The clinical pregnancy rates per cycle were similar (p=0.86), but highest in the letrozole group (see table). A clinical pregnancy was observed in 7.5% of all IUI cycles. There was one multiple gestation total, obtained with gonadotrophins. Analysis controlling for demographic confounders (p≤0.20) (including FSH, estradiol, prolactin, TSH, and total motile sperm count) demonstrated no differences in clinical pregnancy rates (p=0.84).

	Age (females)	Gravidity	Parity	AFC	Clinical pregnancy rate
Clomiphene citrate	40.2 ±1.5	0.9 ±1.0	0.4 ±0.6	4.0 ±1.8	5.3%
Letrozole	40.5 ±1.7	1.5 ±1.8	0.5 ±0.6	4.0 ±1.5	9.1%
Gonadotropins	40.6 ±1.6	1.1 ±1.3	0.4 ±0.7	4.1 ±1.6	7.6%
Total combined	40.5 ±1.6	1.1 ±1.4	0.4 ±0.7	4.0 ±1.6	7.5%

CONCLUSIONS: Letrozole may be the medication of choice for ovarian stimulation in IUI in older women with decreased ovarian reserve, demonstrating the highest pregnancy rate (although not statically so). The overall clinical pregnancy rate of 7.5% remains notable in this typically poor-prognosis population. Gonadotropins offered no benefits over oral medications in this study and likely come with increased associated costs.

PROGNOSTIC FACTORS OF OVARIAN RESPONSE AFTER FOLLICULAR PROTOCOL WITH MPA TRIGGER WITH GnRH AGONIST. Juan Giles, M.D., Ph.D.,[1] María Cruz, PhD,[2] Pilar Alamá, MD PhD,[1] Laura Caracena, MSc,[1] Carmen Vidal, MD PhD,[1] Ernesto Bosch, MD, PhD[3] [1]IVI-RMA Valencia, Valencia, Spain; [2]IVIRMA Global Headquarters, Madrid, Spain; [3]IVI-RMA, Valencia, Spain.

OBJECTIVE: Oocyte donors present frequently a profile related to suboptimal responses to the ovulation induction with GnRH agonist due to hypothalamic suppression. Previous studies analyzed prognostic factors of GnRH antagonist protocol trigger with GnRH agonist (GnRHa). However, no data are available related to cycle outcomes with progestins (PPOS). Our objective is to evaluate predictors of ovarian response in oocyte donation (OD) cycles conducted in follicular phase with medroxyprogesterone acetate (MPA) and rFSH without rLH supplementation and agonist trigger.

DESIGN: Non inferiority prospective RCT study. EudraCT number 2017-002341-30 and ClinicalTrials.gov registration number is 2017-002341-30

MATERIALS AND METHODS: University-affiliated infertility clinic. Period included from October 2017 to June 2019, to evaluate ovarian response in terms of number of oocytes and determine prognostic factors related to suboptimal response to GnRHa trigger in PPOS. We randomized 318 donors in two groups in a 1:1 ratio. In MPA group 161 participants received intervention (10 mg daily administered orally during OS) and 156 were treated with GnRH antagonist (started once the leading follicle had reached 13 mm). Some donors were pre-treated with oral contraceptives.

Transvaginal ultrasound for follicular growth monitoring and serum extractions for analysis of estradiol (E2), LH, and progesterone (P) were performed on days of starting ovarian stimulation, 5, 7, 9 of stimulation and on the day of triptorelin administration.

RESULTS: No significant differences were observed in donor demographic characteristics. For basal levels, we did not observe statistical differences for any of the hormones evaluated, regardless of contraceptive intake.

On trigger day estradiol levels were significantly higher in the group treated with MPA (3363 pg/ml vs. 1330 pg/ml, p=0.011) in donors who were not taking oral contraceptives. LH levels were significantly higher in the MPA group, both in presence (1.5 IU vs. 1.0 IU, p<0.001) and in absence (1.8 IU vs. 1.2 IU, p<0.001) of oral contraceptives. Percentage of donors who developed early luteinization was similar between groups, regardless donors were taking contraceptives or not.

Basal progesterone level (p=0.031) and LH triggering (p=0.027) determination were negatively correlated with the number of oocytes retrieved during retrieval, while estradiol (<0.001) and progesterone (p=0.026) heights the day of ovulation induction were positively associated with the same main outcome. Oral contraceptive administration and age did not significantly affect ovarian response

CONCLUSIONS: Our findings support determination of basal P and E2, P and LH on trigger day in OD cycles stimulated with rFSH, MPA as co-treatment and trigger with GNRHa in order to identify women with a lower response in terms of number of oocytes.

OVARIAN RESERVE PARAMETERS AND IVF OUTCOMES IN 510 WOMEN WITH POOR OVARIAN RESPONSE (POR) TREATED WITH INTRAOVARIAN INJECTION OF AUTOLOGOUS PLATELET RICH PLASMA (PRP).

Yigit Cakiroglu, M.D.,[1] Ayse Saltik, M.D.,[1] Aysen Yuceturk, M.D.,[1] Ozge Karaosmanoglu, M.D.,[1] Sule Yildirim Kopuk, M.D.,[1] Richard Thomas Scott, Jr., MD,[2] Bulent Tiras, M.D.,[1] Emre Seli, MD[2] [1]M.D., Istanbul, Turkey; [2]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Poor ovarian response (POR) accounts for 15% of all assisted reproductive technologies (ART) cycles performed in 2017 and 2018 in the United States, and is associated with increased rate of cycle cancellation, lower number of embryos available for transfer, and overall lower pregnancy rates. Platelet-rich plasma (PRP) is rich in growth factors and cytokines and has been used as an agent that induces tissue regeneration. PRP also promotes follicle development in vitro and has been utilized in small case series as a potential treatment for women with POR. The aim of the current study was to characterize ovarian reserve parameters and IVF outcomes in patients with POR treated with intraovarian injection of autologous PRP.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Reproductive age women (N=510; age range 30-46) diagnosed with POR based on Poseidon criteria ((i) Group 3: Patients <35 years with poor ovarian reserve prestimulation parameters (AFC<5, AMH<1.2 ng/ml) (ii) Group 4: Patients ≥35 years with poor ovarian reserve prestimulation parameters (AFC<5, AMH<1.2 ng/ml)) were included in the study. Autologous PRP was prepared from peripheral blood by centrifugation, and injected transvaginally under ultrasound guidance into at least one ovary using a 35 cm 17 G single lumen needle. Starting on the 2-4th days of the second menstrual cycle after the PRP procedure, AFC and serum AMH and FSH levels were re-assessed, and followed for up to 4 consecutive cycles. Women who were found to have at least one antral follicle were started on ovarian stimulation for IVF-ICSI. Markers of ovarian reserve (AFC, FSH, AMH) and IVF outcome parameters were followed.

RESULTS: A total of 510 patients (mean age 40.3 ± 4.0) with the diagnosis of POR were included in the study. PRP treatment resulted in higher AFC (4.2 ± 2.4 vs 2.6 ± 1.3; p<0.01) and serum AMH (0.52 ± 0.35 vs 0.33 ± 0.26; p<0.01), and lower serum FSH (16.4 ± 14.5 vs 20.9 ± 19.1; p<0.01) levels. After the PRP injection, 20 women (3.9%) conceived spontaneously, and 477 (93.5%) attempted IVF. Among the women who attempted IVF, 50 (9.8% of total) could not undergo oocyte retrieval due to stimulation failure or premature ovulation, 112 (21.9% of total) did not develop embryos due to lack of oocytes or mature oocytes at retrieval, or failed fertilization/cleavage, while 315 (61.8% of total) generated cleavage stage embryos. Among the women who generated embryos, 215 (42.2% of total) preferred to bank embryos for later use, while 100 (19.6% of total) underwent fresh or frozen embryo transfer, resulting in 23 pregnancies (23% per transfer), 18 of which (18% per transfer) resulted in sustained implantation (> 8 weeks) or livebirth.

CONCLUSIONS: Our findings suggest that Intraovarian injection of autologous PRP might be considered in women with poor ovarian response to stimulation. For wider clinical application, its clinical efficacy will need to be demonstrated in prospective randomized clinical trials.

P-865 3:30 PM Wednesday, October 21, 2020

THE EFFECT OF GROWTH HORMONE ON IVF OUTCOMES DURING OVARIAN STIMULATION: A MATCHED COHORT STUDY.

Jillian Kurtz, DO,[1] Nicolle Clements, PhD,[2] Allison Bloom, DO, MPH,[1] John J. Orris, DO, MBA,[1] Michael J. Glassner, MD,[3]

Sharon H. Anderson, PhD[4] [1]Drexel University/Main Line Fertility, Bryn Mawr, PA; [2]Saint Joseph's University, Philadelphia, PA; [3]Main Line Fertility, Bryn Mawr, PA; [4]Drexel University College of Medicine, Philadelphia, PA.

OBJECTIVE: While growth hormone (GH) is commonly used as an adjuvant treatment to controlled ovarian stimulation (COS) for IVF cycles, the data regarding its efficacy is inconsistent.

DESIGN: A retrospective matched cohort study of poor responder patients who underwent COS without the use of GH (COS-GH) subsequently followed by COS cycles that included adjuvant GH (COS+GH) treatment.

MATERIALS AND METHODS: A list of all patients having filled a prescription for GH from January 2018 – March 2020 who were undergoing IVF with a single provider was obtained. GH was administered daily at 3mg (9IU) starting on the first day of stimulation and ending on the day of trigger. Only women who had documentation of a previous cycle without the use of GH were included in the study. Several different outcomes were compared including total dose of gonadotropins used, duration of stimulation, number of follicles, number of mature oocytes, endometrial thickness, maximum estradiol (max E2) level, maximum progesterone (max P4) level, number of oocytes retrieved, number of mature oocytes, number of blastocyst embryos (blasts), number of usable blasts and percentage of usable blasts. Usable blasts were defined as those embryos that were transferred to the uterus or frozen. Paired t-tests were used by an independent statistician to analyze the data, and statistical significance was set at $p<0.05$.

RESULTS: 182 cycles (91 patients) were included in the study, and COS-GH cycles were compared to COS+GH cycles. The total dose of gonadotropins used (4252 vs 5757 mIU, p=0.002), duration of stimulation (10.1 vs 10.4 days, p=-.045), max E2 (1932 vs 2411 pg/ml, p=0.010), endometrial thickness (10.6 vs 11.2 mm, p=0.010), number of oocytes retrieved (11.8 vs 14.2, p=0.001), number of mature oocytes (9.7 vs 11.1, p=0.028), number of blasts (2.56 vs 3.98, p=<0.001) and number of usable blasts (1.6 vs 2.5, p=<0.001) were all significantly greater in the GH group.

CONCLUSIONS: Adding growth hormone to the COS protocol in poor responder patients may lead to improvements in the number of oocytes retrieved, mature oocytes, endometrial thickness, number of blastocysts, and the number of usable blastocysts.

RECOMBINANT LUTEINIZING HORMONE ASSOCIATED WITH RECOMBINANT FOLLICLE STIMULATING HORMONE FOR OVARIAN STIMULATION: DECREASED INCIDENCE OF IMMATURE OOCYTES AND BETTER CLINICAL OUTCOMES. Edson Borges, Jr., PhD, Daniela Paes de Almeida Ferreira Braga, PhD, Amanda Souza Setti, MSc, Assumpto Iaconelli, Jr., MD Fertility Medical Group / Sapientiae Institute, Sao Paulo, Brazil.

OBJECTIVE: It has been demonstrated that the use of GnRH analogues decreases the concentration of LH available to developing follicles, nevertheless, both gonadotrophins, LH and FSH, are crucial to normal follicular development. Luteinizing hormone also plays an important role in oocyte maturation during natural cycles. However, whether patients undergoing COS may benefit from co-administration of r-LH and r-FSH, when either a GnRH-antagonist or a GnRH-agonist protocol is used is to be elucidated. The goal for the present study was to evaluate the effect of the combination of recombinant LH (rLH) with recombinant FSH (rFSH) on ICSI clinical outcomes.

DESIGN: Cohort study.

MATERIALS AND METHODS: Data were obtained via chart review of 6,565 patients undergoing ICSI cycles, with fresh embryo transfer, performed on day five of development, between 2016 and 2019. Ovarian stimulation was achieved by daily doses of r-FSH (FSH-only-protocol); or r-FSH associated with r-LH (FSH-plus-LH-protocol) beginning on day three of the cycle. Pituitary suppression was performed by GnRH-antagonist beginning when at least one follicle $\geq$14mm was visualized, or GnRH-agonist, from day 21 of the previous cycle. The influence of the COS protocol and pituitary blockage on the immature oocytes rate, implantation and pregnancy rates was evaluated by generalized linear models.

RESULTS: The co-administration of r-LH and r-FSH resulted in a significant increase in the mature oocytes rate, either when pituitary blockage was achieved by GnRH-antagonist (85.7% vs 77.2% for FSH-plus-LH-protocol and FSH-only-protocol, respectively, $p<0.001$) or GnRH-agonist (80.1% vs 73.2% for FSH-plus-LH-protocol and FSH-only-protocol, respectively, $p<0.001$). Likewise, the rates of immature oocytes were decreased by the association of r-LH with r-FSH, regardless of the pituitary blockage protocol: for prophase-I (PI) oocytes rate in GnRH-antagonist protocol (2.5% vs 6.5% for FSH-plus-LH-protocol and FSH-only-protocol respectively, $p<0.001$) and in the GnRH-agonist protocol (6.0% vs 8.3% for FSH-plus-LH-protocol and FSH-only-protocol respectively) and for metaphase-I (MI) oocytes rate in GnRH-antagonist protocol (5.5% vs 7.1% for FSH-plus-LH-protocol and FSH-only-protocol respectively, $p<0.001$) and in the GnRH-agonist protocol (6.5% vs 10.1% for FSH-plus-LH-protocol and FSH-only-protocol respectively, $p<0.001$). Additionally, the clinical outcomes were influenced by the COS protocol. The implantation rate was positively influenced by the FSH-plus-LH-protocol, independently on the pituitary blockage type: for GnRH-antagonist (28.2% vs 24.4%, $p<0.001$) and GnRH-agonist (26.0 % vs 21.45%, $p<0.001$). The association of r-LH and r-FSH also led to a significant increase in the pregnancy rate, when pituitary blockage was performed by GnRH-antagonist (38.0% vs 33.0%, p=0.012) but not when it was performed by GnRH-agonist.

CONCLUSIONS: Decreased incidence of immature oocyte and better clinical outcomes are achieved by the use of r-LH associated with r-FSH for COS.

SUPPORT: None.

TO CANCEL OR NOT TO CANCEL? USING AN ARTIFICIAL NEURAL NETWORK (ANN) TO PREDICT UTILITY OF OOCYTE RETRIEVAL VS. CYCLE CANCELLATION IN EXTREMELY POOR RESPONDERS. Baruch Abittan, M.D.,[1] Jill Karten, M.D.,[2] Alixandra Domney, M.D., M.P.H.,[2] Jesse Stewart, B.A.,[3] Oren Segal, PhD.,[3] Randi H. Goldman, M.D.[1] [1]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Hofstra University, Hempstead, NY.

OBJECTIVE: Patients with fewer than three follicles on transvaginal ultrasound following ovarian stimulation are often cancelled, as the risks of undergoing oocyte retrieval may outweigh the benefits of yielding fewer than three mature oocytes (MII). However, sometimes patients with greater than three visible follicles still yield fewer than three MII oocytes. We set out to determine if an artificial neural network (ANN) could be used to predict the likelihood of extremely low MII yield despite ultrasound findings of >3 follicles >14mm.

DESIGN: This was a model-prediction study based on a retrospective cohort of patients who underwent first fresh autologous in vitro fertilization cycles resulting in oocyte retrieval between the years 2016-2019. Patients were included if anti-Müllerian hormone (AMH) and follicle stimulating hormone (FSH) were recorded within one year of stimulation and excluded if an aromatase inhibitor was used during the ovarian stimulation.

MATERIALS AND METHODS: One-thousand eleven cycles were initially analyzed and 999 remained in the final model after excluding 12 cycles for extreme outliers (>28 MIIs retrieved). Exclusion of these cycles preserved the model's accuracy within a confidence of 99%. Cycles were categorized into two groups based on number of MIIs retrieved: 1) MII<3 (n=57) and 2) MII$\geq$3 (n=942). Synthetic minority oversampling technique (SMOTE) was used to oversample group 1 (MII<3) during model training (from n=57 to n=942) given the significant cohort-size imbalance between groups, causing a strong bias toward group 2 (MII$\geq$3), and leading to misclassification of low MII-yielding cycles. Of the various machine-learning models tested, an Extra Trees Classifier (ETC) performed best, with a sensitivity of 42% and specificity of 95%.

RESULTS: Patient- and cycle-specific variables utilized in our final prediction model were patient age, AMH, body mass index, peak estradiol on day of trigger shot, number of visible follicles > 14mm on day of trigger, and total injectable FSH dosage.

The ETC performed exceptionally well at predicting cycles that result in at least three mature oocytes at the time of retrieval (group 2; MII$\geq$3). However, the model correctly predicted that a cycle will result in fewer than 3 MIIs only 42% of the time. Cycles were most likely to be misclassified if a patient had between 3-6 follicles >14mm on the day of trigger.

CONCLUSIONS: The goal of this model is to help guide both physicians and patients when deciding whether or not to proceed with an oocyte retrieval for poor responders. Our model is inherently limited by the small sample size of patients with few follicles, requiring an oversampling technique that limits the generalizability of the results. This tool will be prospectively validated,

additional data will be added, and the prediction model will be modified and strengthened.

P-868 3:30 PM Wednesday, October 21, 2020

FRIENDLY PROTOCOL FOR OOCYTE DONORS: FERTILITY OPTIMIZATION IN TIMES OF SOCIAL ISOLATION DUE TO COVID-19?

Anderson S. Melo, PHD,[1] Camilla T. V. Paula, MD,[1] Thiago L. Santos, Student,[2] Victor A. C. Faria, Student,[3] Marcelo A. F. Rufato, Sr., Embryologist,[1] Rebecca P. Barboza, MD,[1] Jorge Barreto, MD[1] [1]FERTILITY CENTER OF RIBEIRÃO PRETO - CEFERP, RIBEIRAO PRETO, Brazil; [2]Barão de Mauá University Center, Ribeirão Preto, Brazil; [3]University of Ribeirão Preto (UNAERP), Ribeirão Preto, Brazil.

OBJECTIVE: Compare the number of oocytes retrieved from oocyte donors subjected to vitro fertilization (IVF) in two different protocols: friendly (corifollitropin alfa + clomiphene citrate (CC) + dydrogesterone) and conventional (daily rFSH + GnRH antagonist). Secondly, to evaluate the frequency of ovarian hyperstimulation syndrome (OHSS), number of visits to the clinic and the clinical pregnancy rates.

DESIGN: Retrospective study

MATERIALS AND METHODS: One hundred and eighteen infertile women aged 21 to 35 years old were divided into two groups: 1) Friendly: corifollitropin alfa (Elonva®), CC (Indux®) and dydrogesterone (Duphaston®); 2) Conventional: follitropin alfa (Gonal®), menotropin (Merional®) and ganirelix (Orgalutran®). All participated in the egg donation program and had ≥ 20 antral follicles before stimulation for IVF. The presence of hereditary or genetic diseases, infectious diseases, endometrial diseases, chronic diseases, adenomyosis, endometriosis were excluded. The variables analyzed were age, time and cause of infertility, number of days of induction and visits to the clinic (until trigger), number of follicles ≥14mm (trigger day), frequency of early ovulation (visualization of an image suggestive of follicular rupture before ovarian puncture), number of mature oocytes, frozen embryos, clinical pregnancy rate and OHSS (mild: pain (use of scopalamine + paracetamol) and/or nausea and/or vomiting; moderate: increased abdominal volume with evidence of clinical ascites without the need for hospitalization and moderate pain (use of codein); severe: hospitalization due to severe symptoms).

RESULTS: Please, see table below. Ovulatory factor, the number of visits to the clinic and the tubal factor were not predictors of obtaining mature oocytes (only antral follycle number was independent predictor).

Variable	Friendly protocol (n=52)	Conventional protocol (n=66)
Age(years)	30±3,8	29,1±4,9
Infertility time(years)	4,4±3,4	4,5 ± 3,2
Cause of infertility:	49,2	50,8
Male(%)	**37,5**	**62,5**
Ovulatory(%)**	**63,6**	**36,4**
Tubal factor(%)**	2,8	3,1
Other(%)		
Induction days	10,4± 1,1	10,5±1,2
Number of visits to the clinic**	**2,8±0,5**	**4,9±2,3**
Follicles≥14 mm(hCG day)	14,7±5,5	12,7±6,2
Early ovulation	1,9	1,5
Number of mature eggs	18,5±10,1	17,2±9,2
Number of frozen embryos	7±4,7	5,3±2,2
Clinical pregnancy rate[n(%)]	20(40)	27(40,9)
OHSS	43,9	56,1
Mild(%)	5,7	6,1
Moderate(%)	1,9	1,5
Severe(%)		

**p<0,05

CONCLUSIONS: Friendly protocol for IVF seems to be safe (same risk of OHSS) and effective (oocyte mature and clinical pregnancy rate) in comparison to the conventional protocol in oocyte donors. The smaller number of visits to the clinic with the friendly protocol can be a great ally in times of social isolation due to the pandemic by COVID-19.

CHANGES IN ENDOCRINE PROFILES POST-TRIGGER FOR OOCYTE MATURATION YIELD HIGHER-QUALITY OOCYTES.

Evelyn Minis, MD,[1] Kavitha Krishnamoorthy, MD,[1] Jacquelyn Loughlin, MD,[2] Peter G. Mcgovern, MD,[3] Sara S. Morelli, MD, PhD[1] [1]Rutgers New Jersey Medical School, Newark, NJ; [2]Rutgers New Jersey Medical School, Newark, New Jersey, NJ; [3]University Reproductive Associates, NJ, Hasbrouck Heights, NJ.

OBJECTIVE: During the use of assisted reproductive technologies for conception or oocyte cryopreservation, each patient is monitored with serial ultrasounds and serum hormone concentrations: particularly estradiol, progesterone, and the gonadotropins follicle stimulating hormone (FSH) and luteinizing hormone (LH). Several studies have evaluated these levels at the time of trigger for oocyte maturation in comparison with live birth rates. However, very few studies have evaluated the change in endocrine levels on the day after trigger in correlation with oocyte maturation and pregnancy outcomes. Thus, the objective of this study was to determine if the change in endocrine hormone levels on the day after trigger with human chorionic gonadotropin with or without a gonadotropin-releasing hormone agonist affects the number of good quality oocytes during controlled oocyte stimulation cycles.

DESIGN: Retrospective cohort study at an academic-affiliated private practice.

MATERIALS AND METHODS: All patients undergoing controlled oocyte stimulation cycles with the use of gonadotropins for in-vitro fertilization (IVF) or oocyte cryopreservation from September 2018 through December 2019 were assessed for inclusion. The charts of patients with successful oocyte retrieval were systematically examined and all necessary data collected, including serum concentrations of estradiol, progesterone, FSH, and LH throughout each cycle. The primary outcome was the number of mature oocytes (identified as oocytes in metaphase II at the time of oocyte retrieval) in each stimulation cycle. Statistical analysis was performed using student t-test, one-way ANOVA, and Spearman's correlation where applicable. Data are expressed as mean $\pm$ standard deviation. This study was IRB approved.

RESULTS: Of the 372 patients who underwent controlled ovarian stimulation with gonadotropins during the study period, the 360 that were included for analysis had a mean maternal age of 37.3 $\pm$ 4.2 years and BMI of 27.6 $\pm$ 7.8. Most patients underwent antagonist cycles (n=295) compared with those who underwent agonist stimulation cycles (n=65). In all cycles, the percent change in progesterone levels from the day of trigger to the levels one day after trigger was statistically significant with an increasing number of mature oocytes ($R=0.522$; $p<0.0001$). Interestingly, the change in FSH levels before and after trigger were significantly different between antagonist and agonist cycles ($p<0.001$). Antagonist cycles resulted in increased FSH levels post-trigger (17.05% $\pm$ 67.3%), while there was an overall decrease in FSH levels post-trigger in agonist cycles (-11.37% $\pm$ 20.83%).

CONCLUSIONS: The change in serum hormone endocrine levels, particularly progesterone, before and after trigger for oocyte maturation can affect the number of mature oocytes yielded. The greater the change of progesterone levels post-trigger results in a higher number of mature oocytes. The percent change in progesterone levels can be used as a predictor of higher-quality oocyte yield in controlled ovarian stimulation cycles.

P-870 3:30 PM Wednesday, October 21, 2020

PREDICTORS OF VARIABILITY IN OOCYTE YIELD AFTER SUCCESSIVE CONTROLLED OVARIAN STIMULATION CYCLES.

Jerrine R. Morris, MD, MPH,[1] Eduardo Hariton, MD, MBA,[1] John Boscardin, PhD,[2] Martha Noel, MD[1] [1]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA.

OBJECTIVE: To determine predictors of variability in oocyte yield observed within patients undergoing successive controlled ovarian stimulation cycles (COS) utilizing the same protocol.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A retrospective chart review identified patients who completed more than one controlled ovarian stimulation cycle, within a 12-month period, at the University of California, Center for Reproductive Health, between January 2018 and December 2019. Descriptive statistics were performed. A mixed generalized linear model (GLM) was used to determine variables associated with variability in oocyte yield. Subgroup analyses were performed to investigate the variability in oocyte yield by treatment protocol.

RESULTS: There were 520 patients included in the analytic sample. Most patients were 40 years old or younger (71.9%) with a primary diagnosis of diminished ovarian reserve (33.6%). The protocols utilized among patients

included were GnRH antagonist (74.6%), Clomid-Flare (13.6%), and Demi--Halt (11.7%). Mean oocyte yield in the sample was 12.4 oocytes (SD 8.6 oocytes). In univariate analyses, predictors of increased variability in oocyte yield included treatment protocol with GnRH antagonist with least squares mean (LSM) of 3.4 and Demi-Halt (LSM 3.6) compared to Clomid-Flare based protocol (LSM 1.6; p<0.001), age less than 35 (LSM 4.2; p<0.001), and ovulatory dysfunction as the primary diagnosis (LSM 5.3; p<0.001). In the multivariate analysis, predictors of increased variability in oocyte yield included treatment with a GnRH antagonist or Demi-Halt protocol and a diagnosis of ovulatory dysfunction. Patients with a diagnosis of diminished ovarian reserve or undergoing stimulation using a Clomid-Flare based protocol exhibited the least variability between cycles. Age was no longer a predictor of variability in oocyte yield after controlling for covariates. In subgroup analyses restricted by treatment protocol, diagnosis remained as a significant predictor of variability in oocyte yield among those who utilized a GnRH antagonist protocol. Conversely, significant residual variability in oocyte yield was observed among those who utilized a Demi-Halt protocol that was not explained by any of the postulated predictors.

CONCLUSIONS: Variability in oocyte yield exists despite the use of the same protocol within the same year in patients undergoing successive COS cycles. Predictors of variability seen in oocyte yield includes characteristics intrinsic to the patient, such as infertility diagnosis and those related to the stimulation including the chosen protocol. However, there remains variability between cycles that is not accounted for which creates a challenge when counseling patients of expected outcomes of a successive cycles. Further prospective studies are needed to understand how adjustments in COS protocols can be utilized to minimize variability yet maximize oocyte yield in patients undergoing successive cycles.

EMBRYOLOGICAL OUTCOME AND HORMONAL PROFILE AFTER DOUBLE STIMULATION IN PATIENTS WITH POOR PROGNOSIS: INTRA-PATIENT PAIRED STUDY. Bella Martazanova, PhD, Nona Mishieva, PhD, Khava Bogatyreva, PhD, Anna Korolkova, MD, Aydar Abubakirov, PhD Reproductive endocrinology, Moscow, Russian Federation.

OBJECTIVE: Stimulation in both phases of the menstrual cycle became a new approach in poor responder patient's management. Previous studies showed that this approach could be a good opportunity for poor-responder patients because it results in more oocytes and embryos. However, stimulation in the follicular phase makes endocrine and paracrine changes especially in the hormonal profile, which is associated with the corpus luteum function and could lead to changes in the follicle environment during luteal stimulation. Therefore, there is still need for more data about embryological outcomes and hormonal changes after DuoStim, comparing follicular versus luteal phase stimulations in the same ovarian cycle.

DESIGN: A total of 76 patients with a reduced ovarian reserve was included in the intra-patient paired study. Inclusion criteria: age <43 years; AMH <1.2 ng/ml; AFC <6; basal FSH≥11 IU/ml. Exclusion criteria: uterine fibroids≥4 cm, deep endometriosis, cancer, BMI ≥29 kg/m2, smoking, severe male infertility. Group 1 (n=76) received stimulation on the day 2 follicular phase (FP). Group 2 (n=76) received the stimulation in the luteal phase (LP) on the 4th day after the first oocyte pick up (OPU) day in the same menstrual cycle.

MATERIALS AND METHODS: Plasma samples were obtained on stimulation starter day, 6 days after, on triggering and OPU day. Statistical analysis – the Mann-Whitney test, t-test, the chi-squared test; p<0.05 was considered to be statistically significant.

RESULTS: The mean age was 36.7± 3.8 years and anti-mullerian hormone concentration was 0.94± 0.3 ng/ml in the patient's cohort. On the stimulation starting day, the estradiol (E2) and progesterone (P) concentrations were significantly higher in group II LP stimulation patients than in a group I (Table), but then decreased and were similar in both groups on the ovulation triggering day. However, no significant differences in the embryological outcomes were found between the groups (Table).

CONCLUSIONS: The cohorts of oocytes obtained after the luteal phase are similar to their paired follicular phase derived cohorts, and demonstrate an equal number of the blastocyst and Top-quality blastocysts. High estradiol and progesterone levels on the stimulation starting day did not affect the embryological outcome.

CUMULATIVE LIVE BIRTH RATES BETWEEN GnRH-AGONIST AND GnRH-ANTAGONIST PROTOCOL IN ONE ART CYCLE WHEN ALL EMBRYOS TRANSFERRED : REAL-WORD DATA STUDY INCLUDING 17842 WOMEN FROM CHINA. Jingwei Yang, M.D.

OBJECTIVE: To compare the cumulative live birth rate (CLBR) of the first ART cycle including all subsequent frozen-thaw cycles in different ovarian stimulation protocol GnRH-agonist long protocol or GnRH antagonist protocol and find the clinical implication for agent choice.

DESIGN: Real-world observational data, such as electronic medical records(EMRs) contain large amounts of clinical information about heterogeneous patients and their response to treatments. The retrospective real-world data from the EMRs of a reproductive institute (2016-2019) to evaluated patients who commencing their first IVF cycle including fresh and subsequent frozen-thaw cycles from first oocyte retrieval and with no left embryos. A total of 17 842 patients and 29 065 cycles were analyzed which included 16 028 patients treated with GnRH-a long protocol and 1814 patients treated with GnRH-ant protocol.

MATERIALS AND METHODS: A total of 17842 women started their first IVF cycle including fresh and subsequent frozen-thaw cycles. Live birth was defined as delivery of any neonate at ≥28 weeks' gestation. CLBR was defined as once a live birth occurs, patients were considered to get a outcome regardless of subsequent cycles. A proportional hazards model was used to evaluate the relative prognostic significance of GnRH-a protocol and GnRH-ant protocol, female age, BMI, the number of retrieved oocytes, AMH, FSH, and the aviable embryos in relation to the CLBR.

RESULTS: Baseline characteristics were significantly different between the GnRH-a and GnRH-ant groups. Patients The mean age of women commencing IVF treatment was 30.83±4.04 years in GnRH-agonist and 34.11±5.77 years in GnRH-antagonist, and the mean number of oocytes retrieved was 13.15±6.24 in GnRH-a and 9.71±7.27 in GnRH-ant(All P value<0.05). When all embryos transferred derived from the cycle, the CLBR was 10586/16028(66.05%) in the GnRH-a group and 886/1814(48.84%) in

the GnRH-ant(OR: 2.03; 95% CI: 1.85-2.25; $P<0.001$). Mean time to the first live birth was 22.86 months in the GnRH-a group compared to 25.54 months in the GnRH-ant group ($P<0.01$). But when stratified analysis was employed to explore the optimal population selection in terms of oocyte numbers, the significant difference was found in the cumulative incidence of first live birth between treatment groups in sub-optimal group[retrieval oocytes(4-9)], the CLBR of GnRH-ant group is lower than GnRH-a ($P<0.000$, HR=0.56, 95%CI:0.39-0.81; Test of PH assumption: $P>0.05$). No significant difference of CLBR was observed in other subgroups between different treatments.

CONCLUSIONS: This study is the real-word data study comparing CLBR in GnRH-antagonist protocol with long GnRH-agonist protocol. After one complete cycle, despite significantly higher CLBR in the long agonist protocol for sub-optimal ovarian response patients, no significant difference between these two treatments in other patients. It's crucial to optimize the utilization of treatments in different ovarian response patients and consider the field of application of GnRH-antagonist protocols in China.

FREQUENCY AND SEVERITY OF OVARIAN HYPERSTIMULATION SYNDROME (OHSS) AMONG OOCYTE DONORS ACCORDING TO TRIGGER TYPE AND NUMBER OF OOCYTES RETRIEVED.

Diane Tober, PhD,[1] Kevin S. Richter, PhD,[2] Cristina Garibaldi, MS,[3] Kezia Mostak, MS,[3] Shannon Kokjohn, MSc,[4] Raquel Cool, BA,[5] Cris Zubizarreta, BA,[3] Natalia Villegas, BS,[3] Katarina Cook, BS,[3] Said Daneshmand, MD[4] [1]UCSF Institute for Health and Aging, San Francisco, CA; [2]Fertility Science Consulting, Silver Spring, MD; [3]University of California, San Francisco, San Francisco, CA; [4]San Diego Fertility Center, San Diego, CA; [5]We Are Egg Donors, Santa Cruz, CA.

OBJECTIVE: To better understand the frequency and severity of OHSS in a population of paid oocyte donors

DESIGN: Survey

MATERIALS AND METHODS: US egg donors (n=289) undergoing 801 oocyte donation cycles a few months to 27 years earlier (=4.8 years, median 2, interquartile range 1-6) were surveyed regarding egg number per retrieval, trigger type (hCG, Lupron, or combined (Dual)), and severity of OHSS. ANOVA or Kendall's test for significant association were used as appropriate.

RESULTS: Lupron triggers (n=337) had milder OHSS (23.7% moderate, 2.7% severe, no critical) compared to hCG (n=253, 29.6% moderate, 9.9% severe, 0.8% critical, p=0.022) or Dual (n=211, 37.4% moderate, 7.1% severe, 0.9% critical, $p<0.0001$) triggers. Fewer eggs (=24) were retrieved with hCG trigger vs Lupron or Dual triggers (=28 for both, p=0.0004). Adjusting for smaller hCG trigger cohort size (Table), severe OHSS was most common after hCG trigger (10-12% w/10-39 eggs, 19% w/40+ eggs) and lower following dual trigger (5-7% w/10-49 eggs, 14% w/+40+ eggs). OHSS was much milder with Lupron trigger, with more than two-thirds of retrievals of fewer than 50 eggs reporting only mild or no OHSS, and severe OHSS ranging from 1% with 10-29 eggs to 4-9% with 30+ eggs.

CONCLUSIONS: Among high-responding egg donors at risk of OHSS, Lupron trigger results in much milder cases of OHSS compared to triggers that include hCG, but does not completely eliminate risk for the condition. Risk for moderate to severe OHSS appears to increase according to number of eggs produced. There were no reports of severe OHSS on cycles in which donors reported producing 10 eggs or fewer.

SUPPORT: This study was supported by the University of California, San Francisco, Institute for Health and Aging; UCSF Individual Investigator Grant (#7501159); and funding from the National Science Foundation (#1828783).

WHICH IS MORE PREDICTIVE OVARIAN RESERVE MARKER WHEN THERE IS DISCORDANCE BETWEEN ANTI - MULLERIAN HORMONE AND ANTRAL FOLLICLE COUNT IN PATIENTS WITH DIMINISHED OVARIAN RESERVE, AMH OR AFC?.

Kiper Aslan, M.D.,[1] Isıl Kasapoglu, M.D.,[2] Meltem Koc, M.D.,[1] Goktan Kuspinar, PhD. candidate,[1] Berrin Avcı, M.D., PhD,[3] Gürkan Uncu, Prof.[1] [1]Bursa Uludag University Faculty of Medicine, Bursa, Turkey; [2]Uludag University School of Medicine, Gynecology and Obstetric ART Center, Bursa, CT, Turkey; [3]Uludag University School of Medicine, Bursa, Turkey.

OBJECTIVE: To determine the most predictive ovarian reserve parameter in patients with diminished ovarian reserve

DESIGN: Retrospective Cohort Study

MATERIALS AND METHODS: The study was conducted at Bursa Uludag University Hospital, ART Center. Patients who underwent ICSI because of diminished ovarian reserve, age < 40, without chronic systemic disease and without suspicion of malignancy, were screened from electronic database, retrospectively. Patients were subdivided into three groups. The first group (Group A) was consisted of patients with low anti-mullerian hormone (AMH) (<1.1 ng/dl) and low antral follicle count (AFC) (n < 7). The second Group (Group B) was consisted of patients with low AMH (<1.1 ng/dl) and normal AFC (n≥7). The third group (Group C) was consisted of patients with normal AMH (≥1.1 ng/dl) and low AFC (n<7). Demographic values, FORT score (follicle output rate: pre-ovulatory follicle count/antral follicle count x 100) and FOI score (follicle to oocyte index: oocyte number/AFC x 100) of the groups were compared.

RESULTS: Totally 662 cycles were enrolled in to the study. There were 418 cycles in Group A, 167 cycles in Group B and 77 cycles in Group C. Demographic values were comparable, except age. Mean age was lower in group B. (Respectively; 34.7 ± 3.7, 33.1 ± 4.1, 34.7 ± 3.6, p<0.01) As primary result; FORT and FOI score was higher in Group C than the other two groups. (Median FORT Score with quartiles: Group A: 100 (66-150), Group B: 71 (57-100), Group C: 136 (96-200), p<0.01 – Median FOI Score with quartiles: Group A: 83 (50-140), Group B: 71 (40-100), Group C: 108 (66-200), p<0.01) FORT and FOI score had no correlation with age. Thus, the difference of age in the groups does not affect the primary result. (Table-1)

CONCLUSIONS: In this study, we showed that anti-mullerian hormone has more predictive value for stimulation success. Increased AMH level results with increased FORT and FOI score. If there is discordance between AMH and AFC in patients with diminished ovarian reserve, AMH is the more predictive one for stimulation success.

SUPPORT: None.

FINE TUNING OF RECOMBINANT HUMAN FOLLICLE-STIMULATING HORMONE (R-HFSH) DOSE TO INDIVIDUALIZE TREATMENT: REAL-WORLD DATABASE ANALYSIS OF OVULATION INDUCTION CYCLES FOR TIMED INTERCOURSE OR INTRAUTERINE INSEMINATION. Anne E. Martini, DO,[1] Stephanie Beall, MD, PhD,[2] Gilbert L. Mottla, MD,[3] G. David Ball, PhD,[4] Brooke Hayward, SM, MBA,[5] Mary C. Mahony, PhD, HCLD,[5] Allison B. Catherino, PhD[5] [1]National Institute of Child Health and Human Development, NIH, Bethesda, MD; [2]Shady Grove Fertility Center, Towson, MD; [3]Shady Grove Fertility Center, Annapolis, MD; [4]Seattle Reproductive Medicine Center, Seattle, WA; [5]EMD Serono, Inc. (a business of Merck KGaA, Darmstadt, Germany), Rockland, MA.

OBJECTIVE: To describe the real-world incidence and magnitude of individualized gonadotropin dose adjustments (increases and/or decreases) made during ovulation induction (OI) cycles, and to assess the relationship between patient characteristics and dosing changes.

DESIGN: Non-randomized, observational, retrospective cohort.

MATERIALS AND METHODS: Analysis of electronic medical records from a large US database of fertility centers (IntegraMed America, Inc.). Data from r-hFSH–treated OI cycles for patients who had undergone a first OI cycle in 2015–2016, with or without intrauterine insemination, were included. r-hFSH dose could be adjusted in 12.5-IU increments when administered subcutaneously with the follitropin alfa injection device, with or without oral medications for OI (clomiphene citrate or letrozole).

RESULTS: Of the 2832 OI cycles involving r-hFSH administration, 74.6% also included combination treatment with orals whereas 25.4% used r-hFSH only. Patients in the r-hFSH with orals group, compared with those in the r-hFSH–only group, had a lower mean (standard deviation [SD]) age (34.8 [4.85] vs 35.9 [5.04] years) and were more likely to have a normal antral follicle count (≥12; 37.7% vs 28.5%). A greater proportion of patients in the r-hFSH with orals group had normal (1.5–4.0 ng/mL; 28.1% vs 16.3%) or high anti-Müllerian hormone levels (>4.0 ng/mL; 25.9% vs 17.5%), and fewer had a primary diagnosis of diminished ovarian reserve (11.7% vs 26.0%). As expected, the starting dose of r-hFSH was lower for cycles that used r-hFSH with orals than r-hFSH–only cycles (mean [SD]: 74.2 [39.31] vs 139.3 [115.10] IU). Overall, dose changes occurred in 13.7% of r-hFSH with orals vs 43.9% of r-hFSH–only cycles. In those cycles with dose adjustments, dose increases were most common and occurred in 58.8% of r-hFSH with orals and 68.7% of r-hFSH–only cycles; dose decreases occurred in 58.1% and 54.1% of cycles, and both increases and decreases were used in 17.0% and 22.8% of cycles, respectively. Dose adjustments ranged from 12.5 IU to 450 IU. The smallest increments (12.5 IU and 25 IU) were used frequently, more often for upward dose titrations in r-hFSH–only (64.5%) vs r-hFSH with orals (53.5%) cycles than for dose decreases in r-hFSH–only (46.8%) and r-hFSH with orals (35.7%) cycles.

CONCLUSIONS: r-hFSH dose adjustments are common in OI cycles treated with r-hFSH. In OI cycles that also included orals, r-hFSH starting doses were lower and r-hFSH dose changes were fewer than with r-hFSH only. Use of smaller dose-adjustment increments facilitates more individualized treatment, particularly for patients with a good prognosis undergoing a 'low and slow' step-up protocol, to help mitigate risks associated with ovarian hyperstimulation syndrome and multifollicular response leading to multiple pregnancies.

POSTER SESSION: PATIENT EDUCATION AND SUPPORT

P-876 3:30 PM Wednesday, October 21, 2020

IMPACT OF THE INFERTILITY TREATMENT JOURNEY ON THE MENTAL HEALTH AND RELATIONSHIPS OF INFERTILE PATIENTS AND THEIR PARTNERS. Jacky Boivin, PhD,[1] Alice D. Domar, Ph.D.,[2] Rita Vassena, DVM, PhD,[3] Barbara Lynn Collura, MA[4] [1]Cardiff University, Cardiff, United Kingdom; [2]Boston IVF, Waltham, MA; [3]Clinica EUGIN, Barcelona, Spain; [4]RESOLVE: The National Infertility Association, McLean, VA.

OBJECTIVE: To investigate the psychological impact of fertility treatment and its effects on infertile patients and their partners.

DESIGN: An online, international, 30-minute quantitative survey.

MATERIALS AND METHODS: Data were collected from 1,944 respondents across nine countries, between March and May 2019. The survey was developed in English and translated to local languages with translations validated by national linguists. Participants were at different stages of the treatment journey and either infertile patients (n=1,037) or partners to infertile patients (n=907; but not necessarily partners of the patient sample).

RESULTS: Average age was 35.8 (SD=9.66) years, 56% of respondents (n=1,095) were female, 67% (n=1,119) were married and 91% (n=1,773) were heterosexual. The majority of patients were female (n=884; 66%) and the majority of partners were male (n=499; 55%). At infertility diagnosis, the emotion most often experienced for overall respondents was "sadness" (reported by 53%). A diagnosis of anxiety was reported by 43% of infertile patients and 30% of their partners. When undergoing treatment, "anxiety" was experienced by the most respondents (35%).

The infertility treatment journey reportedly had an impact on the mental health of 60% of respondents, but only 44% of respondents sought mental health support. The highest proportion of respondents seeking support was 71% in China, with the lowest in Italy (29%). A greater proportion of patients reported detrimental impacts on mental health (70%) than partners to infertile patients (49%).

One in three respondents indicated their relationship suffered as a result of infertility diagnosis. Overall, 33% of respondents ranked emotional strain within the top two most significant effects on their relationship. Respondents from the United States reported this as the most significant effect.

Patients were more likely than partners to report a detrimental impact on activities of daily living. An "effect on work-life balance" was most commonly experienced, considered to be within the top two most significant activity-associated effects by 31% of patients and 24% of partners.

CONCLUSIONS: Respondents reported a significant impact of their infertility journey on mental health and wellbeing, which in turn negatively

impacted relationships with partners. The disparity between the number of respondents who experienced mental health issues and the number of those who sought support indicates a need for better awareness and accessibility for support services.

P-877 3:30 PM Wednesday, October 21, 2020

LIVE BIRTH RATES ARE HIGHER IN NULLIPAROUS WOMEN WHO ARE REFERRED TO A SPECIALTY FERTILITY CENTER BY A HEALTHCARE PROVIDER THAN IN WOMEN WHO ARE SELF-REFERRED. Audrey J. Panko, BS, Lara Lemon, PhD, PharmD, Marie Menke, MD, MPH Magee Womens Hospital at UPMC, Pittsburgh, PA.

OBJECTIVE: To evaluate differences in fertility outcomes between provider-referred and self-referred nulliparous patients.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: This study examined nulliparous women ages 18-43 years old who presented for a new patient consultation between January 2015 and December 2018 at a fertility clinic. Women who presented for fertility preservation services or did not present for fertility concerns were excluded. Data regarding referring provider, diagnosis of infertility, evaluation, and treatment prior to and after the first visit with the fertility clinic were collected. Rates of and time from the first consultation to pregnancy and live birth, as identified by episode documentation in the electronic medical record, were also obtained. Chi-squared test was performed for categorical variables and unpaired t-test for continuous variables.

RESULTS: A total of 6378 women presented for new patient consultation between 2015 and 2018; 4118 women (64%) met eligibility criteria. Among these, 1582 (38%) were provider-referred (PR) and 2536 (62%) were self-referred (SR). There were no significant differences between the groups in age, body-mass index, race, ethnicity, type of health insurance, and median income or area deprivation index of the patient's area of residence. Prior to their first new patient consultation with the fertility clinic, provider-referred patients were more likely to have a history of an infertility diagnosis (45% PR versus 34% SR, $p<0.0001$), evaluation of ovarian reserve with either FSH or AMH (50% PR vs 38% SR, $p<0.0001$), anatomic evaluation with HSG (21% PR versus 18% SR, $p=0.012$), and treatment with clomiphene citrate (9% PR versus 4% SR, $p<0.001$). With regards to treatment after their new patient consultation, there were no significant differences between the two groups in treatment with insemination (24% PR versus 23% SR, $p=0.249$) or use of assisted reproductive technology (15% PR versus 16% SR, $p=0.713$). However, live birth rates were significantly higher among provider-referred versus self-referred patients (30% PR vs 26% SR, $p=0.006$). There was no significant difference in the time from the new patient consultation to delivery (482 ± 416 days PR versus 460+373 days SR, $p=0.3107$) between the two groups.

CONCLUSIONS: Our results suggest that provider-referral to an infertility specialist is associated with an increased rate of infertility diagnoses and an increased live birth rate as compared to self-referral. This analysis has important interdisciplinary implications for optimizing access to care, referral patterns, and outcomes for women undergoing fertility evaluation.

P-878 3:30 PM Wednesday, October 21, 2020

DOES A SMARTPHONE-BASED SEMEN ANALYSIS KIT PREDICT AZOOSPERMIA AFTER VASECTOMY? Josip Vukina, MD,[1] Hanna Pulaski, PhD[2] [1]UPMC Department of Urology, Pittsburgh, PA; [2]Magee Women's Hospital, Pittsburgh, PA.

OBJECTIVE: We sought to determine if a smartphone-based home semen analysis kit could reliably predict azoospermia after vasectomy.

DESIGN: In our practice, patients are normally instructed to provide a semen sample three months after vasectomy to document sterility. After obtaining Institutional Review Board approval, the study was discussed initially with patients during the vasectomy procedure and then consent was obtained at the time of semen analysis. After traditional semen analysis was performed, a portion of the unused semen sample was used to perform smartphone-based semen analysis using the Seem application.

MATERIALS AND METHODS: The Seem smartphone application by Recruit Lifestyle is available for both iOS and Android platforms and can be purchased online. The kit contains a small collapsible container for semen collection, a slide which is placed over the forward-facing camera of the smartphone, and a dropper to load the semen onto the slide. The application utilizes the high-resolution camera that is now ubiquitous in most smart phones to capture video which is then analyzed by proprietary software to determine sperm concentration and motility. After performance of traditional semen analysis, a small portion of the remainder of the sample (which would otherwise be discarded) was used to perform smartphone-based analysis and the results were then compared.

RESULTS: Patients in the study underwent semen analysis an average of 158 days after vasectomy. Except for one patient (who was instructed to repeat semen analysis in 4 weeks and continue contraception), all patients met American Urologic Association guidelines for successful vasectomy allowing for cessation of contraception. Only two patients met this criteria based on smartphone application concentration. For the remainder of the patients, smartphone-application derived concentrations were shown to be significantly higher and inaccurate compared to traditional semen analysis.

Patient	Smartphone Concentration	Smartphone Motility	SA Concentration	SA Motility	Days Since Vasectomy
1	7.4x10^6	0	2 sperm	0%	103
2	27.2x10^6	90.9	3 sperm	NA	181
3	0.0x 10^6	0	0	0%	119
4	9.9x106^6	25	0	NA	108
5	7.4x10^6	66.7	2 sperm	0%	124
6	5.0x10^6	0	0	NA	120
7	0.0x 10^6	0	17 sperm	0%	unknown
8	57.0x10^60	0	0	NA	486
9	79.2x10^6	0	0	NA	139
10	9.9x10^6	0	1 sperm	0%	234
11	5.0x10^6	0	0	NA	133
12	14.9x10^6	0	1 sperm	0%	90
13	5.0x10^6	0	0	NA	178
14	9.9x10^6	0	282 sperm	54%	78
15	14.9x10^6	0	0	NA	78
16	5.0 x 10^6	0	0	NA	193

CONCLUSIONS: While home semen analysis kits similar in appearance to a pregnancy test do exist, to our knowledge, this is the first study to use smartphone-based technology to evaluate post-vasectomy semen analysis. Unfortunately, this tool does not reliably predict azoospermia after vasectomy.

P-879 3:30 PM Wednesday, October 21, 2020

DOES A WEB-BASED APP DECREASE MEDICATION WASTE, MEDICATION ERRORS AND CLINIC MESSAGES DURING IN VITRO FERTILIZATION CYCLES? Caitlin Elizabeth Martin, MD, MS,[1] Michael Lanham, MD,[2] Courtney A. Marsh, MD, MPH,[3] Kenan Omurtag, MD[1] [1]Washington University School of Medicine, St. Louis, MO; [2]University of Michigan, Ann Arbor, MI; [3]University of Kansas, Overland Park, KS.

OBJECTIVE: To assess whether using a web-based app that assists in medication management during In Vitro Fertilization (IVF) decreases medication waste, errors and patient-initiated messaging, while improving patient satisfaction.

DESIGN: A multicentered, randomized controlled trial.

MATERIALS AND METHODS: There were 104 women recruited prior to starting IVF. Subjects were recruited to assess quality of life during IVF, and then were randomized to use an app, "OnTrack," to assist with medication management vs. no app with conventional medication management. Women in the app arm were also informed of medication changes per clinic protocol. Surveys were e-mailed prior to starting IVF, on day 6 of stimulation, prior to and post egg retrieval. Quantity of medication errors and messages initiated by the patient were recorded. In the final survey, patients listed leftover medication. The approximate cost of medications was obtained from published data[1]. Patient satisfaction was assessed using a Likert scale. University of Michigan Redcap was used for data collection. SPSS v.25 was used for statistical analysis. Independent sample T-tests, Mann-Whitney tests and Fisher's exact tests were used where appropriate.

RESULTS: The median number of portal messages sent by the patient was 3 (range 0-13) in the control arm and 3 (0-18) in the app arm ($p=0.9$); the

median number of calls made by the patient was 0 (0-3) in the control arm and 0 (0-2) in the app arm (p=0.2). Seven patients (7/42, 16.7%) made medication errors in the control arm and 5 (5/46, 10.9%) in the case arm (p=0.5). Patients in the control arm had an average of 492±425 units of rFSH left compared to 455±395 units in the app arm (p=0.7), 5.3±3.9 vials of HMG left in the control arm and 4.4±4 in the app arm (p=0.3), and 1.7±2.3 syringes of GnRH antagonist left in the control arm and 1.8±2.5 syringes in the app arm (p=0.8). The estimated cost of medication waste was $3059±2075 in the control arm and $2766±1798 in the app arm (p=0.5). On a scale of 1-7 (1=completely dissatisfied, 7=completely satisfied), the average patient satisfaction score was 5.85±1.8 in the control and 6.17±1.1 in the case arm (p=0.939).

CONCLUSIONS: A web-based application did not decrease medication errors, waste or patient-initiated messages. The amount of medication ordered may vary per clinic protocols and could depend on insurance coverage, which was not captured by the study. Assessment of medication errors was limited by the medical record. Patient initiated communication was lower than expected; clinics may already excel at giving medication instructions. Patient satisfaction was equal in both groups. The app was a successful adjunct to clinical care. Future directions include studying similar tools alone for medication management and daily decisions as a method to improve clinic efficiency.

P-880 3:30 PM Wednesday, October 21, 2020

AN ANALYSIS OF FERTILITY PODCASTS: WHAT ARE PATIENTS LISTENING TO OUTSIDE OF THE CLINIC? Virginia-Arlene Acosta Go, MD, Karin Wollschlaeger, MD, Cathlyn Sullivan, DO Saint Joseph Hospital, Denver, CO.

OBJECTIVE: To identify and summarize available podcasts pertaining to fertility, infertility and IVF (in vitro fertilization) in order to provide a better understanding of information accessible to patients outside of the clinical setting.

DESIGN: Cross-sectional analysis

MATERIALS AND METHODS: Apple and Google Podcast Player applications were searched using the key words: *fertility, infertility and IVF* in November 2019. Included podcast results were published in English and had over 50% of episodes relevant to the searched topics. Podcasts were excluded if they were not accessible on both Apple and Google Podcast Player applications. Podcasts were assessed for: author credentials, content, dates of air, ratings and length of episodes.

RESULTS: The query produced 310 podcast results, of which 117 were unique podcasts and met inclusion criteria. The dates of initial episode ranged from 2007 to 2019 with only 9% of podcasts dated prior to 2016. The number of fertility podcasts released in 2019 increased 5-fold since 2016. The majority of podcasts had episodes less than one hour in duration and only 29% had any episodes greater than one hour. Thirty-two percent of podcasts were categorized as *Health and Fitness*, 23% as *Alternative Health* and most others fell into categories including *Nutrition, Mental Health, Christianity, Medicine, Sexuality, Society and Culture*. Twenty-two percent of podcasts were published by authors who identified as prior or current patients, 9% by medical physicians and 8% by authors who identified as "coaches" (life, fertility, health). The majority of podcasts targeted patients rather than providers and offered support rather than medical advice. Many podcasts included interviews with patients, health care providers and other experts in the field. The top three most popular podcasts had over 400 reviews, whereas the average number of reviews per podcast was 49. In general, fertility podcasts were well received and had an average rating of 4.8 out of 5 stars.

CONCLUSIONS: With increasing popularity and accessibility of podcasts, it is important to have a sense of what exists in the realm of fertility podcasts. Medical physicians currently author only a fraction of these podcasts thus there is significant opportunity for growth in this platform for education and patient support. Fertility podcasts may be created and utilized by healthcare providers to supplement information outside of the clinical setting in order to better guide patient care.

P-881 3:30 PM Wednesday, October 21, 2020

THE EFFECTS OF FEMALE GENITAL MUTILATION ON THE FEMALE SEXUAL FUNCTION: A CROSS-SECTIONAL STUDY. Ahmed M. Abbas, MD,[1] Mennatallah Mohamed Samir, MBBCh,[2] Reham Maher Abdel-Gaber, MD,[2] Emad Eldien Kamal Ali, MD[2] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Department of Dermatology, Venereology and Andrology, Faculty of Medicine, Assiut University, Assiut, Egypt.

OBJECTIVE: The existing literature on female genital mutilation (FGM) and sexuality is conflicting regarding its effects on sexual functions. ***The aim of the present study is to e***valuate the effects of FGM on the female sexual function.

DESIGN: A cross sectional study

MATERIALS AND METHODS: The study was carried out between April 2018 and January 2019. We included married women, aged 18 – 45 years old, and sexually active during the last six months. All women were asked to complete the Arabic Female Sexual Function Index (ArFSFI) independently. The cut-off score to define sexual dysfunction on the total FSFI score is 28.1. Then, the gynecologist conducted a thorough clinical examination and a detailed assessment of the type and extent of FGM. Continuous data was expressed in the form of mean ± SD while nominal data was expressed in the form of frequency and percentage.

RESULTS: The study included 200 women divided into two groups; group (I) FGM, n=127 women and group (II) no FGM, n=73 women. There was no statistically significant difference in sexual function between both groups [91 women (71.7%) in group I vs. 53 women (72.6%) in group II, p=0.511]. The mean total ArFSFI score in group I was 25.8±3.05 vs 25.4±3.64 in group II (p=0.598). Additionally, There was no statistically significant difference in the sexual function between women with type I and type II FGM (p=0.555). The mean total ArFSFI score in women with type I was 26.6±2.61 vs 25.4±3.64 in women with type II FGM (p=0.071).

CONCLUSIONS: FGM is not associated with reduced scores of ArFSFI either in all domain scores or the total score. Moreover, no difference in the scores of the ArFSFI between women with type I or type II FGM.

SUPPORT: None

P-882 3:30 PM Wednesday, October 21, 2020

A PRECONCEPTION LIFESTYLE INTERVENTION IMPROVES SOME GESTATIONAL OUTCOMES AND NEONATAL MARKERS OF ADIPOSITY IN WOMEN WITH OBESITY AND INFERTILITY. Mehdi Rouissi, PhD,[1] Farrah Jean-Denis, MSc,[2] Matea Belan, MSc,[1] Jean-Patrice Baillargeon, Pr[1] [1]Université de Sherbrooke, Sherbrooke, QC, Canada; [2]Research Center of the Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada.

OBJECTIVE: Obesity during pregnancy is associated with a high risk of many pregnancy and neonatal complications. Our aim was therefore to determine whether a lifestyle program targeting women with obesity and infertility and maintained during pregnancy improves maternal and neonatal outcomes, as well as newborn cord blood markers.

DESIGN: Randomized controlled trial

MATERIALS AND METHODS: We report on 46 women who became pregnant and had available outcome data during pregnancy and at birth, among 127 women with infertility and obesity (BMI $\geq$30 kg/m^2), or overweight with PCOS (BMI $\geq$27 kg/m^2), who were enrolled in a lifestyle randomized-controlled trial. Participants were randomized to the control group (CG, n=20), who received standard of care, or the lifestyle group (LSG, n=26), who followed a lifestyle program alone for 6 months, and then in combination with usual fertility care. Follow-up was for 18 months or until the end of pregnancy. In 24 participants (LSG, N=13; CG, N=11), a sample of umbilical cord blood was obtained after delivery, with measurement of non-esterified fatty acids (NEFA), triglycerides (TG), leptin, adiponectin, IL-6, TNF-alpha, CRP, PAI-1 and oxidized LDL.

RESULTS: Baseline results showed no significant differences between groups for age (29.3 vs 31.0 years), BMI (38.7 vs 38.4 kg/m^2) and waist circumference (113.7 vs 112.7 cm). Preconception weight loss was significantly higher in the LSG compared to the CG (-4.86 kg vs -1.21 kg,

p=0.013), but gestational weight gain was similar. During pregnancy, groups did not differ for the rates of most clinical outcomes (such as preeclampsia, gestational diabetes, etc.), but significantly less women in the LSG required insulin for treatment of their gestational diabetes (12.5% vs 42.1%, p=0.027) as well as urgent cesarean section due to failure of vaginal delivery (0.0% vs 21.1%, p=0.021). Regarding neonatal outcomes, there was no significant difference between groups for gestational age and weight at birth, as well as rates of prematurity, L/SGA, etc. However, babies from the LSG displayed significantly lower tricipital skinfolds at birth (4.73 vs 5.72 mm, p=0.031), and trends for lower sum of four skinfolds (16.6 vs 19.1 mm, p=0.056) and increased length (50.8 vs 49.6 cm, p=0.053). In addition, cord blood levels of TG and IL-6 tended to be lower in babies born from women of the LSG vs CG (medians = 0.20 vs 0.39 mmol/L, p=0.06 and 7.2 vs 21.8 pg/mL, p=0.06), with a higher adiponectin/leptin ratio (3.76 vs 2.95, p=0.14).

CONCLUSIONS: In women with obesity and infertility, a lifestyle program initiated prior to fertility treatments and maintained throughout pregnancy improved their weight and was associated with a reduction of some clinically relevant pregnancy and neonatal complications, as well as markers of adiposity (skinfolds) and dysmetabolic (TG, adiponectin/leptin ratio) and pro-inflammatory (IL-6) states. If these results are replicated in a larger sample, it would strongly suggest that women with obesity should be supported to adopt a healthy lifestyle prior conception in order to increase their likelihood of giving birth to a healthy baby.

P-883 3:30 PM Wednesday, October 21, 2020

LANGUAGE BARRIERS ON FERTILITY CLINIC WEBSITES IN THE WESTERN REGION. Kajal Verma, MD,[1] Christopher de Haydu, MD,[2] Angela H. Liu, MD,[1] Melody A. Rasouli, MD, MBA,[1] Janelle M. Jackman, MBBS,[3] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]New Hope Fertility Center, New York, NY; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Fertility clinic websites are an important tool used by patients in selecting a medical practice for obtaining reproductive endocrinology and infertility (REI) services. Patient accessibility to clinic websites can differ for a variety of reasons, including language barriers. The goal of this study is to examine accessibility of fertility services to non-English speaking patients, specifically looking at website translation links and fertility specialists speaking more than one language, as listed on the websites. The availability of this patient facing information on websites was analyzed using county-level demographics within the Western Region of the US (WRUS).

DESIGN: Cross-sectional analysis.

MATERIALS AND METHODS: A survey was developed and two independent investigators at different institutions assessed clinic websites that contributed to the most recent complete (2017) Society for Assisted Reproductive Technology (SART) database in the WRUS (as defined by US Census Bureau). Websites were assessed for content that was partially or fully translated into another language besides English. REI physicians who speak more than one language, as noted by the website, were also identified. The responses were ordered by county level data obtained from the US Census (most recent complete data sets, 2010-2018) for demographic information including language spoken at home and education. Descriptive statistical analyses performed included Chi-square and t-tests.

RESULTS: 100 SART-reporting fertility clinics are located in WRUS. 42% of clinic websites were partially or fully translatable to a language other than English. 30% of websites reported physicians as speaking more than one language. 67% of these bi- or multilingual physicians reported Spanish as an additional language. Compared to the lower 3 quartiles for language, there was a positive association between website translation links and the highest quartile of language, other than English, spoken at home ($p = 0.02$). There was also a significant association between physicians who were bi- or multilingual and the highest quartile of language, other than English, spoken at home ($p = 0.01$). Regarding education, the quartile of counties with the lowest percentage of persons with a high school graduate degree or higher was also positively associated with websites providing translation services ($p = 0.04$).

CONCLUSIONS: Less than half of SART registered fertility clinics in the WRUS include at least part of their websites translated into a language other than English, and predictive factors of website translation services include clinic location in a region with a higher proportion of people speaking a language other than English at home and lower education level. Fertility clinics can overcome language barriers by offering translation services on their websites, thereby increasing accessibility to non-English speaking patients. Further studies to evaluate whether website translation services or the presence of bi- or multilingual physicians are factors in patient decision-making in regards to choosing a fertility clinic are ongoing.

P-884 3:30 PM Wednesday, October 21, 2020

IS FERTILITY STATUS ASSOCIATED TO SEXUAL DYSFUNCTION? A COMPARATIVE STUDY IN A MEXICAN FERTILITY CENTER. Edelmiro Garza-Padilla, M.D., Julio C. Rosales, M.D., Pablo Diaz-Spindola, M.D., Karla Alejandra Cantú, M. Sc., Irving Olaf Morales, M.D., IECH Monterrey, NL, Mexico.

OBJECTIVE: To determine if the infertility diagnosis correlates with lower scores in the Female Sexual Function Index (FSFI).

DESIGN: Prospective analytical and comparative study.

MATERIALS AND METHODS: The Female Sexual Function Index (FSFI) is a 19-item, self-report scale of female sexual function[1]. Women attending a Mexican fertility clinic from January 2019 to April 2020 were reached via e-mail and requested to fill an online form that included the FSFI questionnaire (Chilean Spanish validated version[2]) and general demographic information, after informed consent. Likewise, a smaller group of non-infertile patients from a general gynaecological practice filled the same forms. Answers were stored in a database for further analysis. Prevalence of sexual disfunction was calculated as a percentage of patients not achieving an overall FSFI score of 26.55[1].

RESULTS: Out of 1,345 participants, 18% responded the online form. Furthermore, 34 patients were excluded to avoid bias favoring sexual dysfunction after selecting, at least one time, the absence of sexual activity in the past 4 weeks in the FSFI questionnaire. The remaining patients were classified in two groups: 142 (69%) self-identified as infertile and 65 (31%) without that diagnosis. Patients from the first group where older (35.15±5.69 vs. 29.5±5.52 years, $p<0.001$) and with higher body mass index (27.76 ±6.45 vs. 23.91 ±5.58 kg/m^2, $p<0.001$). There were no differences in marital status, academic level or gynecological pathologies.

The prevalence of female sexual dysfunction in the infertility group was 68.3%, in contrast to 61.5% for the control group. A tendency for lower scores in the infertile group was seen in each domain and the overall scores of the FSFI, but it only was statistically significant in the arousal domain ($p<0.05$, OR 1.4). After adjusting for age and other variables, this difference gap persisted.

CONCLUSIONS: The present study demonstrated a very high prevalence of sexual dysfunction in our patients, with and without infertility, almost twice as reported in other groups[3,4]. Furthermore, there was no association between the fertility status and the prevalence of female sexual dysfunction (except for arousal) using the FSFI compared to controls. Further studies are warranted to determine if this pattern repeats with larger data set.

P-885 3:30 PM Wednesday, October 21, 2020

"ADD-ONS" IN ART: DO PATIENTS RECEIVE HONEST INFORMATION THROUGH FERTILITY CLINICS' WEBSITES?. Valentina Galiano, MD,[1] Raoul Orvieto, MD,[2] Ronit Machtinger, MD, PhD,[2] Ravit Nahum, MD,[2] Emanuele Garzia, MD, PhD,[1] Patrizia Sulpizio, MD,[1] Anna Maria Marconi, MD,[1] Daniel S. Seidman, MD[2] [1]San Paolo University Hospital, Milano, Italy; [2]Sheba Medical Center, Ramat Gan, Israel.

OBJECTIVE: "Add-on"procedures are actively promoted by some fertility clinics as proven means to improve IVF success rates, especially in couples with repeated implantation failure.The aim of this study was to assess the accuracy of information about "add-ons" on the internet, considering the conflicting evidence on their effectiveness.

DESIGN: A systematic evaluation of fertility clinics websites. We developed a 10-criteria structured questionnaire to evaluate the quality of information on endometrial scratching, assisted hatching, intralipids infusion and PGT-A, available through the internet.

MATERIALS AND METHODS: The search and review were performed in January-February 2020 by a single investigator. We included English language websites that presented in the Google.com search engine after typing the following key words: "endometrial scratching" (ES), "intralipid infusions" (ILI), "assisted hatching" (AHA), "PGT-A" or "PGS". As the previously used term "PGS" is often still used instead of PGT-A, we searched for both words.

RESULTS: 260 unique websites were evaluated. For the procedures listed, almost all the websites belonged to private clinics. Only for AHA (3 clinics), and PGT-A (2 clinics), we also found public institutions that provided information. An accurate description of the "add-on" procedures was provided in most cases (78.8%). However, only a minority (12%) of these websites reported on the inconclusive effectiveness of these procedures. The use of PGT-A was most often encouraged (52.8%), compared to ES (23.6%) and AHA (16%). The additional cost of the "add-on" procedure was rarely presented (6.9%). Literature references were never provided for ILI and only rarely, 12.7%, for ES, 4.0% for AHA and 5.6% for PGT-A. Date of entry of the information was frequently not reported. None of the websites reported the clinic's pregnancy rates following of the "add-on" procedures.

CONCLUSIONS: The information about "add-ons" available to the public from IVF clinics' websites is often inaccurate. This could perpetuate false myths among patients about the effectiveness of these add-on procedures and raises concern regarding possible commercial bias. It is imperative that IVF clinics' websites better communicate the associated risks and uncertainties of "add-on" procedures to prospective patients.

P-886 3:30 PM Wednesday, October 21, 2020

MALE REPRODUCTIVE ONCOFERTILITY SPECIALISTS AT NCI DESIGNATED CANCER CENTERS: ASSOCIATION OF WEB SITE CONTENT WITH INSTITUTIONAL RANKING AND LOCATION SOCIODEMOGRAPHICS. Kassandra E. Zaila, B.A.,[1] Sriram Eleswarapu, M.D., Ph.D.,[1] Cindy Duke, M.D., Ph.D.,[2] Christopher de Haydu, M.D.[3] [1]University of California, Los Angeles, Los Angeles, CA; [2]University of Nevada Las Vegas, Nevada Fertility Institute, Las Vegas, NV; [3]University of Miami, Miami, FL.

OBJECTIVE: We previously demonstrated that the availability and quality of patient directed information regarding male fertility preservation on the web sites of National Cancer Institute (NCI) designated cancer centers was lacking. The aim of this study was to investigate whether there are institutional ranking or sociodemographic factors that influence whether male reproductive oncofertility-focused urologists and cancer survivorship are featured on NCI cancer center web sites.

DESIGN: All NCI designated cancer center web sites were queried in a systematic fashion for patient directed information on male reproductive oncofertility. Cancer survivorship information and male reproductive urologist consultation information were assessed.

MATERIALS AND METHODS: Patient directed information available on the web site of each NCI designated cancer center was evaluated for its male reproductive oncofertility content, with a specific focus on cancer survivorship information and information regarding names and links to urology providers who have specific interests in male infertility and microsurgery. These data were then compared with respect to US News & World Report institutional ranking along with sociodemographic data. Sociodemographic factors evaluated included level of educational attainment for the surrounding county and gender disparities within the surrounding county. Descriptive statistical analysis and chi-squared testing were performed.

RESULTS: All 62 web sites of NCI designated cancer centers were evaluated; 92% were affiliated with academic institutions. Among all cancer centers, 50% made mention of male-specific oncofertility risks. The risk of cancer treatment on fertility (not gender specific) was mentioned by 56% of centers. There was a statistically significant association with a greater proportion of women in a state or county with the presence of increased discussion of male oncofertility cancer survivorship on the web sites (p=0.04). Cities with lower percentages of poverty were more likely to have NCI cancer centers list infertility specialists on their webpages without referring them to university department websites (p=0.04). Higher educational attainment in the NCI designated cancer center's region was associated with greater number of infertility/microsurgery male reproductive urologists featured on web sites (p=0.01).

CONCLUSIONS: Web-based access to provider information and fertility options available to patients is an important component of shared decision making. We found a positive association between the percentage of women in a state or county, as well as level of educational attainment, and access to male infertility specialists and survivorship information. These associations raise important questions regarding possible socioeconomic or educational factors influencing information on NCI cancer centers.

P-887 3:30 PM Wednesday, October 21, 2020

IMPACT OF AN EARLY PREGNANCY EDUCATION PACKET ON PATIENT QUESTION VOLUME. Adina Tanen, BS, Ambika Nohria, BA, Youjin Jenny Jang, BA, Paula C. Brady, MD Columbia University Fertility Center, New York, NY.

OBJECTIVE: To determine whether providing an evidence-based early pregnancy education packet (EPEP) to newly pregnant patients with a prior diagnosis of infertility impacts the volume of patients' pregnancy-related questions.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: The 76 page EPEP - compiled by clinical staff directly from the American College of OB/GYN, the American Society for Reproductive Medicine, the Centers for Disease Control and Prevention and the National Institutes of Health websites - addressed travel, diet, exercise, intercourse, prescription and nonprescription drugs, and pregnancy symptoms. The EPEP was emailed to patients after the first positive serum hCG result. During routine pregnancy scans performed weekly from 6-8 weeks gestation, medical assistants recorded the number and category of patients' pregnancy-related questions, without any identifying information. Data were collected 2 months before and after packet introduction, including demographics of each group (not tied to responses). Univariate comparisons between cases and controls were performed using the Fisher's exact test; a p-value of $\leq .05$ was considered statistically significant. Analyses were performed using online calculators available at http://astatsa.com.

RESULTS: Data were collected during 84 pregnancy scans pre-EPEP and 106 scans post-EPEP. Of note, 40% of patients pre-EPEP had prior deliveries versus only 19% post-EPEP (p=0.001). There was a similar distribution of ART (IVF and IUI) and spontaneous pregnancies (24% pre- and 31% post-EPEP) between the groups. The mean number of questions per visit was 2 pre-EPEP and 1.7 post-EPEP. Pre-EPEP, 73% of patients asked at least one question versus 84% post-EPEP (p>0.05).

CONCLUSIONS: Pregnancy after infertility may be a time of greater stress and lower self-esteem as compared to pregnancies without prior infertility (1-3). In this study, introducing the EPEP was not correlated with a significant change in the volume or distribution of patients' pregnancy-related questions. The study was limited by sample size, and results may be confounded by the higher parity (and thereby, pregnancy experience) of the pre-EPEP group. Methods of educating patients regarding reproductive health and easing the transition of care from reproductive endocrinologist to obstetrician warrant further investigation, particularly as this patient population is potentially more vulnerable to anxiety in pregnancy. Future directions could include utilization of different media and presentation formats, or approaches other than large-volume information-sharing, which some patients may find overwhelming.

Keywords: early pregnancy, patient education, pregnancy-related questions, patient discharge

P-888 3:30 PM Wednesday, October 21, 2020

ARE THE ONLINE RESOURCES FOR PATIENTS OF NCI CANCER CENTERS ASSOCIATED WITH THE PRESENCE AND VOLUME OF LOCAL FERTILITY CENTERS?

Angela H. Liu, MD,[1] Christopher de Haydu, MD,[2] Melody A. Rasouli, MD, MBA,[1] Kajal Verma, MD,[1] Janelle M. Jackman, MBBS,[3] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]New Hope Fertility Center, New York, NY; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Patient access to online resources is important for informed decision making. Prior research showed inconsistent web-based patient information on NCI designated cancer centers' (NCICC) websites related to demographic and geographic factors. We investigated the association between volume and presence of fertility centers in the catchment area of NCICCs as they relate to patient oncofertility information on NCICC websites.

DESIGN: Cross-sectional observational study.

MATERIALS AND METHODS: Two independent investigators used previously validated rubric and methods to assess websites of NCICCs for fertility preservation content. A third reviewer from a different institution assessed discordant evaluations. Specific questions included 1) Does the website discuss the effects of cancer and cancer treatment on fertility? 2) Are options of FP for all patients discussed? 3) Is there a standalone page dedicated to FP content? Local and regional data was used to order and compare NCICCs. Factors included publicly available CDC 2017 National Summary and Clinic Datasets for Assisted Reproductive Technology and US Census (2010-2014) data. Chi-square analyses were performed to assess any statistically significant association (P-value < 0.05).

RESULTS: There was an association between the discussion of cancer treatments risks on fertility and fertility preservation on NCICC websites with the number of fertility centers in the state (p-values 0.0056 and 0.0413, respectively). Presence of a stand-alone page on fertility preservation is associated with the number of fertility centers at the state (p-value 0.0308) and county levels (p-value 0.0085), as well as the number of fertility treatment cycles in the state (p-value 0.0309), county (p-value 0.0193), and city (p-value 0.0193) surrounding the NCICC. Discussion of risks of cancer treatments on male fertility was correlated with the number of fertility centers in the state (p-value 0.041), county (p-value 0.0046), and the number of fertility treatment cycles in the state (p-value 0.0414), county (p-value 0.0046), and city (p-value 0.0046). Web-based information on cancer treatments and female fertility was associated with the number of fertility treatment cycles in the city where NCICC is located (p-value 0.0414). Availability of web-based FP resources for male cancer patients was correlated with population density (p-value 0.0192) and income per capita (p-value 0.0309) at the county level. No associations were noted between web-based oncofertility content and percent population below the poverty line, percent population without insurance coverage, percent population with college degree, and percent foreign language spoken at home.

CONCLUSIONS: Understanding barriers for patient access to oncofertility information is important for improving quality of care at NCICC. Analyses suggest that the gap in access to web-based information on fertility preservation at each NCICC may be more related to regional differences in presence of fertility centers and volume of fertility treatments than socioeconomic disparity.

P-889 3:30 PM Wednesday, October 21, 2020

WHAT DETERMINES HOW PATIENTS ARE COUNSELED REGARDING STIMULATION WITH AUTOLOGOUS OOCYTES?

Eduardo Hariton, MD, MBA,[1] Jerrine R. Morris, MD, MPH,[1] Aileen Portugal, MD,[1] Jake Anderson, MBA,[2] Marcelle I. Cedars, MD[1] [1]University of California, San Francisco School of Medicine, San Francisco, CA; [2]FertilityIQ, San Francisco, CA.

OBJECTIVE: To determine factors associated with a patient being declined from pursuing a cycle of in vitro fertilization with autologous oocytes (IVF-AO).

DESIGN: Cross-sectional study

MATERIALS AND METHODS: Female respondents, aged 35 or over, who visited a U.S fertility clinic from January 2015 to March 2020 responded to an online questionnaire via FertilityIQ questionnaire (www.fertilityiq.com). All respondents were asked if they had been declined from pursuing a cycle of IVF-AO by a fertility clinic and if so, which clinic. Examined demographic and clinical predictors included age, race, education, income, clinic type (private vs. academic), care received in a mandated vs. non mandated state, insurance coverage and self-reported infertility diagnosis. Logistic regression was used to calculate adjusted odds ratios for factors associated with being declined from pursuing IVF-AO.

RESULTS: Of the 8,660 women included, 418 (4.8%) reported being declined a cycle of IVF-AO. In the multivariate analysis, predictors of being declined included increasing age (OR: 1.71, $p<0.001$), higher education (OR: 1.36, $p=0.001$), diagnoses of diminished ovarian reserve (DOR) (OR: 3.39, $p<0.001$) and poor oocyte quality (OR: 1.41, $p=0.015$). Predictors of not being declined a cycle of IVF-AO included a higher level of education attained (OR: 0.82, $p=0.013$), and diagnoses of unexplained infertility (OR: 0.61, $p=0.003$) or tubal blockage (OR: 0.42, $p=0.006$). Notably, none of the following were predictive of patients being declined from pursuing IVF-AO: race, clinic type (private vs. academic), care received in a mandated vs. non mandated state, or insurance coverage.

CONCLUSIONS: Nearly 5% of patients who pursued IVF reported being declined from doing a cycle of IVF with autologous oocytes. Patients who were older, of lower income, more educated, or had diagnoses of DOR or poor oocyte quality were more likely to be declined. While some of the clinical predictors, such as age and diagnoses, are expected, others such as income, are concerning. Further studies are needed to confirm these findings and explore how to mitigate these potential biases in the patients who are allowed to pursue IVF-AO.

DOES THE US NEWS REPORT SCORE OF NCI-DESIGNATED CANCER CENTERS REFLECT ACCESS TO FERTILITY PRESERVATION TREATMENT INFORMATION?

Angela H. Liu, MD,[1] Christopher de Haydu, MD,[2] Melody A. Rasouli, MD, MBA,[1] Janelle M. Jackman, MBBS,[3] Kajal Verma, MD,[1] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]New Hope Fertility Center, New York, NY; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: US News Report provides peer-reviewed ranking that informs patient choice of NCI-designated cancer centers for cancer treatments. Counseling for fertility preservation is recommended as a standard of care for patients with new cancer diagnoses. This study aims to compare the US News Report scores of various subspecialty programs at NCI-designated cancer centers and the quality of the centers' web-based oncofertility resources to assess if patient access to information on fertility preservation treatments will be affected when choosing NCICC based on the US News Report scores.

DESIGN: Cross-sectional observational study

MATERIALS AND METHODS: Patient-directed content on the websites of NCI-designated cancer centers (NCICC) was evaluated for information on fertility preservation and oncofertility by independent reviewers from two institutions. The NCICC websites were systematically queried to assess the following - 1) Does the website discuss the effects of cancer and cancer treatment on fertility? 2) Are options of FP for all patients discussed? 3) Is there a standalone page dedicated to FP content? 4) Was parenting-related cancer survivorship addressed? Affiliation with a fertility center was also examined. Scores of each NCICC in the subspecialties of general oncology, pediatric oncology, gynecology, and urology were obtained from the US News Report. Descriptive analyses were performed using Chi-square statistics. P-value $<$ 0.05 defines statistical significance.

RESULTS: The US News Report scores for adult oncology is associated with available discussion of cancer treatment risks on fertility on the NCICC websites (p-value 0.0260). Higher scores in pediatric oncology is associated with web-based information on parenting after surviving cancer treatments (p-value 0.0066). US News Report scores of gynecology programs at NCICC are not associated with any oncofertility website metric. Correlation between US News Report scores for urology programs and web-based content of cancer treatment risks on male fertility was borderline statistically significant (p-value 0.0645). Affiliation with a fertility center is not correlated with availability of FP resources on NCICC websites.

CONCLUSIONS: US News Report scoring of subspecialty programs may not reflect access to consistent quality web-based oncofertility resources for patients receiving treatments at NCICC. Content is tailored for fertility treatments among cancer survivors for pediatric oncology programs ranked by US News Report. Gender-specific fertility preservation information is not correlated with US News Report scores of gynecology or urology programs, suggesting provision of oncofertility resources may not factor into current US News Report scores of these subspecialties at NCI cancer centers.

P-891 3:30 PM Wednesday, October 21, 2020

COMPLEMENTARY AND ALTERNATIVE MEDICINE CONTENT ON FERTILITY CLINIC WEBSITES IN THE WESTERN REGION. Kajal Verma, MD,[1] Christopher de Haydu, MD,[2] Janelle M. Jackman, MBBS,[3] Angela H. Liu, MD,[1] Melody A. Rasouli, MD, MBA,[1] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD[5] [1]University of Nevada, Las Vegas, Las Vegas, NV; [2]University of Miami, Miami, FL; [3]New Hope Fertility Center, New York, NY; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Information available to patients on fertility clinic websites is a critical component of the shared decision-making process between patients and physicians. Complementary and integrative medicine (CAM) is an emerging offering within fertility medicine. Examples of CAM therapies include acupuncture, yoga, herbal supplements, and homeopathy. The goal of this study is to assess the prevalence of content specific to CAM on fertility clinic websites. The availability of this patient facing information on websites was analyzed using county-level demographics within the Western Region of the US (WRUS).

DESIGN: Cross-sectional analysis.

MATERIALS AND METHODS: Websites of clinics reporting data to the Society for Assisted Reproductive Technology (SART) from the most recent complete year (2017) were queried for the US Census Bureau-designated Western region. Each clinic website was examined for content related to alternative therapies or complementary medicine, as defined by the American Society for Reproductive Medicine. This was correlated to publicly available data by the US Census Bureau (2014-2018) using county as a geographic proxy to estimate demographic variables within the population. Descriptive statistical analyses performed included Chi-square and t-tests.

RESULTS: 100 SART-reporting fertility clinics are located in WRUS. 33% of clinic websites had discussed content referring to CAM services. From the websites that featured this content, 88% of them discussed acupuncture services, either offered in conjunction with the clinic or providing patients with a list of resources on the website. There was a significant and positive association between CAM services being offered on fertility clinic websites and the ratio of non-Hispanic or Latino white persons in the population, in relation to four quartiles of the population distribution. Education level, income level, and health insurance coverage in a given clinic region were not found to be statistically significant in relation to the presence of CAM services offered.

CONCLUSIONS: Approximately one-third of SART registered fertility clinics in the WRUS currently provide CAM content on their websites. The quality of this content is mixed and varies from extensive details about services such as acupuncture and yoga to vague mention of the term CAM. With ASRM's recognition of CAM as an adjunct in fertility therapy, more standardized information on its role in fertility medicine is needed. Currently, many patients assume that CAM is frowned upon by fertility centers and instead of talking to the clinics, patients are turning to unreliable sources for this information which may ultimately even compromise their own fertility treatment protocols in the process. Our study demonstrates that in order to better integrate CAM within our field, it is incumbent upon fertility centers to provide more concise and accurate information and guidance to their patients regarding safe and recommended CAM, including the best timing for CAM. Further study to expand this analysis across all US demographic regions is ongoing.

P-892 3:30 PM Wednesday, October 21, 2020

CHALLENGES OF LACTATION AND BREASTFEEDING AMONG MOTHERS CONCEIVED THROUGH ART - A QUESTIONNAIRE BASED SURVEY. Rajani Chelladurai, MS, DNB, FMAS, DMAS, P. P. Gopinath, MD, DGO, FMMC, FICS, FICOG, MBA, Gayathri Devi S S, IV, MD, FRM, Hema Vaithianathan, MD, MRCOG SIMS hospital, Chennai, India.

OBJECTIVE: BREASTFEEDING AFTER ART - EVERY MOTHER'S NIGHTMARE ? The objective was to study the challenges of lactation and breastfeeding among mothers conceived through ART in our centre @ SIMS hospital, Chennai, India.

DESIGN: A questionnaire based survey conducted among mothers delivered after an ART pregnancy.

MATERIALS AND METHODS: This study was conducted between Jan 2018- Dec 2019. A total of 196 postnatal mothers conceived through ART were given questionnaire on challenges faced with lactation and breastfeeding at 3 months postpartum. Data analysis was done using multivariate logistic regression analysis.

RESULTS: It was found that majority of the mothers experienced some difficulty in breastfeeding in the form of either failure to lactate or latching difficulties. A small group had opted for expressed breastfeeding. It was noted that these difficulties were more pronounced among preterm deliveries and multiple pregnancies. Other factors like Caesarean section , coexisting depression and psychological instability were also attributed towards difficulty with lactation. Around 15% mothers had given up on breastfeeding and chose formula feeds at 3 months postpartum.

CONCLUSIONS: Breastfeeding is difficult at the best of times, but following ART it's even harder. When the importance of breastfeeding is being reiterated all across the globe, this subsect of ART pregnancies have been ignored. It is also noteworthy that breastfeeding and postpartum blues following ART is a vicious cycle with one upsetting the other and vice versa . Psychological support from family, counselling on lactation, forming peer groups among such mothers to encourage each other and lactation helplines can help them to understand that breastfeeding following ART is no longer a nightmare.

POSTER SESSION: REPRODUCTIVE SURGERY

P-893 3:30 PM Wednesday, October 21, 2020

UTERINE DOPPLER BLOOD FLOW EVALUATION OF THE EFFECT OF MISOPROSTOL ADMINISTERED PRIOR TO ABDOMINAL MYOMECTOMY: A RANDOMIZED CONTROLLED TRIAL. Mohamed Khalaf, MD, Ahmed M. Abbas, MD, Asmaa M. Hussein, MBBCh, Hazem Saad El-Dein, MD Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt.

OBJECTIVE: To observe the changes in the vascularity and perfusion of fibroids following administration of sublingual versus rectal misoprostol prior to abdominal myomectomy

DESIGN: A randomized, single-blind, clinical trial

MATERIALS AND METHODS: The study included women with documented uterine fibroids on pelvic imaging scheduled for abdominal myomectomy, aged 18-50 years, pre-operative hemoglobin >8 g/dl, with five or less symptomatic subserous or intramural fibroids and the uterine size less than 24 weeks pregnancy. Sample size was calculated based on a recent study stated that the Resistance index (RI) at 20 min after rectal misoprostol intake was 0.87 ± 0.16. We supposed that sublingual misoprostol will decrease the blood flow to the uterus with increase in RI to 0.97 ± 0.16. Using two sided chi-square test with alpha error of 0.05, a total sample size of at least 82 patients (41 in each arm) had 80% power to detect the difference in mean RI with sublingual misoprostol intake. Women were randomized to (group A) received 400 mcg misoprostol (two tablets) rectally one hour before the operation, and group (B) received 400 mcg misoprostol sublingual at the same time. The fibroid vascularization and that of the surrounding myometrium was visualized using the colour Doppler technique. Blood flow velocity waveforms were obtained by placing the Doppler gate over the maximum colour areas and activating the pulsed Doppler function at that marked site. The vessel was measured after confirming the depth and the angle correction prior to and after insertion. RI and pulsatility index (PI) of the vessel was measured three times (before and 20 min, 40 min after misoprostol intake). The primary outcome was the mean value of intramyometrial blood vessels RI after 20 min misoprostol intake. chi-square test was used to compare the nominal data of the study groups while student t-test was used to compare the quantitative data of the groups.

RESULTS: The study enrolled 82 women (41 in each arm). No statistical significant differences between both groups regarding the baseline or clinical data. No statistical differences regarding RI, PI and systolic/diastolic ratio (S/

D), at different times of assessment between both groups. RI after 20 min was 0.85 ± 0.11 in the rectal group vs. 0.78 ± 0.11 in the sublingual group (p=0.15). similarly, RI after 40 min was 0.90 ±0.11 in the rectal group vs. 0.85 ± 0.19 in the sublingual group (p=0.07). In both groups there were significant increase in RI, PI and S/D ratio after 20 and 40 min in comparison to the pre-operative data (p<0.01).

CONCLUSIONS: Misoprostol significantly decrease the vascularity and perfusion of uterine fibroids weather administered rectal or sublingual one hour prior to abdominal myomectomy.

NEONATAL OUTCOMES AFTER UTERUS TRANSPLANT- DUETS (DALLAS UTERUS TRANSPLANT STUDY). Liza Johannesson, MD, PhD, Jackie York, MD, Giuliano Testa, MD Baylor University Medical Center, Dallas, TX.

OBJECTIVE: Uterus transplantation is restoring fertility in women absolute uterine-factor infertility and allows them to experience gestation and childbirth. Limited data are available on the outcome of infants born after uterus transplantation. Our aim was to describe the hospital course and laboratory findings of the first 6 infants born in the Dallas UtErus Transplant Study (DUETS).

DESIGN: Prospective review.

MATERIALS AND METHODS: Twenty women received a uterus transplant at Baylor University Medical Center in Dallas (a tertiary referral center) from 2016 to 2019 (NCT02656550). Based on the trial protocol, information about the first 6 infants delivered was collected in a prospective fashion, including infant demographics, hospital course, and laboratory values.

RESULTS: Six infants were delivered, all by cesarean section, from mothers who had undergone uterus transplantation. All mothers had an immunosuppressive regimen and none experienced an episode of rejection during pregnancy. The infants had a median gestational age of 36.3 weeks (range 30.6–37.2 weeks) and median birthweight of 2890 g (range 1771–3140 g). APGAR scores were at least 7 at 1 minute and at least 8 at 5 minutes. All were appropriate size for gestational age. Two infants had complete blood counts with bandemia but negative blood cultures. Blood urea nitrogen and creatinine levels were within expected range.

CONCLUSIONS: The 6 infants born from mothers with uterus transplants had a neonatal course that reflected the gestational age at delivery. No baby was born with an identified deformation or malformation attributed to the transplantation or immunosuppression. Despite exposure to a calcineurin inhibitor throughout pregnancy, there were no adverse effects on renal function. Longer follow-up and a larger number of infants are needed to confirm these observations.

P-895 3:30 PM Wednesday, October 21, 2020

ORAL KETOPROFEN ONE HOUR PRE-PROCEDURE IS EFFECTIVE FOR PAIN RELIEF DURING HYSTEROSALPINGOGRAPHY: A RANDOMIZED CONTROLLED STUDY. Ahmed M. Abbas, MD,[1] Marwa Samy, MD,[2] Sara M. Hassanein, MD,[2] Mohammed Khairy Ali, MD,[1] Ahmed M. Abdelmagied, MD,[1] Mohamed Khalaf, MD,[1] Osama S. Abdalmageed, MD[1] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Department of Radiology, Faculty of Medicine, Assiut University, Egypt.

OBJECTIVE: Hysterosalpingography (HSG) is considered the initial diagnostic tool for assessment of tubal patency. Our objective is to examine the analgesic effect of oral ketoprofen in relieving pain during HSG.

DESIGN: A randomized, double-blind, placebo-controlled study (NCT02905045, clinicaltrials.gov).

MATERIALS AND METHODS: Reproductive-aged infertile women scheduled for HSG were considered for enrollment. Eligible women were recruited and randomized (1:1) to ketoprofen or placebo group All women received oral 150 mg ketoprofen or placebo tablet one hour before the procedure. The study outcomes was the participant's self-rated pain perception utilizing a 10-cm Visual Analogue Scale (VAS) during injection of the dye, 5 minutes and 30 minutes post-procedure. A 2 cm difference in VAS score between both arms was considered a clinically significant difference. Secondary outcomes included the women's satisfaction score and the number of women who asked for additional analgesics.

RESULTS: One hundred women were enrolled and randomized to ketoprofen arm (n=50) or placebo (n=50). Both arms were comparable in baseline clinical and socio-demographic criteria. Oral ketoprofen reduce the median VAS pain scores during injection of the dye (2.5 vs. 4.75, p=0.001) and 30 minutes post-procedure (1.25 vs. 3, p=0.003). The mean satisfaction scores were 8.54±0.33 and 8.11±0.24 in the ketoprofen and placebo groups respectively (p=0.83). Additionally, four women asked for additional analgesics in the placebo group versus two women in the study group (p=0.17).

CONCLUSIONS: The use of oral ketoprofen one hour prior to HSG is effective in relieving the induced pain during and 30 minutes after the HSG procedure

IN VITRO FERTILIZATION AND PREGNANCY OUTCOMES AFTER UTERUS TRANSPLANTATION: DUETS (DALLAS UTERUS TRANSPLANT STUDY). J. Michael Putman, M.D.,[1] Lilly Zhang, PhD,[2] Giuliano Testa, MD,[3] Anthony Gregg, MD,[3] Robert T. Gunby, MD,[3] Liza Johannesson, MD, PhD[3] [1]Fertility Center of Dallas, Dallas, TX; [2]Fertility Center Dallas, Dallas, TX; [3]Baylor University Medical Center, Dallas, TX.

OBJECTIVE: To review in vitro fertilization and pregnancy outcomes after uterus transplantation.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: Women with absolute uterine factor infertility who were selected to undergo uterus transplantation (UTx) from September 2016 through August 2019. In vitro fertilization was performed before subjects underwent transplant, and good-quality expanded blastocyst stage euploid embryos were obtained and frozen for post successful uterus transplant single embryo transfer. The main outcome measures were healthy live birth, time from successful UTx to embryo transfer, time from successful UTx to live birth.

RESULTS: Twenty subjects underwent UTx and 14 had successful transplants. Fourteen underwent single embryo transfer of a warmed, good-quality, expanded, euploid blastocyst. In 10 of 14 (71.4%) patients, the first embryo transfer resulted in implantation. Ten subjects had a live birth by cesarean section and 3 pregnancies are ongoing. One recipient had 2 live births before removal of her uterus. Time from successful UTx to embryo transfer averaged 154 days (range, 106-235 days). Time from successful Utx to live birth averaged 16.4 months in the first ten recipients.

CONCLUSIONS: Subjects with absolute uterine factor infertility who have successful UTx can achieve excellent ongoing pregnancy and live birth rates utilizing good-quality, expanded blastocyst stage, euploid embryos.

P-897 3:30 PM Wednesday, October 21, 2020

INTRAPERITONEAL TRIAMCINOLONE MAY REDUCE ADHESION FORMATION THRHOUGH ALTERATION OF MITOCHONDRIAL FUNCTION. Ahmad Arabi, MD,[1] Neeraja Purandare, PhD,[1] Paige Minchella, BS,[1] Siddhesh Aras, MBBS, PhD,[1] Katherine J. Kramer, MD,[2] Maurice-Andre Recanati, MD-MS[1] [1]Wayne State University School of Medicine, Detroit, MI; [2]St. Vincents Catholic Med Ctrs, New York, NY.

OBJECTIVE: To investigate the use of intraperitoneal triamcinolone acetonide in reducing adhesion formation after abdominal myomectomy and determine the molecular mechanism of action in an in vitro model.

DESIGN: Under IRB approval, patients who had previously undergone abdominal myomectomy with uterus >20 weeks) and presented for repeat abdominal surgery (serving as a second look) were enrolled in the study. Patients with a history of intraperitoneal/pelvic infections or intervening surgeries were excluded. The treatment group consisted of patients who had received, during initial surgery, triamcinolone intraperitoneally as documented in the medical record (n=31). Control patients (n=21) received no documented adhesion prevention methods. Human fibroblast cell culture was used as an in vitro model.

MATERIALS AND METHODS: Treatment group received 200mg triamcinolone acetonide in 500 mL dextran at closing of peritoneum. Adhesion number, grade and severity were scored using Leach adhesion score from one individual blinded surgeon with concurrence of the assistant. Age,

race, uterine size, blood loss, operative time, number, aggregate weight and position of fibroids at initial surgery and presenting symptoms were obtained from chart review. Human fibroblasts were incubated at 20%, 2% and 1% hypoxia, cellular ROS measurements were performed with CM-H2DCFDA and ROS-Glo, TGF-b1 was quantified by ELISA, HIF-1a was assessed by western blot and Seahorse Bioanalyzer was used for measurement of intact cellular oxygen consumption. Clinically, Welch's t-test was performed to compare groups assuming unequal variance (F-test) and two tails. Pearson Chi-squared test was performed on categorical data with $p<0.05$ considered significant. Pearson correlation was performed, with p-value analysis. For in vitro experiments, two-sided Wilcoxon rank-sum test was applied to determine statistical significance with $p<0.05$ considered statistically significant.

RESULTS: About 32% of patients (n=10) were found to have adhesions in the treatment group compared to 71% (n=15) in the control group ($p<.01$). Compared to controls, adhesions were significantly less in number (0.71 vs 2.09, $p<0.005$), severity (0.54 vs 1.38, $p<0.004$), and extent (0.34 vs 1.28, $p<0.003$). In vitro studies showed triamcinolone directly prevents the surge of reactive oxygen species (ROS) triggered by 2% hypoxia and prevents the increase in TGF-b1 at 2% hypoxia which leads to the irreversible conversion of fibroblasts to adhesion phenotype. Triamcinolone prevents the increase in ROS in a HIF-1a independent manner, through alteration of mitochondrial function.

CONCLUSIONS: Administration of intraperitoneal triamcinolone significantly reduced adhesion formation by altering mitochondrial function and ROS mediated TGF-b1 release in fibroblasts. Controlling mitochondrial function may allow for adhesion free surgery and reduce postoperative complications and infertility. This is especially relevant when surgeries, such as myomectomies, are indicated for infertility.

P-898 3:30 PM Wednesday, October 21, 2020

PREDICTIVE VALUE OF DOPPLER ANALYSIS IN UTERINE TRANSPLANTATION. Akshaya Jain, MD,[1] Liza Johannesson, MD, PhD,[1] Giuliano Testa, MD,[1] Elizabeth A. Eagle, DO,[1] Tsung-wei Ma, PhD,[2] Anthony Gregg, MD[1] [1]Baylor University Medical Center, Dallas, TX; [2]Baylor University Medical Center at Dallas, Dallas, TX.

OBJECTIVE: Successful pregnancy with uterine transplantation is contingent on numerous factors. Our study of uterus donors prior to transplant and uterus recipients after transplant explored whether uterine artery Doppler blood flow indices (UAQI) could predict successful implantation.

DESIGN: Retrospective review

MATERIALS AND METHODS: During the years 2016-2019 there were 20 uterus transplantations performed with both living (n=18) and deceased donors (n=2) at Baylor University Medical Center in Dallas. The indication for uterus transplantation was absolute uterine factor infertility in all recipients. In this study we compare the UAQI in living uterus donors with their corresponding uterus recipients (n=11). We also evaluate the UAQI two months prior to and three months after embryo transfer. Successful implantation is defined as viable pregnancy at 12 weeks gestation. UAQI include peak systolic velocity, diastolic velocity and resistance index (RI) which were measured in the bilateral uterine arteries (UA). UAQI from the left and right UA were then analyzed separately and pooled for analysis.

RESULTS: The pooled peak systolic velocity of the UA in the donor is positively correlated to the values in the recipient UA pooled peak systolic velocity at 2 months post-transplantation ($r=0.83$, $p<0.05$). There were a total of 11 embryo transfers in the uterus recipient cohort. We noted 7 successful implantations which resulted in 6 live births and 1 miscarriage at 16 weeks. We noted 4 failed implantations (failed embryo transfer (n=3) and missed abortion at less than 12 weeks gestation (n=1)). When the left UA diastolic velocity was compared across the five month time period, the recipients with live births demonstrated a statistically significant percent increase compared to the recipients with failed implantations ($p<0.02$). This translated to a statistically significant decrease in the left UA RI ($p<0.03$). The pooled peak systolic velocity was higher in the recipients with live births, however, the difference was not statistically significant ($p<0.18$). The pooled UA RI was lower in the live birth cohort and this difference was statistically significant ($p<0.04$).

CONCLUSIONS: Uterus transplant does not appear to adversely impact UA peak systolic velocity when measured two months after transplant. Although more data is needed, the RI holds promise to predict successful implantation in uterus transplant recipients. Additional studies are needed to further elucidate the predictive value of UAQI on pregnancy outcomes.

P-899 3:30 PM Wednesday, October 21, 2020

HYSTERO-EMBRYOSCOPY A TOOL FOR DIAGNOSIS IN EARLY PREGNANCY LOSS. Ander M. Morales Vicente, Sr., DOCTOR, Leisy Rodriguez, DOCTOR, Norman R. Gomez Diaz, MD, Sara Fortuño Salais, DOCTOR, Juana Crespo Simó, DOCTOR JUANA CRESPO MEDICAL TEAM, VALENCIA, Spain.

OBJECTIVE: Approximatelly 15 % of all recognized pregnancies are spontaneously aborted in the first trimester. Most common cause of miscarriage is aneuploidies, 60-70 % of abortions are due to chromosome abnormalities. Genetic causes lead to developmental arrest and miscarriage and a majority of embryos present with morphological defects.

Although the incidence of early losses is high, embryonic material is difficult to obtain and often poorly described from a morphological perspective. Currently Hystero – embryoscopy (HE) is the only method that allows direct visualization of uterine cavity, implantation area of the gestational sac and anatomical description of the embryo.

In the present study we describe the results of HE performed over 3 years, trying to identify the value of diagnostic HE in detection of morphologic embryo abnormalities, cytogenetic findings and the intra-uterine pathology in early miscarriage patients.

DESIGN: Retrospective

MATERIALS AND METHODS: This study is a review of 101 infertility patients between 1-1-2017 and 12-31-2019 with a diagnosis of early missed abortion and scheduled for HE and posterior curettage.

RESULTS: The women mean age was 38,6 years (23 - 49 y). They had previous pregnancy losses with no previous live birth.

Successful visualization of the uterine cavity was achieved for all cases. An embryo was visualized by HE in mostly all cases and subjected to an anatomic examination. Some embryos showed abnormal development with microcephaly, embryonic neural tube defects or retarded limb development.

Cytogenetic diagnosis from embryo or chorionic villi was obtained in 90.1% of the cases (n:91). An abnormal cytogenetic result was found in 64 % of the embryos (n:65) comprising: trisomy (84.6%), tetraploidy and triploidy (7.7%), unknown genetic material (3.1%), uniparental dysomia (3.1%) and 1 case of chromosomic deletion.

A total of 26 of the aborted embryos had normal karyotype (25.7%) in our study. All patients with normal karyotype embryos had associated factors as possible causes of abortion: uterine malformations or defects (n:26), hematologic disease (n:9) and endocrine disorder (n:1). Cytogenetic diagnosis turned without result in 10 patients (9.9%).

CONCLUSIONS: In our series of 101 missed abortions, we found that the use of HE to direct evaluation of uterine cavity, embryo morphology and direct HE biopsies were more accurate than the standard curettage technique for diagnosis of first trimester miscarriage.

HE is an easy, safe and elective tool for diagnosis of the site of implantation of the sac and the presence of intrauterine abnormalities which play a role in the aetiology of miscarriages. Using HE we diagnosed some embryos with abnormal development and morphological defects. In our study HE enabled precise sampling with reduced maternal cell contamination compared with curettage. We obtained cytogenetic diagnosis in 90.1% cases. An abnormal cytogenetic result was found in 64 % of the embryos determining the cause of miscarriage. This valuable information is important for diagnosis of miscarriages and genetic counselling and itś in support of previous studies published.

WOMEN WITH A HISTORY OF PRIMARY INFERTILITY HAVE INCREASED RISK OF FUTURE HYSTERECTOMY AND OOPHORECTOMY.

Emily N. Sadecki, BA,[1] Alessandra J. Ainsworth, MD,[2] Lauren Kendall Rauchfuss, MD,[2] Yulian Zhao, Ph.D.,[2] Amy Weaver, MS,[3] Elizabeth A. Stewart, MD[2] [1]Mayo Clinic College of Medicine and Science, Rochester, MN; [2]Mayo Clinic Department of OB/GYN, Reproductive Endocrinology and Infertility, Rochester, MN; [3]Mayo Clinic Division of Biomedical Statistics and Information, Rochester, MN.

OBJECTIVE: To evaluate the incidence of future hysterectomy and oophorectomy for women with a history of primary infertility compared to age-matched referent women from the same community.

DESIGN: A population-based retrospective cohort study.

MATERIALS AND METHODS: A random sample of 300 women first diagnosed with primary infertility between 1980 and 1999 while a resident of Olmsted County, Minnesota, were identified through the Rochester Epidemiology Project (REP) records-linkage system (https://rochesterproject.org/). Records were manually reviewed to confirm the date (index date) and diagnosis of primary infertility. Each woman was 1:1 age-matched (±1 y) to a referent woman residing in the county at the time of the index date who had not been diagnosed with primary infertility or had a prior hysterectomy. The occurrence of hysterectomy and/or oophorectomy both prior to and after index date was collected by manual chart review. Cox proportional hazards models were fit to estimate the hazard ratio (HR) and 95% confidence interval to compare the long-term risk of hysterectomy and oophorectomy, respectively, between infertility cases and referents.

RESULTS: The mean (SD) age at the index date was 29.9 (4.6) and 30.0 (4.6) for 300 infertility cases and 300 referents, respectively. At the time of the index date, 1 infertility case and 1 referent each had a prior bilateral salpingo-oophorectomy (BSO) and 4 infertility cases and 4 referents had a prior unilateral oophorectomy. The median duration of follow-up after the index date was 21.5 years (interquartile range (IQR), 13.0-25.5) and 20.9 years (IQR, 4.9-24.9) for the infertility cases and referents, respectively. Among those without a prior BSO at the index date, risk of subsequent oophorectomy was 2-fold higher in infertility cases compared to referent women (HR 2.06, 95% CI 1.20-3.53) (43 infertility cases and 19 referents). Infertility cases also had a significantly increased risk of hysterectomy (HR 1.56, 95% CI 1.06-2.29) (69 infertility cases and 41 referents). The three most common indications for hysterectomy among both groups (infertility cases vs. referents) were similar: fibroids (25% vs 29%), heavy menstrual bleeding (23% vs. 27%), and endometriosis (17% vs. 15%). Ten of 69 (14%) infertility cases had a hysterectomy for a gynecologic malignancy compared to 3 of 41 (7%) referents.

CONCLUSIONS: Women with primary infertility are at increased risk of subsequent hysterectomy and oophorectomy compared to age-matched referents. Although indication for hysterectomy was similar among groups, more women with a history of primary infertility underwent hysterectomy for treatment of gynecologic malignancy. These findings are significant, as oophorectomy and hysterectomy have been previously demonstrated to negatively impact long-term health.

P-901 3:30 PM Wednesday, October 21, 2020

FALLOPIAN TUBE ENDOMETRIOSIS IN WOMEN UNDERGOING OPERATIVE VIDEO LAPAROSCOPY AND ITS CLINICAL IMPLICATIONS.

Bailey Gill McGuinness, MD,[1] Farr R. Nezhat, MD,[2] Lauren Ursillo, MD,[1] Meredith Akerman, MS,[1] William Vintzileos, MD,[1] Michael White, MD, PhD[1] [1]NYU Winthrop Hospital, Mineola, NY; [2]Nezhat Surgery for Gynecology/Oncology, Valley Stream, NY.

OBJECTIVE: To determine the incidence of macroscopic and microscopic fallopian tube endometriosis in patients undergoing laparoscopic surgery with a pre-operative diagnosis of endometriosis, pelvic pain, infertility and/or cystic adnexal mass.

DESIGN: This was a retrospective cross-sectional study. Inclusion criteria were all patients who underwent surgery July 2015 to June 2018 at a single gynecological oncology practice specializing in endometriosis. Exclusion criteria were age ≥ 55 years, diagnosis of cancer, laparotomy, prior bilateral salpingectomy, and pre-operative diagnosis other than endometriosis, pelvic pain, infertility or cystic adnexal mass.

MATERIALS AND METHODS: Subjects were divided by those who did and who did not have a salpingectomy at the time of surgery. Diagnosis of tubal endometriosis was based on macroscopic evidence of endometrial implants on the fallopian tube(s) noted within the operative report and microscopic evidence of endometriosis noted within the pathology report. The Monte Carlo estimate for the Fisher's exact test was used to compare groups for endometriosis stage. Results with a $p<0.05$ were considered significant.

RESULTS: 444 surgeries were performed with 185 patients meeting study criteria. 97 patients had a salpingectomy at the time of surgery and 88 patients did not. 153 patients (82.7%) had histologically diagnosed endometriosis within the abdominopelvic cavity. Amongst patients with endometriosis, the incidence of tubal endometriosis was 11-12% macroscopically and 42.5% microscopically after salpingectomy. Patients with tubal endometriosis were more likely to have severe disease ($p=0.0196$). Pre-operative diagnoses between the salpingectomy and no-salpingectomy groups were compared and no significant difference was found. Although pre-operative diagnosis of fibroids and abnormal uterine bleeding were not defined as inclusion or exclusion criteria for this study, approximately 1 in 5 patients with a pre-operative diagnosis of endometriosis, pelvic pain, adnexal mass or infertility also had fibroids and/or abnormal uterine bleeding. Parity, gravity, and medical management of endometriosis had no impact on presence or absence of fallopian tube endometriosis.

CONCLUSIONS: Amongst patients with endometriosis, the incidence of microscopic tubal endometriosis is significantly greater than that of macroscopic disease. This is the first study to evaluate the incidence of both macroscopic and microscopic tubal endometriosis with the use of a control group. There is a need for development of new minimally-invasive diagnostic techniques for early detection of fallopian tube endometriosis, which could guide gynecologists in management of patients with infertility and endometriosis.

P-902 3:30 PM Wednesday, October 21, 2020

SUCCESSFUL USE OF INTRAUTERINE AMINOGRAFT FOR ASHERMAN SYNDROME: AN EXPANDED CASE SERIES. Channing Burks, MD,[1] Kathryn D. Coyne, MD,[1] James H. Liu, M.D.[2] [1]University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH; [2]UH MacDonald Women's Hospital, Cleveland, OH.

OBJECTIVE: To evaluate pregnancy outcomes after the use of intrauterine aminograft in infertile women with Asherman Syndrome.

DESIGN: Case series

MATERIALS AND METHODS: Women who presented to our center between the years of 2011-2019 with a diagnosis of moderate or severe Asherman Syndrome, a thin endometrial stripe and a desire for future fertility were offered treatment with an amniotic membrane graft. All were informed that the amniotic membrane, Ambios®, a desiccated biologic ophthalamic graft, is an experimental and novel technique for intrauterine use. The amniograft is reputed to have anti-inflammatory and antimicrobial properties in addition to containing keratocyte growth factor. After informed consent was obtained, women underwent an operative hysteroscopy, lysis of intrauterine adhesions and curettage under general anesthesia. A 3.5x3.5 cm graft was rehydrated with normal saline, wrapped around a Cook intrauterine balloon and inserted into the uterus under ultrasound guidance. The balloon was inflated with 5-7 ml of saline. The stent was maintained for a goal of 2 weeks, during which time patients received oral antibiotic prophylaxis (doxycycline 100 mg bid). Post-operatively, women were prescribed 4 weeks of high dose estrogen therapy (estradiol 2 mg tid) along with progestin (medroxyprogesterone acetate 10 mg daily) for the last 12 days of estrogen therapy. An ultrasound was performed post-operatively to assess the growth of the endometrial lining.

RESULTS: Twenty-two women with Asherman Syndrome were included and received the aminograft between the years of 2011 and 2019. Women ranged from 30 to 48 years old. Nine of the twenty-two (41%) women had amenorrhea prior to surgery and all of the women achieved menses post-operatively. The vast majority of women (20/22, 91%) were parous, only two women (2/22, 9%) had never previously conceived. The average increase in pre- versus post-operative endometrial thickness was 3.02 mm, the range was 1-8.2 mm. Twelve out of the twenty-two women (55%) were able to conceive postoperatively and nine out of twenty-two women (41%) had a live birth.

CONCLUSIONS: This case-series demonstrates positive results in regard to improving endometrial thickness, the ability to conceive and have a live birth with the use of the novel aminograft for women with Asherman Syndrome, many of whom previously failed treatment. Our finding deserves further study with a randomized controlled trial comparing women who undergo hysteroscopic lysis of adhesions with aminograft placement to women who undergo hysteroscopic lysis of adhesions only.

P-903 3:30 PM Wednesday, October 21, 2020

THE PREVALENCE OF SUBTLE DISTAL FALLOPIAN TUBE ABNORMALITIES AND THE RELATIONSHIP WITH ENDOMETRIOSIS IN INFERTILITY PATIENTS:A PROSPECTIVE COHORT STUDY. Xingbang Zheng, MD,[1] Xiaoming Yu, MD,[1] Togas Tulandi, M.D., M.H.C.M.,[2] Yaron Gil, MD,[2] He Cai, MD,[3] Hongjing Han, MD,[1] Jing Guan, MD[1] [1]Peking University People's Hospital, Beijing, China; [2]McGill University Health Centre, Montreal, QC, Canada; [3]Northwest Women's and Children's Hospital Affiliated to Xian Jiaotong University, Xian, China.

OBJECTIVE: Clarify the prevalence of subtle distal fallopian tube abnormalities in the infertile population and its relationship with endometriosis.

DESIGN: prospective cohort study

MATERIALS AND METHODS: It is a prospective cohort study conducted in a single fertility referral center between January 2017 and December 2018 which includes all the infertile patients who underwent a laparoscopy examination. We prospectively examined the abdominal cavity including the condition of the fallopian tubes and the presence of endometriosis. Subtle distal fallopian tube abnormalities include fimbrial agglutination, tubal diverticula, accessory ostium and fimbrial phimosis.

RESULTS: A total of 876 patients consented and enrolled in the study, of those, 251 cases were diagnosed with subtle abnormalities, which accounted for 28.65%. 62 cases presented with more than one type of subtle abnormalities. Tubal fimbrial agglutination composed the largest group with 62% (n=156), followed by tubal diverticula with 26%, (n=66) and fimbrial phimosis with 25% (n=64). Tubal accessory ostium was the least common abnormity with 15% (n=39). In sub – analysis we found that 70.91% (178/251) of the study group had endometriosis. The prevalence of subtle tubal abnormalities in the stage I-II patients was significantly higher than found in the stage III-IV group (57.31% (149/260) VS 20.86% (29/139) (P =0.000).

CONCLUSIONS: The prevalence of subtle distal fallopian tube abnormalities is high in the infertile group. This group of diseases is found in high prevalence and probably connected to endometriosis, especially to the peritoneal disease.

SURGICAL METHODS FOR ENDOMETRIAL POLYPECTOMY AND ASSOCIATED ENDOMETRIAL INJURY. Emily Evans-Hoeker, MD, Adrienne Uphoff, MD, James Casey, MD Carilion Clinic, Roanoke, VA.

OBJECTIVE: Intrauterine procedures have the potential for endometrial injury, possibly leading to formation of intrauterine adhesions and infertility. Methods for removal of endometrial abnormalities, such as endometrial polyps, have traditionally been performed with sharp curettage or hysteroscopic scissors, however, the use of hysteroscopic morcellators has become more common in recent years. It is unclear which method, if any, is associated with lower frequency of endometrial injury. Therefore the purpose of our study was to determine if the frequency of endometrial injury differs between methods for removal of endometrial polyps.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: All pathology samples from polypectomy procedures performed between 2014 and 2019 on women ages 18-50 were included in the study. Because the myometrium is deep to the endometrium and is not itself a target of these procedures, the presence and proportion of myometrium on surgical pathology samples were used to indicate endometrial injury. Pathology samples were re-evaluated by a single, blinded pathologist to measure the primary outcome of presence and proportion of myometrium. Secondary outcomes included operative complications and mention of myometrium on the initial pathology report. Data were evaluated using chi square analysis.

RESULTS: Interim analysis of 195 of the 473 (41%) pathology samples demonstrated increased reporting of myometrial tissue on initial surgical pathology with morcellator use (46% of morcellator pathology reports), in comparison to traditional D&C (8%), and hysteroscopic scissors (3%) ($p < 0.01$). However, blinded pathology review demonstrated no differences in the overall presence of myometrium, presence of isolated myometrium or the proportion of myometrial tissue noted. There was no difference noted in surgical complications between the various methods of polypectomy.

CONCLUSIONS: Interim analysis demonstrated increased reporting of myometrial tissue on initial surgical pathology with hysteroscopic morcellator use, however, no difference was found in the presence or quantity of myometrium upon blinded re-evaluation of samples.

DO REPRODUCTIVE AND OBSTETRIC OUTCOMES AFTER HYSTEROSCOPIC SURGERY FOR DYSMORPHIC UTERUS DIFFER FROM THOSE OF PATIENTS WITH NORMAL UTERINE CAVITY? Umut Göktürk, md,[1] Semra Kahraman, Prof. MD,[2] Hacer Uyanikoglu, ass.prof[3] [1]Istanbul Memorial Sisli Hospital, ISTANBUL, Turkey; [2]Istanbul Memorial Sisli Hospital, Istanbul, Turkey; [3]Harran Üniversitesi, Şanlıurfa, Turkey.

OBJECTIVE: The aim of this study was to evaluate reproductive and obstetric outcomes of women who have undergone hysteroscopic metroplasty for dysmorphic uterus.

DESIGN: This retrospective study was conducted at Istanbul Memorial Hospital ART and Genetics Center between 2011 and 2019. A total of 126 patients diagnosed as having dysmorphic uterus with 3D-USG, hysterosalphingogram and hysteroscopy were evaluated. The diagnosis of dysmorphic uterus (Class U1) was made according to the ESHRE/ESGE concensus on the classification of female genital tract congenital anomalies. Patients with normal uterine cavity undergoing diagnostic hysteroscopy were the control group.

MATERIALS AND METHODS: Patients between 25-42 years old with good and top quality blastocysts were included in the study. In frozen-thawed embryo transfer cycle, the endometrium was prepared with either modified natural or artificial cycles. Preimplantation genetic diagnosis (PGT) was performed in women >36 years old. A total of 253 patients were evaluated. 126 patients underwent hysteroscopy to confirm the diagnosis of dysmorphic uterus (Group 1). Diagnostic hysteroscopy was performed in 127 patients with normal uterine cavity (Group 2). Hysteroscopy was performed at midfollicular phase with a bipolar electrode (Versapoint, Johnson & Johnson, Belgium). Lateral, anterior and posterior walls and fundus were expanded until tubal ostiums could be seen from the internal cervical os.

RESULTS: There was no significant difference in age, AMH level, BMI, infertility duration and endometrial thickness between the groups. The mean ages were 33.9 and 32.9 years old in the study and control group, respectively. Single frozen-thawed blastocysts were transferred to 126 patients in 177 cycles in Group 1 and to 127 patients in 201 cycles in Group 2. Clinical pregnancy rates were 64.9%(n=115) and 59.2%(n=119), clinical micarriage rates were 22.6% (n=26) and 16.8% (n=20), ongoing pregnancy rates were 50.2% and 49.2% and live birth rates were 48.5% (n=86) and 48.2% (n=97) respectively. Preterm delivery, before 37 weeks of pregnancy, was 18.1% (n=16) and 14.1% (n=14) in Group 1 and Group 2, respectively. Although clinical abortion rate and preterm birth were higher in Group 1, there was no statistically significant difference between the groups in any reproductive and obstetric outcomes.

CONCLUSIONS: After hysteroscopic metroplasty, patients with dysmorphic uterus have reproductive and obstetric outcomes which are similar to those of patients with normal uterine cavity.

P-906 3:30 PM Wednesday, October 21, 2020

CERVICAL CERCLAGE FOR PREVENTION OF PRETERM DELIVERY IN WOMEN WITH CONGENITAL UTERINE ANOMALIES: A CASE SERIES. Jenna S. Hynes, MD, Amanda Rae Schwartz, MD, Sarah K. Dotters-Katz, MD, MMHPE Duke University Medical Center, Durham, NC.

OBJECTIVE: To characterize a population of women with congenital uterine anomalies (CUA) and cervical cerclage placement, and to evaluate the subsequent incidence of preterm delivery (PTD).

DESIGN: Case Series

MATERIALS AND METHODS: Subjects were identified from an existing database including women with CUAs and a singleton, non-anomalous gestation with delivery from 2013-2018 at a single tertiary care center. Inclusion criteria included women with a CUA (arcuate, septate, unicornuate, bicornuate, or uterine didelphys) and placement of cervical cerclage for any indication. Women with multiple gestations and fetal anomalies were excluded.

RESULTS: Out of 100 women in the database, seven met inclusion criteria; four bicornuate, one unicornuate, one septate, and one didelphys. Five underwent history indicated cerclage placement, one ultrasound indicated, and one exam indicated (Table). Cerclage was placed at a median gestational age of 14w0d (range: 12w0d to 19w2d). Three women experienced a previable delivery with stillbirth or neonatal demise at a median gestational age of 21w1d. Among those delivering beyond viability, the median gestational age at delivery was 32w4d. Of women with history indicated cerclage, 3 of 5 delivered viable infants, as did the patient with the ultrasound indicated cerclage. Delivery complications included chorioamnionitis (n=1) and placental abruption (n=1). No cases of postpartum hemorrhage, endometritis, or need for maternal admission to the intensive care unit were noted. The median birth weight of the four living infants was 1888g (range: 1320 to 2385g) with a median hospital length of stay of 26 days (range: 2-56). One infant suffered from retinopathy of prematurity, while no neonates had intraventricular hemorrhage, neonatal sepsis, or necrotizing enterocolitis.

CONCLUSIONS: There is limited data available regarding the utility of cerclage placement in women with CUAs to prevent PTD. However, in this small case series, more than half of women experienced birth of a viable neonate who survived to hospital discharge following cerclage placement. Further research is needed to support the benefit of cerclage in women with CUAs.

P-907 3:30 PM Wednesday, October 21, 2020

LAPAROENDOSCOPIC SINGLE-SITE SURGERY VERSUS CONVENTIONAL MULTI-PORT LAPAROSCOPY IN OVARIAN DRILLING: A RANDOMIZED CONTROLLED TRIAL. Ahmed Mohamed Bahaaeldin Mohamed, M.D,[1] Haitham Fathy Gad, M.D,[1] Maya Mahmoud Abdelrazek, Msc[2] [1]Assistant Professor, Cairo, Egypt; [2]Assistant Lecturer, Cairo, Egypt.

OBJECTIVE: To compare the efficacy and safety of Laparoendoscopic single site surgery (LESS) to conventional multiport laparoscopy (CML) for laparoscopic ovarian drilling (LOD) in polycystic ovary syndrome patients (PCOS).

DESIGN: A randomized controlled trial.

MATERIALS AND METHODS: This study was approved by the Faculty of Medicine, Ain Shams University, Research Ethics Committee in August 2017 (protocol no. MD 224/2017). The trial was designed and reported according to the revised recommendations of ClinicalTrials.gov (ClinicalTrial.gov NCT03206892 registered on Jul 2017).

Participants were recruited from the outpatient clinic between August 2017 and June 2019.

The primary outcome of the study was successful procedure without the need of an additional port or conversion to laparotomy. The secondary outcomes measured were: operative time, intraoperative blood loss (using equation: waste irrigation fluid volume X Hb conc in irrigation fluid/ preop

	CUA Type	Cerclage Indication	GA at Prior PTD	GA at Cerclage	Short Cervix	GA at Delivery	Birth Weight (g)	Neonatal Outcome
#1	Bicornuate	History	24w0d	18w0d	No	22w5d	400	Neonatal Demise
#2	Bicornuate	History	18w3d	14w0d	No	29w3d	1320	Living
#3	Bicornuate	History	24w0d	12w0d	No	37w1d	2385	Living
#4	Bicornuate	Exam-indicated	N/A	18w0d	Yes	19w4d	260	Stillbirth
#5	Unicornuate	History	22w5d	12w2d	No	34w3d	2375	Living
#6	Septate	History	16w1d	13w2d	Yes	20w0d	Unknown	Stillbirth
#7	Didelphys	Ultrasound	25w0d	19w2d	Yes	30w5d	1400	Living

Hb) (14), and drop in Hb 24 hours after the procedure, intraoperative complications (extraperitoneal insufflation, blood transfusion, bowel, bladder, or vascular injuries), post operative pain using Visual Analogue Scale (VAS 0-10) at 6, 12, and 24 hours postoperatively, postoperative hospital stay, postoperative complications (hematoma, ileus, wound infection), and cosmetic outcome using Patient and Observer Scar Assessment Scale (POSAS) on day 1 and 7.

Interventions: 70 women with PCOS scheduled for LOD were randomly assigned to either LESS or CML group (35 in each group) underwent LOD using straight laparoscopic instruments. Successful procedure was evaluated by the need of an additional port.

RESULTS: There was no significance difference in demographic characteristics between the groups. In addition, there were no differences in perioperative outcomes regarding operative time, estimated blood loss, postoperative pain, and length of hospital stay, between the two groups. LOD was successful in 94.3% of patients (33/35) in LESS group without the need of an additional port. Port insertion related morbidity were all reported in the CML group in the form of bowel injury by Veress needle (2.9%), extraperitoneal insufflation (5.7%), and wound hematoma (2.9%). While, surgical site infection was reported in the LESS group (5.7%). The median score of the Patient and Observer Scar Assessment Scale (POSAS) was non significant at day 1 (P= .124), while significance on day 7 in favor of LESS group (12 vs. 14, P= .001).

CONCLUSIONS: LESS is feasible, safe, and equally effective to CML with a better cosmetic satisfaction, and less port insertion related morbidity. However, it has a higher risk of superficial wound infection.

SUPPORT: This study was supported by Ain Shams University Maternity Hospital but it did not involve in the analysis or interpretation of data.

THE EFFECT OF BILATERAL TUBAL LIGATION AND BILATERAL SALPINGECTOMY ON FUTURE OVARIAN RESPONSE DURING IVF CYCLES.

Evan Akiva Reshef, MD,[1] Jesse J. Hade, MD,[2] Janet A. Foote, PhD[3] [1]University of Arizona College of Medicine - Phoenix, Phoenix, AZ; [2]Arizona Center for Fertility Studies, Scottsdale, AZ; [3]University of Arizona - Phoenix, Phoenix, AZ.

OBJECTIVE: To determine if prior history of bilateral tubal ligation and bilateral salpingectomy will alter the ability of the ovary to respond to gonadotropins during stimulation for IVF cycles and cause total doses of gonadotropins and days of gonadotropin stimulation to be increased.

DESIGN: Retrospective Cohort Study

MATERIALS AND METHODS: This was a retrospective cohort study looking at patients from the Boston IVF Arizona office who completed IVF cycles between 1/1/2015 and 6/1/2019 and who had the diagnosis of tubal factor infertility. The study group consisted of patients with a known history of a bilateral tubal ligation or bilateral salpingectomy procedure prior to the start of their IVF stimulation. The control group consisted of patients with a history of bilateral tubal occlusion by HSG and did not have a history of tubal surgery (unilateral or bilateral). The primary outcome was the total doses of FSH in IUs and total days of stimulation required during stimulation prior to vaginal oocyte retrieval procedures (VORs). Patients with PCOS, ages <28 and >40 years, were excluded from the study..

RESULTS: After exclusions, 19 cycles were included in the study group with a history of bilateral tubal ligation or bilateral salpingectomy, and 20 patients were included in the control group with a history of bilateral tubal blockage of a non-surgical means. The mean age in the control group was 34.8 vs. 35.6 in the study group. The AMH levels were equivalent at 2.49 in both groups. The mean total FSH dose in the control group was 3099 IU's vs. 3475 IU's in the study group, a 10.8% increase in the study group with a P value of 0.25. The mean total days of stimulation in the control group were not different between groups (9.2 days vs. 9.8 days, P value of 0.09)

CONCLUSIONS: In this study, increased doses of FSH and days of stimulation are required to achieve adequate stimulation during IVF cycles in patients with a history of bilateral tubal ligations or bilateral salpingectomies compared to those with non-surgical tubal factor infertility. At this time, these outcomes are not statistically significant and the number of patients enrolled in the study will need to be increased to prove a statistically relationship in the future.

DETERMINANTS OF SUCCESSFUL PREGNANCY OUTCOME IN ASYMPTOMATIC COMPARED WITH EMERGENT PRESENTATION IN PATIENTS WITH CORNUAL HETEROTOPIC PREGNANCY.

Omosalewa Itauma, MD, MPH,[1] Chidinma Abara, MD,[2] Damla C. Gonullu, MD,[1] Megan Fee, BS,[1] Awoniyi Olumide Awonuga, MD[1] [1]Wayne State University School of Medicine, Detroit, MI; [2]Windsor University School Of Medicine, Cayon, MI.

OBJECTIVE: To compare the pregnancy outcome of patients with incidental and emergent diagnosis of heterotopic cornual and interstitial pregnancy.

DESIGN: Retrospective cohort study of published case reports.

MATERIALS AND METHODS: A computerized MEDLINE search was performed on published case reports of cornual heterotopic pregnancy in English language from 1960 to 2013 using the key words; heterotopic, cornual, interstitial and angular ectopic pregnancy. Reference lists were searched manually for additional relevant studies. Analyses were performed with SPSS version 26.

RESULTS: In eighty-seven (83.7%) of 104 published cases, it was possible to determine that 35 (40.2%) were asymptomatic while 52(59.8%) were symptomatic at the time of presentation (Table 1). The status of the remaining 17 (16.3%) could not be determined as to whether they were asymptomatic or symptomatic.

CONCLUSIONS: Multiple intrauterine pregnancy, cornual rupture, cesarean delivery were significantly more common in patients that were symptomatic compared with those that were asymptomatic at presentation with a trend to being delivered earlier. Asymptomatic patients were more likely to undergo medical treatment for their cornual pregnancy.

MANAGEMENT OF CESAREAN SCAR ECTOPIC PREGNANCIES. A COHORT STUDY. Rahana Harjee, MD,[1] Natasha K. Simula, M.D.,[1] Mohamed Ali Bedaiwy, M.D., Ph.D.,[2] Nicole J. Todd, MD[1] [1]University of British Columbia, Department of Obstetrics and Gynaecology, Vancouver, BC, Canada; [2]University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: Cesarean section scar pregnancies (CSP) are a rare form of ectopic pregnancy occurring in approximately 6% of patients with history of an ectopic pregnancy and cesarean scar. Overall, the prevalence is estimated at 1:1800 to 1:2200 pregnancies. CSPs develop outside the endometrial cavity in the caesarean scar and can be classified as type 1 (growth towards uterine cavity) or type 2 (pregnancy growth toward uterine serosa and abdomen). Primary treatments described include systemic single or multi-dose methotrexate (+/- intra-gestational KCl injection); dilation and curettage (D&C); adjunctive uterine artery embolization; hysteroscopic, transvaginal, laparoscopic or open resection; and hysterectomy. There is no current consensus on CSP management and treatment is currently based on provider preference. Data on fertility outcomes after CSP treatment is sparse.

Our aim was to examine treatment methods and outcomes in CSP patients to provide guidance for a future protocol. Possible risk factors and future pregnancy outcomes would also be examined.

DESIGN: Cohort study at a tertiary centre in Vancouver, British Columbia, Canada.

MATERIALS AND METHODS: A chart review was completed for patients labelled with the International Statistical Classification of Diseases codes associated with ectopic pregnancies between January 2010 and December 2018 at a tertiary care centre (n=404). Patients with CSPs were identified and charts reviewed.

RESULTS: 11 patients had a CSP in the study period. Patients ranged from 25-42 years of age (mean = 36.4); 3 patients had 2 prior cesarean sections, while 8 had only 1 prior cesarean section. 4 patients presented with vaginal bleeding, 1 with bleeding and abdominal pain, and 7 were asymptomatic. Of note, 4 patients were diagnosed on assessment prior to pregnancy termination. On imaging review, 6 patients were found to have type 1 CSPs, while the remaining 5 had type 2 CSPs. A fetal heart rate was detected in 7 patients prior to treatment.

No patients had expectant or primary surgical management. 6 patients were treated with multi-dose methotrexate protocols (4 patients received intra-gestational KCl), and 5 had single dose methotrexate with 1 patient requiring adjunct uterine artery embolization. Of patients managed with multi-dose methotrexate, 2 required additional methotrexate and 1 had hysteroscopic resection (under laparoscopic guidance) for a persistent gestational sac (day 17). In patients with single dose methotrexate, 3 required additional methotrexate and 2 patients had D&Cs for retained products of conception. No patients required a blood transfusion or hysterectomy.

CONCLUSIONS: This study highlights the necessity for a CSP management protocol. Primary medical management, rather than surgical management, appears safe if appropriate follow-up is arranged.

P-911 3:30 PM Wednesday, October 21, 2020

THE SAFETY AND EFFICACY OF AMNIOTIC MEMBRANE GRAFT USE IN PATIENTS WITH INFERTILITY: A PILOT STUDY. Elnur Babayev, MD, MSc, Maryellen Pavone, MD, Magdy P. Milad, M.D., MS Northwestern University, Chicago, IL.

OBJECTIVE: Amniotic membrane graft regulates wound healing by promoting epithelization and suppressing stromal inflammation and scarring. It is being used in ophthalmology, for skin grafting and nerve repair. Promising early studies from China, Egypt and one case series from United States (n=10) suggested therapeutic benefit when placed at hysteroscopy. The aim of this study was to evaluate the safety and efficacy of amniotic membrane graft as an adjuvant to operative hysteroscopy to prevent formation and recurrence of intrauterine adhesions in infertile patients.

DESIGN: Retrospective observational study

MATERIALS AND METHODS: Consecutive infertility patients underwent amniotic membrane graft placement at the time of initial complex operative hysteroscopy at our institution between April/1/2019 and Feb/29/2020. At the end of the procedure, allogeneic, frozen and hydration maintained, commercially available amniotic membrane graft was placed over a Foley balloon and positioned under ultrasound guidance. Patients used oral estrogen for 2-4 weeks followed by a progesterone withdrawal bleed. The Foley

balloon was kept in place for a week. Second look hysteroscopies were performed 5-14 weeks later.

RESULTS: In total, 12 patients with an average age of 37 years (25-46) underwent amniotic membrane graft placement. The initial diagnosis ranged from intrauterine septum (n=5), moderate adhesions (n=2), severe adhesions (n=3) and fibroids (n=2). Among patients undergoing septoplasty, mild intrauterine adhesions were not uncommon at the time of second look (n=2). Interestingly, an additional 2 patients had multiple endometrial polyps on second look hysteroscopy and for one patient "globally thickened endometrium" was described. All patients undergoing initial lysis of adhesions had normal uterine cavity (n=3) or mild adhesions (n=2) at the time of second hysteroscopy. Long term follow-up for 3 patients is pending, however, 2 patients showed recurrence of moderate/severe adhesions 4 months later and they proceeded to use gestational carriers. Of the two patients that underwent amniotic membrane graft placement at the time of hysteroscopic myomectomy, one had a normal endometrial cavity at second look and the other had global endometrial fibrosis and multiple endometrial polyps.

CONCLUSIONS: Our pilot study shows high rate of *de novo* endometrial polyp formation (3/7) following amniotic membrane graft use in patients without prior intrauterine adhesions. This may be secondary to growth promoting effects of amniotic membrane and raises concerns regarding its utility for patients who do not have intrauterine adhesions during initial surgery. For patients with Asherman's syndrome, amniotic membrane graft appears to initially reduce the amount of intrauterine adhesions but may not be efficacious long-term.

P-912 3:30 PM Wednesday, October 21, 2020

COMPARISON OF SURGICAL OUTCOMES BETWEEN REDUCED-PORT ROBOTIC SURGERY, SINGLE PORT LAPAROSCOPY AND CONVENTIONAL LAPAROSCOPY FOR MYOMECTOMY. Hye Jeong Hue, MD,[1] Yeon Hee Hong, MD.,[1] Jung Ryeol Lee, MD, PhD,[1] Chang Suk Suh, MD, PhD,[2] Seok Hyun Kim, MD. PhD.[3] [1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South); [2]professor, United Arab Emirates; [3]Seoul National University College of Medicine, Seoul, Korea, Republic of (South).

OBJECTIVE: To date, few studies have compared the benefits of different surgical modalities for myomectomy. The purpose of this study was to compare the surgical outcomes and postoperative pain scores of reduced-port robotic myomectomy (RPRM) with those of single-port laparoscopic myomectomy (SPLM) and conventional laparoscopic myomectomy (CLM).

DESIGN: Retrospective study

MATERIALS AND METHODS: Data were obtained from medical records of patients who underwent RPRM (n=99) between September 2017 and September 2019. The cases were compared with patients who underwent SPLM (n=74) between December 2013 and September 2017 and who underwent CLM (n=80) between July 2017 and August 2019. The same surgeon performed SPRM and RPRM, and different oncologists performed CLM according to preference. RPRM might have been selected for convenience if the patient had many or large myomas after RPRM had started. Therefore, different periods of data were used for RPRM and SPLM to reduce selection bias. Robotic myomectomy usually requires 4 ports. However, for cosmetic benefits, 3 ports were used, which are called "reduced-port". Patients rated pain for 1, 6, and 24 hours after surgery on the 11-point NRS (0 = no pain, 10 = worst pain). Operative time of RPRM included setup and docking time. Patient basal characteristics and surgical outcomes between the 3 groups were analyzed using Welch, Kruskal-Wallis, Bonferroni, and Pearson chi-square statistically.

RESULTS: There were no differences in basal characteristics (i.e., parity, history of previous abdominal surgery, number, size and location of the largest myoma, and weight of myomas) between the 3 groups. The largest myoma's mean size was 7.3 cm for SPLM, 7.8 cm for CLM, and 8.1cm for RPRM. The mean number of myomas was 1.8 for SPLM, 2.0 for CLM, and 2.3 for RPRM. The total number of myomas ranged from 1 to 5 in all groups. The surgical outcomes (i.e., estimated blood loss, postoperative hemoglobin drop, conversion to multi-port surgery or laparotomy, and complication) were not different significantly between the 3 groups. There was bladder dilatation in 3 patients (1 in SPLM, 2 in RPRM). Wound dehiscence occurred in 8 patients (4 in SPLM, 4 in RPRM). CLM had 3 major complications including wound infection, ileus, or hematoma. This required long-term and re-hospitalization. Operative time was significantly longer in the RPRM than CLM (121.3±48.7 vs. 100.9±38.2 min; p=0.002). SPLM's postoperative hospital stay was significantly shorter than RPRM and CLM (1.97±0.2 vs. 2.07±0.3 vs. 2.24±0.9 days; p=0.003). But, there was no period difference between the RPRM and CLM. Pain scores were significantly lower in the RPRM and CLM compared with SPLM at 1, 6 and 24 hours after surgery (3.3±1.4 vs. 3.3±1.4 vs. 4.5±1.6 at 1hr; p<0.001, 3.3±0.7 vs. 3.1±0.4 vs. 3.8±1.0 at 6hr; p<0.001, 3.1±0.8 vs. 2.9±0.5 vs. 3.1±0.7 at 24hr; p=0.014).

CONCLUSIONS: Most operative outcomes were similar among the three surgical modalities except operative time. The postoperative pain score was significantly lower in the RPRM and CLM than SPLM. RPRM is a safe and feasible option for removing myomas with outcomes similar to SPLM and CLM.

PREOPERATIVE UNDERSTANDING OF POSTOPERATIVE MILESTONES AMONG PATIENTS UNDERGOING REPRODUCTIVE SURGERY. Alexander Kotlyar, MD,[1] Pinar H. Kodaman, MD/PhD[2] [1]Yale School of Medicine, Oange, CT; [2]Yale School of Medicine, New Haven, CT.

OBJECTIVE: We sought to determine patient outlooks and expectations on their post-operative course following hysteroscopic and laparoscopic surgery and to identify the most common areas needed for clarification as far as post-operative milestones.

DESIGN: Single-institution, prospective survey

MATERIALS AND METHODS: Patients undergoing surgery within the section of reproductive endocrinology and infertility were provided with a survey at their pre-operative visit. The survey asked patients about their age, ethnicity, and level of education as well as 10 questions about their understanding of the type of surgery they were having, expectations for postoperative pain levels, and- timing of post-operative milestones, such as when to shower and have intercourse. Statistical analysis involved two-tailed t-tests for numerical variables, Fisher's exact test for categorical variables, independence of variables was assessed using generalized linear modeling with a p-value of <0.05 considered to be statistically significant.

RESULTS: Patients who underwent hysteroscopy were overall older than patients who underwent laparoscopy (37.5 y/o (28.0-47.0) vs. 32.7 y/o (19.0-46.0), p<0.05). There was no difference in ethnic distribution and education levels between the two surgical groups. 12.5% of patients presented to their pre-operative appointment without a clear understanding of what kind of surgery they were undergoing. Hysteroscopy patients anticipated experiencing a greater level of pain (7-10/10) following their surgery compared to laparoscopy patients (3-5/10) (p<0.01). Furthermore, hysteroscopy patients were more likely to be unsure of what their post-operative diet should be (p<0.001). The deficits in overall patient knowledge involved when to expect to have a bowel movement with only 18.7% of patients anticipating a bowel movement within 48 hours of surgery. Patients were also uncertain about when to initiate intercourse postoperatively with over 48% of patients being unsure and only 20% understanding that intercourse is be avoided for two weeks or more. Each of the survey responses was independent of age, ethnicity, and education.

CONCLUSIONS: The preoperative visit represents an important opportunity to educate patients about the surgical plan and to clarify postoperative expectations. Areas for improving and reinforcing counseling include postoperative expectations for patients with respect to expected levels of pain, optimal post-operative diet, anticipation of bowel function, and when to resume intercourse.

P-914 3:30 PM Wednesday, October 21, 2020

LAPAROSCOPIC GRAVID HYSTERECTOMY FOR MORBIDLY ADHERENT PLACENTA. Jessica A. Reid, MD,[1] Lisa L. Bayer, MD MPH,[1] Amanda M. Ecker, MD,[1] Joanna Hatfield, MD,[1] Alyssa Covelli Colwill, MD MCR,[1] Leo Han, MD MPH,[1] Melissa Moffitt, MD[2] [1]Oregon Health & Science University, Portland, OR; [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY.

OBJECTIVE: Definitive treatment of previable pregnancy with morbidly adherent placenta is typically gravid hysterectomy via laparotomy. We describe minimally invasive surgical techniques to these complicated cases utilizing laparoscopy.

DESIGN: Retrospective case series from a single academic institution.

	Pregnancy	Prior # of Cesarean Surgeries	Surgical Team	Pathologic Diagnosis	Estimated Blood Loss (mL)	Operative Time (hh:mm)	Complications	Discharged Home
Case 1	IUP @ 20w5d with fetal anomalies	0*	Gyn-Onc, FP	Accreta	1000	03:15	None	POD#1
Case 2	IUP @ 20w5d with vaginal bleeding	3	Gyn-Onc, FP, MFM	Percreta	1500	03:22	Blood transfusion	POD#2
Case 3	Fetal demise measuring 15w2d with fetal anomalies	5	MIGS, FP	Implantation at cesarean scar	2000	04:21	Blood transfusion	POD#2
Case 4	IUP @ 19w2d with fetal anomalies	1	Gyn-Onc, GYN, FP	Increta	3500	02:52	Blood transfusion	POD#1

* History of Asherman Syndrome
IUP=Intrauterine pregnancy; w=weeks; d=days; Gyn-Onc=gynecologic oncologist; FP=family planning; MFM=maternal fetal medicine; MIGS=minimally invasive gynecologic surgeon; GYN=gynecologic surgeon; mL=milliliter; hh:mm=hours:minutes; POD=postoperative day

MATERIALS AND METHODS: After obtaining IRB approval, we searched our electronic medical record for ICD-10-CM diagnosis codes descriptive of morbidly adherent placenta in the first or second trimester (O43.211-232) from 2008 to 2020. Data was extracted and a descriptive summary reported.

RESULTS: We identified four cases of planned laparoscopic gravid hysterectomy performed from 2017 to 2019 (see Table). All cases were within the second trimester (range 15 to 20 weeks) and the majority (n=3) had pathologic evidence of placental invasion. Median estimated blood loss was 1750mL (range 1000 to 3500mL). Median operative time was 3.3 hours. Three patients required blood transfusion. Surgical technique was consistent with a standard laparoscopic total hysterectomy with the following adjustments: pregnancy tissue was evacuated from the uterus after occlusion of the uterine blood supply to allow for vaginal extraction of the uterus. In two cases, standard dilation and evacuation technique was used prior to colpotomy through cervical dilation (n=1) or cervical transection (n=1). In two cases, pregnancy tissue was evacuated within a specimen retrieval bag after colpotomy via hysterotomy (n=1) or cervical transection (n=1).

CONCLUSIONS: Laparoscopic gravid hysterectomy is feasible in the setting of second trimester abnormal placentation. This approach appears to be safe, with the major complication in our series being need for blood transfusion. This option is recommended only with appropriate surgical expertise and careful surgical planning utilizing a multi-disciplinary team.

P-915 3:30 PM Wednesday, October 21, 2020

EFFECTIVENESS OF A NEW, LOWER-COST MANUAL HYSTEROSCOPIC TISSUE REMOVAL DEVICE (POLYGON) IN AN OFFICE SETTING. Jeremy Michael Groll, MD SpringCreek Fertility, Centerville, OH.

OBJECTIVE: This retrospective single site case series was carried out to evaluate the effectiveness of a new, lower-cost manual hysteroscopic tissue removal device (Polygon) in an office setting.

DESIGN: Retrospective single site in an office setting

MATERIALS AND METHODS: Six consecutive premenopausal women previously diagnosed by sonohystogram with presumed endometrial polyps underwent hysteroscopic polypectomy by two different surgeons using a new manual hysteroscopic tissue removal device (Polygon) through a 6.25 mm 0 degree hysteroscope (Myosure, Hologic Inc). Hysteroscope insertion and removal times, device insertion and removal times, fluid used and number of polyps removed were recorded.

RESULTS: In all six patients, the pathology was completely removed. The average total case time was 7.3 minute (range 5-10) although the average time the device was inserted to remove the pathology was only 4 minutes (range 2-6). The average fluid used was 900 cc (range 500-1350). Three women had 1 polyp removed, two women had 2 polyps removed and 1 woman had 5 polyps removed.

CONCLUSIONS: A new, lower cost manual hysteroscopic tissue removal device (Polygon) is effective in quickly removing endometrial polyps in an office setting and merits further evaluations to compare it with other current technologies.

RELATIONSHIP BETWEEN MATERNAL BODY MASS INDEX AND MATERNAL ORIGIN OF ANEUPLOIDY. Dana B. McQueen, MD, MAS,[1] Lydia Hughes, MD,[1] Katrina Merrion, MS,[2] Emily S. Jungheim, MD, MSCI,[1] Christina E. Boots, MD, MSCI[1] [1]Northwestern Feinberg School of Medicine, Chicago, IL; [2]Natera, Inc., CA.

OBJECTIVE: To evaluate the relationship between maternal body mass index (BMI) and embryonic aneuploidy of maternal origin.

DESIGN: Retrospective Cohort Study

MATERIALS AND METHODS: Institutional Review Board approval was obtained. All in vitro fertilization (IVF) cycles utilizing preimplantation genetic testing for aneuploidy via SNP microarrays with bioinformatics between 1/2015 and 1/2020 were reviewed. BMI prior to egg retrieval was collected. Comparison groups included underweight (< 18.5 kg/m^2), normal weight (18.5 -25), overweight (25 -30) and obese (>30). Overall embryonic aneuploidy and maternal aneuploidy (MA) rates were compared. The MA rate was the number of embryos with either MA or mixed (maternal and paternal aneuploidy) divided by the total number of embryos tested. Continuous variables were compared with a student's t-test or ANOVA and categorical variables with a Chi-square. A generalized estimated equation was performed to account for potential confounders. To detect a 10% difference between groups with 80% power and alpha of 0.05, 1368 embryos in the non-obese group and 228 embryos in the obese group were needed.

RESULTS: A total of 1245 IVF cycles and 4699 embryos were included. Parental origin of aneuploidy was available for 453 cycles and 1717 embryos. Baseline characteristics were compared between groups (Table). Female age, as well as several IVF characteristics, were significantly different across groups and were included in the adjusted model. Both the overall embryonic aneuploidy rate and the MA rate increased with increasing maternal BMI (Table). After controlling for significant confounders, BMI did not significantly predict the rate of MA.

CONCLUSIONS: While embryonic aneuploidy and MA rates were significantly higher among obese women compared to normal weight women, this association was no longer significant after adjusting for confounders.

P-918 3:30 PM Wednesday, October 21, 2020

OBESITY AND ENDOMETRIUM: PROTEOMICS IN A WELL-PHENOTYPED COHORT. Emma Giuliani, MD,[1] Maya Millette, BS,[1] Courtney Julia Burns, BSE,[1] Yolanda R. Smith, MD,[1] Carol Elias, PhD,[1] Henriette A. Remmer, PhD,[1] Lisa M. Neff, MD,[2] Erica E. Marsh, MD, MSCI, FACOG[1] [1]University of Michigan, Ann Arbor, MI; [2]Northwestern University, Chicago, IL.

OBJECTIVE: Obesity, a significant public health issue in the US where more than 66.5% of women are overweight or obese, has been associated with infertility, abnormal uterine bleeding, and miscarriage. The impact of obesity on the physiology of human endometrium is largely understudied. We hypothesized that obesity-driven endometrial differences exist between obese (OW; BMI ≥30 kg/m^2) and normal weight women (NWW; BMI 18.5-24.9 kg/m^2).

DESIGN: Case-control study.

MATERIALS AND METHODS: Healthy, 18-40yo, normally cycling, women who were either normal BMI or obese were eligible to apply. Screening saline infusion sonograms and blood testing were done to confirm normal endometrial cavity and endocrine/ovarian reserve profiles (FSH, estrogen, progesterone, testosterone, TSH, and HgbA1C). If the participant screened in, demographic and anthropometric characteristics were collected. Blood samples, ultrasounds, and follicular phase endometrial biopsies were obtained. Endometrial samples were flash frozen for proteomic analysis by 1D-gel electrophoresis, liquid chromatography and mass spectrometry. Differentially expressed proteins were validated by Western Blot (WB) and chosen for functional and pathway analyses (Ingenuity Pathway Analysis and Panther Gene Ontology - Qiagen GmbH, Hilden, Germany).

RESULTS: A total of 221 women expressed interest in the study, 91 met eligibility criteria, 24 completed the screening visit (cycle day 2-5), and 13 completed the study visit (cycle day 7-10). Age, parity, cycle length, follicular phase estrogen, progesterone, and endometrial thickness did not differ between the two groups. Average BMI, %body fat, and visceral fat score measured by bioimpedance analysis were higher in OW than NWW

Mean (SD)	Underweight (N=33 cycles, 137 embryos)	Normal Weight (N=745 cycles, 2968 embryos)	Overweight (N= 291 cycles, 1040 embryos)	Obese (N= 174 cycles, 554 embryos)	P-value
Age, yr	35.9 (4.0)	36.1 (3.8)	37.4 (3.6)	37.8 (3.5)	<0.01
AMH, ng/mL	4.0 (2.3)	3.1 (2.7)	2.7 (2.4)	2.8 (2.4)	0.017
Peak E2, pg/ml	2744.4 (1596.2)	2593.4 (1563.7)	2155.7 (1160.3)	1988.3 (971.4)	<0.01
Oocytes Retrieved	17.3 (9.3)	16.3 (9.7)	14.9 (8.0)	14.7 (7.6)	0.045
Mature Oocytes	11.7 (7.0)	11.1 (7.8)	10.2 (6.3)	9.6 (5.9)	0.029
Fertilized Oocytes	9.6 (5.7)	9.5 (6.5)	8.4 (5.4)	7.9 (4.8)	0.003
Blastocysts Biopsied	4.2 (3.1)	4.0 (3.0)	3.6 (2.9)	3.2 (2.0)	<0.01
Aneuploidy Rate per Embryo Tested (N)	46.7% (64/137)	48.7% (1445/2968)	53.3% (554/1040)	56.9% (315/554)	<0.01
Maternal Aneuploidy Rate per Embryo Tested (N)	32.3% (21/65)	37.6% (370/983)	44.5% (193/434)	51.5% (121/235)	<0.01

(37.8±5.5 vs. 22.1±2.2Kg/m^2, 42.7% vs. 23.6%, 9.7 vs. 2.2; p<0.05). Histological examination of endometrial samples revealed concordant cycle phase and absence of gross abnormalities. A total of 2,930 unique endometrial proteins were identified with a 2,137±55 average protein per sample. 30 proteins were significantly upregulated (>2-fold) and 291 were downregulated (<0.5-fold) in OW vs. NWW (p<0.05). Array findings were validated by WB. Pathway analysis showed significant enrichment of folate/nucleic acid metabolism (p=0.011), RNA degradation (p=0.017) and immune processes (p<0.05) in OW vs. NWW.

CONCLUSIONS: In this well phenotyped population, obesity is associated with significant changes of the proliferative phase endometrial proteome of healthy women by disrupting specific molecular and cellular pathways. This could lead to menstrual bleeding abnormalities and create an altered environment for luteinization. Further studies are needed to investigate obesity-induced proteome alterations during the different phases of the menstrual cycle and the mechanistic pathways of endometrial dysregulation.

P-919 3:30 PM Wednesday, October 21, 2020

ASSOCIATION OF LEPTIN WITH TOTAL AND FREE TESTOSTERONE: RESULTS FROM THE NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEYS. Thiago Fernandes Negris Lima, MD,[1] Evgeniya Rakitina, MS,[2] Sirpi Nackeeran, BA,[2] Gustavo Fernandes Negris Lima, MEng,[3] Himanshu Arora, PhD,[2] Atil Yilmaz Kargi, MD,[1] Ranjith Ramasamy, MD[1] [1]University of Miami, Miami, FL; [2]University of Miami Miller School of Medicine, Miami, FL; [3]Federal University of Espirito Santo, Vitoria, Brazil.

OBJECTIVE: Leptin is produced in the white adipose tissue and its concentration is positively associated with the amount of body fat. Obese men can have low testosterone (T) but the etiology is unknown. Our objective was to evaluate the effects of leptin on T and calculated free testosterone (cFT). We hypothesized that increased serum leptin can be independently associated with low T.

DESIGN: Cross-sectional analysis.

MATERIALS AND METHODS: We analyzed male participants (ages 20-90) of the NHANES III survey from 1988-1991. We included males who had data on serum leptin, cFT and T levels. Our primary outcome was to evaluate the effect of leptin on T and cFT. The Shapiro–Wilk test was used to determine the normality of variable distributions. Simple linear regression was performed with leptin, age, waist circumference, hypertension, and diabetes as independent variables predicting cFT and T levels. Multiple linear regression was used to determine the best predictors for cFT and T controlling for all confounding variables that were significant in the univariate analysis. All statistical tests were adjusted for NHANES complex survey design.

RESULTS: A total of 1193 men were analyzed. As expected, older and obese men were associated with lower testosterone levels. Interestingly, increasing serum leptin levels was an independent predictor of decreasing serum total and free testosterone levels on multivariable linear regression. An increase of 1ng/mL in leptin levels resulted in a decrease of 5.13 ng/dL and 0.11 ng/dL of T and cFT, respectively (p < 0.05). Also, every additional year of life led to a T and cFT reduction of 2.87 ng/dL and 0.13 ng/dL, respectively, and an increase of 1 cm in the waist circumference corresponded to decrease of 4 ng/dL in T levels (p < 0.05). (Table 1)

CONCLUSIONS: Increasing serum leptin, age and BMI are associated with both decreasing total and free testosterone levels. Leptin could potentially explain the underlying association between obesity and testosterone deficiency.

SUPPORT: no

P-920 3:30 PM Wednesday, October 21, 2020

REPRODUCTIVE AND OBSTETRIC OUTCOMES IN MILDLY AND SIGNIFICANTLY UNDERWEIGHT WOMEN UNDERGOING IN VITRO FERTILIZATION. Phillip A. Romanski, MD,[1] Pietro Bortoletto, MD,[1] Alice Chung, BA,[2] Brady I. Magaoay, BA,[2] Steven Spandorfer, MD[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Weill Medical College of Cornell University, New York, NY.

OBJECTIVE: To determine the effect of low body mass index (BMI, kg/m^2) on clinical pregnancy and live birth outcomes in infertile women treated with oocyte retrieval and fresh embryo transfer.

DESIGN: We conducted a retrospective cohort study performed in an academic hospital setting. Patients who underwent their first oocyte retrieval with planned autologous fresh embryo transfer in our IVF clinic between 01/01/2012 and 12/31/2018 were included. Patients were stratified by BMI (kg/m^2): <17.5 (n=76), 17.5-18.49 (n=231), and 18.5-24.99 (n=4,922). Donor oocyte and gestational carrier cycles, as well as cycles missing vital data, were excluded.

MATERIALS AND METHODS: Demographic outcomes were collected. The primary outcomes were pregnancy and live birth rates; secondary outcomes included oocyte quality and embryo morphology. Logistic regression adjusted *a priori* for patient age and number of embryos transferred was used to estimate the odds ratio with a 95% confidence interval (CI) among the BMI study groups for pregnancy outcomes.

RESULTS: A total of 5,229 retrievals resulting in 4,798 embryo transfers met inclusion criteria. A diagnosis of anovulatory infertility was observed in 9.2% of women with a BMI <17.5, 10.0% of women with a BMI of 17.5-18.49, and 6.1% in normal-weight women. After adjusting for patient age and the number of embryos transferred, there were no significant differences in the pregnancy rates for women with a BMI <17.5 (50.0%, OR 0.97; 95% CI 0.60-1.56) and a BMI of 17.5-18.49 (48.5%, OR 0.91; 95% CI 0.69-1.19) compared to normal-weight women (48.7%). In women who achieved pregnancy, there were no significant differences in pregnancy outcomes. Among pregnant patients, the live birth rate was 67.7% in the normal-weight group, which was statistically similar compared to the BMI <17.5 group (57.9%, OR 0.67; 95% CI 0.40-1.13) and the BMI 17.5-18.49 group (72.3%, OR 0.99; 95% CI 0.73-1.33). The miscarriage rate among pregnant patients was 12.6% in the normal-weight group, which was statistically similar compared to the BMI <17.5 group (13.2%, OR 1.14; 95% CI 0.46-2.86) and the BMI 17.5-18.49 group (17.0%, OR 1.41; 95% CI 0.87-2.30). Additionally, there were no significant differences in preterm delivery rate (<37 weeks gestation), low neonatal birth weight (<2500 grams), or cesarean section rates in singleton deliveries for either underweight patient groups when compared to normal-weight patients.

CONCLUSIONS: Overall, underweight patients treated with IVF have similar pregnancy and live birth outcomes compared to normal-weight women. However, there may be a clinically important decreased live birth rate in women with a BMI <17.5. This should be investigated further in future studies. In addition, underweight patients do not have an increased

P-921 3:30 PM Wednesday, October 21, 2020

EFFECT OF ABDOMINAL FAT ON INTRACYTOPLASMIC SPERM INJECTION CYCLES: PRELIMINARY RESULTS. Alaa A. Makhlouf, Msc, Mohammed Khairy Ali, MD, Ahmed M. Abdelmagied, MD, Dina M. Habib, MD, Esraa Badran, MD, Ihab M. El-Nashar, MD, Tarek K. Al-Hussaini, MD, FRCOG, Hosam Salem, MD Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt.

OBJECTIVE: This study aimed at evaluating whether subcutaneous and pre-peritoneal abdominal fat as well as follicular fluid leptin (FFL) predict intracytoplasmic sperm injection (ICSI) outcomes in women without polycystic ovary syndrome (PCOS).

DESIGN: Prospective cohort study (NCT03778684) in an University-affiliated Assisted Conception Center. University IRB approved the study.

MATERIALS AND METHODS: Infertile non-PCOS women indicated for ICSI were considered for enrollment after consent. Included women were grouped based on their waist circumference (WC) into women with central obesity (WC $\geq$ 80 cm; COB group) and without (WC$<$ 80 cm; Non-COB group). At baseline evaluation, women underwent assessment of obesity using different measures and assessment of homeostasis-model for insulin resistance (HOMA-IR). Obesity measures included body mass index (BMI), visceral adiposity index (VAI), and the novel body fat index (BFI). BFI was calculated by multiplying pre-peritoneal and subcutaneous fat (in mm) and divided by height (in cm). FFL was measured from pooled follicular fluid of $\geq$ 17 mm follicles, containing cumulus oocyte complex. Our primary endpoint was ongoing pregnancy rate (OPR). Comparisons between groups were evaluated utilizing the independent t , Wilcoxon rank sum, and chi-square tests as appropriate. Logistic regression model, receiver operating characteristic (ROC) curve and correlation coefficient (r) were also utilized. We planned a sample size of 168 women. Recruitment was temporarily suspended due to COVID-19 pandemic. Recruitment will continue, once IVF procedures are resumed based on our governmental policy

RESULTS: Of 340 women screened, 72 eligible women were included in this preliminary analysis; 40 in COB group and 32 in Non-COB group. Both groups were comparable in age, AMH, duration of infertility, IVF indication, HOMA-IR, cycle characteristics and FFL concentrations. Women in COB group were more likely to have higher BMI (mean$\pm$SD;30.5$\pm$3.9vs25.3$\pm$2.8 $p < 0.005$), BFI (median(IQR),1.8(1.8) vs0.73(0.2), $p<0.005$), and VAI (median(IQR),1.9 (1.06) vs 1.2 (0.65), $p<0.001$). Both groups showed comparable maturation index (73.8%vs77.9%), fertilization rate (71.2%vs72.1%), and OPR (37.5% vs 43.8%). In the correlation analysis, central obesity was more likely to be due to subcutaneous ($r=0.8$, $p<0.001$) rather than pre-peritoneal fat ($r=0.4$, $p<0.001$). None of the obesity measures were correlated with either FFL or OPR. No significant correlation was found between FFL levels and number of oocytes retrieved, maturation and fertilization indices, or rate of good-quality embryos. In ROC analysis, comparable trend was observed among BMI, BFI, VAI, and FFL for predictability of ongoing pregnancy (AUC: 0.48, 0.53, 0.50, and 0.48, respectively). None of these variables was predictor for OPR in the multivariable logistic regression. The only predictors were peak estradiol (OR:1.2,CI:1.1-1.3, $p< 0.05$) and number of mature retrieved oocytes (OR:0.08,CI:0.67-0.92,$p<0.004$).

CONCLUSIONS: Based on this analysis, we could not find evidence that FFL and abdominal fat thickness affect ICSI outcomes.

MD,[1] Micah J. Hill, DO,[4] Nancy Durso, MD[3] [1]National Institute of Child Health and Human Development, NIH, Bethesda, MD; [2]University of Maryland Medical Center, Baltimore, MD; [3]Shady Grove Fertility Center, Rockville, MD; [4]Walter Reed National Military Medical Center, Bethesda, MD.

OBJECTIVE: In considering impacts of obesity on maternal and fetal health, evidence-based body mass index (BMI) thresholds for fertility treatment are being more commonly implemented. Our goal was to evaluate drop-out rates and time to first treatment by BMI in patients presenting for infertility care.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Charts of patients presenting for infertility care in the first 3 months of 2016 were reviewed to allow 4 years of follow up. Age and BMI at initial consult, time to first treatment (if pursued), infertility diagnosis, treatment type, and cycle outcome were collected. Patients with BMIs recorded >1 month from their initial consult were excluded. Descriptive statistics were applied and stratified by BMI (kg/m^2) and obesity classification. Obesity class III was further subdivided into BMI 40-43.9 and ≥44 based on BMI treatment policies at our center. ANOVA and chi-square were used to compare continuous and categorical variables in obese groups to those with normal BMI.

RESULTS: 2,061 patients met study inclusion criteria, 60.4% of which initiated treatment after initial consult. Mean age and BMI were 33.7 years and 28.2 kg/m^2, respectively. Infertility diagnosis was listed as an-/oligo-ovulation for ≥18% of obese vs ≤12.8% for non-obese women. Drop-out rate and time to treatment increased linearly with BMI, however underweight patients also had longer time to treatment. When obese subgroups were independently compared to normal BMI, drop-out and time to treatment were significantly higher for all obesity classes (P<0.05). If a treatment cycle was pursued, rates of clinical pregnancy decreased as BMI increased.

CONCLUSIONS: Obese patients are less likely to initiate fertility treatment and take longer to do so. Further understanding of weight loss strategies and trends in patients who begin treatment may help to provide better access to and sustainment of effective fertility care in this population.

DOES BODY MASS INDEX IMPACT EMBRYO MORPHOKINETICS? Luce A. Kassi, MD,[1] Dana B. McQueen, M.D., M.A.S.,[2] Rafael Confino, BS,[3] John Zhang, PhD,[4] Anne P. Hutchinson, M.D.,[4] Mary Ellen Pavone, MD, MSCI,[4] Dana Kimelman, MD[4] [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern Feinberg School of Medicine, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL.

OBJECTIVE: To assess the relationship between maternal body mass index (BMI) and embryo morphokinetics on time lapse microscopy (TLM).

DESIGN: Retrospective Cohort Study

MATERIALS AND METHODS: Institutional Review Board approval was obtained. All IVF cycles between June 2015 and April 2017 were reviewed. Female BMI prior to egg retrieval was collected through chart review. Comparison groups included underweight (< 18.5 kg/m^2), normal weight (18.5-25 kg/m^2), overweight (>25-30 kg/m^2) and obese (>30 kg/m^2). Embryo morphokinetic parameters were assessed with TLM and included time to syngamy (TPNf), time to 2 cells, time to 3 cells, time to 4 cells and time to 8 cells. A generalized linear mixed model was used to control for potential confounders and multiple embryos resulting from a single IVF cycle.

RESULTS: 589 IVF cycles were included in the analysis. There were no significant differences in the median maternal age, AMH, days of stimulation, total gonadotropin used, number of oocytes retrieved, number of mature oocytes or number fertilized oocytes between groups (Table). There was a trend toward less intracytoplasmic sperm injection (ICSI) in the underweight group and this was adjusted for in the final model. There was a total of 2,185 embryos assessed by TLM: 56 in the underweight group, 1273 in the normal weight group, 510 in the overweight group and 345 the obese group. After adjusting for race and ICSI, the mean time to the 8 cell stage in the underweight group was 4.3 (95% CI: -8.31, -0.21) hours less than in the normal weight group (P= 0.025) and 4.6 (95% CI: -8.8, -0.21) hours less than in the obese group (P=0.022).

CONCLUSIONS: Embryo morphokinetic parameters were significantly different between BMI groups, with embryos from underweight women having a faster time to the 8 cell stage than normal weight or obese women. This study demonstrates that weight can be an independent factor contributing to embryo development as observed on TLM.

P-924 3:30 PM Wednesday, October 21, 2020

LIVE BIRTH OUTCOMES IN INFERTILE PATIENTS WITH CLASS III AND CLASS IV OBESITY FOLLOWING CONTROLLED OVARIAN HYPERSTIMULATION. Phillip A. Romanski, MD,[1] Pietro Bortoletto, MD,[1] Brady I. Magaoay, BA,[2] Alice Chung, BA,[2] Steven Spandorfer, MD[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Weill Medical College of Cornell University, New York, NY.

OBJECTIVE: To assess the effect of class III (body mass index [BMI, kg/m2] 40-49.9) and class IV obesity (≥50) on clinical pregnancy and live birth outcomes in infertile women treated with oocyte retrieval and fresh embryo transfer.

DESIGN: We conducted a retrospective cohort study performed in an academic hospital setting. Patients who underwent their first oocyte retrieval with planned autologous fresh embryo transfer in our IVF clinic between 01/01/2012 and 12/31/2018 were included. Patients were stratified by BMI (kg/m^2): 18.5-24.9 (n=4,922), 25-29.9 (1,571) 30-34.9 (563), 35-39.9 (218), and ≥40 (115).

MATERIALS AND METHODS: The primary outcomes were pregnancy and live birth rates; secondary outcomes included oocyte quality and embryo morphology. Logistic regression adjusted *a priori* for patient age and number of embryos transferred was used to estimate the odds ratio with a 95% confidence interval (CI) among the BMI study groups for pregnancy outcomes.

RESULTS: A total of 7,389 retrievals resulting in 6,740 embryo transfers met inclusion criteria. Compared to the normal-weight cohort (BMI: 18.5-24.9), women with a BMI ≥40 had a significantly higher rate of cancelled fresh transfer after retrieval (8.3% versus 19.1%, OR 2.59; 95% CI 1.61-4.17 (p-value, test for linear trend with increasing BMI group = 0.003). In patients who had an embryo transfer, there were no differences in pregnancy rates across all BMI groups (BMI 18.5-24.9: 53.1% versus ≥40: 48.4%, OR 0.87; 95% CI 0.57-1.33 (p-value, test for linear trend with increasing BMI group = 0.86)). Among pregnant patients, as the BMI increased, a significant

	Underweight (N=17)	Normal Weight (N= 326)	Overweight (N= 149	Obese (N= 96)	p-value
Age (yr)	35.0 (32.7, 38.4)	35.2 (33.2, 38.6)	36.5 (33.6, 38.5)	36.0 (34.6, 40.5)	0.431
AMH (ng/ml)	2.3 (1.1, 4.3)	2.83 (1.4, 3.9)	3.24 (1.6, 3.8)	2.55 (1.4, 4.3)	0.929
Days Stimulation	10.0 (9.0, 11.0)	10.0 (9.0, 11.0)	10.5 (9.5, 11.5)	10.0 (9.0, 11.0)	0.179
Total IU Gonadotropin	3300 (2400, 4500)	2700 (2025, 3750)	2887.5 (2325, 4500)	3000 (2700, 4537.5)	0.296
Number of Oocytes	14.0 (10.0, 20.0)	14.0 (10.0, 22.0)	12.0 (9.0, 21.0)	12.0 (7.0, 17.5)	0.767
Number of Mature Oocytes	11.0 (7.0, 16.0)	12.0 (8.0, 16.0)	9.0 (7.0, 16.0)	9.0 (6.0, 17.0)	0.781
Number Fertilized Oocytes	8.0 (6.0, 12.0)	9.0 (6.0, 13.0)	7.0 (5.0, 14.0)	8.0 (5.0, 13.0)	0.749
% ICSI	87.5% (14)	97.2% (314)	97.9% (142)	95.8% (92.0)	0.061

Data presented as Median(Q1-Q3) or % (N)

trend of an increased miscarriage rate was observed (BMI 18.5-24.9: 12.6% versus ≥40: 22.2%, OR 1.67; 95% CI 0.85-4.25 (p-value, test for linear trend with increasing BMI group <0.001)). Additionally, among pregnant patients, as the BMI increased, a significant trend of a decreased live birth rate was observed (BMI 18.5-24.9: 67.7% versus ≥40: 53.3%, OR 0.65; 95% CI 0.40-1.05 (p-value, test for linear trend with increasing BMI group = 0.004)). Among singleton deliveries, a significant trend of an increased c-section rate was identified as the BMI increased (BMI 18.5-24.9: 39.0% versus ≥40: 61.5%, OR 2.04; 95% CI 0.65-6.34 (p-value, test for linear trend with increasing BMI group <0.001)).

CONCLUSIONS: Overall, patients with a BMI ≥40 have worse IVF treatment outcomes compared to normal-weight patients. After embryo transfer, the pregnancy rate is comparable to normal-weight women; however, the rate of miscarriage is increased, leading to an overall lower live birth rate for pregnant women in this population. Patients with a BMI ≥40 have a c-section rate that is 50% higher than normal-weight patients. These results are useful for counseling infertile patients with class III and class IV obesity about their expected outcomes with IVF treatment. Prior to infertility treatment, obese patients should be counseled about the general health and infertility-related benefits of weight loss.

SUPPORT: None

DOES EXTRA WEIGHT SLOW AN EMBRYO DOWN? THE EFFECT OF MATERNAL BMI ON EMBRYO DIVISION TIMINGS IN WOMEN UNDERGOING IN VITRO FERTILIZATION. Theresa Piquette, MD, Amy Pan, PhD, Jayme Bosler, MD, Robert Rydze, MD, Kate D. Schoyer, MD Medical College of Wisconsin, Milwaukee, WI.

OBJECTIVE: Obesity affects multiple endocrine pathways and has been associated with lower fecundity and fertility even in normoovulatory patients. These effects can also influence outcomes for couples undergoing IVF, whose embryos tend to have lower cleavage rates and progression to blastocyst. However, the mechanism(s) whereby maternal body habitus affects the developing embryo are not well understood. The purpose of this study is to elucidate what role maternal BMI has on the morphokinetics of embryo development as monitored by a time-lapse system.

DESIGN: Retrospective chart review

MATERIALS AND METHODS: A review of EmbryoScope time-lapse data and patient medical records from women undergoing their first cycle of IVF between September 2016 to January 2019 was performed. Excluded from analysis were patients with factors known to negatively impact embryo quality, such as diminished ovarian reserve, age>37 years, and cigarette smoking. To detect a difference of 0.125 standard deviations at the T2 time point with 80% power (α=0.05), assuming 9 embryos per patient, 188 normal weight patients (1692 embryos) and 94 obese patients (846 embryos) were needed. A multilevel mixed effects model was performed to investigate the relationships between BMI categories and embryo division timings. Log or square transformation are used to improve fit.

RESULTS: 366 patients met inclusion criteria, yielding 4,475 embryos: 1948 embryos from 162 normal weight women (were no differences between BMI groups in age, AMH level, number of oocytes retrieved, or number of blastocysts available. When comparing embryo division timings based on BMI, there were significant differences between T2 (time to division to 2 cell embryo) where patients with obese BMI had the shortest division timings when compared with patients with normal weight (P=0.018), overweight (P=0.043), and morbidly obese BMI (P=0 .032). This effect persisted for T3, T4, and T5 where embryos from obese patients had the most rapid division timings compared to other weight categories (p<0.05). When analyzing BMI as a continuous variable, there was no significant relationship between BMI and embryo division timing (p=0.35).

BMI categories	Mean T2 (hours)	95% CI
Normal Weight	26.36	26.00, 26.74
Overweight	26.33	25.85, 26.81
Obese	25.63	25.16, 26.11
Morbidly Obese	27.04	25.85, 28.30

CONCLUSIONS: Maternal BMI does not appear to influence embryo morphokinetics in a dose-dependent manner. Future studies are warranted to evaluate other potential factors influenced by obesity, such as oocyte mitochondrial function or embryonic metabolic gene expression that could be contributing to the reduced embryo quality and fecundability seen in obese women

P-926 3:30 PM Wednesday, October 21, 2020

THE EFFECTS OF OOCYTE DONOR AND RECIPIENT BODY MASS INDEX ON LIVE BIRTH RATES AND PREGNANCY OUTCOMES FOLLOWING ASSISTED REPRODUCTION. Jiaxin Xu, MPH,[1] Heather S. Hipp, MD,[2] Sarah M. Capelouto, MD,[3] Zsolt Peter Nagy, MD, PhD,[4] Daniel B. Shapiro, MD,[4] Jessica B. Spencer, MD, MSc,[5] Audrey J. Gaskins, ScD[1] [1]Emory University, Rollins School of Public Health, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]University of Texas Southwestern Medical Center, Dallas, TX; [4]Reproductive Biology Associates, Atlanta, GA; [5]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA.

OBJECTIVE: Excess body weight is a risk factor for impaired fertility in women conceiving both with and without medical assistance. However, whether excess body weight negatively influences female fertility on the level of the oocyte and/or uterine environment remains unclear. To expand on the existing literature in autologous and fresh oocyte donation cycles, we used information from a large cohort of vitrified donor oocytes to investigate the influence of donor and recipient body mass index (BMI) on assisted reproductive technology (ART) outcomes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Between 2008 and 2015**,** 338 oocyte donors and 932 recipients underwent 1651 embryo transfer cycles at a private fertility center in Georgia. We evaluated the associations between donor and recipient BMI and probability of positive pregnancy test (PPT) and live birth using log binomial regression with cluster weighted generalized estimating equations adjusting for donor and recipient age, race, retrieval year, and recipient diagnoses of uterine factor infertility and polycystic ovarian syndrome. Secondary outcomes included the % of oocytes that survived warm, fertilized, and developed into usable embryos. Infant birthweight and gestational age were also examined among live born singletons. All models accounted for the correlation between oocytes from the same donor and correlation between cycles/live births from the same recipient.

RESULTS: The mean (standard deviation) BMI of donors and recipients was 22.3 kg/m^2 (2.3 kg/m^2) and 24.5 kg/m^2 (4.7 kg/m^2), respectively. Approximately 25% of the donors and recipients were racial minorities. The percentage of oocytes that survived warming, successfully fertilized, and developed into usable embryos did not differ across categories of donor BMI. There were also no associations between donor BMI and probability of PPT or live birth. In contrast, there was a statistically significant positive association between recipient BMI and risk of PPT (adjusted risk ratio (aRR) 1.01 per 2 kg/m^2, 95% CI 1.00, 1.02) and live birth (aRR 1.02 per 2 kg/m^2, 95% CI 1.00, 1.03). Recipients with a BMI≥35 kg/m^2 had a higher probability of PPT (RR 1.13, 95% CI 1.02, 1.25) and live birth (RR 1.26, 95% CI 1.07, 1.49) compared to normal weight recipients. Among singleton births, recipients with a BMI<18.5 kg/m^2 had a lower risk of delivery (HR 0.64 95% CI 0.43, 0.95), while women with a BMI ≥35 kg/m^2 had a higher risk of delivery in an earlier gestational week (HR 1.45 95% CI 0.96, 2.20) compared to normal weight women. Recipients with a BMI ≥35 kg/m^2 also had a higher risk of having a low birth weight infant (RR 1.76 95% CI 1.02, 3.02) compared to normal weight women. Donor BMI was not associated with birthweight or gestational length.

CONCLUSIONS: In the setting of vitrified donor oocyte ART, recipient BMI was positively associated with probability of live birth but negatively associated with gestational length and birthweight. Our results suggest that impaired oocyte quality rather than endometrial receptivity may be the overriding factor influencing ART success in obese women using autologous oocytes.

SUPPORT: Dr. Gaskins is supported by a career development grant, R00ES026648, from the National Institute of Environmental Health Sciences (NIEHS). REDCap support was provided by UL1 TR000424 at Emory University.

Table 1. Mitochondrial Score and Aneuploidy Rates

	Underweight (n=5)	Normal weight (n=148)	Overweight (n=57)	Obesity I (n=24)	Obesity II (n=12)	Obesity III (n=9)	p-value
Average Mitochondiral Score	22.52 ± 8.67	24.95 ± 6.68	24.80 ± 6.75	24.59 ± 5.40	23.12±5.23	25.70 ± 3.74	0.89

OBESITY DOES NOT IMPACT ANEUPLOIDY RATES OR MITOCHONDRIAL DNA COPY NUMBER IN PATIENTS UNDERGOING PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY. Wes Urian, MD,[1] Molly Siegel, MD,[1] Pamela B. Parker, M.D., M.P.H.,[2] Bharti Garg, MBBS, MPH,[2] Paula Amato, MD,[2] Diana Wu, MD,[2] David Lee, MD,[2] Thomas O'Leary, PhD,[2] Sacha A. Krieg, M.D., Ph.D.[2] [1]Oregon Health and Science University, Portland, OR; [2]Oregon Health & Science University, Portland, OR.

OBJECTIVE: To investigate the impact of body mass index (BMI) on aneuploidy rate and mitochondrial DNA copy number, a known marker of embryo quality, in embryos obtained during in vitro fertilization (IVF) cycles utilizing preimplantation genetic testing for aneuploidy (PGT-A).

DESIGN: This is a retrospective IRB-approved cohort study performed at a single academic institution involving 409 IVF-PGT-A cycles performed during January 2016 to June 2018.

MATERIALS AND METHODS: BMI for all patients was calculated in each respective IVF-PGT-A cycle and classified according to the World Health Organization criteria. Aneuploidy rate was defined as the total number of aneuploidy blastocysts divided by the total number blastocysts from an IVF cycle. Mitochondrial DNA copy number (Mitoscore, iGenomix) was derived for each euploid embryo and averaged across each IVF cycle. Data were analyzed using chi-square tests/Fisher Exact test for categorical variables and one-way analysis of variance (ANOVA) for continuous variables. After excluding donor egg cycles, those utilizing preimplantation genetic testing for mutations or structural rearrangements, cycles with no euploid embryos available for biopsy, and those without a reported Mitoscore, we analyzed a total of 255 IVF cycles.

RESULTS: There were no differences in baseline characteristics such as age, parity, primary infertility diagnosis, or smoking status. We found no significant differences in our primary outcomes of average Mitoscore, euploidy, or aneuploidy rates across the BMI groups. There is a nonsignificant trend towards increased average Mitoscore with increasing BMI (22.52 for underweight vs 25.70 for class III obesity). There were no differences in our secondary outcomes of clinical pregnancy rates, live birth rates, or miscarriages.

CONCLUSIONS: Our study demonstrates that increasing BMI is not associated with changes in mitochondrial score or aneuploidy rates. This suggests that other factors impact IVF success rates in women with obesity, such as inflammatory and endometrial factors.

P-928 3:30 PM Wednesday, October 21, 2020

EFFECT OF BODY MASS INDEX (BMI) ON PREGNANCY OUTCOMES IN FROZEN-THAWED BLASTOCYST TRANSFER (FET) CYCLES. Adrienne R. Schmidt, MD,[1] Prachi N. Godiwala, MD,[2] Reeva B. Makhijani, MD,[2] Chantal Bartels, MD,[2] John Nulsen, MD,[2] Claudio A. Benadiva, MD,[2] Daniel R. Grow, MD,[2] Lawrence Engmann, MD[2] [1]University of Connecticut School of Medicine, Farmington, CT; [2]Center for Advanced Reproductive Services, University of Connecticut School of Medicine, Farmington, CT.

OBJECTIVE: There is limited and conflicting data from either small or non-US cohorts on the effect of body mass index on pregnancy outcomes in FET cycles. We aimed to investigate the effect of BMI on ongoing pregnancy rate (OPR) in FET cycles in a larger US cohort.

DESIGN: Single academic center retrospective cohort study

MATERIALS AND METHODS: 2310 FET cycles (natural, letrozole, or programmed) in patients £42 years using embryos created from autologous oocytes from 2015-2020 were included. Groups were divided by BMI: underweight (BMI <18.5 kg/m^2), normal weight (BMI 18.5-24.9 kg/m^2), overweight (BMI 25-29.9 kg/m^2), and obese (BMI ≥ 30 kg/m^2).The primary outcome was OPR. Secondary outcomes included pregnancy rate (PR), implantation rate (IR), clinical pregnancy rate (CPR), and clinical loss rate (CLR). Chi-square test for categorical data and one-way ANOVA with post hoc Tukey test for continuous data was used. Multiple logistic regression analysis was performed adjusting for age, anovulation diagnosis, number of embryos transferred, FET protocol used, and use of preimplantation genetic testing for aneuploidy (PGT-A). A two-sided p-value of <0.05 was considered statistically significant.

RESULTS: A higher proportion of obese patients carried a diagnosis of ovulation and used a programmed or letrozole FET protocol compared to other BMI groups. Obese and underweight women were less likely to use PGT-A. There was no significant difference in OPR among BMI groups, which persisted after controlling for confounding variables. PR, IR, CPR, and CLR were similar among BMI groups.

CONCLUSIONS: In this large US cohort, BMI did not impact OPR in FET cycles. Large prospective randomized trials are needed to determine the optimal method of in vitro fertilization in obese patients.

TIPPING THE SCALE: BODY MASS INDEX AS A PREDICTOR OF EMBRYONIC MITOCHONDRIAL DNA CONTENT.

Lauren Grimm, M.A.,[1] Zoran J. Pavlovic, M.D.,[2] Nepheli Raptis, B.A., M.A.,[1] Emma Radley, M.A.,[1] Hanna Mandell, M.A.,[1] Christy Oso, B.A.,[1] Jessi Anderson, MPH,[1] Shawn Zimmerman, PhD, HCLD,[3] Angeline Beltsos, MD,[1] Amber R. Cooper, MD,[4] Roohi Jeelani, MD[1] [1]Vios Fertility Institute, Chicago, IL; [2]Rush University Medical Center, Chicago, IL; [3]Vios Fertility Institute, Swansea, SC; [4]Vios Fertility Institute St Louis, St. Louis, MO.

OBJECTIVE: This study sought to determine whether or not there is a correlation between Body Mass Index (BMI) and the quantification of mitochondrial DNA (mtDNA) in euploid embryos.

DESIGN: Retrospective chart review at a private, multi-site fertility clinic.

MATERIALS AND METHODS: All euploid embryos from patients who underwent in-vitro fertilization (IVF) with PGT-A from January to February 2020 utilizing a PGT lab that reports mtDNA (MitoScore; Igenomix) were included. Baseline characteristics were measured and IVF cycle statistics recorded. Patients were then divided into groups based on BMI: <18.5, 18.5-24.9, 25-29.9, 30-39.9, >40. T-tests, linear regression and chi-square analysis were used to analyze the data using SPSS (SPSS Inc., Chicago, IL, USA).

RESULTS: A total of 657 embryos were analyzed. The BMI of patients ranged from 17.2 to 47.6, with the average BMI being 34.9. Linear regression analysis showed there was no statistically significant correlation between BMI and mtDNA quantity, with an r-squared value of 0.00. When divided into groups based on BMI, there was no statistically significant difference in the average mtDNA quantity, where average scores were 21.3, 22.7, 23.3, 23.4, and 22.9, respectively ($p>0.05$). Pregnancy rates between all the groups were similar.

CONCLUSIONS: For women undergoing IVF, there are a limited number of ways to appropriately assess oocyte/embryo quality for optimal success. Yet, the quantification of mtDNA may offer a promising new parameter in assisted reproductive technologies (ART). Increased mtDNA have been linked to decreased pregnancy rates and is thought to be indicative of poor embryo quality due to oxidative stress; while lower mtDNA scores have been associated with improved outcomes. Yet, in order to better understand the mtDNA score, investigation into the underlying biological causes associated with elevated levels is warranted. It is well established that excess weight in women attempting pregnancy has a strong correlation to subfertility. Evidence suggests that increased weight directly impairs oocyte quality, fertilization, and embryo development. This is thought to be a result of oxidative stress due to increased lipid peroxidation and circulating reactive oxygen species (ROS), leading to mitochondrial damage and poor oocyte quality, among other things. Our results indicate that while patients with increased weight may experience reduced oocyte quality due to higher levels of oxidative stress, this does not seem to implicate reduced embryonic development, competence, or metabolic health. Further investigation into the clinical utility of Mitoscore is warranted.

VIDEO ABSTRACT SESSION 1

V-01 10:00 AM Saturday, October 17, 2020

NON-INVASIVE SELECTION OF SINGLE SPERM WITH HIGH DNA INTEGRITY FOR ICSI. Zhuoran Zhang, PhD,[1] Changsheng Dai, MASc,[1] Guanqiao Shan, MASc,[1] Khaled Abdalla, MASc,[2] Iryna Kuznyetsova, PhD,[2] Clifford Lawrence Librach, MD,[2] Keith Jarvi, MD,[3] Yu Sun, PhD[1] [1]University of Toronto, Toronto, ON, Canada; [2]CReATe Fertility Centre, Toronto, ON, Canada; [3]University of Toronto, School of Medicine, Toronto, ON, Canada.

OBJECTIVE: To develop a quantitative and non-invasive technique for selecting single sperm with high DNA integrity for ICSI.

METHODOLOGY: In ICSI, embryologists qualitatively select sperm by subjectively observing sperm motility and morphology. The DNA quality of the selected individual sperm is not known. We first tested the DNA quality of the sperm selected by embryologists following the WHO qualitative criteria. Three embryologists selected sperm from the same sample and the DNA integrity of the selected sperm was measured with comet assay on individual sperm. Indeed, the selected sperm had low DNA fragmentation ($p<0.01$ compared to sample population). However, manual selection is highly subjective, and the results varied significantly among embryologists ($p<0.01$). In order to eliminate subjectivity, we have developed a software that automatically selects sperm using quantitative criteria.

To establish the quantitative selection criteria, we first developed computer vision algorithms to measure each individual sperm's 9 motility (velocity, linearity etc.) and 9 morphology (head size etc.) parameters. The measurement is on live sperm without invasive staining. Then the same sperm was transferred for DNA measurement using the comet assay. We have collected a dataset of 440 individual sperm. For each sperm, its motility, morphology and DNA fragmentation data were recorded. With the collected data, we then established our quantitative criteria. Our criteria were based on the WHO quantitative criteria, but we modified the morphology criteria using our data on live sperm without staining. For motility, considering that WHO criterion ($VSL \geq 25$ μm/s) was defined for semen analysis instead of for ICSI where PVP was used to slow down sperm motion, we scaled the motility criterion by measuring sperm velocity change from semen to PVP. We transferred 30 individual sperm from raw semen to ICSI medium supplemented with PVP, and the velocity of individual sperm decreased to almost the same ratio (~0.5). The new motility criterion was determined ($VSL \geq 13.5$ μm/s). The quantitative criteria were first tested on our collected dataset and reduced the DNA fragmentation by 50%.

The quantitative criteria were built into our automated sperm selection software, and compared to manual qualitative sperm selection. From each new sample, both the software and three embryologists selected good sperm. The software outperformed all three embryologists. Compared to the best embryologist, the software further reduced the DNA fragmentation by 30%. The software also showed smaller standard deviation and provided more consistent selection results. Evaluation of ICSI outcomes using sperm selected by the software is underway.

CONCLUSIONS: The developed automation technique is able to non-invasively and quantitatively select single sperm with high DNA integrity without disturbing ICSI flow. Computer vision and quantitative selection improve the DNA quality of the selected sperm, and eliminate the subjectivity in manual qualitative selection.

NEW ERA OF MALE INFERTILITY MICROSURGERY: 4K3D ORBEYE VIDEO OPERATING MICROSCOPY. Huixing Chen, M.D. Ph.D., Russell P. Hayden, M.D., Omar Al Hussein Alawamlh, M.D., Peter N. Schlegel, M.D., Marc Goldstein, M.D., Philip S. Li, M.D. Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: Early adaptations of the 2-Dimensional (2D) video operating microscope (VOM) have shown to have better ergonomics, flexibility, and versatility compared to the standard operating microscope (SOM) in male infertility microsurgery (MIM). However, the low resolution, 2D view, and depth of field were significant limitations. Therefore, the emergence of the 4K3D ORBEYE VOM has the potential to revolutionize MIM. In this video, we aimed to demonstrate a comparison of various visual parameters between the ORBEYE VOM and the SOM. We also conducted an animal study to evaluate the surgical experience and efficacy of the VOM.

METHODOLOGY: The depth of field, working distance, and operative field were compared between the 4K3D OBYEYE VOM (Olympus/Sony) and the SOM. Four vasovasostomies (VVs) and four vasoepididymostomies (VEs) were performed on Wistar male adult rats using the 4K3D ORBEYE VOM. Data on operating time to anastomotic completion and patency rates were collected.

CONCLUSIONS: The 4K3D ORBEYE VOM provides high-end on-screen visualization, coupled with enhanced ergonomics and overall surgical experience. The ORBEYE VOM has a depth of field three times greater than seen with the SOM at magnifications of x15 and lower, due to its higher image and video quality with quick zoom-in, auto-focus, and zero on-screen latency capabilities. A larger operative field and a more comprehensive working distance (200-550mm vs. 250mm) were also seen on the VOM. The ORBEYE VOM proved to be non-inferior to the SOM in fine anastomoses, characteristic of MIM. The average operating time to complete an anastomosis for VVs and VEs was 37 and 33 minutes, respectively, with superior patency rates for all procedures. This VOM possesses the potential to improve surgical safety and efficiency by reducing postural fatigue and eye strain, which surgeons experience with the SOM. In addition, it can significantly facilitate teamwork and teaching through its high-resolution screens and zero-latency images.

V-03 10:16 AM Saturday, October 17, 2020

FERTILITY-PRESERVING, SURGICAL MANAGEMENT OF A CESAREAN SCAR ECTOPIC PREGNANCY. Christine Hur, MD, Miguel Luna Russo, MD, Cara R. King, DO, MS. Cleveland Clinic, Cleveland, OH.

OBJECTIVE: The objective of this video is to highlight a fertility-preserving surgical technique for the management of cesarean scar ectopic pregnancy.

METHODOLOGY: A video description of the surgical technique used to manage the cesarean scar ectopic pregnancy of a 28-year-old G6P4014 with desires future fertility preservation.

CONCLUSIONS: This video highlights a surgical technique which allows for the laparoscopic removal of a cesarean scar ectopic pregnancy with the concurrent repair of the uterine defect. It reviews strategies to restore normal anatomy, minimize blood loss and allow for healing in order to allow for future fertility.

RESOLUTION OF ABDOMINAL PAIN AFTER COIL EMBOLIZATION OF VARICOCELE WITH ROBOTIC RESECTION OF GONADAL VEIN. Johnathan Doolittle, MD, Viraj Maniar, MD, Peter N. Dietrich, MD, Jay I. Sandlow, MD, Scott Johnson, MD, Jagan K. Kansal, MD, MBA. Medical College of Wisconsin, Milwaukee, WI.

OBJECTIVE: Chronic pain in the region of varicocele embolization is not well described and can be a challenging symptom for a urologist to manage. Metallic coils from embolization are unable to be removed, leaving limited options for treatment after failing conservative measures. It is important to counsel patients of this potential complication when determining the best option for varicocele repair. To our knowledge, there are no reported cases of gonadal vein excision for chronic abdominal pain after coil embolization.

METHODOLOGY: A 63-year-old male presented nine months after coil embolization. His testicular pain resolved but he reported new left sided abdominal pain following coil embolization for a large left varicocele. After failing conservative measures including non-steroidal anti-inflammatory drugs, antibiotics and prednisone, he was referred to urology for further workup and to discuss treatment options. On presentation, the patient reported pain on the left side of his abdomen consistent with the location to gonadal vein. After extensive counseling that surgical removal may not alleviate his pain, robotic gonadal vein excision was offered, and the patient elected to proceed. The video illustrates the robotic excision of the left gonadal vein. Coils were easily visualized through the wall of the vessel. While mild edema of the surrounding tissue in the retroperitoneum was noted, extensive

inflammation was not present, leading to an uncomplicated dissection. The coil-containing gonadal vein was able to be excised in its entirety. The patient was discharged on post-operative day one with only non-steroidal pain medications. Six weeks post operatively, the patient reported no complications, and almost complete resolution of his preoperative pain.

CONCLUSIONS: To our knowledge, this is the first case report demonstrating the surgical removal of the gonadal vein for treatment of chronic abdominal pain after varicocele embolization. After failing conservative measures, this may present another viable treatment option to address this difficult complication in a select group of patients.

V-05 10:31 AM Saturday, October 17, 2020

A NOVEL ROBOTIC ENDOSCOPIC DEVICE USED FOR OPERATIVE HYSTEROSCOPY: ASHERMAN'S SYNDROME. Lara Harvey, MD MPH,[■] Richard Hendrick, PhD,[2] Neal P. Dillon, PhD,[■] Evan Blum, BS,[3] Lauren Branscombe, MS,[3] Scott J. Webster, PhD,[3] Ted L. Anderson, MD PhD.[4] [1]Virtuoso Surgical, Nashville; [2]Virtuoso Surgical, Inc., Nashville, TN; [3]Virtuoso Surgical, Nashville, TN; [4]■ ■ ■.

OBJECTIVE: To trial the use of a novel robotic endoscope prototype for the application of Asherman's syndrome in a uterine tissue model.

METHODOLOGY: The robotic endoscope prototype consists of two arms made of concentric tubes that fit through a standard 23Fr endoscopic sheath. This allows a surgeon to have two-handed capabilities with a variety of endoscopic instruments as well as improved ergonomics. Previous pilot studies have examined the use of this device for hysteroscopic polypectomy and removal of retained intrauterine device.

CONCLUSIONS: The endoscopic robot was successful in lysing simulated intrauterine adhesions in a porcine tissue model in a fluid environment. The device allows two handed surgical technique for hysteroscopic applications. Further study on the utility of this device for gynecologic applications is needed.

SUPPORT: This study was funded by Virtuoso Surgical

V-06 10:38 AM Saturday, October 17, 2020

PELVIC ENDOMETRIOSIS CAUSING HYDRONEPHROSIS. Karine Matevossian, DO,[1] Rachel Yoon, MD,[1] Kirsten Sasaki, M.D.,[2] Charles E. Miller, M.D.[3] [1]Advocate Lutheran General Hospital, Park Ridge, IL; [2]Advocate Lutheran General Hospital, Naperville, IL; [3]The Advanced Gynecologic Surgery Institute/The Advanced IVF Institute, Charles E. Miller, MD & Associates, Naperville, IL.

OBJECTIVE: Step by step narrated demonstration of ureterolysis.

METHODOLOGY: 51 year old female who presents with left sided pelvic pain and hydronephrosis/hydroureter. The patient was positioned in the dorsal lithotomy position in adjustable Allen stirrups. A three port laparoscopic approach was used. The patient underwent a laparoscopic excision of endometriosis with bilateral ureterolysis.

CONCLUSIONS: Laparoscopic excision of endometriosis can be technically challenging and time consuming. A conservative approach with ureterolysis generally resolves the patient's pain. The imaging of choice in diagnosing ureteral complications of endometriosis is MRI. Cystoscopy post surgery can help assess ureteral function but does not guarantee that thermal injury has not occurred.

SURGICAL REPAIR OF A CESAREAN SCAR DEFECT USING A VAGINAL APPROACH. Abigail C. Mancuso, MD,[1] Erin Maetzold, MD,[1] Joseph T. Kowalski, MD,[1] Bradley J. Van Voorhis, MD.[2] [1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]University of Iowa, Iowa City, IA.

OBJECTIVE: To discuss the signs and symptoms of a cesarean scar defect and describe the techniques for the repair of a cesarean scar defect using a vaginal approach.

METHODOLOGY: We demonstrate a case of a 32-year-old patient with a symptomatic cesarean scar defect desiring surgical repair. Repair of the cesarean scar defect was successfully completed using a vaginal approach.

CONCLUSIONS: There are several surgical approaches used for the repair of cesarean scar defect including hysteroscopic and laparoscopic repair. We have found the vaginal approach to be an expeditious and excellent way to access these defects that often occur low at the level of the cervix. It is important to carefully dissect off the bladder to avoid bladder injury and perform cystoscopy at the conclusion of the case to ensure bladder injury did not occur. The vaginal approach avoids the need for abdominal incisions leading to quick postoperative healing and high patient satisfaction.

VIDEO ABSTRACT SESSION 2

V-08 10:00 AM Sunday, October 18, 2020

SURGICAL MANAGEMENT OF UNDESCENDED LEFT OVARY AND RUDIMENTARY UTERINE HORN. Lauren Elizabeth Verrilli, MD,[1] Addison William Alley, MD,[2] Joseph M. Letourneau, MD.[1] [1]University of Utah, Salt Lake City, UT; [2]University of Arizona College of Medicine - Phoenix, Phoenix, AZ.

OBJECTIVE: To describe a rare Mullerian anomaly and review important embryologic origins of the female reproductive tract as well as surgical management of a maldescended ovary and rudimentary uterine horn.

METHODOLOGY: This is the case of a 26-year-old G0 with chronic pelvic pain and three years of conservative management who ultimately underwent a laparoscopic resection of a maldescended left ovary and uterine horn.

CONCLUSIONS: While conservative management remains the standard of care for managing cyclical pelvic pain secondary to Mullerian anomalies, surgery remains an option for patients refractory to this treatment. We present surgical planning and technique for performing a laparoscopic unilateral salpingoophorectomy and resection of rudimentary uterine horn and maldescended left ovary.

A NEW PIEZO DRILL FOR HUMAN ICSI. Changsheng Dai, MASc,[1] Alexander Lagunov, MSc,[2] Zhuoran Zhang, PhD,[1] Guanqiao Shan, MASc,[1] Jason E. Swain, PhD, HCLD,[3] William B. Schoolcraft, MD,[4] Tom Hannam, MD,[5] Yu Sun, PhD.[1] [1]University of Toronto, Toronto, ON, Canada; [2]CCRM Toronto, Toronto, ON, Canada; [3]CCRM Fertility Network, Lone Tree, CO; [4]Colorado Center for Reproductive Medicine, Lone Tree, CO; [5]Hannam Fertility Centre, Toronto, ON, Canada.

OBJECTIVE: To develop a new piezo-ICSI device that is compatible with standard ICSI setup and capable of reducing oocyte deformation and preventing cytoplasm aspiration during ICSI.

METHODOLOGY: In standard ICSI, oocytes often suffer large deformation before penetration, which may damage the spindle and other cellular organelles. Furthermore, cytoplasm is aspirated into the micropipette to break the oolemma, which disrupts the local cytoskeleton of the oocyte. To facilitate oocyte penetration, piezo drills were developed by using piezoelectric actuators to generate micropipette vibration. However, existing piezo drills use a flat-tipped micropipette (vs. standard sharp ICSI micropipette); additionally, to reduce micropipette's lateral vibration, which is perpendicular to the oocyte penetration direction, damping fluid such as mercury is required in the operation of existing piezo drills, which raises biosafety concerns. The new piezo drill we developed uses a standard sharp-tipped ICSI micropipette and requires no damping fluid. It is readily mounted on a standard micropipette holder within 10 seconds and easily operated by pressing a footswitch. To reduce undesired lateral vibration, flexure beams were designed in the piezo drill to guide and constrain the motion of micropipette only along the oocyte penetration direction. The driving signals were optimized by removing resonant frequencies with a bandpass filter. Experiments were performed on hamster and human oocytes by penetration with and without the piezo drill. For hamster oocytes, evaluation metrics included oocyte deformation and survival rate of penetrated oocytes after 12 hours' incubation. For human oocytes, oocyte deformation and aspirated cytoplasm volume were quantitatively evaluated.

CONCLUSIONS: The developed new piezo drill decreased hamster oocyte deformation from over 50 μm to around 5 μm, and increased the survival rate of the hamster oocytes after penetration to 92.5% (vs. 77.5% without piezo drill and 95% for the control group). Tests on human oocytes revealed that the piezo drill reduced human oocyte deformation by 10 times and broke oolemma without aspirating any cytoplasm (vs. >2,000 μm^3 aspirated cytoplasm without piezo drill), with 100% success rate in oocyte penetration. The use of the new piezo drill in ICSI can potentially reduce oocyte damage by reducing oocyte deformation (thus stress) and minimizing disturbance to the cytoplasm in the oocyte. Clinical trials are ongoing to quantify its benefit in improving fertilization rate, blastocyst rate and embryo quality.

CREATION OF A NOVEL INFLATABLE VAGINAL STENT FOR MCINDOE VAGINOPLASTY. Phillip A. Romanski, MD, Pietro Bortoletto, MD, Samantha Pfeifer, M.D. Weill Medical College of Cornell University, New York, NY.

OBJECTIVE: To develop a novel inflatable vaginal stent for use in McIndoe vaginoplasty that can be constructed using standard operating room (OR) supplies.

METHODOLOGY: A McIndoe vaginoplasty is a surgical procedure that is performed to create a neovagina in patients with complete or segmental vaginal agenesis. A cavity is dissected to form the neovagina, and a tissue graft is placed. A stent is then delicately inserted into the cavity to keep the graft in place and promote graft adherence to the dissected space.

Traditionally, a vaginal stent may be created in the OR by placing surgical sponges inside a condom. However, many ORs have restrictions on equipment that can be brought into the OR, as well as restrictions against leaving non-radio-opaque equipment "in" the patient. This device fills the need for a stent that is compliant with OR procedures and is radio-opaque, functional, and can be used for patients with and without a functional uterus. The device is modelled after an effective inflatable vaginal stent that was previously commercially available, but is no longer produced.

An inflatable vaginal stent has multiple advantages compared to a rigid dilator in that it 1) is deflatable so that it does not cause trauma to the delicate tissue graft during insertion, removal, or repositioning; 2) is firm enough to press the tissue graft against the dissected vaginal space, but is soft enough to decrease the risk of pressure necrosis or urethral damage; and 3) has a drainage port to prevent the build-up of fluid that could interfere with tissue healing.

We have developed an inflatable vaginal stent that incorporates all of these unique properties and can be easily constructed using sterile OR supplies. The construction of this device requires: a silicone Foley catheter, sterile foam sponges from a vaginal prep kit, a sterile radio-opaque sponge, a sterile vaginal ultrasound probe cover, a 60cc catheter tip syringe, a long Kelly, a ruler, scissors, 0-vicryl suture, and sterile gloves.

Once inserted, the stent can be left in place for 5-7 days post-operatively, during the critical time of graft adherence. It can then be deflated and gently removed to prevent disruption or trauma to the tissue graft. For those with segmental vaginal agenesis, the Foley may be advanced into the uterus and balloon inflated to further stabilize the utero-vaginal anastomosis.

CONCLUSIONS: Our novel inflatable vaginal stent is useful to surgeons performing a McIndoe vaginoplasty for vaginal agenesis with or without a uterus because it is compliant with OR procedures, as it is constructed from supplies that are accessible in most OR settings. Moreover, it is radio-opaque, adjustable in size, and effective in applying circumferential pressure for graft adherence. We prefer this inflatable vaginal stent to a rigid dilator in the first week of tissue healing to allow for easy insertion and removal of the stent without disrupting the tissue graft, to help prevent tissue necrosis, and to provide a fluid drainage port during graft adherence. We recommend this device as an ideal option for surgeons to consider when performing a McIndoe vaginoplasty.

OHVIRA: FERTILITY SPARING SINGLE-STAGE SURGICAL MANAGEMENT. Abigail L. Bernard, MD,[1] Vaishnavi Purusothaman, MD, MA,[2] Linnea R. Goodman, MD.[1] [1]University of North Carolina, Raleigh, NC; [2]University of North Carolina, Chapel Hill, NC.

OBJECTIVE: Obstructed hemivagina and ipsilateral renal anomaly, or OHVIRA, is a rare, obstructive Mullerian duct anomaly comprised classically of the triad of an obstructed hemivagina, ipsilateral renal agenesis, and uterine didelphys. This video is a review of the background, diagnostic imaging, and surgical management of this condition, as well as video footage of the fertility sparing, single-stage technique performed at a university hospital.

METHODOLOGY: Single-stage vaginoplasty was started with a physical exam displaying a fluctuant vaginal mass arising from the right side wall of the vagina. Next, a syringe was used to aspirate the contents of this mass to confirm that this was in fact the hematocolpos as suspected. Once confirmed, electrocautery was used to incise the mass to create an opening large enough to drain the hematometra and then electrocautery was used to extend the incision caudally. Digital palpation was done to assess the extent of the longitudinal vaginal septum and the position of the right cervix. Next, septum transection with the LigaSure™ device was achieved. As resection continued, the cervix on the right was able to be visualized. The use of bipolar cautery allowed the surgeons to excise the vaginal septum with everted edges to minimize the risk of re-adhesion or fusion. The eversion was accomplished without requiring any additional sutures, which improved the ease of the procedure and decreased operative time.

CONCLUSIONS: The OHVIRA diagnosis requires a high index of suspicion by the clinician. Single-stage surgical vaginoplasty should be employed when technically feasible, but a two-stage procedure can be done when infection or anatomic challenges are present. Hemi-hysterectomy should be avoided when possible, as ipsilateral fertility can recover once the obstruction is removed.

VAGINAL ULTRASOUND PROBE FOR ABDOMINAL OOCYTE RETRIEVAL: DEMONSTRATION OF A NOVEL APPROACH.

Jacquelyn Shaw, MD,[1] Frederick L. Licciardi, M.D.[2] [1]NYU Langone Prelude Fertility Center, New York, NY; [2]NYU Langone Health, New York, NY.

OBJECTIVE: The efficacy and safety of use of the transvaginal ultrasound probe for percutaneous abdominal oocyte retrieval in patients with limited vaginal access has been established in prior studies,[1-2] but the technique has not been demonstrated widely.

METHODOLOGY: This video uses a patient case to explain and demonstrate the technique of percutaneous transabdominal oocyte retrieval with the transvaginal ultrasound probe in a patient without vaginal access to her ovaries. Patient consent was obtained prior to creation of the video.

CONCLUSIONS: Abdominal oocyte aspiration using a high frequency transvaginal ultrasound probe should be considered in patients with ovaries inaccessible vaginally. It is safe, effective and an easily skill to acquire.

SURGICAL MANAGEMENT OF ADENOMYOSIS: LAPAROSCOPIC ADENOMYOSIS RESECTION.

Kaia Schwartz, MD,[1] Elliott G. Richards, MD,[2] Tommaso Falcone, M.D.[3] [1]Clevleand Clinic Foundation, CLEVELAND, OH; [2]Cleveland Clinic, Cleveland, OH; [3]Cleveland Clinic, cleveland, OH.

OBJECTIVE: To demonstrate the steps required for surgical removal of diffuse adenomyosis. in a symptomatic woman desiring future fertility.

METHODOLOGY: De-identified video footage was obtained and edited to reflect key components of the procedure. Preoperative imaging is a critical in determining the surgical approach and for setting expectations for the surgical outcome. In this case preoperative imaging revealed diffuse adenomyosis of the posterior wall extending from endometrium to serosa. This case was performed by laparoscopic assisted technique. Five mm trocars were placed in the typical fashion. A suprapubic gel-point access platform was used to extract lesions and to aid in suturing areas that required extensive re-approximation.

At surgery no pseudo-capsule exists so tissue planes are arbitrary. Typically, a sub-serosal dissection is the upper border and continued laterally until somewhat normal myometrium is identified. This border is not well defined. The dissection is directed towards the endometrium which entry is unavoidable. Lesions are often excised is pieces as there is typically no cohesive tissue. Entry into the endometrial cavity identifies the lower border of excision. Closure without tension requires multiple layers.

CONCLUSIONS: Surgery for adenomyosis requires careful preoperative planning. Excision of diffuse adenomyosis often results in entry into the endometrial cavity. Closure of extensive defects is required.

DO'S AND DON'TS FOR SURGICAL MANAGEMENT OF TYPE 2 UTERINE FIBROIDS IN THE ART PATIENT.

Salomeh M. Salari, MD MS,[1] Rhea Chattopadhyay, MD,[2] Rebecca Flyckt, MD.[2] [1]University Hospitals Cleveland Medical Center, Cleveland, OH; [2]University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH.

OBJECTIVE: Fibroids may impact fertility via multiple proposed mechanisms. Submucosal fibroids in particular may contribute to infertility, recurrent pregnancy loss, and lower implantation rates with embryo transfer. The surgical approach to managing submucosal myomas is guided by FIGO staging. Although hysteroscopic myomectomy may be an appealing option, incomplete resection is a risk with type 2 myomas. The objective of this video is to describe the effectiveness of laparoscopic myomectomy for complete surgical resection of type 2 fibroids in assisted reproductive technology (ART) patients.

METHODOLOGY: We present here a case-based review of an infertility patient seen for second opinion. This patient had undergone treatment with oral fertility medications combined with intrauterine insemination followed by multiple IVF treatments. During the course of her prior IVF cycles, she underwent hysteroscopic myomectomy x 2, with a hysteroscopic resection procedure for a single fibroid prior to each embryo transfer. She was diagnosed with recurrent implantation failure and subsequently underwent prenatal genetic testing for aneuploidy (PGTA), with an endometrial receptivity assay (ERA) as the planned next step. Our evaluation demonstrated residual type 2 myoma with $< 20\%$ endometrial cavity involvement and laparoscopic treatment of this myoma resulted in spontaneous pregnancy.

In this video, we discuss the FIGO classifications of fibroids which were developed based on location and cavity involvement. We review laparoscopic versus hysteroscopic surgical approaches. Though hysteroscopy is desirable due to lack of invasiveness, cost, shorter operating times and faster return to attempting to conceive, in the case of type 2 fibroids, a laparoscopic approach is often the most appropriate. There is no evidence to support shaving "the tip of the iceberg" hysteroscopically, as the intramural component will continue to encroach into the endometrial cavity until it is completely removed.

CONCLUSIONS: Submucosal fibroids can both distort and invade into the endometrial cavity, thus contributing to infertility and failed embryo transfer with assisted reproductive technologies (ART). When type 2 fibroids are incompletely removed, embryo transfer may not be successful. By fully removing type 2 fibroids laparoscopically, the endometrial cavity is optimized for successful pregnancy implantation either by spontaneous conception or ART.

SURGICAL MANAGEMENT OF PROXIMAL TUBAL OCCLUSION: A VIDEO GUIDE FOR CORNUAL CANNULATION.

Kathryn D. Coyne, MD,[1] Channing Burks, MD,[2] Rebecca Flyckt, MD,[3] James H. Liu, M.D.[4] [1]University Hospitals Cleveland Medical Center, OH; [2]University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH; [3]UH Fertility Center, REI Division; [4]UH MacDonald Women's Hospital, Cleveland, OH.

OBJECTIVE: The aim of this instructional video is to help further educate Reproductive Endocrinology and Infertility (REI) physicians on how to assemble cornual cannulation equipment and as well as how to perform cornual re-cannulation surgery for tubal factor infertility patients with proximal tubal occlusion.

METHODOLOGY: The video includes a step by step instruction for the assembly of a hysteroscopic catheterization system for cornual cannulation. This is followed by a demonstration of how to perform a cornual tubal re-cannulation using this cannulation system and includes both hysteroscopic and laparoscopic views.

CONCLUSIONS: Due to the fact that fertility coverage is not mandated in the majority of states across the United States, we feel it is important to provide surgical alternatives to infertility patients affected by tubal factor when applicable, such as patients with proximal tubal occlusion. The goal of this video is to educate REI physicians on how to surgically manage proximal tubal occlusion with cornual cannulation.

ACTIVE TREATMENT OR NO TREATMENT (ACTOR-NOT) FOR PERSISTING PREGNANCY OF UNKNOWN LOCATION; A RANDOMIZED CLINICAL TRIAL. Kurt T. Barnhart, MD, MSCE,[1] Karl R. Hansen, MD PhD,[2] Mary D. Stephenson, M.D., M.Sc.,[3] Anne Z. Steiner, MD, MPH,[4] Emily S. Jungheim, MD, MSCI,[5] Kathleen Hoeger, M.D.,[6] Stephen A. Krawetz, PhD,[7] Suneeta Senapati, MD, MSCE,[8] Marcelle I. Cedars, MD,[9] Hao Huang, md, MPH,[10] Esther Eisenberg, MD MPH,[11] Nanette Santoro, MD,[12] Heping Zhang, PhD,[10] and ASRM Authors group [1]University of Pennsylvania, Perelman School Of Medicine, Philadelphia, PA; [2]University of Oklahoma College of Medicine, Oklahoma City, OK; [3]University of Illinois at Chicago, Chicago, IL; [4]Duke University, Durham, NC; [5]Northwestern Feinberg School of Medicine, Chicago, IL; [6]University of Rochester, Rochester, NY; [7]Wayne State University School of Medicine, Detroit, MI; [8]Department of Obstetrics and Gynecology, University of Pennsylvania, Philadelphia, PA; [9]University of California San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [10]Yale University School of Public Health, New Haven, CT; [11]NIH, Bethesda, MD; [12]University of Colorado School of Medicine, Aurora, CO.

OBJECTIVE: Women in early gestation without a pregnancy visualized on ultrasound (pregnancy of unknown location, (PUL)) and serial hCG values consistent with a nonviable gestation are at high risk for ectopic pregnancy. There is no consensus regarding optimal management of PUL among the possibilities of expectant management, uterine evacuation, or administration of methotrexate. The goal of this trial was to determine if active management options are superior to expectant management, and to determine if the two active management strategies are non-inferior.

DESIGN: Multi-center randomized clinical trial conducted by the Reproductive Medicine Network (RMN)

MATERIALS AND METHODS: Women with a persistent PUL were randomized 1:2 between expectant management and active management, and 1:1 between two active management strategies; a) uterine evacuation followed by methotrexate if needed or b) empiric methotrexate. The primary outcome of the trial was successful resolution of the gestation without change from initial treatment strategy. Secondary outcomes included: number and type of unscheduled interventions, time until resolution, adverse events, patient acceptability, and preference.

RESULTS: Of 255 randomized women 253 competed the trial. Women treated with active management had a significantly higher percentage of successful resolution (Rate Ratio [RR] 1.43 (95% CI: 1.04 – 1.96) intention to treat (ITT), RR 1.64 (1.39 – 1.94) per treatment (PT)) and 1.99 (1.35 to 2.92) Instrumental variable adjustment for potential bias due to cross over. There was a lower rate of unscheduled surgery RR 0.43 (0.25 – 0.74) ITT and RR 0.21 (0.11 – 0.55) PT). The two active treatment strategies were non-inferior (difference 6.6%, [-6.0% to 19.2%] ITT and 2.9%, [-4.4% to 10.2% PT]. Time to resolution was 8.1 days shorter with uterine evacuation compared to methotrexate in the per protocol population. All strategies were safe and were rated with high acceptability and satisfaction. One women was diagnosed with a viable gestation after randomization to expectant management. Women expressed a stronger preference for expectant management.

CONCLUSIONS: A greater percentage of women presenting with a persistent PUL achieved uneventful resolution with active management compared to expectant management. Active management resulted in at least a 50% reduction in unscheduled interventions. Active management strategies were similar with the exception that uterine evacuation resulted in a shorter time to resolution. Acceptability and safety of treatment were high for all strategies, but subjects expressed preference for expectant management.

SINGLE CELL TIPSEQ, A NEW METHOD TO MAP LINE-1 INSERTIONS, PROVIDES INFORMATION ABOUT SUB CHROMOSOMAL GENETIC VARIATION IN HUMAN EMBRYOS. Fabiana B. Kohlrausch, PhD,[1] Fang Wang, PhD,[2] Wilson McKerrow, PhD,[3] David Fenyo, Ph.D.,[3] Jef D. Boeke, PhD,[3] David L. Keefe, MD[4] [1]Fluminense Federal University, Niterói, Brazil; [2]NYU Langone Health, New York, NY; [3]New York University, New York, NY; [4]NYU Grossman School of Medicine, New York, NY.

OBJECTIVE: One third of euploid embryo transfers fail, implicating subchromosomal genetic variation. Retrotransposons play important roles during early development, when they are transiently de repressed during epigenetic re programming. Long interspersed element-1 (L-1), the only autonomous retrotransposon in humans, comprises 17% of the human genome. L-1's repetitive nature limits the utility of conventional assays-positional information is necessary to establish the novelty of L-1 insertions. Recently we developed Single Cell Transposon Insertion Profiling by Sequencing (scTIPseq) to characterize L-1 insertions in individual cells (McKerrow et al, Phil Trans R Soc Lond Bio, 2020). To map L-1 insertions during early human development, we applied scTIPseq to characterize L-1 insertions in human embryos.

DESIGN: Observational study.

MATERIALS AND METHODS: scTIPseq mapped L-1 insertions in 16 human blastocyst stage embryos (6 euploid, 5 trisomic, 5 monosomic) obtained from consenting couples undergoing IVF at NYU Fertility Center. scTIPseq data analysis used TIPseqHunter custom bioinformatics program. This study was reviewed and approved by the NYU IRB.

RESULTS: 18 new and unique insertions were observed in normal (7), trisomic (7), and monosomic (4) embryos. No insertions were located in exons or immediately upstream of genes. Most new and unique insertions were intergenic. Insertions were located in introns of *HS6ST3*, *USH2A, PLEKHG1*, *CD226*, *MET*, *TTLL5*, *MED28*, *SCFD2*, and *EYE*. Just three embryos did not exhibit new and unique insertions. The location or number of novel insertions did not differ by ploidy status.

CONCLUSIONS: Novel L-1 insertions can be detected in human embryos by scTIPseq. The insertions did not differ between euploid and aneuploid embryos, suggesting they are not merely a marker of aneuploidy. Rather, scTIPseq provides novel information about sub-chromosomal structural variation in human embryos. Several studies have measured L-1 expression at different stages of development in mice, but this study for the first time reports new and unique L-1 insertions in human embryos. The intronic L1 insertions do not specifically disrupt genes, as has been reported in some de novo monogenic diseases, but we cannot rule out the possibility that they may affect splicing and/or gene expression during early embryo development.

HIGHER RISK OF PERSISTENT METABOLIC SYNDROME (METSYN) IN BLACK WOMEN WITH POLYCYSTIC OVARY SYNDROME (PCOS): A LONGITUDINAL STUDY. IRIS TIENLYNN Lee, MD, Julia M. Vresilovic, MRA, BS, Maryam Irfan, BS, Robert Gallop, PhD, Anuja Dokras, MD PhD UNIVERSITY OF PENNSYLVANIA HEALTH SYSTEM, PHILADELPHIA, PA.

OBJECTIVE: To evaluate the impact of race on the longitudinal risk of MetSyn among women with PCOS

DESIGN: Prospective cohort study

MATERIALS AND METHODS: Women with PCOS based on Rotterdam criteria with $\geq$2 visits over at least one year seen between 2008- 2019 were included. MetSyn was defined as at least three of the five criteria shown in Table. Presence or absence of MetSyn was determined at each visit. Data were collected on demographics, PCOS work-up, medical history, use of PCOS-specific medications (oral contraceptives, metformin, spironolactone). Two-tailed *t*-tests or rank sum tests were used for continuous variables and chi-square tests for categorical variables. Mixed-effects models were

used for longitudinal data to accommodate repeated measures per person, the varying of amount of data and spacing between assessments per person and examine the impact of race and medication.

RESULTS: 269 women with well-defined PCOS (94.8% with hyperandrogenic phenotype) were followed for a mean 5.8±2.7 visits over 5.4±2.6 years with 1.3±0.7 years between visits. During the study period, the overall prevalence of MetSyn was 31.8% in White women (n=188) and 49.4% in Black women (n=81, $p < 0.01$) and increased with time. This difference in MetSyn remained significant when including only women < 30 years (23.0% in White, 48.5% in Blacks, $p < 0.01$). Use of medications did not significantly interact with race: prevalence of MetSyn was 33.1% in White women compared to 51.2% in Black women not taking medications for PCOS ($p < 0.01$). Among women taking medications, 29.4% of White women and 43.2% of Black women had MetSyn ($p = 0.01$). Absence of Metsyn at a prior visit was associated with a higher prevalence of MetSyn at the next visit in Black woman when compared to White women (31.6% versus 13.5%, $p < 0.01$), even when restricting to women <30years (30.5% versus 11.6%, $p < 0.01$). In contrast, both Black and White women with MetSyn at the prior visit had a similar rate of persistent MetSyn at the next visit (72.5% versus 69.8%, $p = 0.62$).

CONCLUSIONS: This is the first longitudinal study in prospectively identified women with PCOS demonstrating a higher persistent risk of MetSyn in Black women compared to White women, regardless of age or medication use. Our study highlights the importance of frequent follow-up visits, starting at a young age, in this high risk population to allow for early identification of modifiable cardiovascular disease risk factors.

Data at first visit

	White n=188	Black n=81	p value
Age (Years±SD)	27.0 (6.58)	27.2(6.1.6)	0.73
Criteria			
BMI ≥30	48.3%	79.2%	<0.001
BP≥130/85mmHg or hypertension	41.0%	52.6%	0.09
Triglycerides ≥150mg/dl	22.6%	6.3%	0.0016
HDL≤50mg/dl	38.9%	58.2%	0.0041
Glucose≥100mg/dl or diabetes	19.5%	40.8%	0.0005
Prevalence of Metsyn	30.9%	44.4%	0.03

COST EFFECTIVE PROTOCOL WITH LETROZOLE AND 3 DOSES OF GONADOTROPIN COMBINATION AS AN ALTERNATIVE TO CONTINUOUS GONADOTROPIN FOR OVULATION INDUCTION FOR IUI IN CLOMIPHENE CITRATE RESISTANT PCOS PATIENTS - A RCT.

Suvasmita Saha, MD (G&O), Hasibul Hasan Shirazee, MD(G&O) Post Doc Fellow Reproductive Medicine, Fellow in Reproductive medicine, Kolkata, India.

OBJECTIVE: Clomiphene citrate (CC) is the primary drug of choice for ovulation induction in PCOS but resistance to ovarian stimulation or stunted follicular growth is a frequent observation with CC. Inappropriate pregnancy rate & inadequate pregnancy outcomes are also observed with CC. The next approach of ovulation induction in CC resistance cases is using continuous Gonadotropin but it has many disadvantages such as high treatment cost, multi follicular development leading to multiple pregnancy, OHSS and frequent shifting of cycle to IVF-ET treatment. Letrozole induces folliculogenesis by releasing H-P axis from tonic inhibitory effect of estrogen & by augmenting gonadotropin secretion. It helps in follicular development without any adverse effect on the peripheral estrogen sensitive tissues. Adding few ampoules of gonadotropin at interval along with letrozole increases FSH at follicular receptor level & produces good quality oocyte. The purpose of the study was:

-To evaluate the efficacy of combined Letrozole & 3 doses of gonadotropin in CC resistant IUI cases.

-To compare the efficacy and cost effectivity of this protocol with continuous gonadotropin therapy.

DESIGN: This RCT was conducted in a tertiary infertility care centre from July 2017 to January 2019.

MATERIALS AND METHODS: Total 108 anovulatory PCO women in the age group 20 to 36 years who had previous ≥3 failed treatment cycles with CC were randomly divided into Group A (Letrozole plus 3 doses gonadotropin group) & Group B (Continuous gonadotropin group) comprising 54 patients in each group. 2 blood samples from all the patients on Day_2 of cycle and on the Day of hCG triggering were analyzed for endocrine profile. Patients in gr A were studied for total 96 cycles (n = 96) who received tab Letrozole 5 mg daily from D_2 to D_6 and injection U-FSH- HP (75 IU) on D_2, D_5 and D_8 of cycle. Patients in gr B were studied for total 84 cycles (n = 84) & received continuous gonadotropin (U-FSH- HP, 75 IU) starting from D_2 of cycle. Folliculometry was started from D_9 of cycle & ovulation triggering was done by hCG when dominant follicle reached ≥ 18 mm. Single IUI was performed with documented ovulation. Both groups were evaluated in respect of terminal endocrinological profile, number of follicles, ovulation rate, pregnancy rate & outcome, adverse effects & cost effectivity.

RESULTS: Demographic & baseline endocrine profile was comparable. In Gr A & B, mean no of follicles and average terminal estradiol level were 1.8 ±0.6 Vs 4.2 ± 0.8 (p< 0.05) and 266 ± 46 Vs 756 ± 84 pg (p< 0.001) respectively. Ovulation rate and pregnancy rate in both groups were 83.3% Vs 90.5% (p = 0.157) and 18.8% Vs 20.2% (p = 0.774) in Gr A & B respectively. In Gr B, 3 patients (3.6%) developed OHSS and 4 patients (4.8%) needed shifting of cycle to IVF-ET whereas no such incidents happened in Gr A. The average cost per cycle was significantly less in Gr A than Gr B.

CONCLUSIONS: The combined therapy with Letrozole and 3 doses of gonadotropin is a cost effective treatment protocol in CC resistant PCOS patient before proceeding to costly continuous gonadotropin therapy without any significant difference in ovulation and pregnancy rate.

O-269 10:40 AM Wednesday, October 21, 2020

NOVEL ANTI-MULLERIAN HORMONE RECEPTOR 2 BINDING PEPTIDE (AMHR2BP) STALLS OVARIAN FOLLICLE DEVELOPMENT IN A MOUSE MODEL.

Laura Detti, MD,[1] Ghassan M. Saed, PhD[2] [1]Cleveland Clinic, Cleveland, OH; [2]Wayne State University School of Medicine, Detroit, MI.

OBJECTIVE: Anti-Müllerian hormone (AMH) inhibits hormone production, and ovarian cortex follicle development in *in vitro,* and *in vivo*, ovarian cortex, and in luteinized granulosa cells (GCs) [1-3]. We showed a novel binding peptide to AMH receptor 2 (AMHR2BP) to inhibit GCs replication and function [4]. We sought to investigate whether AMHR2BP can inhibit follicular development in vivo.

DESIGN: Translational

MATERIALS AND METHODS: 24 18-weeks old C57BL female mice were assigned to four treatments: Baseline (euthanized just prior to the experiment), AMHR2BP (AMHR2-BP, 50 μg /day), rAMH (recombinant AMH, 1.8 μg /day), and placebo group (normal saline), via intraperitoneal pumps. Mice were euthanized 3 weeks after pump placement and the ovaries were explanted for histological analysis. Primordial (PDF), primary (PRF), secondary (SEF), and tertiary follicles (TEF) were esteemed. In addition, PCR expression of Ki67 (cell proliferation), Caspase3 (apoptosis) and Inhibin B were measured. We used Kruskall-Wallis's test for comparison of medians between groups (SPSS; p<0.05).

RESULTS: AMHR2BP performed similarly to rAMH. Compared with the Baseline (18 weeks' age), the AMHR2BP group showed increased SEFs, and decreased PRFs while PDFs and TEFs were unchanged. Compared with Placebo (21 weeks' age), the AMHR2BP group showed increased PDFs, while PRFs, and TEFs were significantly decreased, and SEFs were unchanged. AMHR2BP also caused a similar Ki67 and Caspase3 expression, and reduced Inhibin B. The table reports the individual groups' data.

CONCLUSIONS: Similarly to rAMH, AMHR2BP treatment for 3 weeks (equivalent to 3 menstrual cycles in the BLC67 mouse) minimized progression of follicular development, thus preserving the ovarian follicle number. In addition, it decreased hormone production, cell replication and apoptosis at cellular level. AMHR2BP could be used to inhibit age-linked loss of ovarian follicle reserve.

Table: Ovarian cortex concentration of PDF, PRF, SEF, TRF, AMH, Ki67, and Caspase3, in the four groups.

Variable	Baseline Median (Q1, Q3)	Placebo Group Median (Q1, Q3)	rAMH Group Median (Q1, Q3)	AMHR2BP Group Median (Q1, Q3)	p-value
PDF/mm^3	1195 (1191, 1248)	614 (538, 705)	1182 (1095, 1248)	1012 (916, 1134)	0.011
PRF/mm^3	788 (670, 817)	1165 (1152, 1176)	514 (497, 548)	383 (306, 533)	0.016
SEF/mm^3	970 (968, 1061)	1613 (1528, 1664)	1144 (1119, 1300)	1371 (852, 1662)	ns
TEF/mm^3	583 (579, 606)	1082 (1076, 1119)	871 (808, 890)	587 (519, 707)	0.045
Inhibin B (pg/μg RNA)	34.53 (34.53, 34.54)	48.41 (47.36, 49.47)	4.07 (3.86, 4.27)	2.22 (1.83, 2.60)	0.001
Ki67 (pg/μg RNA)	22.84 (20.49, 25.21)	69.26 (67.40, 71.12)	8.05 (7.20, 8.89)	5.90 (5.77, 6.02)	0.005
Caspase3 (pg/μg RNA)	1.31 (1.27, 1.36)	3.10 (3.00, 3.20)	0.46 (0.43, 0.50)	0.32 (0.31, 0.33)	0.004

HUMAN PRE-IMPLANTATION EMBRYOS ARE PERMISSIVE TO SARS-COV-2 ENTRY.

Manuel Viotti, PhD,[1] Mauricio Montano, BA,[2] Andrea Victor, MS,[3] Darren K. Griffin, DSc,[4] Tommy Duong, BS,[5] Nathalie Bolduc, PhD,[5] Andrew Farmer, PhD,[5] Isabel Gonzalez, PhD,[3] Frank Barnes, PhD,[3] Christo Zouves, MD,[3] Warner C. Greene, MD, PhD[2] [1]Zouves Foundation for Reproductive Medicine, Foster City, CA; [2]Gladstone Institutes, University of California San Francisco, San Francisco, CA; [3]Zouves Fertility Center, Foster City, CA; [4]University of Kent, Cabterbury, United Kingdom,; [5]Takara Bio USA, Mountain View, CA.

OBJECTIVE: To determine whether human pre-implantation embryos have the potential to be infected by SARS-CoV-2, the virus responsible for COVID-19.

DESIGN: Assessment of expression levels of SARS-CoV-2 entry mediators in human embryo biopsies by RNAseq analysis, and infection of cultured embryos with SARS-CoV-2 Spike glycoprotein pseudotyped reporter virions expressing green fluorescent protein (GFP).

MATERIALS AND METHODS: Trophectoderm biopsies from blastocyst-stage embryos (n=24) were processed for RNAseq using a commercial kit and sequenced; results were analyzed for expression of factors implicated in SARS-CoV-2 cellular entry. For viral infection experiments, blastocyst-stage embryos (n=94) were hatched from zonas mechanically, and infected by spinoculation with GFP-reporter virions pseudotyped with the SARS-CoV-2 Spike glycoprotein (required for SARS-CoV-2 entry). Embryos were subsequently monitored for fluorescence at 24-48 hours post-infection. Various control conditions were used as specified in the 'results' section. A mixed population of euploid, aneuploid, and untested embryos used in the study were from IVF treatment, donated to research by signed informed consent. The project was approved by an Institutional Review Board.

RESULTS: Cells collected from blastocyst-stage embryos robustly expressed the canonical SARS-CoV-2 entry receptor *ACE2* and the putative activator protease *TMPRSS2*, in addition to other reported entry factors. Embryos exposed to reporter virions pseudotyped with SARS-CoV-2 Spike glycoprotein displayed robust GFP signal, often in numerous cells with cytoplasmic localization. Specificity was confirmed by the absences of fluorescence in embryos treated with virions lacking the Spike glycoprotein ("bald" virus), or when embryos were spinoculated with media alone in the absence of virus. Embryos exposed to Spike glycoprotein-positive reporter virus in the presence of neutralizing anti Spike- or anti-ACE2-blocking antibodies exhibited negligible GFP signal, while control monoclonal IgG antibody-treated embryos maintained GFP expression. These results implicated the canonical Spike-ACE2 axis in the viral entry. Lastly, embryos exposed to reporter virions pseudotyped with Spike glycoprotein of SARS-CoV-1 (which also enters cells via ACE2) displayed GFP fluorescence, while embryos exposed to reporter viruses pseudotyped with Spike glycoprotein of MERS (which utilizes Dipeptidyl Peptidase IV (DPP4) instead of ACE2) resulted in no fluorescence.

CONCLUSIONS: Our results indicate that cells present in pre-implantation embryos are permissive to the canonical Spike-ACE2 viral entry mechanism utilized by SARS-CoV-2. These results encourage further investigation into the potential of SARS-CoV-2 infection in human embryos and may have wider implications in natural conception and ART practice.

P-930 3:30 PM Wednesday, October 21, 2020

EFFICACY AND SAFETY OF LINZAGOLIX (LGX) FOR THE TREATMENT OF HEAVY MENSTRUAL BLEEDING (HMB) DUE TO UTERINE FIBROIDS (UF): RESULTS FROM TWO PHASE 3 RANDOMIZED CLINICAL TRIALS. Elizabeth A. Stewart, MD,[1] Hugh S. Taylor, MD,[2] Robert N. Taylor, MD, PhD,[3] Jacques Donnez, PhD, MD,[4] Elke Bestel, MD,[5] Jean-Pierre Gotteland, PhD,[5] Andrew Humberstone, PhD,[5] Elizabeth Garner, MD, MPH.[6] [1]Mayo Clinic Department of OB/GYN Reproductive Endocrinology and Infertility, Rochester, MN; [2]Yale University School of Medicine, New Haven, CT; [3]University of Utah Health, Salt Lake City, UT; [4]Polyclinique Urbain V (ELSAN Group), Brussels, Belgium; [5]ObsEva SA, Plan-les-Ouates, Switzerland; [6]ObsEva Inc, Boston, MA.

OBJECTIVE: To assess the efficacy and safety of LGX, an oral GnRH receptor antagonist, administered with and without hormonal add-back therapy (ABT: 1 mg estradiol/0.5 mg norethindrone acetate), for the treatment of HMB and other symptoms of UF.

DESIGN: PRIMROSE 1 (USA, n=526) and PRIMROSE 2 (Europe and USA, n=511) are randomized, double-blind, placebo-controlled Phase 3 trials, with essentially identical design, investigating the efficacy and safety of LGX ± ABT once daily for 52 weeks. We report results up to 24-weeks for PRIMROSE 1 and up to 52-weeks for PRIMROSE 2.

MATERIALS AND METHODS: Participants had HMB (> 80 mL menstrual blood loss [MBL]/cycle) due to UF and excluded if they had significant risk of osteoporosis. Subjects were randomized to 1 of 5 treatments: placebo, LGX 100 mg, LGX 100 mg + ABT, LGX 200 mg, LGX 200 mg + ABT. PRIMROSE 2 subjects randomized to placebo or LGX 200 mg were crossed-over to 200 mg LGX + ABT after 24 weeks.

The primary efficacy endpoint was reduction in alkaline-hematin documented HMB to ≤ 80 mL MBL and a reduction of ≥ 50% at 24 weeks. Secondary endpoints included amenorrhea, time to reduced MBL/amenorrhea, days of uterine bleeding, hemoglobin, pain, uterine and fibroid volume and quality of life. Safety endpoints included bone mineral density (BMD) assessed centrally using Dual Energy X-ray Absorptiometry and adverse events (AE). Calcium/vitamin D were not provided nor recommended in the trials.

Individual active vs placebo efficacy comparisons were conducted using a 0.0125 significance level to account for multiplicity.

RESULTS: PRIMROSE 1 subjects had a mean age of 42 years and 63% were Black. The mean baseline MBL was 199 mL. HMB at week 24 was significantly ($p \leq 0.003$) reduced in all active treatment groups compared to placebo. Responder rates were 35, 56, 67, 71 and 75% in the placebo, 100 mg, 100 mg + ABT, 200 mg and 200 mg + ABT groups, respectively.

PRIMROSE 2 subjects had a mean age of 43 years and 5% were Black. The mean baseline MBL was 218 mL. HMB at week 24 was significantly ($p<0.001$) reduced in all active treatment groups compared to placebo. Responder rates were 29, 57, 77, 78 and 94% in the respective groups, and were maintained at 52 weeks.

In both trials, significant improvements compared to placebo were observed for key secondary endpoints, including pain and QoL, at week 24. Mean % loss in BMD ranged from 0–2% after 24 weeks in all active treatment groups except 200 mg LGX without ABT (3–4%). The rate of BMD loss slowed between weeks 24 and 52. The most common AE, hot flushes, were reported in 32–35% of subjects in the LGX 200 mg without ABT group and less than 15% in the other active treatment groups at week 24.

CONCLUSIONS: Once daily LGX 100 and 200 mg, both with or without ABT significantly improved HMB and other symptoms of uterine fibroids at 24 weeks and these improvements were maintained at 52 weeks. An effective GnRH antagonist treatment without hormonal ABT could be important for up to 50% of patients who may have contraindications to hormonal ABT. Limited BMD loss in the LGX 200 mg with ABT and LGX 100 mg without ABT arms suggests these dosing regimens could be suitable for longer-term treatment.

SUPPORT: The work was funded by ObsEva SA.

P-931 3:30 PM Wednesday, October 21, 2020

LINZAGOLIX MAY ADDRESS THE LONG-TERM TREATMENT NEEDS OF WOMEN WITH UTERINE FIBROIDS (UF) WHO HAVE CONTRAINDICATIONS TO HORMONAL ADD-BACK THERAPY (ABT): RESULTS FROM TWO PHASE 3 RANDOMIZED CLINICAL TRIALS. Linda D. Bradley, MD,[1] Erica E. Marsh, MD, MSCI, FACOG,[2] Elizabeth Garner, MD, MPH.[3] [1]Cleveland Clinic Cleveland, OH; [2]University of Michigan, Ann Arbor, MI; [3]ObsEva Inc, Boston, MA.

OBJECTIVE: GnRH antagonists comprise a new class of orally active medications that dose-dependently reduce estradiol (E2) levels, allowing partial suppression for symptom relief of estrogen-driven conditions without the bone (BMD) loss seen with full suppression. A GnRH antagonist developed using a full suppression dose that requires use of hormonal ABT was recently approved for the treatment of UF. Its labeling lists obesity, hypertension, and dyslipidemia as ABT contraindications associated with higher risks of thrombotic, stroke and cardiac events, which disproportionately affect black women. Given the propensity of black women to develop severe UF, availability of a GnRH antagonist that can be used long-term without ABT is important.

Linzagolix (LGX) is a GnRH antagonist being developed for UF treatment. In addition to a high dose (200 mg) with ABT (1 mg E2/0.5 mg NETA), a low dose (100 mg) without (w/o) ABT is being assessed as a potential long-term treatment option for women with ABT contraindications.

DESIGN: PRIMROSE 1 (P1; US, n=526) and PRIMROSE 2 (P2; Europe/US, n=511) are randomized, double-blind, placebo-controlled Phase 3 trials investigating the efficacy and safety of LGX 100 mg and 200 mg once daily, with and w/o ABT. Here we present results from 24 weeks (wks) (P1 and P2) and 52 wks of treatment (P2) with the 100 mg dose w/o ABT.

MATERIALS AND METHODS: Inclusion criteria included having UF and Heavy Menstrual Bleeding (HMB) (> 80 mL menstrual blood loss [MBL]/cycle). The primary endpoint was HMB reduction defined as ≤ 80 mL MBL (by alkaline hematin method) and ≥ 50% reduction at wk 24. Secondary endpoints included amenorrhea, hemoglobin (Hb), pain, and quality of life (QoL). Safety endpoints included BMD and adverse events (AEs). Calcium/vitamin D were not provided.

RESULTS: The 100 mg w/o ABT dose was studied in 191 women, 64% (P1) and 4% (P2) of whom were black; results were similar across the studies. P1 and P2 responder rates (RRs) were statistically significantly better than pbo, at 56.4% (p=0.003) and 56.7% ($p \leq 0.001$), respectively, with an RR of 53.2% in P2 at wk 52. Amenorrhea rates were 34.0% ($p<0.001$) and 38.3% (p=0.009), respectively, and in P2 at 52 wks, 39.2%. MBL reduction was rapid, with ~60% mean % change from baseline within the first 4 wks of treatment. Statistically significant improvements in pain, Hb levels and QoL were also observed.

Week 24 mean % BMD changes were -2.0% [95% CI: -3.3, -0.8] and -2.1% [95% CI: -2.6, -1.5] for P1 and P2, respectively, with additional -0.3% mean change at wk 52 in P2. AEs occurring in > 5% of women were hot flushes (6.0%/14.1%; pbo: 6.7%/3.8%), headache (8.0%/4.0%; pbo 5.8%/5.7%), and anemia (1.0%/19.2%; pbo: 3.8%/10.5%) in P1 and P2, respectively. In the 100 mg w/o ABT arm, one drug-related serious AE (hypertension) (HTN) was observed.

CONCLUSIONS: LGX 100 mg w/o ABT significantly improved HMB and other UF symptoms, with low AE rates and minimal associated BMD loss that showed evidence of plateauing after 24 wks. This regimen has the unique potential to address the needs of black women with UF, many of whom have ABT contraindications.

P-932 3:30 PM Wednesday, October 21, 2020

IS COVID-19 A SEXUALLY TRANSMITTED DISEASE? A SYSTEMATIC REVIEW. Tomer Tur-Kaspa, Grace Hildebrand, BA, David Cohen, MD, Ilan Tur-Kaspa, MD. Institute for Human Reproduction (IHR) Chicago, IL.

OBJECTIVE: SARS-CoV-2 has led to a rapidly spreading COVID-19 global pandemic. From a public health perspective, it is crucial to determine if SARS-CoV-2 is sexually transmitted and its possible effects on human reproduction.

DESIGN: A systematic review of English publications to July 15, 2020, was conducted according to PRISMA guidelines. A search in PubMed, NIH iCite COVID-19 portfolio, Cochrane Library, and Google Scholar

databases was conducted for SARS-CoV-2 and COVID-19 with fertility, reproduction, testes, seminal, prostatic and vaginal fluids, and in cervical smears. The focus of this review is sexual transmission by vaginal intercourse. Fecal-oral transmission has been discussed by others.

MATERIALS AND METHODS: The search revealed 1,107 publications after removal of duplicates, which were reviewed for eligibility by examining titles and abstracts. 141 full-text articles were reviewed and evaluated by two independent reviewers. 57 studies were included in this review based on relevance, including 14 studies which tested the male and female reproductive tracts for SARS-CoV-2 RNA.

RESULTS: COVID-19 may have detrimental effects on male reproduction by inducing orchitis and decreased testosterone levels, sperm count, and motility. No study investigated its effects on female fertility. No epidemiological investigation to date has suggested COVID-19 is a sexually transmitted disease (STD). The lack of co-expression of ACE2 receptors and the TMPRSS2 modulatory protein, needed for SARS-CoV-2 cell entry, in testicular cells, sperm, and oocytes, supports rejection of the hypothesis that gametes transmit SARS-CoV-2. 14 molecular detection studies of SARS-CoV-2 RNA in the male reproductive tract (in testicular biopsies, seminal and prostatic fluids), and the lower female reproductive tract (in vaginal fluids and cervical smears) were published. Only 1 out of 7 studies found positive SARS-CoV-2 RNA tests in seminal fluid (6 out of 143 total men). Interestingly, all seminal fluids of 7 men that demonstrated orchitis-like symptoms, identified in 2 other studies, tested negative. All 28 prostatic fluids tested negative. Only 1 out of 11 postmortem testicular biopsies tested positive, but electron microscopy found no viral particles in the testes. In women, all 35 cervical smears tested negative and only 1 case report described a positive SARS-CoV-2 RNA result in vaginal fluid (1 out of 58 total women). All together, sexual transmission of SARS-CoV-2 has not been confirmed.

CONCLUSIONS: Based on the current world published information, COVID-19 is not an STD. This information is important for clinicians, guidelines for public health, FDA guidelines for gamete and tissue donor eligibility, and for fertility treatments. Universal precautions, practiced in clinical settings and in IVF laboratories to prevent transmission of known or unknown viral infections, are adequate and sufficient at this time. We suggest that recovered patients of COVID-19, especially those with infertility, should be evaluated for their ovarian and testicular function. Prospective longitudinal follow up studies are warranted.

SUPPORT: Supported in part by the Institute for Human Reproduction (IHR), Chicago, IL.

TRENDS IN FERTILITY PRACTICE DURING THE COVID-19 PANDEMIC: A GLOBAL SURVEY OF 299 CLINICS REPRESENTING 228,500 IVF CYCLES.

Justin Tan, MD, MPH,[1] Michael H. Dahan, M.D.,[2] Mustafa Baris Ata, M.D.,[3] Suresh Nair, MD,[4] Zeev Shoham, MD,[5] Seang Lin Tan, MD, MBA.[2] [1]University of British Columbia, Vancouver, BC, Canada; [2]Division of REI, McGill University and OriginElle Fertility Clinic and Women's Health Centre, Montreal, QC, Canada; [3]Koc University School of Medicine, Istanbul, Turkey; [4]Seed of Life Fertility & Women's Care Medical Centre, Singapore, Singapore; [5]Kaplan Medical Center, Rehovot, Israel.

OBJECTIVE: The COVID-19 pandemic is an unprecedented health crisis that has affected IVF practices globally and recommendations by local health authorities and reproductive medicine societies vary widely. Hence, the purpose of this study was to compare regional responses to the COVID-19 pandemic among infertility clinics and gain insight into the extent of practice modifications.

DESIGN: Self-administered online survey.

MATERIALS AND METHODS: Between March–June 2020, a multiple-choice 11-question survey was distributed through the IVF-worldwide online network (https://ivf-worldwide.com/survey/infertility-treatment-during-covid-19-pandemic.html). Responses were screened for completeness and duplicate clinics.

RESULTS: Responses from 299 clinics representing 228,500 IVF cycles were received, with respondents distributed across all 5 continents (34.8% Europe, 25.1% Asia, 18.1% South America, 15.4% North America, 5.3% Africa, and 1.3% Australia/New Zealand).

86.6% of respondents reported that their reproductive medicine society released pandemic-specific recommendations for a complete (53.8%) or partial shutdown (23.7%), which was higher than limits imposed by health authorities (32.5 and 19.7%, respectively). With respect to changes in IVF case volume, 76.6% and 80% of clinics reported a ≥75% reduction in fresh and frozen cycles, respectively, while 73.6% reported a ≥75% IUI case reduction. 3.7% of clinics reported no reduction in case volume.

Among clinics that stopped or reduced services, 69.5% cited government-mandate as a reason for closing, 31.1% due to employer concern for the health and safety of staff, 35.4% due to patient concerns, and 34% due to concerns regarding possible effects of COVID-19 on pregnancy. Lack of PPE was only acknowledged by 5.3% as a reason for closure. The most cited provisions planned prior to re-opening include increased hand sanitization (87%), spacing between appointments (86%), COVID symptom screening (84.3%), and temperature checks (71.6%). Among clinics that continued operations, the most cited provisions that were implemented included hand sanitizing (63%), symptom screening (60.4%), spacing between appointments (56.9%), and temperature checks (52.7%). Interestingly, 37% of clinics that stayed open did not report additional hand sanitization measures and 39.6% did not screen patients and staff for COVID symptoms.

Finally, 93.6% of respondents supported additional provisions for patient counselling including risk of cycle cancellation if a patient or provider tests positive for COVID-19 (85.6%) and possible risks of COVID-19 on adverse pregnancy outcomes (69.9%), miscarriage (67.2%), and fetal anomalies (58.9%).

CONCLUSIONS: COVID-19 resulted in a substantial reduction in IVF cycles, despite significant implications for such a delay on the probability of having a child. Data suggests that there remains room for improvement among clinics that remained open to decrease transmission using accepted procedures. Interestingly, clinics that stayed open were less aggressive at implementing protective provisions than clinics that closed.

PREDICTING CUMULATIVE LIVE BIRTH BEFORE THE FIRST AND SECOND COMPLETE CYCLE OF IVF: A POPULATION-BASED STUDY OF LINKED CYCLE DATA FROM 79,512 WOMEN.

David J. McLernon, PhD,[1] Edwin Amalraj Raja, MSc, PhD,[1] Valerie L. Baker, MD,[2] Kevin J. Doody, M.D.,[3] Paul C. Lin, M.D.,[4] David B. Seifer, MD,[5] Amy E. Sparks, PhD,[6] James P. Toner, Jr., MD, PhD,[7] Ethan Wantman, MBA,[8] Siladitya Bhattacharya, MD., FRCOG,[1] Bradley J. Van Voorhis, MD.[9] [1]University of Aberdeen, Aberdeen, United Kingdom; [2]Johns Hopkins Fertility Center, Lutherville, MD; [3]CARE Fertility, Bedford, TX; [4]Seattle Reproductive Medicine, Seattle, WA; [5]Yale University, Orange, CT; [6]University of Iowa Center for Advanced Reproductive Care, Iowa City, IA; [7]Emory University, Atlanta, GA; [8]Redshift Technologies, Inc., New York, NY; [9]University of Iowa, Iowa City, IA.

OBJECTIVE: To develop prediction models that can estimate the cumulative probability of live birth over three complete cycles of IVF.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: Linked fresh and frozen cycle data from women who underwent IVF (including intracytoplasmic sperm injection) in 2014-2016 were extracted from the Society for Assisted Reproductive Technology Clinic Outcome Reporting System database. Discrete time logistic regression was used to develop two models to predict cumulative live birth over three complete cycles of IVF. A complete cycle was defined as all fresh and frozen-thawed embryo transfers originating from one episode of ovarian stimulation. The pre-treatment model estimates the chance of live birth before starting treatment using couple characteristics, while the post-treatment model revises predictions using updated information before the second complete cycle. Potential predictors were female age, body mass index (BMI), serum anti-Mullerian hormone (AMH), previous full-term birth, male infertility, tubal factor, diminished ovarian reserve, polycystic ovaries, endometriosis, uterine factor and unexplained infertility. The post-treatment model also included number of eggs. Age, BMI and AMH were modelled as restricted cubic splines due to their non-linear relationship with probability of live birth. To assess optimism in model discrimination and calibration, internal validation using 300 bootstrap samples was done.

RESULTS: Of 79,512 women who underwent 103,270 complete cycles, 36,850 (46.3%) had a live birth from the first complete cycle, and cumulatively, 44,172 (55.6%) had a live birth over three complete cycles. Factors that were predictive of live birth in the pre-treatment model included female age (35 vs 25 years, adjusted odds ratio 0.62, 95% confidence interval 0.59 to 0.66), BMI (35 vs 25, 0.81, 0.77 to 0.84), previous full-term birth (1.13, 1.09 to 1.17), male infertility (1.21, 1.18 to 1.25), uterine factor infertility (0.85, 0.80 to 0.91), unexplained infertility (1.20, 1.15 to 1.25) and serum AMH (5 vs 2.4ng/mL, 1.23, 1.18 to 1.27). The post-treatment model included these factors as well as egg number (15 vs 9, 1.34, 1.25 to 1.44). The C-statistic for all models was between 0.70 and 0.72. Internal validation showed no over-optimism in discrimination or calibration performance. In a 36-year-old

woman with unexplained infertility, no previous live births, BMI of 25 and AMH of 2ng/L, our pre-treatment model predicts a 51% chance of live birth over her first complete cycle (82% over three complete cycles). If the first treatment is unsuccessful and the same woman starts a second cycle at 38 years old with AMH = 1.5ng/mL, our post treatment model estimates her chance of live birth at 21% after the second complete cycle and 40% over the second and third complete cycles.

CONCLUSIONS: These novel prediction models show accurate performance and are available to patients and clinics free of charge at sart.org. We anticipate that by providing individualised chances of success at two critical stages of IVF, they will help couples prepare emotionally and financially for IVF.

ENDOMETRIOSIS AND ADVERSE PREGNANCY OUTCOMES: A POPULATION-BASED COHORT STUDY. Maria P. Velez, MD, PhD, Leah Bahta, BSc, Jessica Pudwell, MSc, MPH, Rebecca J. Griffiths, BSc, Susan Brogly, PhD, MSc, Olga Bougie, MD, MPH. Queen's University, Kingston, ON, Canada.

OBJECTIVE: To assess the risk of adverse pregnancy outcomes in women with endometriosis.

DESIGN: Population-based retrospective cohort study using universal health care databases from Ontario, Canada.

MATERIALS AND METHODS: All singleton pregnancies with an estimated date of confinement between October 2006 and February 2014 were eligible for inclusion. Endometriosis was determined based on a surgical and/or medical diagnosis (defined as an in-hospital surgery with a diagnosis code of ICD9-617 or ICD10-N80 and/or two medical consults billed as ICD9-617). Log-binomial models were used to calculate risk ratios between endometriosis exposure and pregnancy outcomes. Models were adjusted for age, parity, BMI, smoking, income, rurality, medical history, history of infertility and use of Assisted Reproductive Technology (ART- IVF/ICSI).

RESULTS: A total of 19,099 women with and 768,350 women without a history of endometriosis were identified in the cohort. The mean age of endometriosis diagnosis was 26.6 years (± 5.8) with a mean time until pregnancy of 5.6 years (± 4.3). Compared to women without endometriosis, women with endometriosis were older at delivery [33.0 (± 4.9) vs. 30.0 (SD 5.6)], had a higher rate of infertility diagnosis (57% vs. 16%), history of fibroids (9% vs 2%), and use of ART (8% vs. 0.9%), all p-values <0.001. A higher proportion of women with endometriosis received antenatal care by an Obstetrician (79% vs 73%), with a greater mean number of visits coded as a high-risk prenatal assessment (1.1% vs. 0.08%), all p-values <0.001. In the adjusted models, endometriosis was associated with a greater risk of preterm birth, caesarean delivery, placenta previa, and other placental disorders and a reduced risk for induction and a small for gestational age baby (Table).

CONCLUSIONS: Endometriosis is associated with adverse pregnancy outcomes. Future studies should consider care plans and interventions to decrease the risk of adverse pregnancy outcomes in women with endometriosis.

TABLE. Pregnancy outcomes in women with history of endometriosis compared to women with no endometriosis

Outcome	Adjusted RR (95% CI)	p-value
Hypertensive Disorders of Pregnancy	0.98 (0.91 - 1.05)	0.55
Stillbirth	1.25 (0.98 - 1.58)	0.08
Small for Gestational Age (<10%)	0.92 (0.87 - 0.98)	0.01
Preterm Birth (< 37 weeks)	1.14 (1.07 - 1.21)	<0.001
Induction	0.97 (0.95 - 0.99)	0.01
C-Section	1.11 (1.08 - 1.14)	<0.001
Placenta Previa	1.82 (1.58 - 2.10)	<0.001
Placenta Abruption	1.23 (0.99 - 1.53)	0.06
Other Placental Disorders	1.94 (1.37 - 2.74)	<0.001
Postpartum Hemorrhage	1.03 (0.90 - 1.19)	0.64
Uterine Atony	0.86 (0.64 - 1.15)	0.30

DOES ENDOMETRIAL SCRATCH INJURY HELPS IN IMPROVING REPRODUCTIVE OUTCOMES OF INTRA-UTERINE INSEMINATION TREATMENT? A RANDOMISED CONTROLLED TRIAL. Navdeep Kaur Ghuman, MBBS, M.S. (Obstetrics and Gynaecology), DNB Obstetrics and Gynaecology), FMAS, Pratibha Singh, MBBS, MS(O&G), Sunil Raikar, MBBS, MS(O&G), Priya Singhmor, MBBS. All India institute of Medical Sciences, Jodhpur, Jodhpur, India.

OBJECTIVE: Current evidence suggests that endometrial injury improves clinical pregnancy rate while having no effect on miscarriages in women undergoing IVF/ICSI. However, there is no substantial evidence to advocate the use of endometrial injury to benefit the outcomes of IUI treatment. Additionally, there is no clear consensus about the ideal timing, underlying mechanism and optimum intensity of endometrial injury required. The study examines the effect of intentional endometrial injury/scratch in the early proliferative phase of stimulated cycle on reproductive outcomes (clinical and ongoing pregnancy rates and miscarriage occurrence) of intra-uterine insemination treatment (IUI).

DESIGN: This prospective, randomized control interventional study was conducted in a tertiary level teaching institution from April 2018 to February 2020.

TRIAL REGISTRATION NUMBER: CTRI/2018/04/013501

MATERIALS AND METHODS: 150 eligible couples requiring IUI treatment who agreed to participate were randomly allocated on 1:1 basis to either control or intervention group. The trial participants received up to 3 cycles ovulation induction with clomiphene citrate and intra-uterine insemination. In addition, women in intervention group were subjected to endometrial scratch injury on day 6-7 of their stimulated cycle. 154 cycles in control arm and 128 cycles in intervention group were analyzed for clinical pregnancy, miscarriages and pain experienced by the women during endometrial scratch injury using the statistical package SPSS (version 21).

RESULTS: Similar cumulative clinical pregnancy rates (12.5% Vs 13.6%, RR 1.21, 95% CI 0.44-3.37, p=0.713), biochemical pregnancy rates (17.1% vs 22.9%, RR 1.43, CI 0.59-3.47, p=0.421) and ongoing pregnancy rates (10.93% Vs 11.47%, RR 1.05, CI 0.35-3.21, p=924) were observed in control and intervention arms. Likewise, the relative risk of miscarriage occurrence in the intervention arm was 1.32 (95% CI 0.39-4.32, p=1.000) which was not statistically different from control group. Mean pain score of 6.93 on numerical pain rating scale was experienced by women whilst having endometrial scratch injury.

CONCLUSIONS: There is insufficient evidence to defend the use of endometrial scratch injury in intra-uterine insemination treatment, as it is moderately painful and have uncertain beneficial influence on reproductive outcomes.

SUPPORT: The study received funds from the institution as per institutional norms to procure consumables. No funding was received from any individual or external funding agency.The authors do not have any conflicts of interest to declare.

P-937 3:30 PM Wednesday, October 21, 2020

INFLAMMATION IN RESPONSE TO SATURATED FAT INGESTION IN NORMAL WEIGHT WOMEN WITH POLYCYSTIC OVARY SYNDROME (PCOS) DOES NOT DEPEND ON THE PRESENCE OF ABDOMINAL ADIPOSITY (AA). Frank González, M.D.,[1] Robert V. Considine, Ph.D.,[2] Ola A. Abdelhadi, M.D., Ph.D.,[3] Anthony J. Acton, Jr., B.S.[2] [1]University of Illinois at Chicago College of Medicine, Chicago, IL; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of California at Davis, Davis, CA.

OBJECTIVE: Lipid-stimulated inflammation is increased in PCOS independent of obesity.[1] We evaluated the effect of saturated fat ingestion on nuclear factor-κB (NFκB) activation, inhibitory-κB (IκB) protein content and tumor necrosis factor-α (TNFα) mRNA content from mononuclear cells (MNC) of normal weight women with PCOS with and without AA, compared with normal weight body composition-matched ovulatory controls; and their relationship with HCG-stimulated ovarian androgen secretion and insulin sensitivity.

DESIGN: Cross-sectional study

MATERIALS AND METHODS: We studied 14 normal weight women with PCOS (7 with & 7 without AA) diagnosed on the basis of oligo-amenorrhea and hyperandrogenemia and 14 normal weight ovulatory controls (7

with & 7 without AA) ages 18-40. AA was defined as the % ratio of truncal fat to total body fat measured by DEXA that was 2SD above the mean of controls without AA. NFκB activation, IκB protein content and TNFα mRNA content were respectively quantified by electrophoretic mobility assay, Western blotting and RT-PCR in MNC isolated from blood samples drawn fasting and 2, 3 and 5 hours after dairy cream ingestion (100 ml). Androgens were measured by RIA from blood samples drawn fasting and 24, 48 and 96 hours after HCG administration (5000 IU). Insulin sensitivity was derived by IS_{OGTT}.

RESULTS: Compared with controls, the change from baseline (%) in NFκB activation and TNFα mRNA content increased ($p<0.02$) and IκB protein content decreased ($p<0.0001$) in both PCOS groups at 2 hours (NFκB – with AA: 27±4 vs. 4±5, without AA: 23±4 vs. -17±1; TNFα – with AA: 23±6vs. -13±3, without AA: 26±9 vs. -8±9; IκB – with AA: -35±2 vs. 18±5, without AA: -30±4 vs. 17±5) and 3 hours (NFκB – with AA: 25±4 vs. 2±4, without AA: 20±4 vs. -16±1; TNFα – with AA: 25±12 vs. -14±3, without AA: 29±15 vs. -14±6; IκB – with AA: -41±2 vs. 23±6, without AA: -35±5 vs. 20±5), and returned to baseline at 5 hours (NFκB – with AA: 1±1 vs. 0±1, without AA: 1±1 vs. -1±1; TNFα – with AA: 2±12 vs. -7±4, without AA: 2±6 vs. -3±6; IκB – with AA: -1±1 vs. 1±1, without AA: -1±1 vs. 1±1). Compared with controls, both PCOS groups exhibited greater ($p<0.05$) HCG-stimulated area under the curve (AUC) for testosterone (T) (with AA: 6466±775 vs. 3858±531, without AA: 6157±1026 vs. 3064±587) and androstenedione (A) (with AA: 501±35 vs. 307±24, without AA: 516±38 vs. 300±36). For the combined groups, the lipid-stimulated incremental AUC (iAUC) for NFκB activation and TNFα mRNA content was positively correlated with HCG-stimulated androgen AUC (NFκB – T: $r=0.53$, $p<0.006$; A: $r=0.62$, $p<0.0009$; TNFα – T: $r=0.41$, $p<0.05$; A: $r=0.55$, $p<0.004$). IS_{OGTT} was negatively correlated with the lipid-stimulated iAUC for NFκB activation ($r= -0.39$, $p<0.05$) and TNFα mRNA content ($r= -0.48$, $p<0.02$), and positively correlated with the lipid-stimulated iAUC for IκB protein content ($r=0.53$, $p<0.006$).

CONCLUSIONS: Lipid-stimulated NFκB activation and TNFα mRNA content are increased and lipid-stimulated IκB protein content is decreased in PCOS independent of AA. We speculate that this proinflammatory phenomenon in PCOS promotes hyperandrogenism and insulin resistance, and is further perpetuated by AA.

P-938 3:30 PM Wednesday, October 21, 2020

EXOSOMES DERIVED FROM HUMAN UMBILICAL CORD MESENCHYMAL STEM CELLS PROMOTE PROLIFERATION OF ENDOMETRIAL STROMAL CELL.

Yajie Chang, Master,[1] Yingying Liu, Master,[2] Xiaolan Li, M.D.[3] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Research Center of Reproductive Medicine, The 6th Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China; [3]Laboratory of Reproductive Endocrinology, The Research Center of Reproductive Medicine, The 6th Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China.

OBJECTIVE: To investigate whether the exsomes derived from Umbilical cord mesenchymal stem cells (UCMSCs) could improve the regeneration of endometrium in an experimental model of thin endometrium.

DESIGN: Randomized, control trial, animal research.

MATERIALS AND METHODS: UCMSCs were isolated and characterized. UCMSC-exos were extracted by differential ultracentrifugation and identified by western blots, transmission electron microscopy, and nanoparticle tracking analysis. A thin endometrium rat model was established by infusing ethanol into the uterine cavity of Sprague-Dawley rats. In all, 24 rats with thin endometrium and 12 normal rats were divided into 3 groups: (1) normal group, (2) experimental group transplanted with UCMSC-exos into uterine cavity, and (3) control group transplanted with saline into the uterine cavity. Three rats were killed at time 0 h, 7 d, 14 d and 28 d and bilateral uterus were obtained at each time points for the subseqent experiments. Morphological changes were determined by hematoxylin-eosin staining or Masson staining.The amount of fibrosis, vascularisation, inflammation and immunohistochemical staining with vascular endothelial growth factor (VEGF), Bcl-2 and Caspase-3 level were evaluated in the endometrial tissues.

RESULTS: The isolated UCMSC-exos had a typical cup-shaped morphology with a monolayer membrane, expressed the specific exosomal markers Alix, CD63, and TSG101 and were approximately 60 to 200 nm in diameter. The rats in group2 had a significantly thicker endometrial lining and exhibited higher expression of cytokeratin, vimentin than that of group3 ($P < .05$), which were similer with group 1. The amount of fibrosis, VEGF were similar between group1 and 2. In group2, comparing to group3, show less fibrosis but upregulated VEGF staining and Bcl-2 level was observed, while Caspase-3 level was downregulated($P < .05$).

CONCLUSIONS: UCMSC-Exos improved the proliferation of endometrium. UCMSC-Exos upregulated VEGF, Bcl-2 level as well as downregulated Cleaved Caspase-3 level and activated the PTEN/AKT signaling pathway to regulate the proliferation and antiapoptosis. Thus, UCMSC-Exos could be used as a potential treatment to promote endometrial repair.

COVID-19 PANDEMIC EFFECT ON EARLY PREGNANCY – ARE MISCARRIAGE RATES ALTERED, IN ASYMPTOMATIC WOMEN?.

Keren Rotshenker Olshinka, M.D.,[1] Alexander Volodarsky-Perel, M.D.,[2] Namaa Steiner, MD,[1] Eryn Sarah Rubenfeld, M.D.,[1] Michael H. Dahan, M.D.[1] [1]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Center, Montreal, QC, Canada; [2]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Centre, Montreal, QC, Canada.

OBJECTIVE: To evaluate the effect of the COVID-19 pandemic state on early, 1st trimester pregnancies, in light of a link described between war-induced stress and adverse pregnancy outcomes.

DESIGN: Retrospective cohort study conducted in a University fertility center.

MATERIALS AND METHODS: All 1ST trimester viability scans done since the COVID-19 shut down, March13-May 6, 2020 (Study group), and between March 1-May 17, 2019 (pre-pandemic Control), were reviewed. Early 1st trimester pregnancy outcomes (Viable pregnancy, Arrested pregnancy including biochemical pregnancy loss and miscarriage, and ectopic pregnancy (EP)) were measured. A multivariate analysis was performed to control for significant confounders. Power analysis revealed that a sample size of 58 patients per group has a 90% power with a 15% difference in outcomes and α=5%. The study group denied symptoms of COVID-19.

RESULTS: 113 women were scanned in the study, and 172 in the control periods (5-11 weeks gestational age). The groups had similar demographics, gestational history, fertility diagnosis and treatment characteristics (Table). No significant differences were noted in the rate of recurrent pregnancy loss (RPL). Viable clinical pregnancy rates were not different between the groups (76.1% vs. 80.2% in the pandemic and pre-pandemic groups p= 0.41). No significant difference was seen in number of 1st trimester miscarriage (14.2% vs 12.8% p=0.76), biochemical pregnancies (3.5% vs 1.7% p=0.34), or in total miscarriage rate (22.1% vs 16.9% p=0.32), nor in EP rates (0.9% vs 2.3% p=0.36)

Mean serum TSH levels were higher in the control but fell in the normal range for both groups. Use of donor sperm was higher in the control and may have favored lower miscarriage rates in that group.

CONCLUSIONS: The COVID-19 pandemic environment does not seem to affect early first-trimester miscarriage rates in asymptomatic patients.

Characteristic	Study(n=113)	Pre-pandemic Control (n=172)	*P*-value

QUANTITATIVE DETECTION OF BIOLOGICALLY RELEVANT ANTI-MULLERIAN HORMONE (AMH) AND PROGESTERONE IN HUMAN HAIR SAMPLES. Alice K. Crisci, BS,[1] Brian Ring, PhD,[1] Sarthak Sawarkar, MS,[2] Yolanda Cabello, PhD,[3] Laura Garcia-Calvo, PhD,[2] Maria Hebles Duvison, PhD,[4] Carmen Ochoa Marieta, MD,[5] Maria Jose Figueroa-Garcia, Embryologist,[6] Laura García De Miguel, Gynecologist,[7] Santiago Munne, PhD,[1] Manuel Alvarez-Rodríguez, PhD,[2] Manel Lopez-Bejar, PhD.[8] [1]MedAnswers, San Pedro, CA; [2]Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Hospital Ruber Juan Bravo, Madrid, Spain; [4]Ginemed Sevilla, Sevilla, Spain; [5]CER Santander, Santa Cruz de Bezana, Spain; [6]HC Marbella International Hospital, Marbella, Spain; [7]Clinica Tambre, Madrid, Spain; [8]Western University of Health Sciences, Pomona, CA.

OBJECTIVE: Anti-Mullerian Hormone (AMH) and progesterone are used as biomarkers in assessing fertility and readiness for assisted reproductive procedures, usually measured in blood samples. The objective of this study was to determine if biologically relevant quantities of AMH and progesterone in human hair samples could be assessed.

DESIGN: The study design was prospective in nature. A total of (n=152) human female participants between the ages of 18-65 years were included in the study over a period of 10 months (recruitment ongoing).

MATERIALS AND METHODS: Sample collection was performed in a clinical setting, with blood and hair samples collected from patients. Hair follicles were not required, with a minimum of 100mg of hair cut from the participants. A doctor or a clinical technician measured the antral follicle count (AFC) by ultrasound. Biologically active AMH and progesterone was extracted from hair using a proprietary method. Hormone presence in hair extract was confirmed in a set of samples using Western Blotting. Hormones were measured in plasma and hair extract by ELISA.

RESULTS: AMH was detected via ELISA (n=95 in hair, 42 in plasma), and confirmed on a set of samples via western blots on denatured gel with bands at 70kDa. An average level of 9.37 pg/ml (95%CI 6.77-12) was detected in hair and 3.68 ng/ml (95%CI 2.79-4.56) in plasma in age-group <25 yrs. This is in contrast to the age group >39 years, within which a mean of 3.02 pg/ml (95%CI 2.19-3.85) AMH detected in hair and 0.92 ng/ml (95%CI 0.43-1.41) in plasma samples. AMH in hair did not significantly associate with measurements in plasma (effect size 0.19, p value 0.0852). AMH measured in hair correlated with age more strongly than plasma AMH (p-value =1.26 x10-5 (hair), p-value 0.088 (plasma)). AMH levels in hair were also strongly associated with AFC when corrected for hair weight, with an effect size of 3.75 (95% CI: 1.7; 5.8), and P value of 0.0168. Progesterone was measured via ELISA (n=76 in hair, n=91 in plasma) via ELISA. The association between progesterone in plasma and hair was significant (p value of 0.0298, p value of 0.013 when adjusted for hair weight).

CONCLUSIONS: We found that progesterone and AMH could be detected in human hair samples, and levels of AMH in hair were positively associated with maternal age and antral follicle count. The stronger association of AMH in hair versus plasma with age and AFC suggests that, though AMH is relatively stable during the monthly cycle, acute measurements of AMH may have variability that may make measurement via hair samples of greater utility for assessing reproductive health. Hair is a medium that can accumulate biomarkers over several weeks, while serum is an acute matrix that can represent only current levels. Detection of steroid hormones in hair has been used in neuroendocrinological studies in human and animals. However AMH measurements in hair are not currently employed for clinical purposes. In addition to this benefit, assessing reproductive hormone via a non-invasive method may allow an increased adoption of the use of these hormones in addressing reproductive health.

FOLLICULAR-PHASE SINGLE-DOSE GNRH AGONIST PROTOCOL VS GNRH ANTAGONIST PROTOCOL IN PATIENTS WITH REPEATED IVF FAILURE. Rui Huang, MD, PhD, Xing Yang, Ph.D., Qian Li, Master. The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To compare the clinical outcomes between follicular-phase single-dose gonadotropin-releasing hormone (GnRH) agonist protocol and GnRH antagonist protocol in patients with repeated IVF failure.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: The IVF cycles conducted on 764 patients with repeated IVF failure (No. of previous failed IVF cycle>=2) and normal ovarian reserve (AMH >1.1ng/ml) from Jun. 2017 to Dec. 2019 were included in this retrospective cohort study. The follicular-phase single-dose GnRH agonist protocol, in which 3.75 mg Triptorelin was administrated on cycle day 2 and exogenous gonadotropin (Gn) was initiated 4 weeks later, was applied in 303 patients and GnRH antagonist protocol utilized in the remaining 461 patients. The clinical outcomes, including stimulation duration, total dose of exogenous Gn, No. of oocytes retrieved, No. of transferrable embryos, clinical pregnancy rate and miscarriage rate between the two groups were compared respectively. P<0.05 was considered as statistical significance.

RESULTS: No significant difference was observed in basic characteristics between two groups. Comparing with the antagonist group, both the stimulation duration and the total Gn dose were significantly longer and higher in the agonist group. More oocytes and transferrable embryos were obtained, and the clinical pregnancy rate per fresh embryo transfer cycle was significantly higher in the agonist group. The basic and cycle characteristics were listed in the following table.

CONCLUSIONS: In patients with repeated IVF failure, follicular-phase single-dose GnRH agonist protocol resulted in a significantly higher clinical pregnancy rate than antagonist treatment, implying that single-dose GnRH agonist treatment may offer additional benefits for this specific group of patients.

SUPPORT: This work was supported by theÂ Natural Science Foundation of Guangdong Province (No.2019A1515011764).

P-942 3:30 PM Wednesday, October 21, 2020

THE POSITION OF POINT OF HATCHING (POH) AND ITS ANGLE VIS-À-VIS THE INNER CELL MASS IS A ROBUST CRITERIA FOR SELECTION OF HATCHING BLASTOCYST FOR ENHANCED LIVE BIRTH RATES IN IVF CYCLES. Bindu N. Chimote, M.Sc., M.Phil, Ph.D.(Biochemistry); M.Sc. Clinical Embryology (Leeds-UK),[1] Nishad N. Chimote, M.Sc.,[2] Amogh N. Chimote, M.D.,[2] Riju A. Chimote, M.D.,[2] Natchandra Manoharrao Chimote, M.Sc., Ph.D.[3] [1]Consultant Clinical Embryologist, Nagpur, India; [2]Vaunshdhara Fertility Centre, Nagpur, India; [3]Scientific Director, Vaunshdhara Fertility Centre, Nagpur, India.

OBJECTIVE: Hatching of blastocyst from zona pellucida is extremely essential for implantation and live birth. It has been arbitrarily believed that the point of hatching (POH) should be diagonally opposite the inner cell mass (ICM). However, there is no documentation yet of the impact of angle of POH vis-à-vis ICM on the implantation (IR) and live birth rates (LBR) in vitro. We aimed at measuring the actual angle of POH and evaluating its correlationship with IVF outcomes.

DESIGN: Retrospective analysis of single hatching blastocyst transfer cycles carried out from 2014 to 2019. To avoid any bias due to blastocyst quality, we retrospectively included cycles involving transfer of only Grade AA or Grad AB hatching blastocysts. The angle formed between the imaginary tangent from the midpoint of ICM arc and the line from this ICM midpoint to POH, drawn on the photographic image of blastocyst, constituted our angle of POH. Cycles were classified into three groups on the basis on angle POH as Group A (0-30°), Group B (31-60°) and Group C (61-90°).

MATERIALS AND METHODS: Serum βhCG was measured on day 8 post blastocyst transfer. A βhCG value > 25 mIU/ml was considered as positive indication of pregnancy. Gestational sac with foetal cardiac activity on ultrasound at 6th week gestation confirmed clinical pregnancy. Missed abortion was defined as a spontaneous loss of cardiac activity after 6 weeks gestation. IR and LBR were also evaluated. Data was analysed using the graph pad prism V software. P<0.05 was considered significant. The statistical power of our study is >85%.

RESULTS: An overall comparison between pregnant and non-pregnant groups showed no significant difference in the angle of POH (56 vs. 53). However, interesting results were obtained when transfer cycles were classified on the basis of POH angle. Of the total 2350 hatching blastocysts evaluated, n=440 (18.7%), n=800 (34%) and n=1110 (47%) belonged to Group A, Groups B and Group C respectively. The clinical pregnancy rate differed significantly between the 3 groups (20.45% vs. 36.25% vs. 37.4%, One way ANOVA p<0.0001) respectively.

Significant differences were observed (Group C >Group B >Group A) in degree of blastocyst expansion (One way ANOVA p=0.0068) and gradation of trophoblastic (TE) cells (p<0.0001) whereas there was no difference in ICM grades between the 3 groups.

The IR was significantly lower (20%, p<0.0001) in Group A compared to that in Groups B and C. Although the implantation rates in both Groups B and C were comparable (36 vs. 38%, p>0.05); the rates of missed abortion were significantly higher in Group B compared to Group C (5 vs. 1.8%, p<0.0001). The live birth rates were significantly higher in Group C compared to Group B (37% vs. 30%, p=0.031).

CONCLUSIONS: The angle at which point of hatching originates vis-à-vis the ICM greatly influences IVF outcomes. Thus, in addition to morphometric evaluation of blastocyst, it is imperative to assess the angle of POH as a selection criteria so as to minimize the chances of missed abortion and to enhance live birth rates in IVF cycles.

DIAGNOSTIC EFFICIENCY OF BLASTOCYST CULTURE MEDIUM IN NONINVASIVE PREIMPLANTATION GENETIC TESTING (NIPGT). Jingbo Chen, M.D. candidate,[1] Lei Jia, PhD,[1] Shujing He, MM,[2] Cong Fang, Ph.D.[1] [1]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China.

OBJECTIVE: To evaluate the diagnostic efficiency of spent blastocyst culture medium (BCM) in noninvasive preimplantation genetic testing (niPGT) by comparing the karyotype concordance with corresponding inner cell mass (ICM) among initial trophectoderm (TE) biopsy, TE re-biopsy and BCM sampling.

DESIGN: Re-analysis aneuploid/mosaic blastocysts donated for research by couples.

MATERIALS AND METHODS: A total of 26 blastocysts with aneuploid (n=23) or mosaic diagnosis (n=3) were donated for research from 12 couples with indications of preimplantation genetic testing for chromosomal structural rearrangements (PGT-SR) or preimplantation genetic testing for aneuploidy (PGT-A), at Reproductive Medicine Research Center of the Sixth Affiliated Hospital of Sun Yat-Sen University, from July 2018 to July 2019. TE and ICM were biopsied (5-10 cells) in a routine procedure; TE was re-biopsied (more than 10 cells) at other sites of trophectoderm compartment. The MALBAC single-cell whole genome amplification (WGA) method was used to amplify DNA from all cells and BCM samples. Embryos were diagnosed as euploid, aneuploid or mosaic by NGS results. Embryos were classified as mosaic if the level of mosaicism ranged from 40% to 70%, while less than 40% was labeled as euploid and more than 70% as aneuploid. But for chr13, chr16, chr18 and chr21 chromosomes, the criterion for mosaicism was set to be 30%. The primary outcomes of this study, concordance rates with ICM biopsies, were compared among groups (initial TE biopsies, TE re-biopsies and BCM samples). The karyotype concordance of each two groups was defined as the presence of the same abnormal chromosome, especially in the target chromosome in different testing results compared. The clinical concordance of all four samples was defined as the concordance in embryo diagnosis, such as uniform aneuploid or not. To assess the diagnostic efficiency of BCM sample, false positive rate (FPR), false negative rate (FNR), sensitivity, specificity, accuracy, positive predictive value (PPV) and negative predictive value (NPV) were calculated according to the corresponding ICM results. Statistical analyses were performed with the Chi-Square test, Yates' correction, or Fisher's exact test accordingly when comparing frequencies or proportions. All statistical analysis was performed using SPSS 22.0. $P<0.05$ was considered as significant.

RESULTS: For 23 embryos diagnosed as aneuploid by initial TE biopsy, 78.3% of initial TE samples, 87.0% of TE re-biopsies and 78.3% of BCM samples were concordant with corresponding ICM samples ($P>0.05$); but for 3 mosaic embryos, the concordance rates with ICM of these three groups were 0%, 100% and 100% ($P<0.05$), respectively. With the corresponding ICM result as the true result, sensitivity of both niPGT-A and initial TE were 100%; but the FPR of initial TE was higher than that of niPGT-A (100% vs. 0, $P=0.100$).

CONCLUSIONS: NiPGT-A using spent BCM had similar diagnostic efficiency as TE-biopsy PGT-A. And in case of mosaic embryos, niPGT-A using BCM may be more reliable for predicting the karyotypes of ICM than initial TE biopsy.

FIBROTIC CHANGES IN TRANSGENDER OVARIES DUE TO TESTOSTERONE EXPOSURE. Anamika Ratri, BA, Riley Mickelsen, BS, Meredith Gray, MD, Nika C. Gloyeske, MD, Courtney A. Marsh, MD, MPH, Lane K. Christenson, PhD. University of Kansas Medical Center, Kansas City, KS.

OBJECTIVE: Transgender men (TGM) undergo extensive testosterone (T) exposure as part of gender conformation therapy. Androgens have well known impacts on the HPG axis as well as direct effects on the ovary. Reports conflict on whether TGM ovaries have characteristics of PCOS, which can also heighten T levels in the patient. Elevated androgens and aging can both increase collagenization of the ovary. In this study, we evaluated ovarian morphologic differences in young and old TGM patients, examining fibrosis of the tissue. Ovarian fibrosis could impede ovulation, which may lead to problems with fertility.

DESIGN: Ovarian fibrosis in TGM was compared to age-matched cisgender (CG) ovaries. All patients were divided into two age groups, young ($\leq$35 yr) and old (>36 yr). Fibrosis was detected by histological quantitation of picrosirius red (PSR) staining.

MATERIALS AND METHODS: Ovaries from young and old TGM patients (n=5/3, respectively) were collected during gender confirming surgeries. Ovaries from young and old CG donors (n=3/4, respectively) were obtained from patients undergoing oophorectomy for benign reasons. All samples were collected following KUMC IRB approval. Ovaries were fixed in 4% formaldehyde, processed and embedded in paraffin. 7μm-thick histological sections were stained with 0.1% PSR/0.1% Fast Green. Four randomly selected cortical areas of each ovarian section were imaged at 10x using bright field microscopy. PSR staining intensities were quantified using ImageJ per NIH recommended methodology. One-Way AVOVA ($p<0.05$) followed by LSD means separation tests were completed using SPSS program. To correct for heterogeneity of variance, data was log transformed.

RESULTS: Young (29$\pm$2.0yr) and old (40.0$\pm$0.7yr) TGM patients underwent 34.8$\pm$4.2mo and 40.6$\pm$39.2mo of T-therapy, respectively; note one old TGM patient was exposed for 119mo. Age matched young and old CG patients were 31$\pm$2.0 and 36$\pm$0.5yr of age. Ovarian PSR staining levels in young TGM patients were higher (292,184$\pm$122,991 $p<0.05$) compared to young CG donors (39,154$\pm$14,643). Ovaries from old TGM also showed increased PSR staining, (98,775$\pm$17,887) compared to old CG (34,359$\pm$5,540; $p<0.05$). TGM ovaries had few large follicles, which were atretic, whereas CG ovaries typically contained a few large healthy follicles.

CONCLUSIONS: This study establishes quantitatively that long-term testosterone exposure increases collagen deposition within young and old TGM ovarian tissue compared to CG age matched tissues. Our findings indicate a lack of multiple follicles in TGM ovaries, which diverges from several prior observations that TGM ovaries exhibited a PCOS-like morphology. Increased number of subjects will clarify whether age of TGM and duration of T-therapy impacts the extent of ovarian fibrosis. By understanding the time frame of ovarian fibrosis, this may give TGM greater control over fertility as they transition.

NOVEL AND UNIQUE KEY MARKERS IN THE INFLAMMATORY PATHWAYS FOR GENITAL TUBERCULOSIS (GTB). Madhavi M. Panpalia, MS,[1] Trupti Mehta, DGO, DNB,[1] Shiva Chettiar, Ph.D.,[2] Alpesh Patel, Ph.D.,[2] Sapna Agarwal, MD,[1] Jyotshna Palgamkar, DGO, DNB,[1] Swapneil R. Parikh, DNB,[3] Firuza Rajesh Parikh, MD DNB PhD.[1] [1]Jaslok Hospital and Research Centre, Mumbai, India; [2]Genexplore Diagnostics and Research Centre, Ahmedabad, India; [3]Kasturba Hospital of Infectious Diseases, Mumbai, India.

OBJECTIVE: To identify novel and unique diagnostic markers for the presence of Genital Tuberculosis (GTB).

DESIGN: Infertile women suspected of GTB were included in the study. An array of tests including endometrial biopsies for TB culture, nested TB-PCR, Immunocytochemistry, TNF alpha, P27, $\alpha_1\beta_3$integrins and evaluation of CD138 and endoscopy including either laparoscopy and or hysteroscopy was carried out. Those confirmed with GTB by two or more parameters were considered as TB positive and those with either one or none of the parameters positive were considered to be TB negative. Expressional analysis was performed on the same sample of the endometrial biopsy that had been collected. Pathway analysis to establish markers associated with TB and integrated pathways differentially associated to normal physiology were mapped.

MATERIALS AND METHODS: A total of 97 samples were subjected to diagnostic tests mentioned above. Results were tabulated to differentiate between TB positive and TB negative samples. Based on the screening tests, 34 samples were positive and 63 were negative. All these samples were subjected to custom designed gene expression analysis by microarray technique using Agilent G3 scanner and results were analysed on GeneSpring 14.9 software (Strand Lifescience). Data was normalized and those with fold chain more than 2 were considered for further analysis. Expression fold change of TB positive samples was compared to TB negative samples with respect to focused inflammatory pathway analysis comprising of 1052 genes. Through literature survey, a total of 1052 genes were identified as associated with inflammatory pathways and data of expression analysis was compared to these genes.

RESULTS: Bioinformatics analysis of the study revealed that 129 genes were differentially regulated in TB positive endometrial tissue as compared to TB negative endometrial tissue. Further, expression of 47 genes was statistically significant and considered for further pathways and marker identification analysis. Results showed that apart from innate immune response pathways like MAPK and cytokine pathways, we observed that genes involved in cell migration, Adhesion-Extravasation, G-protein coupled receptor pathways were also altered in TB positive endometrium thus, explaining the associated infertility.

CONCLUSIONS: Early detection of GTB is important in salvaging reproductive potential. GTB has a detrimental impact on female fertility. However its diagnosis by conventional methods is at times difficult in this form of extra-pulmonary TB and delay in diagnosis can negatively impact on future fertility. The present study has identified novel markers in the form of differential expression of 52 genes involved not only in classical inflammatory response pathways but pathways associated with inflammatory dysfunction in GTB.

P-946 3:30 PM Wednesday, October 21, 2020

EMBRYONIC EVENTS AND NOT UTERINE EVENTS ARE ASSOCIATED WITH PREGNANCY OUTCOMES IN A DECEASED DONOR UTERUS TRANSPLANT PROGRAM: PRELIMINARY RESULTS. Elliott G. Richards, MD,[1] Marjan Attaran, M.D.,[2] Cynthia M. Austin, M.D,[2] Cristiano Quintini, MD,[3] Andreas G. Tzakis, MD,[3] Tommaso Falcone, M.D.[4] [1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Beachwood, OH; [3]Cleveland Clinic, Cleveland, OH; [4]Cleveland Clinic, Cleveland, OH.

OBJECTIVE: Uterus transplantation is an emerging treatment for absolute uterine factor infertility. The majority of uterus transplants to date have utilized living donors (LDs). Only a few sporadic case reports exist with deceased/cadaveric donors (DDs), an approach with prolonged graft ischemia times. Our objective is to determine whether pregnancy rates are similar in DD to LD uterus transplantation.

DESIGN: Prospective trial of DD uterus transplantation.

MATERIALS AND METHODS: Candidates with absolute uterine factor infertility underwent extensive screening and testing. In vitro fertilization was performed prior to uterus transplantation. DDs were matched to potential recipients by ABO compatibility and CMV status. First embryo transfers were attempted at six months post-transplant.

RESULTS: Eight DD uterus transplantations in total were attempted, with four patients achieving pregnancy (two with live born children by cesarean hysterectomy and two with ongoing pregnancies), two additional patients

with uterus still in situ but with recurrent implantation failures, and two patients experiencing postoperative complications necessitating graft hysterectomy prior to embryo transfer attempt. For those achieving pregnancy, the average baseline anti-mullerian hormone was 4.9±3.0, compared to 1.3±0.1 for the non-pregnant group. The average number of frozen embryos prior to transplant was 8.5 (6.62 frozen blasts per IVF cycle) in the pregnant group and 5.0 (1.88 frozen blasts per IVF cycle) in the nonpregnant group. All donors were multiparous except two (one recipient with recurrent implantation failure and one with early graft loss). Average cold ischemia time in minutes was 255±115 in the pregnant group and 324±47 in the non-pregnant group. All six patients with graft survival had onset of menses within 34 days of transplant. Average endometrial thickness at embryo transfer was 9.8±1.9 mm in the pregnant group and 10.3±1.7 mm in the non-pregnant group. The average total number of transfers performed was 1.25±0.5 in the pregnant group and 4±1.4 transfers thus far in the nonpregnant group.

CONCLUSIONS: Our series is the largest trial of DD uterus transplantation to date. Preliminary data show similar rates of key success milestones (graft survival, pregnancy, live birth) as in LD series. DD recipients with multiple implantation failures had poorer IVF outcomes pre-transplant, suggesting that failures to conceive are due to embryo factors and not endometrial function. Given this, candidates for uterus transplantation should meet stringent criteria of number of cryopreserved blastocysts before undergoing a uterus transplant procedure.

P-947 3:30 PM Wednesday, October 21, 2020

CONTINUOUS AND INTERMITTENT AEROBIC TRAINING DID NOT CHANGE TELOMERE LENGTH, ALTHOUGH IT REDUCES HYPERANDROGENISM AND ANTROPOMETRIC INDEXES IN POLYCYSTIC OVARY SYNDROME. Cristiana Libardi M. Furtado, PhD,[1] Victor Barbosa Ribeiro, PhD,[2] Daiana CC. Pedroso, PHD,[3] Gislaine S. Kogure, PhD,[4] Rui A. Ferriani, MD, PhD,[4] Rodrigo T. Calado, MD, PhD,[4] Rosana M. dos Reis, MD, PhD.[4] [1]Federal University of Ceara, Fortaleza, Brazil; [2]Federal Institute of São Paulo, Jacareí, Brazil; [3]FERTILITY CENTER OF RIBEIRÃO PRETO - CEFERP, RIBEIRAO PRETO, Brazil; [4]Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil.

OBJECTIVE: To evaluate the effects of continuous (CAT) and intermittent (IAT) aerobic exercises on telomere length and the implications on anthropometric, hormonal and metabolic parameters of PCOS.

DESIGN: Randomized controlled clinical trial.

MATERIALS AND METHODS: 87 PCOS women were stratified randomly according to body mass index (BMI) into CAT (n=28), IAT (n=29) and non-training control group (n= 30). Aerobic exercises were performed on a treadmill, three times per week for four months. Telomere length was evaluated using qPCR and anthropometric, hormonal and metabolic parameters were measured, before and after 16-week of training or observation. Statistical analyses were carried out using SAS 9.0 software.

RESULTS: CAT and IAT did not change telomere length or the inflammatory biomarkers homocysteine and c-reactive protein after 16 weeks of training in PCOS. However, a negative correlation was observed between telomere length and age (p=0.0324) and BMI (p=0.0192). Booth exercises reduced waist circumference (CAT, p=0.045 and IAT, p=0.014) and testosterone levels (CAT, p=0.032 and IAT, p=0.019). Specifically, CAT reduced hip circumference (p=0.032) and cholesterol (p = <0.01) and low-density lipoprotein levels (LDL, p=0.03), and IAT decreased the waist-hip ratio (p=0.012) and free androgen index (p=0.037). In the controls, WC (p=0.049) and total cholesterol (p=0.010) increased after the observation period.

CONCLUSIONS: Four months of CAT or IAT did not change telomere length and inflammation in PCOS. Both protocols are important treatment strategies for women with PCOS, reducing anthropometric indexes and hyperandrogenism, and the CAT was effective in the control of lipid parameters in PCOS.

P-948 3:30 PM Wednesday, October 21, 2020

DEVELOPMENT AND VALIDATION OF A NOVEL MAIL-IN SEMEN ANALYSIS SYSTEM AND THE CORRELATION BETWEEN ONE HOUR AND DELAYED SEMEN ANALYSIS TESTING. Mary Katherine Samplaski, MD,[1] Owen Falk, MS,[2] Stan Honig, MD,[3] David Shin, MD,[4] William J. Matthews, BS,[5] James Smith, MD, MS.[6] [1]University of Southern California, Los Angeles, CA; [2]Fellow, San Francisco, CA; [3]Yale University, New Haven, CT; [4]Hackensack University Medical Center, Hackensack, NJ; [5]Fellow Health Inc., San Francisco, CA; [6]University of California, San Francisco UCSF, San Francisco, CA.

OBJECTIVE: To compare the results of standard one hour and delayed semen analysis (SA) testing to establish the effectiveness of a novel mail-in SA system.

DESIGN: Prospective cohort.

MATERIALS AND METHODS: Men undergoing SA in the San Francisco Bay Area were recruited for SA testing with social media advertisements. One-hour SA (World Health Organization 5th edition), then repeat SA testing (on the same sample) was performed, at multiple time points over 52 hours utilizing a novel technique for maintaining sperm viability.

RESULTS: 164 subjects were recruited with a subset of 26 for the validation portion of the study. One hour SA on 104 ejaculates from these 26 patients demonstrated mean semen volume 2.82 ml (SD±1.08 ml), sperm concentration of 75.0 million/ml (SD±36.6 million/ml), total motility of 59.8% (SD±9.1%), and normal morphology of 11% (SD±2.7%). With up to 52 hours of observation and 4 subsequent SA measurements per ejaculate, sperm concentration was found to remain stable, motility declined by 0.39% per hour, and normal morphology declined by 0.1% per hour (Table 1. Measured 1 hour and calculated motility (correlation coefficient (CC) 0.87) and morphology (CC 0.82) were strongly correlated. The low coefficient of variation within concentration (3.9%), motility (3.0%), and morphology (4.7%) measurements exceeded minimal FDA standards (10.0%) for SA testing.

CONCLUSIONS: This novel, mail-in, CLIA-approved SA testing system demonstrates a high degree of correlation between 1-hour SA testing and delayed SA testing. This test was highly reproducible with coefficient of variation exceeding current FDA standards for sperm concentration, motility and morphology. This test is particularly applicable given recent needs for social distancing, concerns for rising prevalence of male infertility and possible patient concerns regarding privacy and embarrassment with face-to-face communication with a medical laboratory staff. Reliable home produced,

TABLE 1. Baseline Semen Parameters and Mean Change Per Hour with Repeated Measurements up to 52 Hours from Production (N= 104 ejaculates from 26 subjects)

	Mean	Median	Min	Max	Mean Change per Hour*	95% CI**	
Volume (ml)	2.82	2.5	1.5	6.0	N/A	N/A	
Concentration (million sperm/ml)	75.0	74.4	9.3	162.0	0.05	-0.09	0.19
Motility (%)	59.8	61	34	77	-0.39%	-0.044%	-0.35%
Normal Morphology (%)	11	11	5	18	-0.10	-0.11%	-0.09%

*Samples incubated in 5ml sperm media at random moderate temperatures. Semen analysis performed at least 3 times up to 52 hours after production.
**Concentration P=0.29; Motility P < 0.0001; Morphology P < 0.0001

mail-in testing may increase access to SA testing and allow a reproductive specialist to address any identified abnormalities in a timely manner.

P-949 3:30 PM Wednesday, October 21, 2020

ABSENCE OF COVID-19 VIRUS WITHIN AN ACTIVE IVF LABORATORY USING STRICT PATIENT SCREENING AND SAFETY CRITERIA. Sandeep K. Rajput, PhD,[1] Shaihla A. Khan, PhD,[1] Benjamin B. Goheen, BS,[1] Heidi J. Engelhorn, MS,[1] Deirdre M. Logsdon, M.S.,[1] Courtney K. Grimm, MS,[1] Rebecca Kile, MS,[1] Rachel C. West, PhD,[1] Ye Yuan, PhD,[1] William B. Schoolcraft, MD,[2] Rebecca L. Krisher, PhD,[1] Jason E. Swain, PhD, HCLD.[2] [1]CCRM Colorado, Lone Tree, CO; [2]CCRM Fertility Network, Lone Tree, CO.

OBJECTIVE: In the early stages of the COVID-19 pandemic, most IVF clinics stopped the majority of patient treatment cycles to minimize the risk of disease transmission. When ASRM and other professional societies recommended resumption of treatments, procedures were put into place to ensure patient and staff safety. However, the risk of SARS-CoV-2 viral exposure and potential cross contamination within the IVF laboratory remains largely unclear. The objective of this study was to assess the true risk of exposure to SARS-CoV-2 in an active IVF laboratory when strict patient screening procedures are in place.

DESIGN: Prospective analysis.

MATERIALS AND METHODS: Prior to restarting IVF treatments, a COVID-19 safety protocol was implemented. Patients and staff were required to wear masks, fill out a symptom-based questionnaire daily, have their temperature taken, and practice social distancing in patient waiting areas. Each female patient undergoing transvaginal oocyte retrieval (TVOR) was required to have a negative SARS-CoV-2 RNA test 3-4 days prior to the procedure. Male partners were not tested. All cases examined utilized ICSI. The first tube of follicular fluid aspirated during TVOR (FF), culture media drops following removal of embryos on day 5 (M), and vitrification solution (VS) after blastocyst cryopreservation were analyzed. Self-inactivating replication incompetent lentivirus particles containing the single stranded viral RNA genome were immediately inoculated into each sample after collection as a positive control for viral RNA stability, prior to direct RNA isolation (M, VS) or sample concentration (FF). For FF, cell debris was removed by centrifugation and filtration (0.22 um) prior to concentration of virus particles with an Amicon filter. RNA was isolated using the optimized QIAamp viral RNA minikit, RNA quantity and quality determined, and cDNA synthesized using SuperScript IV VILO master mix. A multiplex TaqMan-based qPCR assay was developed for SARS-CoV-2 and lentivirus RNA (detection limit 5 SARS-CoV-2 copies/qPCR reaction and 50 viral copies/2 mL sample), and used to test all diagnostic samples. SARS-Cov2 synthetic RNA and lentivirus RNA were used as an RT-qPCR positive control. Samples with no amplification of lentivirus genome were removed from the analysis (false negative).

RESULTS: In total, culture medium from 30 patients, vitrification solution from 98 patients, and follicular fluid from 156 patients were analyzed. All samples were negative for the presence of SARS-CoV-2 viral RNA.

CONCLUSIONS: With stringent safety protocols in place, including patient testing and use of ICSI, the presence of SARS-CoV-2 RNA can be avoided in the IVF laboratory. Importantly, this study does not indicate that virus from an actively infected patient cannot be found in follicular fluid or make its way into the IVF lab. However, it does provide reassurance that with proper patient testing and safety measures, cross-contamination of the virus between gametes and embryos (including within liquid nitrogen storage dewars), as well as exposure of embryologists, is minimal.

P-950 3:30 PM Wednesday, October 21, 2020

TRANSCRIPTOMIC AND GENOMIC SEARCH OF ENDOMETRIAL RECEPTIVITY MARKERS IN WOMEN WITH RECURRENT IMPLANTATION FAILURE. Wan Tinn Teh, MBBS, MRMed, FRANZCOG, PhD,[1] Peter AW. Rogers, BSc, PhD.[2] [1]Melbourne IVF, East Melbourne, VIC, Australia; [2]University of Melbourne, Parkville, VIC, Australia.

OBJECTIVE: The primary aim was to perform differential gene expression (DGE) of endometrium to identify receptivity genes that are associated with implantation failure. The secondary aim was to interrogate recent endometrial genome-wide association studies (GWAS) data to identify expression quantitative trait loci (eQTLs) for receptivity genes that had been identified through the DGE study.

DESIGN: Transcriptomic and genomic studies of secretory phase endometrium.

MATERIALS AND METHODS: Women with history of subfertility were recruited from the Royal Women's Hospital and Melbourne IVF in Australia. Clinical outcomes were followed up for at least 3.5 years. Participant were then assigned into recurrent implantation failure (RIF) group or control group. We defined RIF as absence of pregnancy after >3 embryo transfers (ETs) with high quality embryos or the transfer of ≥10 cleavage stage embryos (or ≥5 blastocysts) in multiple transfers. Controls were women who had been pregnant within the last 2 years or who had conceived during the follow-up period after participation in the study.

Endometrial biopsy and venesection were performed at LH plus 6 (+/- 1 day). Gene expression array of the endometrium was performed using Illumina Human HT-12 v4.0. DNA isolated from blood samples was analysed on HumanCoreExome chips and Infinium PsychArray. Gene expression data was normalized for cycle stage.

RESULTS: There were 31 participants in the control group, and 41 participants in the RIF group. Participants in the RIF group had significantly more previous unsuccessful ETs (p=0.00), higher total number of embryos transferred (p=0.00) and shorter average menstrual cycle length (p=0.04). No other significant differences were noted between the two groups.

Initial DGE analysis showed significant differences in expression of some genes between the control and RIF groups after correction for cycle stage. However, after correcting for multiple testing, there were no genes with significantly different expression between the two groups (FDR = 0.9999).

The top 100 differentially expressed genes from the RIF group were compared with a published gene expression signature for endometrial receptivity (Koot et al. 2016). Two common genes were identified - *SMAD9* and *NR5A2*. Naïve calculation showed that these two genes were likely not significant, and due solely to chance.

52 endometrial samples from this study were incorporated in a larger cohort of endometrial samples for endometrial eQTL analysis (Fung et al. 2018). Five cis-eQTLs were identified – *PIGP*, *MYOM2*, *RER1*, *POLR2J*, *SCHIP1* in the top 100 differentially expressed genes for the RIF group.

CONCLUSIONS: Our results demonstrate in conjunction with the published literature that no consistently reproducible endometrial genes linked to implantation failure have yet been identified. The identification of true genetic association requires a large sample size and replication in different populations. RIF due to reduced uterine receptivity is not a common occurrence, hence recruitment of subjects with true endometrial implantation failure is challenging.

PERFLUORINATED COMPOUND (PFC) EXPOSURE IN OVARIAN GRANULOSA CELLS ALTERS GAP JUNCTION GENE EXPRESSION. Henry P. Mishek, Medical Student, Kendra L. Clark, PhD, John S. Davis, PhD. University of Nebraska Medical Center, Omaha, NE.

OBJECTIVE: Perfluorinated compoundc (PFCs) are synthetic chemicals that are persistent in the environment and bioaccumulate in humans and animals. These substances are ubiquitous in drinking water, cookware, stain repellents, food storage, packing materials, and cosmetics. Perfluorooctanoic acid (PFOA) is the most commonly detected PFC and has been associated with reduced fecundity and infertility. Ovarian gap junctions facilitate the transfer of various nutrients, ions, metabolites, and nucleotides between follicular cells and the oocyte. It is possible that PFOA mediates its effects by disrupting gap junction intracellular communication (GJIC) between granulosa cells or altering expression of gap junction-related genes. In this experiment, we aim to determine the effects of perfluorooctanoic acid (PFOA) exposure on connexin-43 (CX43) gene expression and GJIC in granulosa cells.

DESIGN: This study utilized a dye coupling method to assess GJIC in HGrC1 cells, an immortalized human granulosa cell line, after 24-hour (24h) exposure to environmentally relevant concentrations of PFOA.

MATERIALS AND METHODS: Previous work in this lab has shown that environmentally relevant concentrations (1-10 μM) of PFOA stimulate HGrC1 cell proliferation as early as 24 hours. Therefore, we utilized

concentrations of 1μM, and 10μM to assess GJIC with the vehicle dimethyl sulfoxide (DMSO, <0.1%) used as control. Cells were grown to confluence and then treated with PFOA for 24h. Luciferase Yellow (LY) and Rhodamine-dextran (RhoD) dyes were loaded into cells using the scrape load technique. Cells were incubated with the dyes for 5 minutes with subsequent washes to remove any residual dye, fixed, then imaged with confocal microscopy. The degree of dye migration was assessed using ImageJ. RNA was isolated and real-time qPCR was performed to quantify CX43 gene expression.

RESULTS: Preliminary results showed that treatment with 10 μM PFOA significantly ($P < 0.025$) reduced the distance traveled by the dye compared with vehicle treated controls. qPCR analysis determined that 1μM PFOA induced a 2.1-fold increase in CX43 transcripts relative to vehicle control.

CONCLUSIONS: Few studies have been reported using environmentally relevant concentrations of PFOA to elucidate the relationship between PFOA exposure and impaired ovarian processes. This study uses concentrations that are relevant to levels reported in human serum. Initial results indicate that PFOA reduces GJIC which may affect granulosa and follicle function. The increase in CX43 mRNA suggests a possible compensatory mechanism in response to PFOA exposure.

P-952 3:30 PM Wednesday, October 21, 2020

RELATIONSHIP BETWEEN THE DURATION OF EQUILIBRATION STEP OF THE VITRIFICATION AND CHANGES ON ABUNDANCE AND COMPOSITION OF OOCYTE MEMBRANE LIPIDS.

Thalita S. Berteli, MSc,[1] Eduardo D. Borges, MSc,[1] Caroline M. Da Luz, MSc,[1] Christina R. Ferreira, PhD,[2] Paula A. Navarro, MD, PhD,[1] Alessandra A. Vireque, PhD.[3] [1]Faculty of Medicine of Ribeirão Preto - USP, Ribeirão Preto, Brazil; [2]Purdue University - Metabolite Profiling Facility, Bindley Bioscience Center, IN; [3]Invitra – Assisted Reproductive Technologies LTD, Supera Innovation and Technology Park, Ribeirão Preto-SP, Brazil.

OBJECTIVE: Volumetric damages and cytotoxicity due to cryoprotectants exposure are time-sensitive in the vitrification process and can trigger the lipid remodeling of the plasma membrane. Here, we investigate the effects of exposure time to equilibration solution (ES) on membrane lipid profile of C57BL/6J mice oocytes using *MRM-profiling*, a sensitive exploratory method for lipidomics of oocytes and embryos[1]. We also assessed the effects of supplementing ES with antioxidants and unsaturated fatty acids. Experimental groups included oocytes equilibrated with Irvine Scientific (IRV), a commercial standard vitrification medium; Tvitri-4 (T4) produced in small scale for research by INVITRA®, and Tvitri-4 supplemented with L-carnitine (LC) and oleic and linoleic fatty acids (FA) (T4-LC/FA; Patent n. BR102019013697-9).

DESIGN: Experimental study.

MATERIALS AND METHODS: Oocytes were randomly divided in 7 groups: non-exposed (NE) and exposed to either 10-minute equilibration step (ES10) according to the manufacturer's procedure or 7-minute equilibration step (ES7), using IRV, T4, or T4-LC/FA media. After equilibration, oocytes were washed in methanol: H2O and lipids extracted with methanol. Diluted lipid extracts were flow injected into the triple quadrupole spectrometer with electrospray ionization (ESI). Relative ion intensities were used for univariate (ANOVA, fold-change, t-test, volcano plot) and multivariate analysis (PCA, PLS-DA, cluster analysis). Most informative lipids were sorted out using statistical significance of $p<0.05$ or partial least square discriminant analysis (PLS-DA) variables of importance (VIP) scores>1.

RESULTS: One-way ANOVA showed PC (38:8) differently represented among NE, ES7 and ES10 groups, upregulated in T4-LC/FA oocytes. In ES7 groups, two by two comparisons between IRV, T4 and T4-LC/FA using volcano plot (p-value$\leq$0.05; fold-change$\geq$2.0) detected 4, 5, and 4 significant lipids between IRV vs. T4, IRV vs. T4-LC/FA, and T4 vs. T4-LC/FA, respectively, with the PEo(36:1) overrepresented in IRV (fold-change=12.5). In ES10 groups, were detected 11, 19 and 4 lipids differentially represented among IRV vs. T4, IRV vs. T4-LC/FA, and T4 vs. T4-LC/FA, respectively. PLS-DAVIP scores identified in IRV oocytes 8 free- fatty acids, phosphatidyletanolamine PEo(36:1), phosphatidylcholines PCo(32:0) and PC(36:3), phosphatidylserines PS(14:1), PS(16:0), PS(30:2), PSo(40:5), and phosphatidylinositols PI(22:4) and PI(40:8) among the top features, whereas unsaturated PC and SM predominated in T4 and T4-LC/FA oocytes. Significant lipids observed between T4 and T4-LC/FA pointed oleic (18:1) and linoleic (18:2) acids upregulated in T4-LC/FA oocytes exposed for 10 min to ES.

CONCLUSIONS: The duration of the equilibration phase changed the abundance and composition of membrane lipids. Phospholipids were upregulated at 10-minute exposure to ES, except in IRV oocytes. The oleic and linoleic acids used as supplements in T4-LC/FA medium were promptly detected in the oocytes and seem contribute to better preserving membrane phospholipids during cell equilibration.

IDENTIFICATION AND CHARACTERIZATION OF HUMAN ENDOMETRIAL STROMA CELL-DERIVED EXOSOMES BY PROFILING THE PROTEIN COMPONENTS.

Eing-mei Tsai, MD, PhD,[1] ChiaYi Hsu, PhD.[2] [1]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]No. 100, Shih-Chung 1, Kaohsiung, Taiwan.

OBJECTIVE: To characterize and investigate the exosomes composition present in the pathogenesis of endometriosis.

DESIGN: We collect and purified exosomes that were derived from human eutopic and ectopic endometrioal stromal cells (EuESCs and EcESCs). We employed a proteomic approach to profile the protein composition of ESCs and comparison the EuESCs-exos and EcESCs-exos protein to evaluate the role of exosomes on endometriosis pathogenesis.

MATERIALS AND METHODS: Exosomes were isolated from ESCs culture supernatant by a combination of differential centrifugation. ESCs-exos obtained were extensively characterized using western blot to identify specific exosomal markers , transmission electron microscopy (TEM), and nanoparticle tracking analysis (NTA) to identify specific exosomal structure and size. The proteomics profiling of exosomes derived from ESCs via UPLC-MS/MS. Identified exosomes protein were analysed using Ingenuity Pathway Analysis (IPA) to determine the associated functions and pathways. We performed the XTT assays, migration assay and angiogenesis to examine the function of exosome protein.

RESULTS: A total of 105 proteins were identified from EuESCs-exos and EcESCs-exos by UPLC- MS/MS analysis. Among these, 36 proteins were different in EcESCs-exos compared to EuESCs-exos. We noted that ANXA2 was as one of the potential candidate expression protein in EcESCs-exos. The identified proteins were subjected to IPA for pathway prediction and function annotations. The data showed that ANXA2 were closely associated with cell morphology, amino acid metabolism, cell cycle, cell to cell signaling and interaction, and cellular assembly and organization. The data show that ANXA2 was high expression in EcESCs-exos, suggesting that exos-ANXA2 were association with endometriosis. We found that exos-ANXA2 increased cell growth, motility and angiogensis. It indicated that exos-ANXA2 was involved in regulating endometriosis. Our data suggest the function of ANXA2 mediated by exosomes can regulate cell proliferation and motility of ESCs, which can imply in endometriosis pathogenesis.

CONCLUSIONS: In conclusion, we demonstrate a function of ANXA2 in endometriosis pathogenesis mediated by exosomes, and through regulation of the ERK/STAT3 pathway and angiogenesis in endometriosis.

IMPACT OF ADJUVANT CHEMOTHERAPY OR TAMOXIFEN ALONE ON THE OVARIAN RESERVE OF YOUNG WOMEN WITH BREAST CANCER: A PROSPECTIVE LONGITUDINAL STUDY.

Kutluk H. Oktay, M.D., Ph.D.,[1] Volkan Turan, M.D.,[2] Giuliano Bedoschi, MD,[3] Enes Taylan, MD,[1] Heejung Bang, PhD,[4] Maura Dickler, MD,[5] Shari Goldfarb, MD.[5] [1]Yale University School of Medicine, New Haven, CT; [2]Memorial Bahcelievler Hastanesi, CT; [3]Ribeiaro Preto School of Medicine, CT; [4]UC Davis, New Haven, CA; [5]Memorial Sloan Kettering Cancer Center, New York, NY.

OBJECTIVE: To determine the longitudinal impact of adjuvant chemotherapy and tamoxifen-only treatments on the ovarian reserve recovery patterns of women with breast cancer by using a ultra-sensitive Anti-Mullerian Hormone (AMH) assay.

DESIGN: Multi-Center Prospective Longitudinal.

MATERIALS AND METHODS: One-hundred.-and-forty-two women with a primary diagnosis of breast cancer were prospectively followed with serum AMH assessments before the initiation, and 12, 18 and 24 months after the completion of adjuvant chemotherapy or the start of tamoxifen-only treatment. The chemotherapy regimens were classified into Anthracycline-Cyclophosphamide-based (AC-based) and Cyclophosphamide-Methotrexate+5-Fluorouracil (CMF). Longitudinal data were analyzed by mixed effects model for treatment effects over time, adjusting for baseline age and BMI.

RESULTS: Both chemotherapy regimens resulted in significant decline in ovarian reserve compared to the tamoxifen-only treatment ($p<0.0001$ either regimen vs. tamoxifen for overall trend). The AMH levels sharply declined at 12 months and the level of decline did not differ between the two chemotherapy groups ($p=0.53$).There was no significant recovery from 12 to 18 and 18 to 24 months after the completion of AC-based or CMF regimens ($p=0.97$). While the mean/median AMH level was 0.34/0.09 ng/dl at the 12-month time point, it was 0.40/0.06 ng/dl and 0.42/0.07 ng/dl at 18- and 24-month time points for the AC-based regimens group. These values were 0.11/0.03, 0.12/0.02 and 0.20/0.03 at the 3 time points for the CMF group. These mean levels are substantially below the threshold for normal ovarian reserve, which is generally 1.1 ng/mL or higher for the age group. AMH levels remained undetectable in 20% (15/76) vs. 38% (5/13) of women in the AC-based regimens vs. CMF groups at 24 months ($p=0.16$ from Fisher exact test). In contrast, tamoxifen-only treatment did not significantly alter the age-adjusted serum AMH levels over the 24-month follow up. Likewise, the use of adjuvant tamoxifen following AC-based regimens did not affect AMH recovery.

CONCLUSIONS: Our study is the first to assess ovarian reserve changes with serum AMH in a prospective longitudinal fashion, with multiple time points up to 24-month post-completion of chemotherapy, and in comparison with tamoxifen-only treatments. It shows that both AC-based regimens and CMF significantly compromise ovarian reserve, without a recovery beyond 12 months post-chemotherapy. In contrast, tamoxifen-only treatment does not alter serum AMH levels. The latter also indicates that the ovarian reserve of women who are on long-term tamoxifen treatment can be reliably assessed by serum AMH. This study provides novel information which will be useful in counseling young women with breast cancer for fertility preservation and in assessing post-chemotherapy ovarian damage and recovery.

SUPPORT: This study was supported by RO1 HD053112 from the Eunice Kennedy Shriver. National Institute of Child Health and Human Development (NICHD), and National Cancer Institute.

SHOULD THERE BE AN "AI" IN TEAM?: EMBRYOLOGISTS IMPROVE SELECTION OF HIGH IMPLANTATION POTENTIAL EMBRYOS WITH THE AID OF AN ARTIFICIAL INTELLIGENCE ALGORITHM.

Victoria W. Fitz, MD, MSCR,[1] Manoj Kumar Kanakasabapathy, MS,[2] Prudhvi Thirumalaraju, BS,[2] Leslie B. Ramirez, PhD,[3] Jason E. Swain, PhD, HCLD,[4] Carol Lynn Curchoe, PhD, TS (ABB),[5] Kaitlyn E. James, PhD,[1] Irene Dimitriadis, MD,[1] Irene Souter, MD,[1] Charles L. Bormann, PhD,[1] Hadi Shafiee, PhD.[2] [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Extend Fertility, New York, NY; [4]CCRM Fertility Network, Lone Tree, CO; [5]San Diego Fertility Center, San Diego, CA.

OBJECTIVE: A deep learning artificial intelligence (AI) algorithm has been demonstrated to outperform embryologists in identifying euploid embryos destined to implant with an accuracy of 75.3% (1). While initial AI selection results are promising, this method of selection is completely driven by an algorithm and does not factor in the visual assessment of an embryologist. Our aim was to evaluate the performance of highly trained embryologists in selecting top quality day 5 euploid blastocysts with and without the aid of a deep learning algorithm.

DESIGN: Before and after.

MATERIALS AND METHODS: A non-overlapping series of 200 sets of Day 5 euploid embryo images with known implantation outcomes was distributed to 14 highly trained embryologists from multiple centers in the US. They were asked to select which of two embryos to transfer from each set. The same 200 sets of embryos, but with indication of which embryo in each set had been identified by the algorithm was then distributed and they were again asked to select which to transfer. Paired t-test and receiver operating curves were performed in Stata to compare the percent of embryos with successful implantation selected by embryologist visual assessment alone to those selected with aid of the algorithm.

RESULTS: Embryologists provided with AI results selected embryos which successfully implanted in 76.5% of cases compared to 69.5% for those selected using visual assessments alone ($p<0.019$). All 14 embryologists improved in their ability to select embryos with the aid of the AI algorithm with a mean percent improvement of 11.1% (range 1.4% to 15.5%). Accuracy of selection improved after addition of AI as well. The AUC (95% CI) for embryo selection by an embryologist alone compared to the same embryologist with AI was 0.69 (0.62-0.75) and 0.76 (0.70-0.82) respectively ($p<0.016$). There were no differences in degree of improvement by embryologist level of experience (junior, intermediate, senior).

CONCLUSIONS: The incorporation of an AI framework for blastocyst selection enhanced the performance of trained embryologists in identifying PGT-A euploid embryos destined to implant. A large randomized controlled trial is warranted to confirm that embryologists in combination with AI can improve in-vitro fertilization outcomes by selecting embryos with higher implantation potential than the current method of visual assessments alone.

P-956 3:30 PM Wednesday, October 21, 2020

OLDER OLIGOASTHENOZOOSPERMIC MEN HAVE ALTERED TELOMERE BIOLOGY AND LESS CHANCES THAN CONTROLS FOR ASSISTED REPRODUCTIVE TECHNOLOGY OUTCOMES (ART).

Isabel Córdova-Oriz, MSc,[1] Raquel García-Panadero, MSc,[2] Guillermo De Alba, MSc,[2] Alberto Pacheco, PhD,[3] Carlos Balmori, MD,[4] Lucía Chico-Sordo, MSc,[1] Alba M. Polonio, MSc,[1] Marta Medrano, B.Sc,[5] Juan A. Garcia-Velasco, MD, PhD,[2] Elisa Varela, PhD[5] [1]IVI Foundation, IIS La Fe, Valencia, Spain; [2]IVI Madrid, Rey Juan Carlos University, Madrid, Spain; [3]IVIRMA Madrid, Madrid, Spain; [4]Rey Juan Carlos University, IVI Madrid, Madrid, Spain; [5]IVI-RMA Madrid, Rey Juan Carlos University, Madrid, Spain.

OBJECTIVE: The male factor accounts for half of the infertility cases that request ART. Beyond known causes, such as genetic, metabolic, endocrine, infectious or anatomic, new pathways could enlighten the 30% unexplained cases of male infertility. Because the telomere pathway affects organ function, due to telomere attrition with age, it is a good candidate to explain idiopathic infertility. Telomeres consist of DNA tandem repeats, which are bound by a protein complex, known as shelterin, which localize at the ends of linear chromosomes, safeguarding chromosome integrity. While in somatic differentiated cells telomere lenght (TL) decreases with age, spermatozoa show long telomeres. The objective of the study is to evaluate whether the telomere pathway is associated with low quality sperm parameters and ART outcomes.

DESIGN: Analytic prospective cohort study.

MATERIALS AND METHODS: 80 males were recruited between 2018 and 2019 from IVIRMA Madrid. The cohort includes two different age groups, younger than 25 and older than 40, composed of normozoospermics (NZ) or oligoasthenozoospermics (OAZ) men (25 people per group). Leukocytes and spermatozoa were extracted and then, evaluated for TL and TRF1 levels by Quantitative Fluorescent In Situ Hybridization followed by image acquisition using high resolution confocal microscope. CY3-fluorescent intensity (telomeres) was analyzed with the Definiens software. Seminal and IVF s parameters were assessed according to IVIRMA standard protocols.

RESULTS: In blood, a tendency to higher TL in young NZ compared with OAZ was observed. In addition, a lower percent of long telomeres was observed in OAZ (30% vs 45.26%, $p = 0.015$). Interestingly, a trend towards telomere lengthening with age was observed in NZ spermatozoa from both

age groups. TL was similar in young groups while in older groups TL was statistically significantly different (134.6 ± 15.95 a.u vs 113.6 ± 12,99 a.u, NZ and OAZ respectively, $p = 0.035$). Moreover, an accumulation of critically short telomeres was found in older OAZ (3.28 % vs 11.68 %, NZ and OAZ respectively; $p = 0.043$). To analyse telomere protection, TRF1 levels were studied. In blood, younger OAZ showed lower levels of TRF1 (317.3 ± 49.93 a.u vs 267.7 ± 40.02 a.u, NZ and OAZ respectively; $p = 0.010$) and accumulated a higher percent of low TRF1 levels at telomeres (16.9% vs 25.22 %, $p = 0.001$). Regarding ART outcomes, a lower rate of fertilization per Metaphase II oocytes (0.358 ± 0.072 vs 0.811 ± 0.019, $p < 0.0001$) and a higher rate of abortion (0.277 ± 0.188 vs 0.014 ± 0.014, $p = 0.032$) was found in older OAZ after intracytoplasmic sperm injection using donor oocytes and transfer.

CONCLUSIONS: OAZ patients have a shorter systemic TL already detectable at young age and also patent in sperm at older ages, possibly due to telomere unprotection with low levels of TRF1. Therefore, in OAZ patients, alteration of telomere biology could cause the premature aging of the reproductive system. Additionally, older OAZ had worse ART outcomes in contrast with NZ, suggesting that correct TL maintenance is a potential molecular marker of sperm quality to consider at older ages, before performing ART.

P-957 3:30 PM Wednesday, October 21, 2020

THE IMPACT OF THE COVID-19 PANDEMIC IN TERMS OF QUALITY OF LIFE AND DISTRESS IN INFERTILITY, A QUESTIONNAIRE STUDY.

Simone Cornelisse, MD, Dagmar E. Besselink, MD, Merel Sabine Vos, BSc, Aleida G. Huppelschoten, MD, PhD, Didi DM Braat, Proffesor, and Chris M. Verhaak, Professor (Associate) Radboud University Medical Centre, Nijmegen, Netherlands.

OBJECTIVE: The COVID-19 pandemic has an impact on daily life as well as fertility care. Evidence supports the notion that infertility causes substantial emotional distress and has a significant impact on a person's quality of life. The effects of the COVID-19 pandemic on experiencing emotional distress in subfertile patients compared with their pre pandemic situation are unclear. In this study the impact of the restrictive consequences of COVID-19 in terms of emotional distress and infertility related quality of life is investigated, by comparing the pre pandemic emotional distress in a cohort of men and women at time of the first consultation in our fertility clinic with distress and quality of life during the COVID-19 pandemic.

DESIGN: An online questionnaire study regarding couples with an indication for IVF, whose treatment was, due to the restrictive measures of the COVID-19 pandemic, interrupted or postponed without knowledge of the length of time.

MATERIALS AND METHODS: Pre pandemic, all patients in our clinic received the SCREENIVF questionnaire during their first consult as a standard procedure (T0). After closure of our clinic in March due to the restrictive consequences, were patients invited by email, on the 16th of June 2020, to participate in an online questionnaire study (T1). Consenting participants provided demographic information and completed the validated FertiQoL and SCREENIVF questionnaires.

Mean scores were compared using the Paired-Samples T Test, while the McNemar test was used on paired nominal data.

RESULTS: From the 336 invited patients, 120 responded. More women (n=79) than men (n=41) agreed to participate in the study. Of the 120 participants, 72 (60%) completed the SCREENIVF at T0. We analyzed the difference between scores at T0 and T1 of those 72 participants. At T1, the mean score of the SCREENIVF was higher in the domains Anxiety, (mean score T0 4.0±3.2 vs T1 5.3±3.5, p=0.002), and Helplessness (mean score T0 10.7±3.0 vs T1 12.7±4.7, p<0.001). There was no significant difference in the domains Social support and Acceptance. In the domain depression, the mean score was higher at T0 (mean score T0 6.2±4.7 vs T1 3.7±3.2, p<0.001). The number of participants scoring high at risk of emotional distress on the different domains of the SCREENIVF was higher at risk on T0 (29.2% vs 11.1%, p=0.011).

During COVID-19 pandemic, the total score of the FertiQoL off all participants was 71.1(± 12.5). Women had lower total FertiQoL scores (68.7 ± 11.4) than men (75.8 ± 13.8; P = 0.003); this was true for each domain (except Relational).

CONCLUSIONS: This study shows the impact of the COVID-19 pandemic on emotional distress, especially revealed by more feelings of anxiety and helplessness. Meanwhile, patients' level of depression showed a decrease in times of pandemic compared to the time of the first consultation. Those results might be explained with the thought that due to the pandemic there is more loss of control (i.e. related to anxiety) than loss of hope (i.e. related to depression). We need to address the increased feelings of anxiety and helplessness in our patients.

P-958 3:30 PM Wednesday, October 21, 2020

ASSOCIATIONS AMONG MORPHOLOGICAL PARAMETERS, CLINICAL FACTORS AND EUPLOID BLASTOCYST FORMATION.

João Paolo Bilibio, PhD,[1] Pânila Longhi Lorenzzoni, MsC,[2] Arivaldo José Conceição Meireles, PhD.[3] [1]Federal University of Pará, Belém, Brazil; [2]Federal University of Rio Grande do Sul, Porto Alegre, Brazil; [3]Pronatus Human Reproduction Clinic, Belém, Brazil.

OBJECTIVE: To evaluate the association among embryonic morphological parameters, clinical factors and euploid blastocyst formation.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: There were a total of 430 blastocyst embryos that underwent PGT-A by next-generation sequencing (NGS) from 135 patients who underwent intracytoplasmic sperm injection (ICSI) during the study period, June 2018 to June 2019. Embryo biopsy occurred on D5 or D6 according to the blastocyst morphology. Only blastocyst embryos with a visible inner cell mass and with a degree of expansion greater than 2 were submitted to biopsy. After embryo biopsy, all fragments were sent for PGT-A. After the results were obtained, statistical analysis was performed to assess the association of the risk of aneuploidy with the characteristics of embryonic development and the couple's clinical infertility factors.

RESULTS: Of 422 blastocysts, 200 (47.4%) were euploid, and 222 (52.6%) were aneuploid. Women over 38 years old were more likely to form aneuploid embryos (OR: 3.4, CI: 2.2-5.4, P<0.001). Poor ovarian reserve (OR: 3.3, P<0.001), increased male age (39.0 versus 40.7, P=0.019), and decrease in the percentage of sperm with normal morphology (2.5% vs. 1.9%, P=0.047) were associated with aneuploidy. Type C trophoectoderm (TE) and type C inner cell mass type were associated with a

TABLE 1. Predictive value, likelihood ratio, sensitivity, and specificity for diagnosis of embryo aneuploidy

	Pretest prevalence	PPV	NPV	LR+	LR-	Sensitivity (%)	Specificity (%)
Two factors							
Maternal age > 38 years + ICM type C	52.6	81.8	49.6	4.0	0.9	12.0	97.0
Maternal age > 38 years + TE type C	52.6	88.6	51.4	7.0	0.8	17.4	97.5
Three factors							
Maternal age > 38 years + TE type C + ICM type C	52.6	85.0	48.8	5.1	0.9	7.6	98.6

PPV: Positive predictive value; *NPV: Negative predictive value; LR: Likelihood ratio; ICM: Inner cell mass; TE: Trophoectoderm.*

high risk of embryo aneuploidy with an OR of 4.1 (CI: 2.2-7.7, P<0.001) and (OR: 1.7, CI: 1.01-3.0, P=0.048), respectively. Logistic regression analysis revealed maternal age and type C TE as the main risk factors for aneuploidy. Among combinations of factors (table 1), the best marker for the risk of aneuploidy was maternal age above 38 years combined with an embryo with trophoectoderm type C, which had a positive predictive value of 88.6% and specificity of 97.5%.

CONCLUSIONS: The trophoectoderm and inner cell mass type C are the major embryo risk factors for aneuploidy, explaining approximately 71% and 60% of the risk, respectively. Among clinical factors, advanced maternal and paternal age (greater than 38 and 36 years, respectively), antral follicle (< 5), and low percentage of sperm with normal morphology increased the risk of embryonic aneuploidy.

P-959 3:30 PM Wednesday, October 21, 2020

IS UNIVERSAL SCREENING OF IVF PATIENTS FOR SARS-COV-2 JUSTIFIED? Daniel S. Seidman, MD,[1] Arik Kahane, MD,[2] Adrian Shulman, MD,[1] Eyal Schiff, MD,[1] Tal Shavit, MD[1] [1]Assuta Medical Center, Ramat-Hachayal, Tel-Aviv, Israel; [2]Assuta Medical Center, Rishon LeZion, Israel.

OBJECTIVE: Resuming all ART treatments in Israel, following the COVID-19 lockdown put into effect on March 22, 2020, was fraught with concern, as the pandemic is still raging. One of the safety measures implemented was universal screening for SARS-CoV-2 of all ART patients. Our aim was to assess the usefulness of this measure.

DESIGN: Cohort study.

MATERIALS AND METHODS: All women initiating ART treatment from May 1st, through July 17, 2020, at one of the two IVF Units of the Assuta Medical Centers, were required to undergo screening with nasopharyngeal swabs and a quantitative polymerase-chain-reaction test to detect SARS-CoV-2 infection. All women with symptoms of Covid-19 or those with recent exposure to an infected person were not allowed to commence ART treatment. Since almost all of the IVF cycles performed at our centers are fully covered by the Israeli national health insurance, treatment is very accessible, and thus we believe that our sample is representative of the country's COVID-19 prevalence.

RESULTS: A total of 4,259 asymptomatic women underwent ART treatments at the Assuta Medical Centers, 2,787 ovum pick-ups and and 1,472 frozen embryo transfers. Overall, 23 women (0.54%) tested positive for SARS-CoV-2. The rate of women who tested positive was similar in our IVF center in Tel-Aviv, 11 of 2,299 women (0.48%), and in our more southern Rishon Lezion center, 12 of 1,970 (0.61%). An additional 11 women had to cancel their IVF treatment as their male partner was tested positive for SARS-CoV-2. Only a fifth of the positive patients came from cities declared by the Ministry of Health as Covid-19 hotspots.

CONCLUSIONS: Our use of universal SARS-CoV-2 testing in all ART patients initiating ART treatment revealed that at this point in the pandemic in central Israel, one in 200 asymptomatic women starting an ART treatment cycle was positive for SARS-CoV-2. This ratio is approximately 10 times lower than the current rate among women screened in Israel due to Covid-19 related symptoms or exposure to a positive person. The potential benefit of universal testing for Covid-19 includes the ability to protect patients and health care staff during these challenging times by lowering the risk of novel coronavirus exposure in the ART clinic. However, universal screening may burden the limited testing resources and may lead to less vigilant use of personal protective measures.

CAN WE DIAGNOSIS ENDOMETRIOSIS WITH A PHONE APP? NEZHAT ENDOMETRIOSIS ADVISOR MOBILE APPLICATION AS A PREDICTOR FOR ENDOMETRIOSIS IN PATIENTS EXPERIENCING PELVIC PAIN, INFERTILITY OR UNEXPLAINED INFERTILITY. Janelle M. Jackman, MBBS,[1] Anuj Vaid, BA,[2] Shruti Agarwal, DO,[1] Azadeh Nezhat, MD,[3] Camran Nezhat, MD.[3] [1]Camran Nezhat Institute, Center for Special Minimally Invasive and Robotic surgery, Stanford University Medical Center, Palo Alto, CA; [2]Drexel University, Philadelphia, PA; [3]Camran Nezhat Institute, Center for Special Minimally Invasive and Robotic surgery, Stanford University Medical Center, University of California San Francisco, Palo Alto, CA.

OBJECTIVE: Endometriosis has a debilitating impact on women's lives, including severe pain, infertility and interference with daily life. For most women with endometriosis, the diagnosis is often missed, misdiagnosed and it is usually takes years before the right diagnosis is made. The first step in alleviating the adverse sequelae on endometriosis is to promptly and accurately diagnose it. Unfortunately, there is usually a delay especially in women with lower socioeconomic background as the diagnosis is made surgically. Our study is to evaluate the positive predictive value (PPV) of Nezhat Endometriosis Advisor

mobile application questionnaire as a noninvasive screening test for the diagnosis of endometriosis in patients experiencing severe or chronic pelvic pain, recurrent pregnancy loss, or unexplained infertility.

DESIGN: Retrospective study design.

MATERIALS AND METHODS: Retrospective cohort study at a university-affiliated private practice. Inclusion criteria were women who had no previous surgical diagnosis of endometriosis who utilized the app and was scheduled for laparoscopic surgery due to history. Patients then underwent laparoscopic

surgery with an indication of diagnosing and treatment of suspected endometriosis. The primary outcome

measured was the PPV of Nezhat Endometriosis Advisor mobile application questionnaire to the

surgical diagnoses of endometriosis. Statistical analysis was performed using SPSS v.25.0.

RESULTS: 30 patients met the inclusion criteria so far for our on going study. 95.0% of patients who had a screening test result of 90% or more on the app, had a surgical pathology confirmed diagnosis of endometriosis. However 100% of the patients who had a screen result of >90% on the app, had visual diagnosis of endometriosis at different stages at the time of surgery. The 8% who did not have pathological confirmation of endometriosis, had fibrosis diagnosed which may be due to late presentation of endometriosis example burnt out endometriosis presentation. The PPV of the screening questionnaire for endometriosis was 95.0%. In patients with app scores between 75-90%, pathology confirmed endometriosis 80% of times. Few patients who had diagnostic surgery despite low scores, endometriosis was confirmed in less than 10% of the cases. All patients had complete resolution or improved symptomatology after surgery.

CONCLUSIONS: Nezhat Endometriosis Advisor mobile application questionnaire has a high PPV of 95% for diagnosing endometriosis and can help identify a patient population that may require surgical treatment for pelvic pain or unexplained infertility. This will be helpful as it may lead to earlier presentation of endometriosis which will help with treatment and management. This is also very beneficial to patients in lower socioeconomic demographics who may not have easy access to healthcare and may otherwise suffer for a long time with pain or infertility before a diagnosis is made. More research is needed to determine the continued accuracy of the app in different patient population and demographics.

A COMPREHENSIVE COVID-19 RISK MITIGATION STRATEGY FOR SAFE PATIENT CARE AND STAFF WELLNESS DURING A GLOBAL PANDEMIC. Mandy G. Katz-Jaffe, PhD,[1] Lauren Henry, BS,[1] Nathan McCubbin, BS,[1] Rachel Tucci, BS,[1] Rachel S. Mann, BS, MS,[1] Susanna McReynolds, PhD,[1] William B. Schoolcraft, MD[2] [1]Colorado Center for Reproductive Medicine, Lone Tree, CO; [2]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: In the midst of the COVID-19 epidemic and the estimation that the vast majority of the population remains susceptible to SARS-CoV-2 infection, a comprehensive risk mitigation strategy to identify asymptomatic and pre-symptomatic carriers is key to providing safe clinical care during fertility treatment. The objective of this study was to evaluate the efficiency of a combined triage protocol and molecular testing for active SARS-CoV-2 viral infection for both patients and staff from a multi-site IVF network.

DESIGN: Prospective study.

MATERIALS AND METHODS: A symptomatic triage was performed whereby all patients were contacted by phone for the presence of COVID-

19 symptoms or if they had been in contact with someone suspected or confirmed to be positive for the virus. Only patients determined to be at low risk for COVID-19 were allowed to enter the clinic for fertility treatment. Both patients and staff were required, upon arrival at the clinic, to wear a mask, complete a symptom-based questionnaire, record body temperature, and keep a safe social distance of more than 6 feet at all times. Any individual recording a fever over 100.4^{O}F and/or two or more symptoms was instructed to stay/return home for self-quarantine. Specimen collection for viral screening involved an anterior nare sampling method and storage in a FDA approved viral transport medium. Viral RNA was isolated using the MagMAX™ Viral/Pathogen II (MVP II) Nucleic Acid Isolation Kit (Thermo Fisher Scientific). Molecular testing for active SARS-CoV-2 viral RNA infection was performed using the FDA emergency use authorized TaqPath™ RT-PCR COVID-19 test (Thermo Fisher Scientific) for every patient within 3-5 days prior to oocyte retrieval or an attempt to achieve a pregnancy, and for all staff bi-weekly. Positive cases were reported to each respective local State Health Department.

RESULTS: Of the 2,074 patients tested for COVID-19 between May and July 2020 across nine fertility clinics in the US, only 3 (0.15%) were found to be positive for SARS-CoV-2 viral RNA infection. In all cases the patients were asymptomatic and passed the triage protocol. PCR testing of staff bi-weekly identified 6 positive cases. All but one indicated having one or two mild symptoms. There were no recorded community transmissions among either patients to staff or between staff members.

CONCLUSIONS: A comprehensive risk mitigation strategy that includes a combined triage protocol, safe social distancing and molecular testing for active SARS-CoV-2 viral RNA infection in both patients and staff enables early detection and isolation of infected asymptomatic or pre-symptomatic individuals, thereby creating a safe environment for patient care and staff welfare during the global COVID-19 pandemic.

SEMINAL TEX-101 MAY PREDICT RESTORATION OF SPREMATOGENESIS AFTER VARICOCELECTOMY IN AZOOSPERMIC MEN WITH PALPABLE VARICOCELE.

Ahmed Mohamed El Guindi, M.D,[1] Mina Saad, MSc,[1] Zeinab Nour, M.D,[2] Hamed Abdallah Hamed, M.D,[1] Mohamed Wael Ragab, M.D[1] [1]Cairo University, Cairo, Egypt; [2]Cairo University, Cairo, Egypt.

OBJECTIVE: around 40% of men with non-obstructive azoospermia (NOA) and palpable varicocele may benefit from varicocelectomy with appearance of sperms in ejaculate. Testicular histopathology predicts the outcome of varicocelectomy and men with hypospermatogenesis or late maturation arrest have better prognosis compared to men with early maturation arrest or Sertoli cell only (SCO) syndrome.

Testis expressed protein (TEX-101) is a seminal plasma protein that shed from testicular germ cells and it has been found to be significantly lower in men with SCO in compare with other NOA subtypes.

We aimed to assess the predictive role of seminal TEX-101 in recovery of sperms in ejaculate after varicocelectomy.

DESIGN: Prospective cohort.

MATERIALS AND METHODS: Forty male patients with NOA and palpable bilateral varicocele were subjected to seminal TEX-101 by ELISA (Wuhan Fine Biotech Co., Ltd. China), serum gonadotropins and total testosterone evaluation, followed by sub-inguinal microsurgical varicocelectomy. Two seminal analyses were performed in 3- and 6-months follow-up periods to assess appearance of sperms in ejaculate.

Mann Whitney test was used to compare pre-operative seminal TEX-101, FSH, LH and testosterone between the group of men with observed sperms in ejaculate during follow-up (group 1) and men with persistent azoospermia (group 2). Receiver operating curve (ROC) test was used to calculate a cut-off value and diagnostic indices (sensitivity and specificity) of pre-operative seminal TEX101.

RESULTS: After varicocelectomy, spermatozoa were found in the ejaculate of 10/40 (25%) through the follow-up (7 patients at the 3-months follow-up and additional 3 patients at 6-months follow-up). In these ten patients (G1), no significant differences were observed in pre-operative testicular volume or serum testosterone levels in compare with patients with persistent azoospermia during follow-up period (G2).

Pre-operative seminal TEX-101 was significantly higher in G1 in compare with G2 (p=0.014), while serum FSH and LH were significantly higher in G2 (p=0.001, p=0.01 respectively), as shown in table (1).

TABLE (1).

	G1 (n=10)	G2 (n= 30)	P value
TEX101 (ng/ml)	13.5 (7.5-22.3)	9.8 (2.8-18.2)	**0.014**
FSH (mIU/ml)	5.1 (3.5-9.2)	13.9 (3.5-31.2)	**0.001**
LH (mIU/ml)	4.2 (2.4-6.5)	6.3 (2.7-27)	**0.01**
Total testosterone (nmol/L)	5.1 (2.2-13)	4.5 (1.9-10.8)	0.818

Data are expressed as median (range).

Area under curve using ROC was 0.76 and a cut-off value of ≥9.9 ng/ml showed sensitivity of 90% and specificity of 57% in pre-operative TEX-101 prediction of recovery of sperms.

CONCLUSIONS: Pre-operative seminal TEX-101 can be used as a predictor for recovery of sperms in the ejaculate after varicocelectomy in men with NOA and palpable varicocele.

NCT04397887.

EFFECT OF HORMONAL CONTRACEPTION ON ILLNESS SEVERITY IN WOMEN WITH POSITIVE SARS-COV2 TESTS.

Vaidehi Mujumdar, MD,[1] Ariel T. Levy, MD,[2] Rachel Madding, BA,[3] Vincenzo Berghella, MD,[1] Johanna Quist-Nelson, MD,[4] William D. Schlaff, MD,[1] Brent C. Monseur, MD, ScM[5] [1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Weill Cornell Medical Center, New York Presbyterian Hospital, New York, NY; [3]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [4]University of North Carolina, Chapel Hill, Chapel Hill, NC; [5]Stanford Hospitals and Clinics, Sunnyvale, CA.

OBJECTIVE: To evaluate if hormonal contraception affects illness severity in SARS-CoV2 positive women.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Chart review of reproductive age (12-49 yo) women who tested positive for SARS-CoV2 at a tertiary medical center from March 28-April 27, 2020. Exclusion criterion was pregnancy. Women using hormonal contraception were compared to patients not using hormonal contraception. Patients were not contacted to confirm contraception. The primary outcome was hospital admission rate. Secondary outcomes included a composite score for illness severity and clinical signs of infection (Table 1). Multivariable logistic regression was used to control for differences at baseline. Results are reported as adjusted odds ratio (aOR) with a 95% confidence interval (CI). Calculated p values $\leq$ 0.05 were statistically significant.

RESULTS: A total of 2044 women were screened for SARS-CoV2. Of the 132 positive women, 46 used hormonal contraception: levonorgestrel IUD (n=9; 19.6%), injectable progestin (n=2; 4.35%), oral progestin (n=3; 6.52%), oral contraceptive (n= 24; 52.1%), transdermal patch (n=4; 8.70%), vaginal ring (n=4; 8.70%) and 86 did not use hormonal contraception. The rate of hospitalization for SARS-CoV2 was low for users and non-users of hormonal contraception (2.3% vs. 3.8%, respectively) and was not statistically different between groups. There was no difference between the rate of symptoms and clinical signs of infection between groups.

CONCLUSIONS: Sex hormones may play a significant role in regulating immune response and can impact disease state. We provide preliminary evidence that use of hormonal contraception does not have a significant effect on the illness severity in SARS-CoV2 as measured by hospitalization.

TABLE 1. Primary and secondary outcomes

	Hormonal contraception (n= 44)a	Not on hormonal contraception (n=79)a	Adjusted OR (95% CI)
Primary Outcome			
Hospital admission	1 (2.3)	3 (3.8)	0.99 (0.68-1.44)
Clinical Signs			
Composite score of illness severity[b]	1 (2.3)	2 (2.5)	0.98 (0.67-1.43)
Heart rate > 100 beats/min	4 (9.1)	3 (3.8)	0.99 (0.68-1.45)
Respiratory rate > 22 breaths/min	1 (2.3)	1 (1.3)	0.97 (0.67-1.42)

TOLL-LIKE RECEPTOR-2 AND TISSUE INHIBITOR OF MATRIX METALLOPROTEINASE-2 GENETIC VARIANTS AS PREDICTORS OF TOBACCO-MEDIATED FEMALE INFERTILITY AMONGST *MYCOBACTERIUM TUBERCULI*-POSITIVE ASIAN INDIAN COHORT. Saumya Pandey, M.Sc., Ph.D. Indira IVF Hospital, Udaipur, India.

OBJECTIVE: Tobacco-consumption is a significant predictor of metabolic-perturbations in female reproductive physiology, including endometriosis/stillbirths/miscarriages/infertility worldwide. Targeting Toll-like receptor-2 and Tissue Inhibitor of Matrix Metalloproteinase-2 genetic polymorphisms in demystifying the underlying genetic/cellular/molecular basis of tobacco-mediated female infertility amongst Asian Indian cohort is an immunotherapeutically attractive strategy for cost-effective infertility management. This study aimed to evaluate the role of TLR-2(-196 to -174del) and TIMP-2 (-418G>C) [rs8179090] gene-polymorphisms in susceptibility to tobacco-mediated infertility amongst Asian Indian women.

DESIGN: Prospective case-control (1:1) hospital-based study.

MATERIALS AND METHODS: 100 Asian Indian *Mycobacterium tuberculi*-positive infertility patients (>35 years) and 100 unrelated/age-matched/*M. tb.*-negative/married (parity: 2-4 children) female controls of similar ethnicity were enrolled (sample-size calculation using Quanto); *M. tb.*-positivity was assessed using Gene-Expert/TB-Gold PCR-testing. Endometrial thickness was determined using Color-Doppler imaging. Genomic DNA extraction from peripheral blood samples collected from study subjects (N=200) was carried out using salting-out method. TLR-2/TIMP-2 genotyping was performed using polymerase chain reaction-based restriction fragment length polymorphism. Self-reported tobacco-usage was ascertained using bilingual Questionnaire in English/Hindi dialects. Statistical data-analysis was performed using multivariate logistic regression analysis with Bonferroni's corrections for multiple comparisons in stratified subgroups (SPSS ver.16.0).

RESULTS: The findings demonstrated no significant association between TLR-2 (-196 to -174del) and TIMP-2 (-418G>C) gene-polymorphisms and risk of developing *M. tb.*-mediated infertility in the study-population; stratified-analysis using case-only study-approach revealed no effect of TLR-2/TIMP-2 polymorphisms on *M. tb.*-positive infertile patients (N=100) with thin endometrium <6.0 mm; recombinant Granulocyte-Colony-Stimulating-Factor infusion (300 mcg) significantly increased endometrium thickness (p>0.05). TLR-2 and TIMP-2 genetic variants modulated the risk in infertile patients who smoked/chewed tobacco (55% tobacco-users) with borderline association (p=0.046); TLR-2 ins/del genotype showed strong association (OR=1.9 [95%CI=1.1-3.3]) with tobacco-usage in infertile women with *M. tb.*-positivity. Overall, the study demonstrated lack of association between TLR-2 and TIMP-2 gene-polymorphisms and infertility susceptibility in women of Asian Indian ethnicity.

CONCLUSIONS: The study highlighted the significance of TLR-2/TIMP-2 genetic variants in tobacco-mediated infertility susceptibility in Asian Indian women providing fascinating avenues for future development of TLR-2/TIMP-2 predictive biomarkers in stratifying *M. tb.*-positive infertile patient-populations.

PRETERM BIRTH SUBTYPES BY FERTILITY STATUS AND FERTILITY TREATMENT: A POPULATION-BASED COHORT STUDY. Yimin P. Wang, MSc,[1] Jessica Pudwell, MSc, MPH,[1] Joel G. Ray, MD, MSc,[2] Yingwei Peng, PhD,[1] Maria P. Velez, MD, PhD[1] [1]Queen's University, Kingston, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada.

OBJECTIVE: To evaluate preterm birth (PTB) subtypes, according to both fertility status and infertility treatment (IT).

DESIGN: Retrospective cohort study using linkage of universal health databases from Ontario, Canada.

MATERIALS AND METHODS: Included were all singleton births, April 2006-March 2014. Exposure categories were defined as spontaneous conception (reference); subfertility (history of an infertility consult billed as ICD-9 code 628 in the absence of IT); non-invasive IT (ovulation induction or intrauterine insemination); and invasive IT (IVF or ICSI). PTB outcome subtypes were classified as spontaneous or provider-initiated (iatrogenic). Modified Poisson regression generated risk ratios (RR) for the association between exposure categories

TABLE. Risk of preterm birth subtypes according to exposure by fertility status and fertility treatment

	Relative risk of preterm birth (95% CI)		
Exposure category	Any preterm birth	Spontaneous preterm birth	Provider-initiated preterm birth
Spontaneous conception	1.00 (ref)	1.00 (ref)	1.00 (ref)
Subfertility	1.16 (1.13 to 1.20)	1.15 (1.10 to 1.19)	1.23 (1.16 to 1.31)
Non-invasive IT	1.27 (1.17 to 1.36)	1.19 (1.09 to 1.31)	1.48 (1.29 to 1.69)
Invasive IT	1.63 (1.52 to 1.75)	1.40 (1.27 to 1.53)	2.35 (2.09 to 2.64)

and risk of PTB. Models were adjusted by inverse probability weighting, accounting for age, parity, obesity, smoking, hypertension, diabetes, income quintile, rurality and immigration status.

RESULTS: A total of 723,810 deliveries were included, of which 646,926 (88.3%) were by spontaneous conceptions; 68,822 (9.4%) in women with subfertility; 9024 (1.2%) by non-invasive IT; and 8038 (1.1%) by invasive IT. IT exposed women were significantly more likely to be older, nulliparous, obese, and have diabetes and chronic hypertension. PTB rates were 6.0% in women with spontaneous conceptions, 7.7% in those with subfertility, 8.0% with non-invasive IT, and 10.8% following invasive IT. Compared to women who had spontaneous conception, the RR of any PTB rose by degree of IT invasiveness (see Table). This was especially so for the outcome of provider-initiated PTB (Table).

CONCLUSIONS: Infertility, and its treatments, are associated with a higher risk PTB, especially provider-initiated PTB. Accordingly, strategies to reducing the risk of provider-initiated PTB are recommended.

SUPPORT: Canadian Institutes of Health Research (CIHR)

PLOIDY STATUS AND DEVELOPMENTAL POTENTIAL OF HUMAN BLASTOCYSTS CONTAINING NONDIVIDING BLASTOMERES OR FRAGMENTATION. Yimin Shu, MD, PhD, Jun Yang, Ph.D. Wake Forest University School of Medicine, Winston Salem, NC.

OBJECTIVE: Nondividing blastomeres are arrested cells that are excluded from developing embryos and remain outside the developing blastomeres at morula stage, leading to decreased blastocyst formation and blastocyst quality. Although remaining developing cells try to compensate the cell loss, very little data is available regarding its ploidy status and further developmental potential.

DESIGN: This retrospective data analysis involved infertility patients undergoing PGT-A through NGS in an academic IVF Program between January 2015 and February 2020.

MATERIALS AND METHODS: Artificial shrinkage of blastocoel by laser during the biopsy process allows us an opportunity to carefully observe the presence and extent of nondividing blastomeres/fragmentation under zona pellucida. We define a nondividing blastomere as an embryonic cell arrested during the first four embryonic divisions (2- to 16-cell stage). To differentiate fragmented polar bodies from real embryo fragmentation, only blastocysts with 10% or above fragmentation were defined as fragmented embryos. Biopsied trophectoderm cells were analyzed with NGS by CooperGenomics. The primary outcome measures are euploid/aneuploid rates. Clinical outcomes following transfer of euploid embryos were also investigated. Embryo implantation was defined as detection of a gestational sac and fetal heart beat.

RESULTS: Among 2891 biopsied blastocysts from 512 PGT-A cycles of 427 patients, 1945 did not have nondividing blastomere/fragmentation (67.3%) and 946 had (32.7%). Blastocysts without nondividing blastomeres had a significantly higher chance to be euploid (48.9% vs 40.6%, $p < 0.001$). This trend was also observed for each age group (<35, 35-37, 38-40, and >=41). On the other hand, higher percentage of euploid embryos containing nondividing blastomeres had complex chromosomal abnormalities (3 or more chromosomal abnormalities) (17.4% vs 10.2%). Embryo implantation rate of those euploid blastocysts without nondividing blastomeres was significantly higher than those with nondividing blastomeres (70.0% (255/366) vs 57.3% (75/131), $p<0.01$). More euploid blastocysts without nondividing blastomeres implanted for each patient group (<35, 35-37, >=38) (73.0%, 72.0%, and 60.2% respectively) as compared to those with nondividing blastomeres/fragmentation (66.1%, 55.6%, and 40% respectively) but their differences were not significant. Among the 28 euploid blastocysts with fragmentation, 19 implanted (67.9%). However, when there were 3 or more nondividing blastomeres in an euploid blastocyst, implantation rate (14/32, 43.8%) significantly decreased as compared to those with 1 or 2 nondividing blastomeres (42/74, 56.8%).

CONCLUSIONS: Our results showed that embryos with arrested nondividing blastomeres can maintain euploid and result in live births. However, its further developmental potential is compromised if remaining developing cells could not efficiently compensate the early cell loss. Our findings provide new insights regarding the extent to which blastocysts containing arrested blastomeres are capable of producing ongoing pregnancies.

SHEDDING LIGHT ON THE PSYCHOLOGICAL AND DEMOGRAPHIC PREDICTORS OF GAY AND BISEXUAL MEN'S DESIRE FOR PARENTHOOD AND PREFERRED TIMING OF PARENTHOOD. Hoi Yan Celia Chan, PhD,[1] Yuen Kiu Georgina So, MSc,[2] Yu Te Huang, PhD[2] [1]The University of Hong Kong, Hong Kong, Hong Kong; [2]The University of Hong Kong.

OBJECTIVE: In spite of improved accessibility of ART to parenthood in some parts of the world, sexual minority individuals still face significant psychosocial barriers in actualising their desire to become parents. Having internalized negative beliefs about homosexuals and lacking social support from LGBT communities are detrimental to the mental well-being of sexual minority individuals. However, little is known whether these factors influence gay and bisexual men's decision to parent. The study addressed how internalized homophobia, minority stress, and connectedness with the LGBT community influenced Taiwanese gay and bisexual men's desire for and preferred timing of parenthood?

DESIGN: A cross-sectional online survey was conducted in May 2018, the time before legalisation of same-sex marriage in Taiwan. 1,381 Taiwanese men self-identified as either gay or bisexual were recruited.

MATERIALS AND METHODS: Primary outcomes of interest were whether respondents wish to have children (yes vs. no) and whether they wish to children before or after 35 years. Importance of childbearing, internalized homophobia, minority stress, LGBT community connectedness, and a select set of demographic variables were treated as predictor variables and entered into two hierarchical binary logistic regression models for estimation of parenthood desire and timing of parenthood, respectively.

RESULTS: Overall 74% of respondents reported a desire to have children. Wanting children was associated with being bisexual (β=0.94, p< .001), having a university degree (β=0.69, p< .01), and being in a more satisfactory relationship among those who have a partner (β=0.04, p< .001). Higher perceived importance of childbearing to the self (β=1.49, p< .001), the relationship with one's partner (β=0.40, p< .01) and parents (β=0.25, p< .01), but not importance of childbearing to one's partner, was associated with greater odds of wanting children. While controlling for these variables, higher levels of internalized homophobia uniquely predicted greater parenthood desire (β=0.03, p< .05), while minority stress and LGBT community connectedness were not significant predictors. A second set of analyses were performed to examine factors associated with the preference to delay parenthood. Age is the only demographic factor predicting the wish to delay parenthood (β=0.16, p< .001). Respondents who reported higher levels of community connectedness with the LGBT community had a greater tendency to wish to have children after the age of 35 (β=0.07, p< .01). Neither perceived importance of childbearing, internalized homophobia or minority stress played a role in predicting the wish to delay parenthood.

CONCLUSIONS: Gay and bisexual men's desire for and preferred timing of parenthood are influenced respectively by levels of internalized stigma and connectedness with the LGBT community. More systematic efforts should be directed at exploring factors that underline gay and bisexual men's perceived self-competence as parents, paying particular attention to internalized homophobia and LGBT community connectedness affecting parenthood decisions.

RELATIONSHIP BETWEEN TEMPORAL CHANGES OF ENDOMETRIAL BLOOD FLOW IMPEDANCE IN A NATURAL AND HORMONE REPLACEMENT CYCLE AND PREDICTION OF PREGNANCY DURING VITRIFIED-WARMED EMBRYO TRANSFER. Toshifumi Takahashi, M.D., Kuniaki Ota, M.D. Fukushima Medical University, Fukushima, Japan.

OBJECTIVE: Frozen-thawed embryo transfer (ET) is performed in a natural or hormone replacement therapy (HRT) cycle for endometrial preparations. However, how to determine which endometrial preparation method is suitable for the individual is unknown.This study was to examine the relationship between the temporal changes in endometrial blood flow impedance during natural and HRT cycles and clinical outcomes in vitrified-warmed ET.

DESIGN: A single-center retrospective observational cohort study.

MATERIALS AND METHODS: This study was approved by the institutional review board of the Fukushima Medical University. This study

included a total of 60 women, 28 with natural and 32 with HRT cycles, who underwent vitrified-warmed ET. Uterine radial artery resistance index (RA-RI) was measured during the natural and HRT cycles at the early follicular phase, days of the human chorionic gonadotropin trigger during a natural cycle or start of progesterone administration during the HRT cycle, and the day of ET. The association between the RA-RI at the different measurement point and the pregnancy were examined in the natural and HRT cycles by univariate analysis and multivariate logistic analysis. Receiver-operating characteristic analysis was used to determine the cut-off value of the RI with respect to pregnancy in natural and HRT cycles. The area under the curves (AUC) and their 95% confidence intervals (CI) were calculated.

RESULTS: The clinical pregnancy rates of the natural and HRT cycles were 32.1% and 34.4%, respectively. In the univariate analysis, the RA-RI at the early follicular phase was significantly lower in the pregnant group than that in the non-pregnant group in the natural but not HRT cycle (P=0.04). In the multivariate logistic analysis, the RA-RI at the early follicular phase was an independent predictive factor for pregnancy in the natural but not HRT cycle (P=0.02). The odds ratio for pregnancy was 0.7 (95% CI, 0.52–0.95) when the levels of RA-RI at the early follicular phase was increased by 0.01 in the natural cycle. With the natural cycle, the area under the receiver-operating characteristic curves for the RA-RI at the early follicular phase with a threshold of 0.68 was 0.75 (95% CI, 0.57–0.93). The positive predictive and negative predictive values were 0.53 (95% CI, 0.37–0.59) and 0.92 (0.74–0.99), respectively.

CONCLUSIONS: With the natural cycle, the RA-RI at the early follicular phase was associated with pregnancy, and this might have a potential in predicting pregnancy in vitrified-warmed ET cycles. Our findings suggest that RA-RI at the early follicular phase might be an effective and useful tool in choosing natural or HRT cycles for vitrified-warmed ET. This provides a clue to the individualization of the choice of an endometrial preparation method during the frozen-thawed ET.

P-969 3:30 PM Wednesday, October 21, 2020

"EVALUATION OF DUAL TRIGGER (GNRH AGONIST PLUS HCG) VS HCG IN IMPROVING IVF CYCLE OUTCOME IN NORMAL RESPONDER GROUP- A PROSPECTIVE RANDOMIZED CLINICAL STUDY. Ritika Gupta, MBBS, DNB (OBGY) FELLOWSHIP IN REPRODUCTIVE MEDICINE,[1] Sanjay Makwana, MBBS, MS, DIPLOMA IN REPRODUCTIVE MEDICINE,[2] Rahul K. Sen, MSC, PHD[3] [1]FELLOW, VASUNDHARA HOSPITAL AND FERTILITY CENTER, JODHPUR, INDIA, GURUGRAM, India; [2]MEDICAL DIRECTOR VASUNDHARA HOSPITAL AND FERTILITY CENTER, JODHPUR, INDIA, JODHPUR, India; [3]chief embryologist, vasundhara hospital, jodhpur, JODHPUR, India.

OBJECTIVE: To assess role of Dual trigger (GnRH agonist plus Human chorionic gonadotropin) vs Human chorionic gonadotropin (hCG) in optimizing GnRH antagonist IVF- ICSI cycle outcome in normal responder group.

DESIGN: A Prospective randomized clinical study.

MATERIALS AND METHODS: Normal responder patients were allocated in two groups: case group who has received dual trigger (GnRH agonist (Triptorelin 0.2 mg) + rec-HCG (Ovitrel 250 μg) and control group who has received rec-hCG (Ovitrel 250 μg) only for ovulation trigger. Follicular aspiration was done 35 hr after trigger. Outcome variables measured were no. of follicles $>$ 15 mm on trigger day, no. of COCs retrieved, no. of M II oocytes retrieved, proportion of MII Oocyte (MII oocyte/ total no of oocyte), no. of day 3 good quality embryos, positive β -hCG cases, implantation rate, clinical pregnancy rate (CPR).

RESULTS: Total 100 patients were included for study: 50 in study and 50 in control group. Both groups were similar in terms of age (28.62 vs 28.54, P= NS), BMI (24.27vs 24.49, P=NS), AMH (2.53vs2.69, P=NS), AFC (11.48vs12.02, P =NS). There was no significant difference in duration and etiology of infertility, length of stimulation and no. of follicles $>$ 15 mm on trigger day between case and control group. Total no. of OCC retrieved in case and control group was 10.92$\pm$2.59 and 10.54$\pm$2.96 respectively. There was no significant (p$>$0.7) difference in no. of oocytes between dual and hCG trigger group(P value=0.7, NS). There was significantly higher no. of MII oocytes (7.24$\pm$2.60 vs 6.68$\pm$2.28, P value=0.02) in dual trigger as compared to hCG trigger group. Proportion of MII oocytes (65.62 vs 62.85, P= 0.03) was significantly higher in dual trigger group. There was no significant difference in no. day 3 embryos (5.42vs 4.82, P value=0.25,NS), implantation rate (23.56 vs 21.35, P value=0.07,NS) and CPR(36.73 vs 34.7, P value=0.36,NS) between both groups. Though, clinical pregnancy rate was slightly higher in dual trigger group but difference was not significant.

CONCLUSIONS: Dual trigger improves the no. and proportion of MII oocytes as compared to hCG trigger alone in normal responder group. The promising effect of dual trigger in improving oocyte maturity may potentially be utilized in improving IVF cycle outcome. Further larger prospective trials are needed for validation of beneficial effect of dual trigger in normal responder patient in future.

P-970 3:30 PM Wednesday, October 21, 2020

IMPACT OF 2008 AND COVID-19 ECONOMIC RECESSIONS ON FERTILITY TREATMENTS AND LIVE BIRTHS. Fady I. Sharara, M.D.,[1] Piotr Gromski, PhD,[2] Andrew D. A. C. Smith, PhD,[3] Deborah A. Lawlor, PhD,[4] Scott M. Nelson, MD, PhD[2] [1]Virginia Center for Reproductive Medicine, Reston, VA; [2]University of Glasgow, Glasgow, United Kingdom; [3]University of the West of England, Bristol, United Kingdom; [4]MRC Integrative Epidemiology Unit at the University of Bristol, Bristol, United Kingdom.

OBJECTIVE: The economic and reproductive medicine response to the COVID-19 pandemic in the United States has reduced the affordability and accessibility of fertility care. We sought to determine the impact of the 2008 financial and the COVID-19 recession on fertility treatments and cumulative live-births.

DESIGN: prospective projection modeling.

MATERIALS AND METHODS: We examined annual US natality, CDC IVF cycle activity and live birth data from 1999 to 2018 encompassing 3,286,349 treatment cycles, to estimate the age-stratified reduction in IVF cycles undertaken after the 2008 financial recession, with forward quantitative modelling of IVF cycle activity and cumulative live-births for 2020 to 2023.

RESULTS: The financial recession of 2008 caused a four-year plateau in fertility treatments with a predicted 53,026 (95% CI 49,581 to 56,471) fewer IVF cycles and 16,872

(95% CI 16,713 to 17,031) fewer live births. A similar scale of economic recession would cause 67,386 (95% CI: 61,686 to 73,086) fewer IVF cycles between 2020 and 2023, with women younger than 35 years overall undertaking 22,504 (95% CI 14,320 to 30,690) fewer cycles, as compared to 4,445 (95% CI 3,144 to 5749) fewer cycles in women over the age of 40 years. This equates to overall 25,143 (95% CI: 22,408 to 27,877) fewer predicted live-births from IVF, of which only 490 (95% CI 381 to 601) are anticipated to occur in women over the age of 40 years.

CONCLUSIONS: The COVID-19 recession could have a profound impact on US IVF live-birth rates in young women, further aggravating pre-existing declines in total fertility rates.

P-971 3:30 PM Wednesday, October 21, 2020

ALTERED FOLLICULAR FLUID MICRO RNA PROFILES IN POLYCYSTIC OVARIAN SYNDROME MAY SERVE AS PREDICTIVE BIOMARKERS OF OOCYTE MATURATION STAGE. Tamar Matitashvili, MD,[1] Sezgi Arpag, MSc,[2] Seifeldin Sadek, MD,[1] Gerard Celia, Jr., PhD,[1] Laurel Stadtmauer, MD, PhD,[1] Anca Dobrian, PhD[2] [1]Jones Institute, Norfolk, VA; [2]Eastern Virginia Medical School, Norfolk, VA.

OBJECTIVE: Our objective was to define extracellular vesicle's (EV) miRNA cargo in follicular fluid (FF) of polycystic ovarian syndrome (PCOS) and control patients to determine: potentially novel mechanistic pathways responsible for oocyte maturation and to establish correlations between EV miRNA cargo and oocyte maturation stage that could lead to discovery of novel biomarkers.

DESIGN: Prospective pilot study.

MATERIALS AND METHODS: Our study included 6 women diagnosed with PCOS based on Rotterdam criteria and 6 non-PCOS controls matched for age and BMI. Patients in both groups were on the standard gonadotropin releasing hormone antagonist protocol for controlled ovarian stimulation.

FF was obtained from the first punctured follicle in each ovary during oocyte retrieval, and further processed for isolation of small EVs using a commercially available kit. Following RNA extraction, miRNA composition was quantitated using the nanoString nCounter FLEX Analysis platform. Oocytes isolated from each of the individual follicles were scored for maturity staging, after the removal of cumulus cells. Comparisons between the two groups were performed using the Kruskal-Wallis test and correlations

between miRNA expression and clinical parameters were done using Spearman's non-parametric test.

RESULTS: In vitro fertilization cycle (IVF) characteristics, number of oocytes and blastocytes were not statistically different between the PCOS and control groups. FF-EVs were similarly in numbers and total amount of mRNA cargo. Out of 828 human miRNAs screened in the FF, expression of 19 miRNAs were above the detection limit. 7 miRNAs (miR-502-5p, miR-603, miR-548aa, miR-548t-3p, miR-1246, miR-548n, miR-627-5p and miR-4531) were exclusively found in PCOS samples and 2 miRNAs (miR-21-5p and miR-411-5p) were detectable in the non- PCOS group only. MiR-1253 and miR-302d-3p were present in both groups and were significantly lower in the PCOS group ($p<0.03$).

Using ingenuity pathway analysis (IPA) we identified 3930 potential miRNA-regulated target genes. One of the validated target genes of miR-302d-3p is FOXL-2, which is upregulated in the presence of miR-302d-3p. FOXL-2 is a transcription factor known to be involved in ovarian development. Knockout of FOXL-2 leads to formation of cystic follicles with an androgen predominant environment, which is a feature of PCOS.

To examine association between follicular fluid EV-miRNAs and oocyte maturity we compared FF samples that had metaphase II (MII) oocytes to those that had metaphase I (MI) or germinal vesicle. FF that contained MI oocytes had less miR-302d-3p compared to samples with MII oocytes ($p<0.01$).

CONCLUSIONS: MiR-302d-3p level in EVs of FF might become a potential biomarker used to predict oocyte maturity or fertilization rate in IVF subjects, including PCOS patients. Future studies focused on miR-302d-3p in oocyte development and further validation of this EV miRNA in FF could lead to a promising new biomarker to predict fertility rates or oocyte quality. This and other miRNAs can also reveal new pathways responsible for oocyte maturation arrest in PCOS patients.

P-972 3:30 PM Wednesday, October 21, 2020

SARS-COV-2 HERD IMMUNITY, INFECTIVE AND NAÏVE INCIDENCE IN FERTILITY CLINICS AFTER PANDEMIC LOCKDOWN. A MULTICENTER STUDY. Russell A. Foulk, MD,[1] Denny Sakkas, PhD,[2] Refik Kayali, PhD,[3] Diana Valbuena, MD, PhD,[4] Carlos Simon, MD, PhD,[5] Juliana Cuzzi, PhD[3] [1]Utah Fertility Center, Pleasant Grove, UT; [2]Boston IVF, Waltham, MA; [3]Igenomix US, Miami, FL; [4]Igenomix, Paterna (Valencia), Spain; [5]Igenomix Foundation, INCLIVA, Valencia, Spain; Department of Obstetrics and Gynecology, Valencia University, valencia, Spain; Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Valencia, Spain.

OBJECTIVE: COVID19 was declared a global pandemic by the WHO in March, 2020 and lockdown was imposed to a third of the world's population. Now, determining the transmission potential and immune status among sheltering in place asymptomatic patients and clinical staff resuming their activity is crucial. Here, we report herd immunity, infective, and naïve incidence for SARS-CoV-2 after the lockdown period, among asymptomatic medical personnel and patients in two US ART centers located in states with different COVID19 incidences.

DESIGN: Prospective multicenter study (ClinicalTrials.gov NCT04466644).

MATERIALS AND METHODS: A total of 339 asymptomatic individuals (personnel and patients) were analyzed from June 18 to July 30, 2020 in two ART centers reopening after lockdown following CDC safety guidelines. In Clinic A (Utah Fertility Center), located in a low prevalence State (312 cases per 100,000 on 06/01/2020), 154 individuals were analyzed. In clinic B (Boston IVF), in a high prevalence scenario (Massachusetts, 1,462 cases per 100,000 on 06/01/2020), 185 individuals were tested. Asymptomatic individuals attending or working in the indicated clinics were tested by RT-PCR on nasopharyngeal swab for SARS-CoV-2 RNA detection (Thermofisher, Waltham, MA, USA), and for IgG quantification on blood samples (Abbott Inc, Scarborough, ME, USA), following FDA-Emergency Use Authorization protocols. IRB approval was obtained from WIRB Protocol #20201490.

TABLE 1. Incidence of immune, infective, and naïve individuals for COVID19.

	IMMUNE RT-PCR (-)/ IgG(+)	INFECTIVE RT-PCR (+)	NAÏVE RT-PCR (-)/IgG (-)
CLINIC A	**0.65%** (1/154)	**0.65%** (1/154)	**98.7%** (152/154)
CLINIC B	**2.2%** (4/183)	**0.5%** (1/183)	**97.3%** (178/183)

RESULTS: From 339 asymptomatic individuals tested, the percentage of non-informativity was 0 for RT-PCR and 0.6% (2 out of 339) for the IgG test. Only those individuals with informative results for both tests (n= 337) are presented.

CONCLUSIONS: In the population investigated, our results suggest that the impact of the pandemic is far from reaching the level required to achieve herd immunity (i.e., 50% of a population). Therefore, transmission remains a risk since potential infectivity is present in 0.6% of the asymptomatic population tested. This figure was maintained despite their different geographical locations and the adherence to CDC guidelines of the IVF clinics involved. Interestingly, the two PCR+ individuals were IgG + suggesting virus persistence or reinfection that, if tested by serology alone, would be considered immune. These results together with the high incidence of naive individuals draws attention for the implementation of a consistent program of testing for COVID19 as a means of preventing reemerging outbreaks in our fertility centers.

P-973 3:30 PM Wednesday, October 21, 2020

IMPACT OF ENDOCRINE DISRUPTOR LEVELS FOUND IN URINE AND FOLLICULAR FLUID ON CLINICAL PARAMETERS OF IVF PATIENTS IN A EUPLOID SET/FET CYCLE. Andrea Palomar, MSc,[1] Roberto Gonzalez-Martin, MSc,[1] Caroline Zuckerman, BS,[2] Christine V. Whitehead, BSN, RN,[2] Richard Thomas Scott, Jr., MD,[2] Francisco Dominguez, Ph.D.[1] [1]IVI Foundation - ISSLaFe Biomedical Research Institute, Valencia, Spain,; [2]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Exposure to certain exogenous compounds associated with lifestyle habits has become a risk factor that could threaten reproductive success. This heterogeneous group of compounds known as endocrine disruptors (ED), which are present in the patient's daily intake, such as phytoestrogens (daidzein, genistein), parabens (beauty products) and phthalates (daily use plastics) play a major role in infertility-related problems. As there is a pressing need to investigate the effect EDs have on human reproduction, this research aimed to detect a set of non-persistent ED in urine and follicular fluid (FF) samples of women undergoing infertility treatment to establish its impact on IVF clinical parameters.

DESIGN: 60 patients attending IVI-RMA New Jersey undergoing an euploid single frozen embryo transfer (SET/FET) after PGT-A analysis were included in this study. All patients recruited were age 18 to 42 years old and had a BMI of 18.5 to 29.9 kg/m^2. Urine collected at oocyte retrieval and FET as well as FF from patients were analysed by liquid chromatography coupled to mass spectometry (HPLC-MS) for mono(2-ethylhexyl) phthalate (MEHP), methyl-paraben (m-Par), propyl-paraben (p-PAR), daidzein and genistein. These measurements were correlated with pre-implantation IVF clinical parameters.

MATERIALS AND METHODS: Patients included underwent PGT-SET/FET cycles following standard protocols. Measurements of ED levels in FF and urine collected at two different time-points were performed by HPLC-MS (Triple Quad 1290-6460, Agilent) with internal standards for each compound tested. Urine ED levels were normalized by creatinine and measured by Jaffe reaction (R&D Systems). Number of oocytes retrieved, oocyte maturation, fertilization, blastocyst development and aneuploid rates were correlated with ED levels using Poisson regression models.

RESULTS: Among all compounds and clinical outcomes analyzed, only MEHP levels show an outstanding relative effect on the number of oocytes recovered in patients. Specifically, MEHP found in FF showed the highest relative effect over number of oocytes recovered (-31.37; [95% CI: -53.57, -9.17]; $p=0.0056$). This effect is also observable in urine collected at the oocyte retrieval (-9.37 [-17.15, -1.59]; $p=0.0182$). The impact of MEHP levels is maintained in urine collected at the time of embryo transfer, although the relative effect is lower (-1.16; [-2.65, 0.32]; $p=0.1247$) possibly due to its non-persistent nature. No significant effect was found in fertilization, blastocyst development or aneuploid rates in these patients.

CONCLUSIONS: This study suggests that among all EDs found in urine and FF of the patients, high levels of MEHP correlates with fewer retrieved oocytes, thus threatening the chances of reproductive success. Urine and FF levels of MEHP at the time of oocyte retrieval may indicate the damaging effect of this compound on oocyte development. Therefore, it is essential to reduce the patient's exposure to this kind of compound during ovarian

stimulation to minimize its impact on the number of oocytes retrieved to allow maximum optimization of IVF treatments.

SUPPORT: This research is supported by predoctoral contract for training in research into health (PFIS; PI/00009), APOTIP/2018/010, Miguel Servet Contract (CPII18/00002) and ISCIII FIS project (PI17/00931)

P-974 3:30 PM Wednesday, October 21, 2020

MAY AUTOIMMUNE DISEASE BE A PREDICTOR FACTOR OF INFERTILITY IN WOMEN WITH ENDOMETRIOSIS? Larissa Milani Coutinho, Doctorate student, Gabriel Duque Pannain, Medical doctor, Luzia Ribeiro Nasser Salomão, Medical doctor Universidade Federal de Juiz de Fora, JUIZ DE FORA, Brazil.

OBJECTIVE: Although endometriosis physiopathology has not been totally clarified yet, it must be a multifactorial disease and immune pathways may take part of the onset and progression of the disease. A recent meta-analysis has suggested that patients with endometriosis are at higher risk to have at least one other immune condition, such as rheumatoid arthritis (RA), autoimmune thyroid disorder (ATD), inflammatory bowel disease (IBD). Maybe the high levels of inflammation related to endometriosis might be associated to an imbalance of immune response. Infertility is a frequent consequence of endometriosis. Although the mechanisms capable to explain endometriosis-associated infertility remain obscure, studies have shown that inflammatory and immune factors may take a role in the process as well. We aimed to investigate whether autoimmune diseases could be associated to the occurrence of infertility in patients with endometriosis.

DESIGN: A retrospective study was performed at a Public University Hospital, by analyzing medical records of all the 162 patients with a diagnosis of endometriosis, followed up in the Endometriosis specific outpatient clinic, since its creation, in February 2017, until March 2020.

MATERIALS AND METHODS: After excluding patients with other causes of infertility aside endometriosis, patients that had never tried to conceive and those who had achieved pregnancy after a surgical treatment, the remaining patients were divided in two groups: fertile (n=61) and infertile (n=86). The two groups were analyzed for socio demographic variables as well as features related to the disease and the association with autoimmune disease. Among autoimmune diseases, we observed patients with hypothyroidism (5), type 1 diabetes (4), ulcerative colitis (2) and rheumatoid arthritis (1).

RESULTS: It was a sample composed by 162 women aged between 19 and 53 years old with an average age of 35.2 years and standard deviation of 7.23. After analyzing the two groups, we calculated logistic regression to verify whether it is possible to correlate the variable presence of autoimmune disease with the infertility outcome. For autoimmune disease, the confidence interval was from 1.194 to 17.802 to 95% with a p-value of 0.027, corroborating that there is a correlation between autoimmune diseases and infertility in patients in this sample. We also calculated the prevalence ratio in these patients, which was higher in patients with autoimmune disease than in those without (mean of 1.527, being 1.439 the lower and 1.615 the upper bound with 95% confidence interval).

CONCLUSIONS: Despite of the scarcity of data associating endometriosis and autoimmune disease, the coexistence of such conditions might be related to a greater difficult in achieving pregnancy. Maybe patients presenting both diagnosis should be advised to pay special attention to their reproductive plans, by avoiding postponing either natural attempt to get pregnant or fertility treatments when indicated. For those women with no current plans to conceive, an interesting strategy would be to offer the possibility of performing social oocyte cryopreservation.

SUPPORT: No financial support was given.

P-975 3:30 PM Wednesday, October 21, 2020

ASSESSING FERTILITY AWARENESS IN WOMEN IN AN INNER NEW YORK CITY HOSPITAL. Janelle M. Jackman, MBBS,[1] Fernando Polanco, MD,[2] Shelena Ali-Bynom, M.D., M.P.H,[3] Natasha Fievre, MD[3] [1]Camran Nezhat Institute, Center for Special Minimally Invasive and Robotic surgery, Stanford University Medical Center, New York, CA; [2]Providence Hood River Hospital, Hood River, OR; [3]The Brooklyn Hospital Center, Brooklyn, NY.

OBJECTIVE: Maternal age is the single most important determinant of fertility. Ovarian function declines as women age and fertility naturally declines around mid-thirties.However childbearing has increased between the ages of 35 to 39 years. Increased maternal age may also affect maternal and fetal health, leading to permanent chronic conditions. Fertility literature has suggested that female fertility and reproduction biology awareness is poor. This is especially true for women in lower socioeconomic groups and minorities who may not have access to health care education. This study aimed to look at fertility awareness in women at a single NYC community hospital.

DESIGN: An anonymous cross sectional survey administered in an OB-GYN clinic at a single NYC community hospital.

MATERIALS AND METHODS: An anonymous cross sectional survey was administered at an OBGYN clinic between April and July 2019. Patients participated voluntarily and their participation implied consent. They were asked a series of 28 fertility related questions and all information was anonymous. Inclusion criteria was all willing women at the clinic over the age of 18 years old. Statistical analysis utilized descriptive statistics, the Students t-test for equality of means and linear regression. Probability outcomes <0.05, were statistically significant.

RESULTS: There were 66 patients who participated in the survey. African Americans ethnicity made up 66% of the patients, 24% were Hispanic and 10% comprised of Caucasian, Middle Eastern and Asian. Around 92% had greater than high school education. The majority of patients,73% knew that complications increased in pregnancies in women greater than 35 years. However, an alarming 28% believed that age did not affect fertility and 59% of them stated if they knew, they would have began childbearing earlier. Patients with a history of infertility were slightly more knowledgable on age and infertility but this difference was not statistically significant. Our results showed that nulliparous patients were less educated about age of decreased fertility (0% vs 13%) compared to multiparous patients, however overall there was a low correct response to this question (11%).

CONCLUSIONS: Our results show that there is a need for greater education regarding the decline in fertility in women with respect to age and other factors that affect fertility. This will assist in women being able to make well informed family planning decisions. Factors such as our race, ethnicity and socioeconomic status should not play a role in health care access or education. More research is needed to fully understand the barriers to health and health education as well to determine ways to decrease health disparities and ensure patients are knowledgeable about their fertility and health.

CLINICIAN TRAINING NEEDS IN REPRODUCTIVE HEALTH COUNSELING FOR SEXUAL AND GENDER MINORITY AYA WITH CANCER. Gwendolyn P. Quinn, Ph.D.,[1] Amani Sampson, B.A.,[1] Ash B. Alpert, M.D.,[2] Rhyan Jenifer Toledo, BA,[1] Megan E. Sutter, PhD,[3] Paige W. Lake, MPH,[4] Matthew B. Schabath, Ph.D.,[4] Susan T. Vadaparampil, Ph.D.[4] [1]NYU Langone School of Medicine, New York, NY; [2]URMC, Rochester, NY; [3]NYU Langone Health, New York, NY; [4]Moffitt Cancer Center, Tampa, FL.

OBJECTIVE: Adolescent and young adults (AYA) with cancer have distinct psychosocial needs, with reproductive health being a chief concern. Reproductive health includes fertility, contraception, romantic relationships, body image, sexuality and disease prevention. Along with the unique needs of AYAs with cancer, health disparities exist among sexual and gender minority (SGM) AYAs, and there is a gap in clinician training. Our NCI-funded R25 Enriching Communication skills for Health professionals in Oncofertility (ECHO) provides reproductive health communication training to psychologists, social workers, nurses, and physician assistants who provide care for AYA people diagnosed with cancer. To refine our curriculum to address the unique needs of SGM AYAs with cancer, we conducted a survey of prior ECHO trainees to evaluate knowledge and comfort in obtaining sexual orientation and gender identity (SOGI) information from patients and providing reproductive health counseling.

DESIGN: A 28-item electronic survey was distributed to 601 prior ECHO trainees.

MATERIALS AND METHODS: Quantitative items assessed: SOGI data collection at their institution; SGM AYA cancer-related health knowledge; adequacy of ECHO training for SGM AYAs; desire for additional training; comfort discussing reproductive health with SGMs; and confidence in knowledge of SGM health needs *(pre- and post-survey)*. Response options ranged from 1=strongly agree to 5=strongly disagree, or 'prefer not to answer. Total knowledge score was computed and ranged from 0=no correct responses to 7=all correct. Self-perceived comfort and confidence were assessed with regard to specific patient subgroups (i.e., gay/lesbian; bisexual/queer; and trans/nonbinary patients). Four open-ended items invited respondents to describe personal experiences, reservations, and suggestions for improving SGM AYA cancer care. Quantitative responses were summarized with descriptive statistics. Paired t-tests were used to analyze changes in confidence. Content analysis was applied to qualitative responses.

RESULTS: Of the 346 who completed the survey (58% response rate), only 7.4% correctly answered all knowledge questions (M=3.76, SD=1.72). One-third thought ECHO training adequately addresses SGM needs, and the majority (89%) wanted additional training in SGM reproductive health. Confidence in knowledge of SGM health was neutral in all subgroups prior to survey completion (M=3.05, SD=1.02), but reduced significantly for bisexual/queer (ΔM=-0.21 $t(307)$=4.70, $p<.001$) and transgender/nonbinary health(ΔM=-0.12 $t(307)$=2.66, $p=.008$). Open-ended responses focused on experiences caring for SGM AYAs with cancer; training needs; and appreciation for the survey.

CONCLUSIONS: Results demonstrate a need to refine ECHO curriculum to include SGM reproductive health concerns and strong desire for SGM content among trainees. We are developing a module to improve reproductive health communication for the care of SGM AYAs with cancer and survivors.

IMPACT OF AMBIENT TEMPERATURE ON OVARIAN RESERVE AMONG WOMEN FROM A FERTILITY CLINIC.

Audrey Jane Gaskins, ScD,[1] Lidia Mínguez-Alarcón, PhD,[2] Trang M. VoPham, PhD, MS,[3] Jaime E. Hart, ScD,[2] Jorge E. Chavarro, MD, Sc.D.,[2] Joel David Schwartz, PhD,[2] Irene Souter, MD,[4] Russ Hauser, MD, MPH, Sc.D.,[2] Francine Laden, ScD[2] [1]Emory Rollins School of Public Health, Atlanta, GA; [2]Harvard T.H. Chan School of Public Health, Boston, MA; [3]Fred Hutchinson Cancer Research Center, Seattle, WA; [4]MGH Fertility Center and Harvard Medical School, Boston, MA.

OBJECTIVE: In most mammalian species, heat stress caused by high ambient temperatures has a deleterious effect on reproductive function including impaired follicular growth. Recent climate projections predict that heat waves will increase in frequency, intensity, and duration, necessitating the need to better understand the relationship between temperature and reproductive health in humans. Our objective was to determine the effect of ambient temperature and extreme weather events on antral follicle growth among women attending an infertility clinic.

DESIGN: Our prospective cohort study included 632 women attending the Massachusetts General Hospital Fertility Center (2005-2015) who had an antral follicle count (AFC) measured with transvaginal ultrasonography.

MATERIALS AND METHODS: We collected data on the daily average, maximum, minimum, and apparent temperatures at a woman's residential address for the 90 days prior to their antral follicle scan using information from the Parameter-elevation Regressions on Independent Slopes Model at a 4 km^2 resolution. Heatwaves and cold spells were defined as $\geq$3 consecutive days where the maximum temperature exceeded the 99th or fell below the 1st percentile for the region, respectively. We evaluated the association of AFC with ambient temperature and extreme weather events using Poisson regression, adjusting for relative humidity, fine particulate matter exposure, age, education, smoking status, year and month of AFC, and diagnosis of diminished ovarian reserve and ovulation disorders.

RESULTS: High ambient temperatures during 3 months prior to antral follicle scan (corresponding to exposure during the preantral to preovulatory stages of follicular development) were associated with lower AFC. Specifically, a 1°C increase in average maximum temperature was associated with a -1.6% (95% CI -2.8, -0.4) lower AFC. Associations remained negative, but were attenuated, for average maximum temperature exposure in the month (-0.9% 95% CI -1.8, 0.1) and 2 weeks (-0.8 95% CI -1.6, 0.0) prior to antral follicle scan. The negative association between average maximum temperature and AFC was stronger among women who had their antral follicle scans performed November through June, where average maximum temperatures ranged from 0 to 23 °C, rather than during the summer months (July-October). Exposure to a heatwave in the 3 months prior to AFC was associated with a -7.2% (95% CI -14.9, 1.3) lower AFC while exposure to a cold spell was associated with a 14.3% (95% CI 2.0, 28.2) higher AFC.

CONCLUSIONS: Exposure to higher than average temperatures, particularly outside of the summer months, were associated with lower ovarian reserve. These preliminary results raise concern that rising ambient temperatures worldwide may result in accelerated reproductive aging among women.

P-978 3:30 PM Wednesday, October 21, 2020

A CROSS-SECTIONAL SURVEY OF TAIWANESE GAY AND BISEXUAL MEN'S PARENTHOOD DESIRES AND PREFERRED MEANS OF FAMILY FORMATION.

C. Chan, PhD,[1] Yuen Kiu Georgina So, MSc[2] [1]The University of Hong Kong, Hong Kong, Hong Kong; [2]The University of Hong Kong.

OBJECTIVE: Desires for parenthood and knowledge about the means to parenthood are important determinants of reproductive behaviours. Despite ART and adoption becoming more accessible in select parts of the world, sexual minority individuals consistently report lower desire for parenthood and anticipated higher levels of stigma surrounding parenthood than did heterosexual individuals. While there is a burgeoning literature on parenthood orientations, attitudes and demographic composition among same-sex couples, gay men, and, to a larger extent, bisexual men, are significantly under-represented. The study investigated the parenthood desires and preferred methods of family formation among Taiwanese gay and bisexual men before legalization of same-sex marriage in Taiwan.

DESIGN: A cross-sectional online survey was administered to Taiwanese men who self-identified as gay or bisexual recruited through social media. Data collection took place before legalization of same-sex marriage in Taiwan in May 2018.

MATERIALS AND METHODS: Respondents completed an online survey with a list of items relating to their parenthood desires, preferred method(s) of family formation, and reproductive awareness for respondents who endorsed surrogacy and ART as a preferred method. Men who self-identified as transgender, queer and asexual were precluded from analyses due to small cell sizes, yielding a final sample of 1,381 men. Variables were compared between age and other demographic groups using independent-samples t-tests or chi-squared tests.

RESULTS: Respondents were on average 27, the majority were homosexual, employed, university-educated, and non-religious. Among the 1,023 (74%) respondents who desire to have children, they desire to have two children, and to have the first child at 32 years and the last child no later than 43 years. Adoption was the most preferred method of family formation (83%), followed by surrogacy and ART (73%) and marriage with an opposite sex (12%). Surrogacy and medically assisted reproduction is more frequently desired among men aged 35 or above (82% in men aged >35 vs. 69% in men aged 18-24, $p<.05$), and among men who preferred to have the first child after 35 years (77% first child after 35 years vs. 61% first child before 35 years, $p<.05$). However, among those who preferred surrogacy and assisted reproduction, only 6% had ever received semen analysis, and over 17% had no knowledge of the legality of surrogacy arrangements in Taiwan. Further, bisexual men were more likely than homosexual men to endorse marriage with an opposite sex as a preferred method of family formation (36% vs. 6%, $p<.001$). Preferred method of family formation is not correlated with relationship status or education level.

CONCLUSIONS: The majority of gay and bisexual men wish to have children via adoption or surrogacy and ART albeit reporting low reproductive awareness. The rarity of fertility-optimising behaviours and inadequate awareness of legality issues in this Taiwanese sample highlights the importance for accessible fertility- and treatment-/adoption-related resources among sexual minority communities.

NOVEL INDICES FOR THE EVALUATION OF OBESITY IN ERECTILE DYSFUNCTION PATIENTS. Sujith M. Jose, MBBS, MS, MCh, Vaibhav Vishal, MBBS, MS, MCh, Alphonse Jithin Jayan, MBBS, MS, MCh. Urology Resident, calicut, India.

OBJECTIVE: The association between Metabolic Syndrome (MetS) and erectile dysfunction(ED) is bidirectional. Inflammatory mediators from the visceral fat induce oxidative damages in the penile microvasculature resulting in ED. Waist circumference(WC) is not a reliable indicator of visceral fat as it includes subcutaneous fat also. Greater prevalence of MetS in Asian men compared to African-American men with the same WC is due to the relatively higher levels of visceral fat in them. Visceral Adiposity Index (VAI) and Lipid Accumulation Product (VAP) are novel indices that include functional parameters along with anthropometric parameters and gives better assessment of visceral adipose dysfunction.The purpose of the study is to investigate the potential link between these novel indices and ED severity.

DESIGN: Observational Cross-sectional study.

MATERIALS AND METHODS: In this study,ED patients were divided into mild ED group (score >11) and severe ED group (score ≤11) based on International index of Erectile Function-5 scores. WC, Body Mass Index(-BMI) and lipid profile were obtained and VAI, LAP were calculated using formulas, VAI=WC/[39.68+(1.88×BMI]×triglycerides/1.03×1.31/high density lipoprotein and LAP=[WC–65]×triglycerides.Mean, standard deviation and p values were calculated using appropriate formulas and p value<0.05 was accepted as statistically significant.

RESULTS: Of 116 men included in the study, 60 had mild ED and 56 had severe ED. Mean age was 51.83±6.2 for mild ED group and 52.16±5.8 for severe ED group. Mean VAI was statistically significantly higher in severe ED group compared to mild ED group (8.452±2.33 vs 4.753 ±1.52 ;p <0.001). Mean LAP was also significantly higher in severe ED group (89.427±31.48 vs 52.21± 29.96;p< 0.001). Interesting, difference in WC(95.5±9.5 vs 95±8.5 ; p =0.146) and BMI(26.48± 3.72 vs 24.67 ± 4.15; p= 0.363)was not statistically significant among two groups.Mean serum estradiol level showed a statistically significant difference among two groups (110.4 ± 43.8 vs 99.87 ± 45.7 ; p<0.001).

CONCLUSIONS: VAI and LAP have stronger correlation with ED severity than single antrapometric tools.Severe ED patients have higher estradiol level compared to mild and moderate ED patients due to their higher visceral fat and VAI. Considering the simplicity and reliability, these novel indices should be included in the evaluation of obese ED patients.

RISK FACTOR ANALYSIS FOR SARS-COV-2 SERO-POSITIVITY WITHIN ASSISTED REPRODUCTIVE. Nicolás Prados, PhD MSc,[1] Cristina González-Ravina, PhD,[2] Vanessa Vergara, MD,[1] Javier Herrero, MSc,[1] María Cruz, PhD,[1] Antonio Requena, PhD, MD.[1] [1]IVIRMA Global Headquarters, Madrid, Spain; [2]IVIRMA Global Headquarters, Sevilla, Spain.

OBJECTIVE: Making decisions about how to fight the SARS-CoV-2 pandemic without completely disrupting our activity requires better tools that inform the extent of transmission. Understanding risk factors of virus susceptibility could help us to establish intervention policies. The objective of our work is to assess risk factors and seroprevalence in our patients in order to plan evidence-based strategies.

DESIGN: Multicenter retrospective, anonymized cohort analysis performed in 11 private clinics belonging to the IVIRMA group in Spain.

MATERIALS AND METHODS: Between April 27th and June 26th, 2020, 6140 individuals undergoing an assisted reproductive treatment were tested for SARS-CoV-2. Before tested, a symptomatic triage had been carried out and only patients classified with a negative triage attended the clinic for further testing. SARS-CoV-2 specific IgG and IgM antibodies in serum were detected using EDI Novel Coronavirus COVID-19 ELISA kit (Epitope Diagnostics, USA) according to the manufacturer's instructions. We divided our clinics into two different geographic areas: region A (seroprevalence <5%) and region B (seroprevalence >5%) based on the results obtained in our population. Statistical analyses were performed using the Statistical Package for Social Sciences 19.0 (IBM Corporation, Armonk, NY, USA).

RESULTS: Of the 6140 persons tested for SARS-CoV-2, 4470 (72.8%) were women and 1670 (27.2%) men. Over the course of the study, 42 (0.7%) tested positive for SARS-CoV-2 IgM antibodies. Seropositivity does not vary significantly with age and we did not observe differences regarding gender or blood group. However, we found that individuals with negative rhesus (Rh) factor had a slightly greater risk of being seropositive (RR 2.5 [129-2.13]) than those Rh positive. There are no differences in the percentage of people in the active phase of the disease depending on the geographical area (RR 0.8 [0.43-1.52]). However, when we analysed the data according to time, the rate of positive individuals does not vary throughout the weeks in region A, while for the region B the incidence of IgM drops significantly (p=0.003) from the first week of the study (3.7%) to the last (0.0%), which would indicate decline of the virus transmission over time. When we analysed the seropositivity rate according the partner's serological status, the data showed that there is approximately 10 times more incidence of being positive IgG in couples than in random population.

CONCLUSIONS: We show that in areas with higher prevalence of the disease, the percentage of IgM positive individuals is also higher. Also, there is a greater risk of being infected when the couple is already seropositive. No differences were observed according the age and there is higher prevalence in Rh-negative individuals.

P-981 3:30 PM Wednesday, October 21, 2020

IDENTIFICATION OF NOVEL MUTATIONS IN CANDIDATE GENES ASSOCIATED WITH POLYCYSTIC OVARY SYNDROME (PCOS) IN WOMEN WITH ARAB ETHNICITY. Maha Al-Khaduri, MD FRCSC,[1] Fatima Ahmed Al Kindi, Bsc, Msc,[2] Yahya Tamimi, Msc, Phd,[2] Ammar Hamed Nomani, Bsc,[2] Yahya M. Al-Farsi, MD Phd.[2] [1]College of Medicine, Sultan Qaboos University, Muscat, Oman; [2]College of Medicine, Sultan Qaboos University, Al Khodh, Oman.

OBJECTIVE: There is a genetic component to the etiology of Polycystic Ovary Syndrome (PCOS) with candidate genes identified by Genome-wide studies in Chinese and European populations. However, in Middle Eastern populations, where genes are expected to be concentrated due to prevalence of consanguineous marriages, this is not yet explored. To our knowledge this is the first study analyzing 11 candidate genes by exome sequencing in women of Arab ethnicity diagnosed with PCOS.

DESIGN: Prospective case control study.

MATERIALS AND METHODS: A sample size of 49 cases and 49 controls was estimated for a significance level of 5% at 60% power, with minor allele frequencies of 12% and 1% in cases and controls respectively with a 1:1 ratio. We recruited 50 cases and 50 controls (Omani women) from the Gynecology clinic at Sultan Qaboos University Hospital in Oman. All cases fulfilled the Rotterdam criteria for PCOS. Controls were randomly selected from non-pregnant women within reproductive age who were not diagnosed with PCOS. Genetic disorders, congenital adrenal hyperplasia, androgen secreting tumors, Cushing syndrome, and hyperprolactinemia were excluded. The data collected included family history of PCOS, parental consanguinity, biochemical laboratory test results, physical examination and pelvic ultrasound findings. Targeted Exome Sequencing using a custom gene panel of 11 genes [LEPR, THADA, LHCGR, FSHR, YAP1, SUOX, DENND1A, VDR, VEGFA, CYP1A1, KISS1] was conducted on DNA extracted from blood samples of cases and controls then data was analyzed using ANNOVAR software to identify variants with a frequency less than 1%.

RESULTS: Family history of PCOS was significantly higher among cases (46.9%) than controls (16.0%), P=0.001. Parental consanguinity was prevalent in both cases (26.6%) and controls (38%). Infertility, an-ovulation, Luteinizing hormone, anti-Mullerian hormone, total Testosterone and Thyroid Stimulating Hormone (TSH) were significantly higher among cases (P<0.05). There was an association between TSH and fasting insulin (OR=1.30). We found three nonsynonymous variants in the LEPR gene, two of which were predicted by SIFT software to be harmful (pathogenic). In the THADA gene, one nonsynonymous mutation, found in three patients was predicted to be pathogenic, in addition to one novel non-frameshift deletion found in one patient. A controversial novel nonsynonymous variant was found in the LHCGR gene, predicted as neutral, and disease-causing mutation by SIFT software, and mutation tester, respectively. Another nonsynonymous variant was found to be novel, and pathogenic in the FSHR gene. Moreover, in the YAP1 gene, a nonsynonymous variant was detected and predicted by SIFT and other software to be neutral (nonpathogenic). Two nonsynonymous variants were found in the SUOX gene, with one of the variants reported in Clinvar with uncertain significance related to sulfite oxidase deficiency condition. The other variant was found to be tolerated with no effect on protein function.

CONCLUSIONS: We report Novel mutations in THADA, LHCGR and FSHR genes in Omani women of Arab ethnicity diagnosed with PCOS.

PREGNANCY OUTCOMES IN FEMALE PATIENTS EXPOSING TO CYCLOSPORIN VERSUS TACROLIMUS AS PRIMARY IMMUNOSUPPRESSION AFTER SOLID ORGAN TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS.

Jingjie Li, M.D.,[1] Pan Chen, PhD,[2] Xiaojiao Gong, Bachelor,[2] Xiaoyan Liang, M.D.[1] [1]the Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: Tacrolimus and cyclosporin are both calcineurin inhibitors (CNIs) recommended as first-line immunosuppressants for solid organ transplantation, we aim to compare the influences of tacrolimus and cyclosporin on pregnancy outcomes for female transplant recipients.

DESIGN: Systematically review of observational studies comparing pregnancy outcomes of tacrolimus and cyclosporin as primary immunosuppression after solid organ transplantation.

MATERIALS AND METHODS: A comprehensive literature search was conducted between January 1, 2000 and March 20, 2020 according to the database of PubMed, EMBASE, and Web of Science. The following combination of text terms was searched in [Title]: Transplant / Transplants / Grafts / Graft / Transplantations / Transplantation, and Pregnancy / Pregnancies / Gestation / Pregnant / Gravidity / Gravidities. Weighted mean difference (WMD) and odds ratio (OR) was calculated to compare continuous and dichotomous variables respectively with 95% confidence intervals (CIs). Publication bias was estimated by funnel plots. Quality of study was assessed according to the modified Newcastle-Ottawa scale.

RESULTS: 24 observational studies including a total of 1492 pregnant post-transplant recipients were identified in our analysis. Tacrolimus-treated recipients experienced lower risk of gestational hypertension (44.6% vs 29.0%; OR:1.58; 95% CI,1.20-2.08; $P < 0.01$) and infections (24.7% vs 13.6%; OR:1.87; 95% CI, 1.25-2.80; $P < 0.01$). Cyclosporin-treated recipients showed a lower incidence of abortions (16.7% vs 25.5%; OR: 0.59; 95% CI, 0.41-0.86; $P < 0.01$), gestational diabetes (2.3% vs 9.3%; OR: 0.24; 95% CI, 0.13-0.44; $P < 0.00001$) and cesarean section (41.7% vs 48.8%; OR:0.71; 95% CI, 0.54-0.93; $P = 0.01$). Additionally, cyclosporin performed better regarding the live birth rate (78.4% vs 70.8%; OR: 1.43; 95% CI, 1.08-1.87; $P = 0.01$). There were no significant differences in the incidences of preeclampsia, postpartum rejection, preterm delivery and low birth weight.

CONCLUSIONS: Cyclosporin is safer in delivery outcomes, while tacrolimus is associated with lower risk of maternal complications except gestational diabetes.

EVALUATING THE UTILITY OF A GLOBAL WEBINAR FOR MENTORING MEDICAL STUDENTS AND OB-GYN RESIDENTS IN REI.

Eliana Fine, BA,[1] Valerie Rose Libby, MD, MPH,[2] Eduardo Hariton, MD, MBA,[3] Kamaria C. Cayton Vaught, MD,[4] Kelsey L. Anderson, MD,[5] Serena H. Chen, M.D.,[6] Eric J. Forman, M.D.,[7] Kenan Omurtag, MD,[8] Bradley Scott Trivax, MD.[9] [1]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY; [2]Shady Grove Fertility, Atlanta, GA, Atlanta, GA; [3]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [4]Johns Hopkins University School of Medicine, Lutherville, MD; [5]Washington University in St. Louis, St. Louis, MO; [6]Division of Reproductive Medicine, IRMS at St Barnabas, Livingston, NJ; [7]Medical and Laboratory Director, New York, NY; [8]Washington University St Louis School of Medicine, St. Louis, MO; [9]Stony Brook University Hospital, Commack, NY.

OBJECTIVE: The aim of this study is to evaluate the effectiveness of a live Q&A webinar on improving trainees' access to mentorship and knowledge of the path to becoming a reproductive endocrinology and infertility (REI) physician.

DESIGN: Prospective Paired Cohort Study.

MATERIALS AND METHODS: US and international medical students and OBGYN residents participated in a global live Q&A webinar featuring REI physicians and fellows. Webinar surveys were given and a total of 161 pre-webinar and 73 post-webinar surveys were reviewed. After application of exclusion criteria, 70 pre- and post-webinar surveys were compared. Paired nonparametric tests (Wilcoxon Signed-Rank Test) were performed to assess whether post-webinar knowledge was significantly different from pre-webinar knowledge.

RESULTS: In total, 268 people registered for the webinar and 162 attended live (60%). The majority of the 70 respondents who completed both surveys were female (90%) and MD medical students (80%). Of the respondents, only 31% reported their home institution had an REI fellowship program and 37% an affiliated REI office. Only 34% had previously shadowed an REI physician and 23% had rotated in an REI office. Thirty-three percent reported it was not easy and 13% it was extremely not easy to find research opportunities within the field of REI in medical school or residency, while 14% reported it was easy, and 39% unsure. Seventy-seven percent reported receiving minimal advice about a career in REI from their medical school or residency program, while 22% reported receiving some advice, and 1% extensive advice.

After the webinar, participants were more likely to report that social media can be utilized by trainees to connect with REI physicians to find networking and mentoring opportunities ($P = .022$) and they were more likely to use social media (ex. Instagram) to network with physicians and potential mentors ($P = .041$). When asked to what extent they agree that their interest in REI increased due to this webinar, 39% strongly agreed, 43% agreed, 13% were unsure, and 6% disagreed.

Overall, after the webinar, more trainees reported a better understanding of what the field of REI entails ($P = <.00001$), the path required to become an REI ($P = <.00001$), opportunities to find mentors in the field of REI ($P = <.00001$), opportunities at medical school or residency conducive to learning more about REI ($P = <.00001$), and applying for rotations in the field of REI ($P = <.00001$).

CONCLUSIONS: Most medical students and OBGYN residents have difficulty finding mentorship and research opportunities within the field of REI as many institutions do not provide trainees with opportunities to learn about the specialty. A webinar featuring REI physicians and fellows can provide the much-needed mentorship for trainees to help increase their interest in REI and provide them with advice regarding pursuing a career in the field. Additionally, trainees can utilize social media to connect with REI physicians and fellows to find mentorship, research, and networking opportunities within the specialty.

OOCYTE VITRIFICATION CAN ALTER OOCYTE AND EMBRYO REPAIR PROCEEDS IN CONFRONTING WITH SPERM DNA DAMAGE.

Niloofar Khajedehi, MSc,[1] Leila Rashki Ghaleno, Ph.D. student,[2] Rouhollah Fathi, Ph.D.,[2] Hamid Gourabi, Ph.D.[3] [1]Department of Molecular Genetics, Faculty of Basic Sciences and Advanced Technologies in Biology, University of Science and culture, Tehran, Tehran, Iran (Islamic Republic

Parameters	Untreated Sperm	0.2 LD50 treated Sperm	0.3 LD50 treated Sperm
Round spermatids	44.47±10.55[a]	35.29±16.89[b]	37.05±15.51[b]
Elongated spermatids	36.84±11.97[a]	31.04±16.67[b]	28.89±12.98[b]
Spermatogonial stem-cells	10.89±5.90	12.44±6.17	12.36±6.40
Concentration (M/ml)	10.72±5.77	7.13±3.47	6.34±2.30
	Non-vitrified Oocytes		
Fertilization rate (%)	96.42±9.44	96.77±6.32	89.11±16.16
Blastocyst rate (%)	56.01±18.40	32.40±20.04	21.80±14.58
	Vitrified Oocytes		
Fertilization rate (%)	96.75±8.59	86.84±18.61	93.67±11.71

of); [2]Department of Embryology, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Tehran, Iran (Islamic Republic of); [3]Department of Genetic, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Tehran, Iran (Islamic Republic of).

OBJECTIVE: Oocyte vitrification has different effects on mitochondrial function, gene expression and overexpression of repair proteins after vitrification and warming. Examining the capability of vitrified oocyte to repair sperm DNA fragmentation was the main objective of this research.

DESIGN: Non-vitrified and vitrified Cumulus-Oocyte-Complexes (COCs), were inseminated with Intact and two models of DNA fragmented sperms. Subsequent embryo development was followed until blastocyst stage. Pursuit of repair procedure was done by following changes in *Rad51* expression between different groups in zygote and blastocyst stage.

MATERIALS AND METHODS: Male mice were intraperitoneally injected with tert-Butyl hydroperoxide (tBHP) with 0.2 and 0.3 LD50 dosages for 14 days. Testis and epididymal sperm assessed by histology and TUNEL assay analysis. Obtained COCs from superovulated mice were vitrified and saved in LN2 on Cryotop for 2 weeks. Following warming, COCs were inseminated by DNA fragmented sperms. Expression level of *Rad51* was assessed with qRT-PCR in zygote and blastocyst stage.

RESULTS: Decreasing number of round and elongated spermatids and increasing number of spermatogonial stem cells, also decreasing sperm concentration of both treated groups indicated that tBHP injection reduced meiosis division. Sperm DNA fragmentation index in both treated groups was more than 20%, but in untreated group was less than 20%. Fertilization rate was not different between the groups; although, both sperm DNA damage and oocyte vitrification led to significant decrease in blastocyst formation. Moreover, zygotes derived from 0.3 LD50 sperms crossed with non-vitrified oocytes down-regulated *Rad51*; in contrast, 0.3 LD50 sperm with vitrified oocyte up-regulated the same gene. In blastocyst stage, 0.3 LD50 sperms with non-vitrified oocytes up-regulated *Rad51*; on the other hand, this gene was down-regulated in 0.3 LD50 sperms fertilized with vitrified oocytes (P-value<0.05). All data showed by mean±SD.

CONCLUSIONS: Oocyte vitrification and sperm DNA damage not only reduce blastocyst formation but also altered sperm repair *Rad51* gene expression.

P-985 3:30 PM Wednesday, October 21, 2020

ESTABLISHING PAIN SCALES FOR GYNECOLOGIC PROCEDURE USING A NOVEL VAS APP. Lauren Y. C. Au, BA,[1] Wakako Horiuchi, BS,[1] Jasmine Tyson, MS,[1] Mary Tschann, PhD, MPH,[2] Bliss Kaneshiro, MD, MPH.[1] [1]University of Hawaii, Honolulu, HI,; [2]Society of Family Planning, Denver, CO.

OBJECTIVE: The pain experienced during procedures like intrauterine device (IUD) insertion, is a function of both the level of pain experienced and the duration the pain is felt. Some interventions may diminish the level of pain but prolong the procedure. In these instances, whether a given intervention provides benefit to the patient is difficult to assess. Researchers often use a traditional visual analog scale (VAS) where a patient makes a mark along a line to indicate the level of pain they experience, but these measurements only provide a snapshot of the patient's pain. The continuous VAS (cVAS) app records both pain scores and the duration of time an individual experiences various levels of pain. Our goal was to understand the feasibility of using the cVAS app during IUD insertion and to compare these measurements to a traditional VAS.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: We recruited 33 patients who were 18 years of age or older having an IUD insertion. Patients were oriented to the cVAS app prior to the procedure. During the procedure, the patient held the tablet, with the app loaded, and traced their finger along the line throughout the procedure according to the pain level experienced. Procedure milestones were logged on a synchronized app by a research assistant in the room and data was sent to a secure database. After the procedure, patients indicated overall pain on a paper-based 100 mm VAS and provided qualitative data about the amount of pain experienced and ease of use of the app. Without reviewing patient data, the provider who performed the procedure indicated the overall pain the patient experienced during the procedure on a paper-based 100 mm VAS. A cVAS pain score was calculated for each patient by graphing the level of pain recorded on the app on the y-axis and time on the x-axis. Area under the curve (AUC) was calculated and correlated with the patient reported VAS, provider estimated VAS, and maximum pain recorded on the cVAS app.

RESULTS: Of the 33 patients enrolled, 28 provided enough data for analysis (5 had missing or incomplete data). Mean procedure time was 4.94 minutes (sd=4.60, range 1.48 to 20.8). Mean overall patient reported and provider estimated VAS was 40.8 mm (sd=24.3, range 5.5 to 98.0) and 41.0 mm (sd=23.0, range 1.0 to 94.0), respectively. Mean maximum cVAS score recorded was 56.5 mm (sd=28.1, range 12 to 100) and mean AUC was 7005.8 (sd=6394.7, range 462.6 to 21919.3). Patient reported VAS score correlated strongly with AUC (r=0.53). Maximum cVAS score correlated moderately with AUC (r=0.47). Provider estimated VAS score correlated weakly with AUC (r=0.15). AUC correlated well with the amount of pain patients reported qualitatively. All patients found the app easy to use.

CONCLUSIONS: While this pilot app requires further refinement, the AUC represents a novel and accurate representation of patient pain levels. Using the cVAS in studies to investigate interventions to decrease pain with IUD insertion could result in the development of better techniques to reduce pain and improve patient satisfaction.

P-986 3:30 PM Wednesday, October 21, 2020

DIFFERENT PROTEOMICS ANALYSIS INDICATES METFORMIN AS A NOVEL THERAPY TO AMELIORATE ENDOMETRIAL RECEPTIVITY OF ENDOMETRIOSIS. Xin Huang, Doctor,[■] Wei Huang, Professor,[2] Li Xiao, Doctor,[3] Ying Long, Doctor.[3] [1]West China Second Hospital; Key Laboratory of Birth Defects and Related Diseases of Women and Children, Ministry of Education, Sichuan University, Chengdu, China; [2]West China Second University Hospital of Sichuan University, Chengdu, China; [3]■.

OBJECTIVE: Endometriosis reduces female fecundity, decreased endometrial receptivity should be responsible for the pathogenesis. Metformin inhibited the growth of ectopic lesions, while the effect of metformin on eutopic endometrium of endometriosis has not been reported. This study aims to identify whether metformin can ameliorate endometrial receptivity of women with endometriosis and endometriosis model mice.

DESIGN: Compare protein expression of eutopic endometrium of minimal/mild endometriosis patients after 2 months treatment of Metformin (1000mg/d) and verify biomarkers associated endometrial receptivity that upregulated after Metformin treatment.

MATERIALS AND METHODS: Protein expressions profile of eutopic endometrial tissues from participants with minimal/mild endometriosis in secretory phase were analyzed by liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) based proteomics with data-independent acquisition (DIA) workflow. Up-regulated endometrial receptivity associated markers were screened out after metformin treatment in paired endometria. Parallel reaction monitoring (PRM) and immunochemistry were used for validation these markers. Endometria of endometriosis mice model on day 4 of pseudopregnancy were used for measured above screened markers, LIF and integrin $\alpha v\beta 3$ expression.

RESULTS: Compared to baseline, 149 differentially expressed proteins were detected in the endometria after metformin therapy. Insulin-like growth factor-binding protein 7 (IGFBP-7), α-antitrypsin (AAT), apolipoprotein D (ApoD), Rho GDP-dissociation inhibitor 1 (Rho-GDI), brain form glycogen phosphorylase (PYGB) and Cathepsin B (CTSB) that associated with endometrial receptivity had up-regulated after metformin therapy ($P<0.05$); while the expressions of those protein had no significant change in non-received controls. Up-regulated expression of IGFBP-7 and ApoD had been validated by PRM. IGFBP-7 and integrin$\beta 3$ were up-regulated after metformin treatment in endometria of endometriosis mice model during window of implantation.

CONCLUSIONS: Our study revealed that metformin may ameliorate expression of proteins related to endometrial receptivity in women with minimal/mild endometriosis and endometriosis mice model. Metformin could be used as potentially novel therapy to improve endometrial receptivity of infertile women with endometriosis.

SUPPORT: The study was funded by National Key R&D Program of China (Grant number: 2017YCF1001200).

ASSESSING THE CHANGE IN INFERTILITY PATIENT'S SOCIAL MEDIA USE DURING COVID-19 RELATED CLINIC CLOSURES.

Julie Morgan, MSc.,[1] Andreia Trigo, MSc,[2] Kate Davies, BSc.[3] [1]All About Infertility Ltd, United Kingdom; [2]Andreia Trigo Consulting Ltd, United Kingdom,; [3]Your Fertility Journey Ltd, United Kingdom.

BACKGROUND: Instagram is a popular app and social media networking platform that is utilised by patients to obtain and share health information.

OBJECTIVE: To assess whether infertility patients changed or altered their user engagement on Instagram in the time period around fertility clinic closure and reopening during the Covid-19 pandemic.

DESIGN: Content Analysis.

MATERIALS AND METHODS: The Instagram native insights analytics tool was used to analyse five social media accounts used by three independent Fertility Nurse Consultants in the United Kingdom (UK). Posts were examined between 1/03/20 - 02/07/20 for comments, likes, reach, profile visits, sharing and saving, growth and engagement, together with audience subdivision by gender, age and geography.

RESULTS: 436 posts were identified, saved by users 388 times generating 1834 profile visits. Average increases were noted in: followers 266%, comments 700%, likes 225%, reach 311% and user engagement 176%. Users were 89.2 % female and 10.8% male, predominantly from the UK, United States and Portugal. The age demographic was: Female $<$ 24 years $<$ 4%, 25 – 34 years 43%, 35 – 44 years 41.8%, 45 – 54 years 6.8%, $>$ 55 years 4.4% and Male $<$ 24 Years 8.6%, 25 – 34 years 33.2%, 35 – 44 years 37%, 45 – 54 years 11.8%, $>$ 55 years 9.4%.

Posts with the highest user engagement contained factual information regarding fertility clinics closure and reopening, validating increased anxiety concerning the impact of delay on chances of conception and managing negative thinking and uncertainty. Recurring themes in patients' comments related to information provided by fertility clinics. For example, 'I called my clinic yesterday and all I got was we have absolutely no idea', 'we haven't heard a peep from our clinic since lock down', 'I just want to hear from my clinic if they are opening or not', 'I am normally pretty resilient but this has floored me'.

As a result of increased user engagement and direct messaging, all five social media accounts posted daily to keep up with demand. They also participated in homogeneous podcasts, commenced support webinars and engaged with followers in real time weekly Instagram Live sessions. One account commenced a support group which had a 95% weekly engagement rate.

CONCLUSIONS: The results of this study indicate that Infertility patients increasingly relied on Instagram to manage their expectations surrounding treatment suspension, which they perceived as providing information and a support network that they felt was missing from their health provider.

Moving forwards, as Covid-19 continues to cause uncertainty, it is clear that fertility clinics should offer an additional psychological aspect to care, providing regular, updated information that matches patient preferences to their needs.

The authors are aware of the limitations and reason for caution with this study. Only five Instagram accounts were analysed. Therefore, only a small amount of data was available, with a particular user segment, which may not be indicative of the whole population.

P-988 3:30 PM Wednesday, October 21, 2020

COVID CONCEPTION CATASTROPHE?: THE EXPERIENCE OF FERTILITYIQ USERS.

Christina E. Boots, MD, MSCI,[1] Anu Venkatesh, BS,[1] Jake Anderson, MBA,[2] Lauren Citro, BSN, RN,[2] Angela K. Lawson, Ph.D.[3] [1]Northwestern Feinberg School of Medicine, Chicago, IL; [2]FertilityIQ, San Francisco, CA; [3]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, CA.

OBJECTIVE: To assess concern about COVID-related clinic exposure, pregnancy risks, and treatment cancellations in a sample of infertility patients across the United States.

DESIGN: Analysis of a cross-sectional survey.

MATERIALS AND METHODS: FertilityIQ, an online educational platform, surveyed its 53,600 users via email between 05/27/2020-06/30/2020 to better understand their experiences with the delay of fertility care due to the COVID-19 pandemic. 13,490 email recipients opened the email and 1,730 women participated in the survey. Survey questions included the collection of demographic information (i.e., U.S. state of residence, age, gender, fertility diagnosis, and annual household income) and both quantitative and qualitative questions about fertility and the COVID-19 pandemic.

RESULTS: Two thirds of respondents were 31-40 years old. Of the women who responded, 43% were planning to start treatment immediately and 35% were actively undergoing fertility treatment when the pandemic began. Twenty-one percent chose to delay their own treatment and 58% had treatment postponed by their providers. Of the 943 women whose clinic delayed their treatment, 86% (n= 809) felt sad, but 67% (n= 630) agreed with the delay. Women with a higher income were more likely to agree with the decision to postpone ($P=0.019$). In addition, women with diminished ovarian reserve were more likely to feel sad about the COVID-related treatment delays ($P = 0.007$); age was associated with feelings of anger due to the delay ($P = 0.03$) and being "highly concerned" that the delay would affect pregnancy outcomes ($P = 0.006$). Overall, 46% of women were comfortable undergoing treatment during the pandemic, while 39% were unsure. Half of all women were "somewhat concerned" about pregnancy risks and 19% were "not concerned". Additionally, 38% were "not concerned" about exposure to COVID in the clinic, whereas 59% were "highly concerned" about treatment cancellation. The vast majority of women felt it was "highly important" that their clinic practice social distancing (71%). In regards to the financial burden, 33% of women were "highly concerned" about paying for treatment during the economic downturn whereas 29% were "not concerned". Importantly, 44% of women were "highly concerned" about their partner not being present during their treatment.

CONCLUSIONS: As expected, the majority of women were concerned and sad about delays in their fertility treatment during the COVID pandemic. Concerns include pregnancy risk, exposure risk, and having their partners present during their care. Both age and a diagnosis of diminished ovarian reserve were associated with emotional distress by these delays. A wide spectrum exists in the number of women with and without these concerns, and thus, additional education is needed for these patients to ensure their understanding of COVID exposure and potential pregnancy risks. Lastly, we recommend the provision of emotional support to fertility patients affected by the cancellation of fertility care and/or ongoing distress due to the COVID-19 pandemic.

P-989 3:30 PM Wednesday, October 21, 2020

CHROMOSOMAL STRUCTURAL REARRANGEMENTS IN COUPLES DOES NOT INFLUENCE THE RATE OF MOSAICISM IN THEIR EMBRYOS.

Shujing He, MM,[1] Lei Jia, PhD,[2] Yida Wang, bachelor,[2] Zhiqiang Zhang, master's degree,[3] Cong Fang, Ph.D.,[2] Xiao-yan Liang, M.D., Ph.D.[3] [1]The Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [3]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate whether the rate of mosaicism in preimplantation embryos is influenced by the chromosomal structural rearrangements in couples and the sex of the translocation carrier in preimplantation genetic testing (PGT).

DESIGN: A single center retrospective study performed between June 2018 and June 2020.

MATERIALS AND METHODS: The study included the data analysis of 754 blastocysts from 231 couples detected with Next Generation Sequencing(NGS). The cut-off values for reporting mosaic levels in our laboratory ranged from 40% to 70% .

According to the couples' chromosome karyotype, blastocysts were divided into three groups: reciprocal translocation carriers(N=442), Robertsonian translocation carriers(N=104), and couples with normal karyotype(N=208). The mean female age in all groups was similar and statistically non-significant(30.6±4.1, 31.2±2.7 and 31.0±5.0 for reciprocal translocation carriers, Robertsonian translocation carriers and couples with normal karyotype, 30.5±4.0 and 30.9±4.4 for male and female carriers). Statistical analyses were performed with IBM SPSS statistics 22.0 (SPSS, Inc., Chicago, IL). Independent-Sample T test and Chi-square test was used as appropriate. All statistical analysis was performed using SPSS 22.0. $P<0.05$ was defined as a statistically significant difference.

RESULTS: The mosaicism rate of reciprocal translocation carriers, Robertsonian translocation carriers and couples with normal karyotype were 4.30%(19/442), 10.58%(11/104) and 6.73%(12/208), respectively. There was no statistical significance in the mosaicism rate of reciprocal translocation carriers and couples with normal karyotype (4.30% vs. 6.73%, P=0.118). And Robertsonian translocation carriers were not statistically prone to have more mosaic embryos than couples with normal karyotype (10.58% vs. 6.73%, P=0.238).

When considering the sex of the translocation carrier, in reciprocal translocation group, the mosaicism rate of male carriers and female carriers was 5.19%(14/270) and 2.86%(5/172) respectively without statistical difference(P=0.250). The mosaicism rate of male Robertsonian translocation carriers and female Robertsonian translocation carriers was 14.55%(8/55) and 6.12%(3/49) respectively, and there was no statistical significance, too(P=0.163).

CONCLUSIONS: The frequency of mosaic embryos was not influenced by the chromosomal structural rearrangements in couples. Chromosomal translocation carriers generated more aneuploidy embryos, but they did not tend towards generating more mosaic embryos compared with couples with normal karyotype. And the sex of the translocation carrier did not influence the mosaicism rate, too. The possible reason is that reciprocal or Robertsonian translocation may not lead to errors in mitotic divisions during embryo early development.

SUPPORT: Medical Scientific Technology Research Foundation of Guangdong Province of China (A2020226); National Natural Science Foundation of China (81801449).

P-990 3:30 PM Wednesday, October 21, 2020

THE EFFECT OF SMOKING ON PREGNANCY COMPLICATIONS IN WOMEN WITH THE POLYCYSTIC OVARIAN SYNDROME (PCOS): A STUDY OF ALMOST 15,000 WOMEN.

Ido Feferkorn, MD,[1] Ahmad Badeghiesh, M.D. , MPH,[2] Haitham Baghlaf, MD, MPH,[3] Michael H. Dahan, M.D.[1] [1]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Center, Montreal, QC, Canada; [2]Division of REI, McGill University and OriginElle Fertility Clinic and Women's Health Centre, Montreal, QC, Canada; [3]McGill University, Montreal, QC, Canada.

OBJECTIVE: The risk of pregnancy complications in patients PCOS is increased, including; pregnancy induced hypertension, preeclampsia, preterm birth and gestational diabetes mellitus (GDM). In the non PCOS population, prenatal smoking is associated with preterm birth, placental abruption, intra-uterine growth restriction and an inverse relationship with pregnancy induced hypertension (PIH). It remains unclear whether an association between smoking and GDM exists with studies reporting confliction results. We sought to investigate whether there is an association between pregnancy complications and smoking in women with PCOS.

DESIGN: This is a retrospective population-based study utilizing data from the HCUP-NIS over 11 years from 2004 to 2014. A dataset of all deliveries between 2004 and 2014 inclusively was created. Each patient was included only once. Women with PCOS were identified; of them 631 smokers and 14,251 none smokers.

MATERIALS AND METHODS: The HCUP-NIS is comprised of hospital inpatient stays submitted by institutions throughout the entire country and is representative of ~ 20% of admissions to US hospitals across 48 states and the District of Columbia. A multivariate logistic analysis was done adjusting for any statistically significant confounding effect ($p<0.05$).

RESULTS: While the risks of preterm premature rupture of membranes, preterm delivery (aOR 1.22 CI 0.77-1.93), placental abruption (aOR 1.08 CI 0.37-3.15), and PIH (aOR 1.01 CI 0.69-1.48) were not higher in smoking PCOS subjects, a significant association between smoking and diabetes mellitus (both GDM (aOR 1.46; 95%CI 1.01-2.10) and pregestational diabetes mellitus (6.5% vs. 4.0%, p=0.003)) was detected. There were no significant statistical differences in the rate of operative vaginal delivery or cesarean section. Risks of maternal infections and thrombotic complications and neonatal outcomes (small for gestational age, intrauterine fetal demise and congenital anomalies) were comparable.

CONCLUSIONS: Among women with PCOS who smoke the risk of gestational diabetes is increased; however, the expected decrease in PIH and specifically preeclampsia did not occur possibly due to the inherent risks of the syndrome itself.

P-991 3:30 PM Wednesday, October 21, 2020

LINE 1 COPY NUMBER DECREASES AND TELOMERE LENGTH INCREASES WITH AGING IN SPERM CELLS.

Thalita S. Berteli, MSc,[1] Fang Wang, PhD,[1] Paula A. Navarro, MD, PhD,[2] Fabiana B. Kohlrausch, Ph.D,[1] David L. Keefe, MD.[3] [1]New York University, Langone Medical Center, New York, NY; [2]Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil; [3]NYU Grossman School of Medicine, New York, NY.

OBJECTIVE: Telomeres, repetitive sequences and associated proteins which cap and protect chromosome ends, undergo attrition with age in most tissues, providing an aging clock. Unlike other tissues, sperm telomeres increase rather than decrease with paternal age. The function of age-related sperm telomere elongation remains poorly understood. In yeast, mice and humans, telomeres can cause reversible silencing of genes, called the telomere position effect (TPE). We hypothesize that telomere elongation may help suppress Long Interspersed Nuclear Element 1 (L-1), a retrotransposon which becomes active in the germ line and can contribute to human genetic variation and genomic instability. Here we compare L-1 copy number in sperm samples from older and younger men to investigate the effect of paternal age and telomere elongation on L-1.

DESIGN: Prospective case-control study.

MATERIALS AND METHODS: Sperm samples (n=25) were donated for research by consenting men, aged 32-55, undergoing treatment at NYU Langone Fertility Center (NYUFC). Baseline semen parameters were evaluated, and samples processed by swim-up. Sperm genomic DNA was obtained using DNeasy Blood & Tissue Kit, QIAGEN® following manufacturer's recommended protocol, with an additional lysis step using X2 buffer (20 mM Tris-Cl, pH 8.0, 20 mM EDTA, 200 mM NaCl, 4% SDS); 80 mM dithiothreitol (DTT) and 12.5 μL/mL Proteinase K. Average sperm telomere length (STL) was assayed by mmqPCR and L-1 copy number by qPCR. Linear regression with Pearson Correlation Coefficient characterized the relationships between age, STL and L-1 copy number. Comparisons between old (age $\geq$ 45 years) and young men (age $\leq$ 40 years) were performed by t-test or Wilcoxon Test using GraphPad Prism 8 software. P-value < 0.05 was considered significant.

RESULTS: STL was positively correlated with age ($r^2 = 0.2851$; $p = 0.006$), as previously reported. STL from older (age $\geq$ 45 years, n: 5; Mean: 1.398 ± 0.3715) was significantly longer than younger men (age $\leq$ 40 years, n: 13, Mean: 0.9749 ± 0.1319) ($p = 0.0002$ Wilcoxon Test). L1 copy number in sperm decreased significantly with paternal age ($r^2 = 0.1585$; $p = 0.048$). T-test showed this effect was even more pronounced when comparing old (age $\geq$ 45 years, n=5; Mean: 0.8505 ± 0.1176) vs. young men (age $\leq$ 40 years, n=13, Mean: 1.012 ± 0.0885) ($p < 0.0001$).

CONCLUSIONS: We confirm increasing sperm telomere length with advancing paternal age. L1 copy number, in contrast, decreases significantly with paternal age, as sperm telomeres lengthen. Telomere elongation in the male germ line may represent a surveillance mechanism to repress retro transposition and maintain genomic instability. De repression of L-1 has been implicated in neuropsychiatric syndromes, so it will be of interest to determine whether failure of this mechanism contributes to the paternal age effect on neuropsychiatric syndromes.

Kaplan Fund of the NYU Grossman School of Medicine (to DLK).

P-992 3:30 PM Wednesday, October 21, 2020

ADULT WEIGHT CHANGE IN RELATION TO SEMEN QUALITY AMONG MEN ATTENDING AN ACADEMIC FERTILITY CENTER. Vibha Singhal, MD,[1] Irene Souter, MD,[2] Jorge E. Chavarro, MD, Sc.D.[3] [1]MGH Weight Center, Boston, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Harvard School of Public Health, Boston, MA.

OBJECTIVE: In adults, obesity is associated with changes in some semen parameters especially sperm concentration. Most obesity related complications are influenced by the duration of obesity and age of onset. However, it is unclear if the degree of weight change during adult life has any impact on semen parameters. To address this question, we examined the association between weight changes during adult life and semen parameters.

DESIGN: Cohort Study.

MATERIALS AND METHODS: We recruited men in subfertile couples presenting to the Massachusetts General Hospital Fertility Center. Participants filled standardized questionnaires and provided a semen samples on site. We calculated weight change since age 18 years as the difference between current measured weight and self-reported weight at age 18 years, and classified men as weight stable (+2 to -2 kg), weight loss (<-2kg), weight gain below the median (+2 to 14kg) and weight gain above the median (>+14kg). We computed odds ratios (95%CI) of semen parameters below WHO reference limits using logistic regression adjusted for age, smoking status and abstinence time and separately for current and age 18 years body mass index (BMI). Last, we evaluated whether associations differed according to BMI at age 18.

RESULTS: We examined 845 men who were mainly Caucasian (86.6%), had a median (IQR) age of 36 (33-40) years, BMI of 27 (25-30) kg/m^2, and weight change since age 18 years of 14 (8-22) kg. Compared to men with stable weight, men who lost weight had (odds ratio [95%CI]) 3.2 (1.1-9.6) higher odds of low sperm morphology and 4.9 (1.6-15) higher odds of low motility. These estimates did not change substantially in models additionally controlling for current BMI or BMI at age 18 years. Men who had gained weight also had increased odds of semen parameters below WHO reference limits, but these estimates did not reach statistical significance. In models stratified by BMI at age 18 years, men who were overweight or obese at age 18 years and subsequently lost weight had a greater odds of sperm morphology (6.3 [0.9-40]) and motility (10.8 [1.6-71]) below WHO reference limits compared to men who were overweight/obese at age 18 and did not lose weight, whereas the relations of weight loss with morphology and motility were substantially weaker among men who were normal weight at age 18: 2.2 [0.4-11] and 1.8 [0.3-9.9], respectively.

CONCLUSIONS: Weight loss during adulthood among men with overweight/obesity at age 18 years is associated with increased odds of below reference sperm morphology and motility in men attending an academic fertility center. This finding is consistent with literature of semen abnormalities after weight loss surgery which suggests, at best, no benefit and in some cases harm of weight loss on markers of spermatogenesis. An important limitation of the study is the lack of information on the modality and rate of weight loss and if it was associated with any nutritional deficiencies. Clarifying the implications of these findings for future fertility of young men with obesity is critical.

P-993 3:30 PM Wednesday, October 21, 2020

BLASTOCYST MOSAIC RATES DEMONSTRATE A DECREASING TREND WITH MATERNAL AGE. Liz R. Dulle, BS,[1] Jessi Anderson, MPH,[1] MacKenzie Purdy, MD.[2] [1]Vios Fertility Institute, Chicago, IL; [2]Vios Fertility Institute, Swansea, IL.

OBJECTIVE: Since chromosomal abnormalities increase drastically with maternal age while mosaicism, which occurs when there are 2 or more genetically different sets of cells in the body has not conclusively demonstrated change with age, we analyzed if there is a change in mosaic embryos with age.

DESIGN: A retrospective analysis was performed to determine if the percent of mosaicism was related to maternal age when undergoing an in vitro fertilization cycle (IVF) using Preimplantation Genetic Testing-Aneuploidy (PGT-A) with Next Generation Sequencing (NGS).

MATERIALS AND METHODS: Mosaic results were obtained for 2,597 embryos that underwent biopsy from 1/2019 to 6/2020 at two IVF centers. Patient age was separated into four categories: <35, 35-37, 38-40, and >40. All embryos were tested by using NGS and reports were given to the provider as euploid, aneuploid, mosaic or no results. The standard cut-off for reporting mosaicism was >20% abnormal cells in a sample and <80% abnormal. Statistical analysis was performed by chi-square testing and Cochran-Armitage trend test, assessing for a linear trend in the proportions across the age groups.

RESULTS: Based on 2,597 embryos biopsied, 121 (5%) were noted to be mosaic. Mosaicism based on age demonstrated: <35 age group, 78/1,414 (6%), 35-37 age group, 26/567 (5%), 38-40 age group, 10/375 (3%), and > 40 age group, 7/234 (3%). When comparing the four groups p=0.0611 for chi-square test and p=0.0095 for Cochran-Armitage test for trend.

TABLE 1. Mosaic samples compared to non-mosaic samples based on age

	<35	35-37	38-40	>40	Total
Mosaic	78 (6%)	26 (5%)	10 (3%)	7 (3%)	121 (5%)
Not Mosaic	1,336	541	365	234	2,476
Total	1414	567	375	241	2,597

CONCLUSIONS: We generally think of genetic abnormalities in the form of an all or nothing process but based on the timing of genetic changes there can be discordance of cell types leading to mosaicism. Many studies have demonstrated that abnormal meiotic division increases substantially with maternal age, but this has not been demonstrated for mosaic changes. With the development of PGT-A with NGS we can assess mosaic rates and trend with increasing age. In this large multi-site study, we determined that there is a trend toward decreasing mosaic rates with maternal age.

AN EVALUATION OF COMMERCIAL FERTILITY APPS: ALGORITHMIC PREDICTIONS AND USERS' PERCEPTIONS. Mayara Costa Figueiredo, MS,[1] H. Irene Su, M.D., M.S.C.E.,[2] Yunan Chen, PhD.[1] [1]University of California, Irvine, Irvine, CA; [2]University of California San Diego, La Jolla, CA.

OBJECTIVE: Fertility apps have been increasingly used to predict ovulation and fertile window, but it is unclear how these predictions are made (e.g., what indicators are used, how cycles are calculated) and how users perceive and trust them. The goal of this study is to evaluate current commercially available fertility apps focusing on their algorithmic feedback and users' experiences. More often patients are bringing apps to clinical appointments, so it becomes critical to analyze the type of support apps offer and how patients interact with their predictions.

DESIGN: We evaluated 30 best rated fertility apps obtained from the two main app stores, analyzing algorithmic feedback, app features, and user reviews of the selected apps.

MATERIALS AND METHODS: Each app was evaluated using a single dataset simulating four months of regular fertility cycles, including data for period dates, temperature, ovulation, and cervical mucus. Two researchers inputted the data in each app, analyzing how different types of data may visibly change the predictions of ovulation date and fertile window. Finally, user reviews from the app stores were qualitatively analyzed to surface users' experiences and perceptions of interacting with the fertility predictions.

RESULTS: Predictions varied considerably among apps. The first day of the fertile window varied by five days, with 13 apps predicting the same start day. Ovulation day varied by five days, with 19 apps predicting the same day and 2 apps not providing predictions. Length of fertile window ranged from 3 to 14 days (mean=7.167, sd=2.036). The start day of periods affected the

fertility predictions of 29 out of 30 apps (96.66%). Among the 30 apps, 20 provided ovulation tracking features but entering ovulation data only affected the prediction of 13 apps (65%). Similarly, temperature and cervical mucus tracking were present in 25 and 22 apps but entering temperature and mucus data affected predictions in only 6 (24%) and 1 app (4.54%) respectively. The analysis of app reviews suggests users have mixed reactions towards the apps, some fully trust algorithmic predictions, but many are confused about how the apps make predictions and why the predictions are incorrect comparing to the results of OPKs, or inconsistent with other fertility apps they use.

CONCLUSIONS: Our study reveals substantial inconsistencies in fertility predictions among the popular fertility apps we reviewed. Other than period dates, most data tracked by users do not lead to changes in predictions, which suggests that indicators that may require daily and disciplined work are not used. Our analysis show that the lack of clear description of what data are used in making fertility predictions can cause potential tracking burden, distrust of fertility technologies, or over-trust in predictions that may not be accurate. These issues may further affect users' fertility experiences and their interactions with healthcare providers. This study shows fertility technologies have to be designed more transparent with regard to their algorithmic feedback and to make the uncertainty intrinsic to fertility more visible to users.

P-995 3:30 PM Wednesday, October 21, 2020

DEVELOPING A DECISION SUPPORT TOOL TO DETERMINE OPTIMAL NUMBER OF EUPLOID EMBRYOS BANKED TO ACHIEVE A DESIRED FAMILY SIZE. Devora Aharon, MD,[1] Cory Weinfeld, MS,[2] Alan B. Copperman, MD,[1] Erkan Buyuk, MD.[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: As women get older, the likelihood for pregnancy decreases: the chance of live birth (LB) after one IVF cycle at the age of 40 is 23%, but it declines to 4% at the age of 43, an 83% decrease.[1] This poses a challenge in particular for women above 35 who desire more than one child. After delivery of the first baby, the chance for pregnancy through a new IVF cycle will most likely be decreased. Ideally, women would bank the total number of euploid embryos needed to complete their family at a younger age. It is currently unknown how many euploid embryos need to be frozen for patients to achieve their ideal number of children. The aim of this study is to develop a decision support tool to inform patients about the number of euploid embryos that would result in a high likelihood of achieving their desired family size.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All patients who underwent single euploid frozen-thawed embryo transfer (FET) from January 2013 through October 2019 were included. The probabilities of one and 2 LB according to cumulative number of single euploid FET performed were calculated. Data were stratified by SART age group. Events of monozygotic splitting that resulted in twin LB were counted as 2 LB.

RESULTS: 4,169 single euploid FET cycles were included in the study. Overall, 69% of patients who attempted for one baby achieved a LB, and 67% of patients who attempted for two children achieved two LB. 78.8% of patients who transferred 2 euploid embryos achieved 1 LB and 13.1% achieved 2 LB (Table 1). The likelihood of 1 LB and 2 LB increased to 92.5% and 39.7% after 3 FETs, and to 97.9% and 71.7% after 4 FETs, respectively.

CONCLUSIONS: The goal of achieving two live births increased by 81% when 4 embryos were transferred compared to 3, indicating that patients who desire two children would be advised to bank at least 4-5 euploid embryos. Patient-focused decision support tools are now possible due to big data; a calculator will be built incorporating patient-specific factors to determine how many euploid embryos patients should bank in order to achieve their desired family size.

TIMING OF INITIATING GNRH ANTAGONIST DOWN-REGULATION IN IVF CYCLES AFFECTS CLINICAL OUTCOMES OF PCOS PATIENTS. Li Yujie, Doctor. Sixth Affliated Hospital of Sun Yat-sen University.

OBJECTIVE: Whether the timing of use of gonadotropin-releasing hormone (GnRH) antagonist down-regulation for IVF cycles affects pregnancy outcomes of polycystic ovary syndrome (PCOS) patients?

DESIGN: Retrospective cohort study of 1008 PCOS patients undergoing first IVF cycles using GnRH antagonist protocol from January, 2014 to December, 2019

MATERIALS AND METHODS: According to the dominant follicle size on the day of GnRH antagonist administration, the included patients were divided into three groups: Group A, dominant follicle diameter (DFD) < 10mm; Group B, 10mm ≤ DFD < 14mm; Group C, DFD ≥ 14mm. The parameters regarding demographic and clinical characteristics, ovarian stimulation characteristics, clinical outcomes including number of oocytes retrieved, top quality embryo number, clinical pregnancy rate, live birth rate, etc were compared among different groups.

RESULTS: The age, anti-Mullerian hormone level and body mass index were comparable among different groups. Total FSH dosage of Group A (1492.7IU) was more than Group B (1292.7IU) and Group C (1243.6IU). Group A needed longest FSH stimulation duration and GnRH antagonist duration (9.6days, 5.1days, respectively), then group B (8.9days, 4.8days, respectively), then group C (8.27days, 3.4days, respectively). Progesterone level on HCG day was higher in group B (1.00ng/ml) than in group A (0.88ng/ml) and group C (0.75ng/ml). The number of oocytes retrieved was highest in group B (18.3), then group A (16.3) and the lowest in group C (14.5). The number of fertilization embryos, transferable embryos, top-quality embryos and blastocysts in group B (10.8, 8.7, 7.2, 3.1, respectively) were more than in group C (8.5, 7.2, 5.9, 1.6, respectively), while comparable in group A (9.7, 8.2, 6.8, 3.3, respectively). Following the patients' first embryo transfer (ET) cycles, although there were no significant differences in the rate of chemical pregnancy, clinical pregnancy nor live birth in fresh or frozen ET cycles, the live birth rate of group C was the lowest (fresh ET, frozen ET: group A, 50.0%, 52.7%;group B, 48.0%, 54.7%;group C, 46.5%, 46.3%, respectively).

CONCLUSIONS: For PCOS patients, initiating GnRH antagonist when dominant follicle diameter between 10mm to 14mm could reduce FSH dosage, shorten FSH stimulation duration, retrieve more

TABLE 1. Likelihood of achieving 1 or 2 LB according to number of euploid single FET performed

oocytes, get more top-quality embryos and achieve higher live birth rate in IVF cycles.

P-997 3:30 PM Wednesday, October 21, 2020

IDENTIFICATION OF WOMEN AT HIGH RISK FOR GYN HEREDITARY CANCERS MADE SIMPLE.

Bailey Gill McGuinness, MD,[1] John Wagner, MD.[2] [1]NYU Winthrop Hospital, Mineola, NY; [2]Huntington Hospital, Huntington, NY.

OBJECTIVE: The purpose of this project was to create and trial a screening form to be used in the out-patient setting to identify high-risk carriers for GYN hereditary cancer genes, such as BRCA, Lynch Synd., etc. This screening tool can be applied in internal medicine, OB/GYN and subspecialties, like REI. Early identification of genetic carriers allows for the opportunity to use PGT to prevent transfer of embryos carrying cancer genes when undergoing IVF.

The form identifies women who qualify for hereditary cancer screening and referrals to breast health programs (BHP) for consultation, increased surveillance, chemo-prophylaxis or prophylactic surgery. Several genetics companies promote forms that simplify the National Comprehensive Cancer Network (NCCN) guidelines for hereditary GYN cancer screening, such as this form. However, this is the only available form that combines NCCN guidelines with the Gail Model, which calculates a women's lifetime breast cancer risk.

DESIGN: Quality improvement project.

MATERIALS AND METHODS: Stage 1: The form was used in an OB/GYN office in East Northport, NY for one month. During this time, feedback from attendings, staff and patients was used to edit the form until the form was deemed not only accurate but user-friendly.

Stage 2: The form was introduced at an OB/GYN practice in Garden City, NY. Success of the form was measured by the number of patients identified who met criteria either for genetic testing or for referral to the local BHP, defined by an elevated Gail Model score. 6-week control (4/8/19 to 5/17/19) and study (5/21/19 to 7/5/19) periods were compared.

Descriptive statistics were performed.

RESULTS: During the control period prior to introduction of the form, there were 171 annual and new-patient visits, of which zero patients were identified as candidates for genetic testing or referred to the BHP. During the 6-week period following introduction of the form, 197 annual and new-patient visits were performed and 141 of these patients (71%) were screened with the form. One patient was unable to complete the form due to lack of family history. 11% of patients met criteria for referral to genetic counselors for testing and 7.8% of patients met criteria for referral to the BHP.

Physicians described the form as a tool to learn the NCCN guidelines. The form generated income for physicians who coded and billed for performing cancer screening or genetic counseling. Patients benefitted from appropriate referrals with significant clinical implications. Both patients and physicians described the form as simple to complete and navigate.

CONCLUSIONS: Identification of women at high risk for GYN hereditary cancers allows for appropriate referrals to genetic counselors for testing and to BHPs for cancer screening and prevention. Identifying genetic carriers prior to undergoing IVF is vital due to available technology, such as PGT, to prevent transfer of carrier positive embryos. This form proves to be user-friendly, accurate, income generating, and clinically relevant, as evidenced by continued use of this form beyond completion of the study.

P-998 3:30 PM Wednesday, October 21, 2020

MITOCHONDRIAL DNA CONTENT IS NOT A USEFUL METHOD TO PREDICT THE REPRODUCTIVE OUTCOME OF EUPLOID BLASTOCYSTS.

Mariana Gomez Peña, BSc,[1] Laura J. Kopcow, MD,[1] Fabio L. Sobral, Physician,[1] Marcos Horton, Physician,[2] Mercedes Papayannis, BSc,[1] Evelyn De Martino, BSc,[1] Ignacio De Zuñiga, Physician,[3] Alejandro Oubiña, Physician,[1] Claudio Bisioli, MSc.[1] [1]Pregna Medicina Reproductiva, Buenos Aires, Argentina; [2]Juncal 3490, CABA, Argentina; [3]Pregna medicina reproductiva, Buenos Airesl, Argentina.

OBJECTIVE: To evaluate if the assessment of mitochondrial DNA (mtDNA) content is a useful tool to predict implantation and pregnancy performance in frozen euploid blastocysts transfer cycles.

DESIGN: Retrospective comparative study.

MATERIALS AND METHODS: One hundred and eighty-two elective single frozen blastocyst transfers after preimplantation genetic testing for aneuploidy (PGT-A) and mtDNA content assessment via next generation sequencing (NGS) were performed between May 2016 and October 2019. Euploid blastocysts for transfer were selected based on standard morphological criteria and independently of the mtDNA content result. Blastocysts transferred were grouped according to the value of a mtDNA content score (MS) as following: group A (MS < 18.19, N $= 30$), group B (MS $= 18.19$ to 24.15, N $= 55$) and group C (MS $= 24.15$ to 50.58, N $= 94$). Three of the studied blastocysts had MS > 50.58 and were excluded from the study. Study groups were comparable regarding patients' age, indication for PGT-A and proportion of good quality blastocysts. Student's t and Chi-squared tests were used as appropriate.

RESULTS: No differences were observed between groups regarding implantation, clinical and ongoing pregnancies and miscarriage rates (table 1).

TABLE 1. Outcomes results between groups

Study groups	A	B	C
Implantation	43.3 (13/30)	45.4 (25/55)	37.2 (35/94)
Clinical Pregnancies	43.3 (13/30)	43.6 (24/55)	35.1 (33/94)
Miscarriages	15.3 (2/13)	12.5 (3/24)	18.2 (6/33)
Ongoing pregnancies	36.7 (11/30)	38.2 (21/55)	28.7 (27/94)

CONCLUSIONS: Our study did not find any differences in mtDNA content with regards to embryo implantation or pregnancy outcomes. A bigger sample size would be crucial to confirm these preliminary results.

P-999 3:30 PM Wednesday, October 21, 2020

THE SUPPRESSIVE EFFECT OF CELASTROL ON GROWTH OF ENDOMETRIOSIS IN VITRO IS ASSOCIATED WITH ANTAGONISM OF ESTROGEN RECEPTOR ACTIVITY.

Jingjie Li, M.D,[1] Pan Chen, PhD,[2] Jiayu Lin, Bachelor,[1] Xiaoyan Liang, M.D.[1] [1]the Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: Celastrol is a quinine methide triterpenoid derived from the root of *Trypterigium Wilfordii*, which has been used in the oriental medical settings to treat various inflammatory and neurodegenerative disorders. We firstly explored its role in the growth of endometriosis in vitro.

DESIGN: Pharmacologic interventions in primary cultured human endometriotic stromal cells.

MATERIALS AND METHODS: Primary cultured human endometriotic stromal cells were prepared from ectopic endometrium of 15 patients with endometriosis undergoing laparoscopy at the Sixth affiliated Hospital of Sun Yat-sen University from January 2018 to May 2020. The cells were incubated with Celastrol at concentrations of 0.1μM, 1μM and 10μM for 24 hours, and the cell viability, proliferation ability and apoptosis were detected by MTT assay, BrdU incorporation assay and Caspase-Glo luminescent-based assays respectively. Dual luciferase activity assay with transient transfection of an ERE-tk-Luc reporter was applied in measuring the effect of Celastrol on estrogen receptor (ER) activation.

RESULTS: Celastrol dose-dependently inhibited the viability of human primary endometriotic stromal cells, and 35.2 % of cell viability was observed at 10μM of Celastrol. Similarly, the Brdu assay proved that the cells proliferation ability was also inhibited by Celastrol dose-dependently, with 34.8% decrease seen in 10μM. Furthermore, Celastrol induced a significant upregulation of caspase-3 activity in endometriotic stromal cells, and 3.61 folds of maximum increase was observed at 10μM. Besides, the dual luciferase reporter gene assay demonstrated that Celastrol inhibited activation of ER in a dose-dependent manner, and 10μM of Celastrol led to 12.7% of ER activity as compared to that in vehicle group.

CONCLUSIONS: Celastrol inhibits the cell viability and proliferation, while induces the apoptosis of human primary endometriotic stromal cells. The effects are associated with the antagonism of ER activity.

SUPPORT: Chinese Universities Scientific Fund of Sun Yat-sen University (NO.19ykpy04)

P-1000 3:30 PM Wednesday, October 21, 2020

WOMEN WITH ENDOMETRIOSIS-ASSOCIATED INFERTILITY HAVE DECREASED LIVE BIRTH RATES AFTER FROZEN EMBRYO TRANSFER – ANALYSIS OF THE "EIVF" DATABASE. Alex Finlinson, MD,[1] Henok G. Woldu, PhD,[2] Judy E. Stern, PhD,[3] Albert L. Hsu, MD.[4] [1]The Center For Health Analytics For National and Global Equity, Columbia, MO; [2]Dartmouth-Hitchcock, Lebanon, NH; [3]Department of Obstetrics and Gynecology; University of Missouri, Columbia, MO; [4]■.

OBJECTIVE: To determine whether women with surgically-confirmed endometriosis have decreased live birth rates after frozen embryo transfers (FETs), compared with either male factor or tubal factor infertility.

DESIGN: Retrospective analysis FETs in Massachusetts between 2003-2019, from the "eIVF" database.

MATERIALS AND METHODS: FET cycles in women with surgically-confirmed endometriosis were compared with those in couples with either male factor infertility or tubal factor infertility. Women were only classified as endometriosis if they had a surgical record of endometriosis of the uterus, ovary, fallopian tube, pelvic peritoneum, or rectovaginal septum. Any women who were noted to have clinical endometriosis that was not surgically confirmed, were excluded from analysis.

For the male factor analysis, couples with both endometriosis and male factor infertility were excluded; similarly, for the tubal factor analysis, couples with both endometriosis and tubal factor infertility were excluded; this resulted in different numbers of patients with surgically-confirmed endometriosis in these two analyses. Mean ages and BMI between the two groups were compared using the two sample t-test. Chi-square test and multivariable logistic regression were used to assess differences in live birth rates between surgically-confirmed endometriosis and either male factor or tubal factor infertility. Odds Ratios (OR) and 95% CI of the ORs were extracted from the fitted models. Two sided alpha level of 0.05 was used to determine statistical significance.

RESULTS: We compared 3,441 FET cycles in women with surgically-confirmed endometriosis to 11,510 FET cycles in couples with male factor infertility; groups had similar average age (35.1 vs 35.0, P=0.1947) and BMI (25.7 in both groups, P=0.527). Women with surgically-confirmed endometriosis had a 25% chance of live birth, compared with a 37% chance of live birth with male factor infertility (P<0.0001). Adjusting for age and BMI, the odds of live birth was 76% higher in male factor infertility (OR =1.76, 95% CI [1.61-1.91]), compared to women with surgically-confirmed endometriosis.

We compared 2,995 FET cycles in women with surgically-confirmed endometriosis to 4,558 cycles in couples with tubal factor infertility. The chance of live birth was 24% for surgically-confirmed endometriosis vs 28% for the tubal factor infertility group (P=0.0011). Adjusting for age and BMI, the odds of live birth were 26% higher in women with tubal factor infertility (OR 1.26, 95% CI [1.13-1.41]), in comparison to surgically-confirmed endometriosis.

CONCLUSIONS: Compared with either male factor or tubal factor infertility, surgically-confirmed endometriosis is associated with lower odds of live birth in couples undergoing FET.

P-1001 3:30 PM Wednesday, October 21, 2020

THE STATE OF FERTILITY PRESERVATION COUNSELING FOR WOMEN WITH CYSTIC FIBROSIS REPORTED BY CYSTIC FIBROSIS PROVIDERS. Sigrid Ladores, PhD, RN, PNP, CNE, FAAN, Leigh Ann Bray, PhD, RN, CNL, Janet Brown, MSN, RN, Caitlin Campbell, BSN, RN, Peng Li, PhD, Jessica Corcoran, PhD, CRNP, CPNP-PC. University of Alabama at Birmingham, Birmingham, AL.

OBJECTIVE: Fertility preservation (FP) counseling is part of comprehensive care provided to women of childbearing age undergoing oncologic treatments; however, this is not standard for patient populations with other chronic conditions. The purpose of this study was to examine the current state of FP counseling for women with cystic fibrosis (CF) from the perspective of their healthcare providers, with the goal of identifying the gaps, barriers, and facilitators to implementation of counseling in clinical practice. This knowledge can lead to the development of FP guidelines for women with CF and enhance shared decision making by broadening their reproductive options.

DESIGN: This study utilized a quantitative, exploratory, cross-sectional design.

MATERIALS AND METHODS: Healthcare providers (e.g., physicians, nurse practitioners, clinic coordinators, pharmacists, social workers, nurses) were recruited from CF Foundation accredited clinics throughout the United States and via snowball sampling. Participants completed a web-based, anonymous FP survey with 39 items that took approximately 30 minutes to complete. Participants received $20 for their participation. The descriptive statistics were provided using R software.

RESULTS: Fifty healthcare providers completed the survey (M_{age}= 40.8, SD=11.1). The majority of the healthcare providers were female (n=45). Despite the fact that 92% (n=46) of the providers felt that FP discussions should be standard for all female patients with CF, 28% (n=14) of providers reported that FP topics were not discussed with female patients with CF at any age. Most providers felt that initiation of FP discussions was the responsibility of the healthcare team (n=34), but some felt that patients should initiate the FP discussions (n=11). Lack of knowledge (n=17) and lack of time (n=12) were the two most substantial barriers to FP discussions by healthcare providers. According to the providers, the two best facilitators for FP discussions in clinic would be having national guidelines or standards (n=41) and integrating partnerships with sexual and reproductive health specialists (n=39) as part of comprehensive CF care delivery. Having educational materials to foster FP discussions between providers and patients was another facilitator reported (n=50). Healthcare providers preferred having educational information and resources shared via online format (n=46) and written pamphlets (n=44).

CONCLUSIONS: Fertility preservation counseling is an important part of comprehensive care for women with CF; however, many women do not receive FP information. This national sample of CF healthcare providers reported that they lacked the knowledge and time to discuss FP with their patients. Removing the barriers and optimizing the facilitators to encourage FP discussions between women with CF and their providers will broaden these women's reproductive options by facilitating fully informed decision making to improve overall health outcomes.

SUPPORT: This study was supported by a grant from the National Institute of Child Health and Health Development.

HUMAN PAPILLOMAVIRUS INFECTION GENOTYPE IN INFERTILE WOMEN AND ITS IMPACT ON REPRODUCTIVE OUTCOMES OF INTRAUTERINE INSEMINATION. Yujie Li, Doctor. Sixth Affiliated Hospital of Sun Yat-sen University.

OBJECTIVE: The purpose of this study was to evaluate the prevalence, genotype of HPV infection in women attending assistant reproductive treatment and to assess the relationship between HPV infection and outcome of intrauterine insemination (IUI).

DESIGN: A observational study in a tertiary hospital in southern China

MATERIALS AND METHODS: During December 2019 and July 2019, cervical-swab samples were collected for detecting HPV from 1743 infertile women seeking for assistance at the assisted reproductive technology center (ART). 28 HPV genotypes were detected, including 18 high-risk HPV (hrHPV) genotypes (types 16, 18, 26, 31, 33, 35, 39, 45, 51, 52, 53, 56, 58, 59, 66, 68, 73 and 82), and 10 low-risk HPV (lrHPV) genotypes (types 6, 11, 40, 42, 43, 44, 54, 61, 81 and 83). We evaluated the prevalence of HPV in infertile women and evaluated associations between HPV and IUI reproductive outcome.

RESULTS: 181 (10.38%) of the 1743 infertile women tested positive for HPV. Of these, 117 (64.64%) tested positive only for high-risk subtypes, 51 (28.18%) tested positive only for low-risk subtypes, and 13 (7.18%) tested positive for both high- and low-risk subtypes. Overall, 7.46% of all patients tested (130/1743) were positive for a high-risk type. The most common HrHPV genotype was HPV52 (2.29%), followed by HPV16 (1.03%), HPV58 (0.98%), HPV51 (0.80%). For the LrHPV genotypes, the most common type was HPV44 (1.15%), followed by HPV81 (0.57%), HPV42 (0.52%).The prevalence of HPV infection was higher in the age group of 41-50 years (14.94%) than in the age group of 21-30 years (9.33%) and 31-40 years (9.73%). For women undergoing IUI, the chemical pregnancy rate of hrHPV infection group (27.27%), lrHPV infection group (25.0%) were higher than non-HPV infection group (12.85%).

CONCLUSIONS: 10.38% of the infertile women tested positive for HPV, of these 71.82% were positive for a high-risk type. The most common HPV genotype was HPV52 for HrHPV and HPV44 for the LrHPV. For those undergoing IUI, HPV infected women benefit more than non-HPV infected women.

P-1003 3:30 PM Wednesday, October 21, 2020

AURKC PATHOGENIC SINGLE NUCLEOTIDE VARIANTS ARE NOT INCIDENT IN ABORTED FETUSES WITH ANEUPLOIDY. Amin - Khosravani, Researcher,[1] Masood Bazrgar, Assistant Professor,[2] Maryam Eslami, Assistant Professor,[3] Amir Amiri-Yekta, Sr., Associate Professor.[2] [1]Faculty of Advanced Science and Technology, Tehran, Iran (Islamic Republic of); [2]Reproductive Biomedicine Research Center, Tehran, Iran (Islamic Republic of); [3]Applied Biotechnology Research Center, Tehran, Iran (Islamic Republic of).

OBJECTIVE: AURKC pathogenic single nucleotide variants are not incident in aborted fetuses with aneuploidy

DESIGN: A main cause of infertility is recurrent miscarriage; additionally a considerable portion of miscarriages occur due to chromosomal abnormalities with/without risk of aneuploidy recurrence.

Although fetal aneuploidy is associated with maternal age, it is incident in young women. AURKC protein kinase is an essential factor in the cell cycle and its dysfunction can reduce the accuracy of chromosome segregation.

MATERIALS AND METHODS: We collected 50 DNA samples of aborted fetuses with confirmed aneuploidy by QF-PCR and/or array CGH method. In order to rule out advanced maternal age as a contributing factor in fetal aneuploidy, samples from mothers older than 36 years were not included. We focused on two pathogenic single nucleotide variants (SNVs) of the Exons 5 and 6 of AURKC gene in Exon 6, rs397515484 and rs121908654 using Sanger sequencing method by analyzing the results with FinchTV software.

RESULTS: In 50 samples, there was no evidence of heterozygosity and homozygosity of rs397515484 and rs121908654 pathogenic SNVs

CONCLUSIONS: Considering that the targeted mutations were not observed in 50 samples, these SNVs (rs397515484 and rs121908654) do not seem to be prioritized for future screening of aneuploidy origin in parents with a history of abortion due to aneuploidy.

P-1004 3:30 PM Wednesday, October 21, 2020

COVID-19 AND ART OUTCOMES. Isaac J. Chamani, M.D.,[1] David H. McCulloh, Ph.D.,[2] James A. Grifo, MD, PhD,[3] Frederick L. Licciardi, M.D.[4] [1]Baylor College of Medicine, Houston, TX; [2]NYU Langone Fertility Center, New York, NY; [3]NYU Langone Prelude Fertility Center, New York, NY; [4]NYU Langone Health, New York, NY.

OBJECTIVE: The ongoing COVID-19 pandemic has disrupted the normal methods of communication used by physicians and patients, as well as the standard protocols and procedures by which medical clinics operate. Pandemic related stresses may have also influenced patient's fertility goals and/or their ovarian response. We questioned whether these changes resulted in any unanticipated effects in the treatments and outcomes of ART patients.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Patients who underwent GnRH-antagonist IVF cycles from January 2020 through June 2020 at NYU Fertility Center, a period in New York City over which the COVID-19 pandemic escalated and life in the city drastically changed as a result of new social distancing measures, were separated by month of treatment and compared with patients from the corresponding month in the prior year (January 2019 through June 2019). Patient age, AMH, days gonadotropin, #oocytes retrieved, #oocytes matured, #fertilized, #blastocysts, and #euploid embryos were compared using Student's T-test.

RESULTS: 1881 patients were compared over the parallel six-month periods. Clinic visits were markedly decreased over the months of March and April of 2020, when the pandemic was at its peak in NYC and treatments were suspended as per the ASRM pandemic guidelines. There were no differences in age, AMH, #oocytes retrieved, #mature oocytes, or #fertilized between the two years. In April of 2020 there were significantly more blastocysts per patient, as compared to April of 2019, however, in May and June of 2020 there were significantly fewer euploid embryos per patient, as compared to May and June of 2019 (see table).

CONCLUSIONS: In the months following the end of the COVID-19 treatment suspension, there were no apparent differences in patient characteristics or the quantitative responses to stimulation. However, there was a significant qualitative difference as expressed in the number of euploid embryos. It remains unclear if or how the pandemic is related to this difference.

P-1005 3:30 PM Wednesday, October 21, 2020

DOES CULTURING EMBRYOS IN THE TIME LAPSE INCUBATOR IMPROVE THE EMBRYO QUALITY AND PREGNANCY OUTCOME DURING IVF/ICSI TREATMENT? Alex C. Varghese, Ph.D,[1] Maria Teresita Lao, MSc,[1] Nnenna Maduabum, MD,[2] Essam S. N. Michael, M.D., FRCSC,[1] Kannamannadiar Jayaprakasan, Ph.D.[3] [1]Astra Fertility Clinic, Mississauga, ON, Canada; [2]University of Nottingham, Nottingham, United Kingdom; [3]Department of Obstetrics and Gynaecology, Derby, United Kingdom.

OBJECTIVE: To evaluate whether the use of time-lapse incubator (TLI) improve embryo quality and IVF outcome in comparison to standard trigas benchtop incubator.

DESIGN: A retrospective study in a tertiary fertility unit.

MATERIALS AND METHODS: Women aged <40 years undergoing IVF treatment from Jan 2018 to June 2019 were included. Poor responders with <4 oocytes retrieved and those needed treatment with surgical sperm retrieval for severe male factor were excluded. Mature oocytes, retrieved from 297 patients, were inseminated. Inseminated oocytes were cultured to the blastocyst stage either using a TLI (GERI Plus) with a single step media (n=188) or in a conventional Planer BT-37 Bench top incubator with sequential culture and Day-3 media change (n=109). 161 participants underwent fresh embryo transfer with one (70.2%) or two (29.8%) embryos. The outcome measures were usable blastocysts, proportion of top quality cleavage stage embryos and blastocysts, pregnancy rates and live birth rates. The Mann Whitney-U test was used to compare the demographics and the Chi-square test and the relative risk analysis were used to compare binary outcome variables.

RESULTS: The mean (±SD) age of the participants were similar in the study and the control groups (33.1± 3.8 vs 32.8± 3.8 years). Table 1 shows the comparison of outcome variables. Day-3 compaction rate and the

	Year	N	Age	AMH	#Oocytes	#Mature	#Fertilized	#Blasts	#Euploid
January	2019	190	37.1	2.8	14.8	8.4	6.5	3.2	2.0
	2020	235	36.5	2.7	15.7	7.9	6.0	3.2	2.1

June	2019	160	37.0	2.4	14.9	7.5	5.6	3.0	2.3*
	2020	176	36.5	2.4	14.4	7.0	5.4	2.7	1.0*

*indicates $p < .05$ for comparison between 2019 and 2020 values

	GERI Plus(n=188)	PLANER (n=109)	P-value
Gr.I & II embryos on D-3	80.9% 1637/2022	85.46% 1005/1176	0.24
Compaction on D-3	19.88% 402/2022	5.44% 64/1176	<0.001
Useable Blastocysts	64.59% 1306/2022	62.33% 733/1176	0.27
Top quality blastocysts (AA, AB, BA)	13.80% 279/2022	6.03% 71/1176	<0.001
CPR (sET+dET)*	31/64 (48.4%)	31/71 (43.6%)	0.58
LBR (sET+dET)*	29/64 (45.3%)	26/71 (36.6%)	0.31
CPR (sET)*	25/48 (52.0%)	15/44 (34.0%)	0.82
LBR (sET)*	23/48 (47.9%)	14/44 (31.8%)	0.12

*Pregnancy outcome data not available for all the participants.

proportion of top-quality blastocysts were higher in the TLI group. However, the pregnancy and live birth rates were similar.

CONCLUSIONS: While the proportion of compacted embryos on day 3 and of top-quality blastocysts developed were higher with TLI culture system, the live birth rates were similar between the two groups, albeit a better trend with TLI. A large randomized trial is warranted to evaluate this research question further.

P-1006 3:30 PM Wednesday, October 21, 2020

IMPROVEMENT IN THE BLASTOCYST FORMATION AND SUBSEQUENT CLINICAL PREGNANCY RATES FOLLOWING THE USE OF COLD-PLASMA BASED AIR PURIFICATION SYSTEM IN THE EMBRYO CULTURE LABORATORY. Satish Manohar Patki, Sr. M.D.,[1] Rajvi H. Mehta, Ph.D.[2] [1]Patki Hospital, IVF Consultant, Kolhapur, India; [2]Trivector Boimed LLP, Mumbai, India.

OBJECTIVE: To study the effect of installation of a cold-plasma based air purification system in the embryo culture laboratory on the quality of air and the effect on the blastocyst formation and subsequent clinical pregnancy rate.

DESIGN: After clearance by our Institutional Ethical Committee, a cold-plasma based air purification system was installed in the embryo culture laboratory which already had a well-maintained Heating Ventilation Air-Conditioning (HVAC) System. The ambient air quality, with specific reference to microbial contamination, volatile organic compounds (VOC) and particulate matter (PM) was compared before and after the installation of this air purification system. The blastocyst formation rate and clinical pregnancy rates was also compared during these two time frames.

MATERIALS AND METHODS: A portable Novaerus NV-1050 air purification system which consists of cold plasma technology along with activated carbon and HEPA filters was installed in embryo culture laboratory. The microbial count was determined weekly while the VOC and PM counts were monitored daily at the same time of the day.

410 patients underwent IVF procedures during 6 months. Of these, 199 patients underwent IVF before (Group I) and 211 patients (Group II) after the installation of Novaerus air purification system. Patient characteristics such as age, indication for IVF, ovarian stimulation protocol, fertilization techniques, embryo culture conditions, embryo transfer techniques and luteal support were similar in both the groups.

Embryos were cultured till the blastocyst stage and the percentage of excellent quality blastocyst formed per oocyte was recorded. All the blastocysts were vitrified and embryo transfer was performed after two months. The clinical pregnancy rate per embryo transfer was calculated in each group. The data was compared using unpaired t-test, with the help of SPSS software version 21.

RESULTS: No microbial growth was detected in both the groups. The levels of VOC, PM, Blastocyst formation and clinical pregnancy rate is tabulated.

CONCLUSIONS: The addition of a cold plasma based air purification system to the culture laboratory with an existing HVAC system significantly reduces the VOC levels and results in a significant increase in the blastocyst formation and clinical pregnancy rates. It could be an adjunct in the laboratory in these COVID times where there is an increased use of VOC releasing sanitizers.

P-1007 3:30 PM Wednesday, October 21, 2020

QUALITY OF ONLINE INFORMATION PROVIDED BY FERTILITY CLINIC WEBSITES: COMPLIANCE WITH BRAZILIAN MEDICAL COUNCIL (CFM) AND AMERICAN SOCIETY FOR REPRODUCTIVE MEDICINE (ASRM) GUIDELINES. Marcia C. Ferreira, MD, PhD, Caio Nobuyoshi Koga, Medical student, Marcela Chagas Lima Mussi, Medical student, Pollyanna Faria Fradico, Medical student, Marcia M. Carneiro, MD, PhD. UNIVERSIDADE FEDERAL DE MINAS GERAIS, Belo Horizonte, Brazil.

OBJECTIVE: To evaluate fertility clinic websites registred in the11th Report of the National Embryo Production System Platform (SisEmbrio 2017) in Brazil regarding their compliance with the 2004 American Society for Reproductive Medicine (ASRM) and the Brazilian Medical Council (CFM) guidelines for advertising and to survey the general features of their websites and social media.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: We performed a cross-sectional online evaluation to obtain data on the SiSembrio registered clinics websites using 2004 ASRM guidelines for advertising (Success rates published; Presence of data to support success rate ;Comparison marketing; Live birth rate (LBR) reported ;Method of calculating LBR; LBR for time period given ;Success rates based on age and diagnosis; Experimental/Investigational nature of

Parameter	Group I	Group II	Significance level/P Value
Mean Particle Matter Count	200 (SD ± 11.25)	195 (SD ± 10.37)	0.245
Mean VOC levels(ppb)	12.2 (SD ± 3.2)	7.5 (SD ± 2.6)	0.003
Mean Blastocyst formation rate	45.5 % (SD ± 6.9)	60.5 % (SD ± 5.3)	0.0009
Mean Clinical pregnancy rate	53.26% (SD ± 8.9)	66.35% (SD ± 7.1)	0.001

procedure defined) and compliance with CFM guidelines (practice director visible with respective council number; no information on treatments' costs, no photos of patients shown nor success stories with patient identification) for advertisement. The general characteristics of these fertility clinics websites and their social media were also assessed.

RESULTS: All 163 SiSEmbrio-registered clinics were evaluated; 155 (95,1%) had functional websites (8 public, 153 private, 8 public, 2 no information).Social media participation was as follows: WhatsApp 87(87;53.3%) Facebook (143 ;87.7%) and Instagram (135;82.8%) while 84 (51.5%) had other social media (YouTube, Linkedin and Twitter). Regarding CFM recommendations only 49 (31.6%) displayed a registered director, 84(54.1%) showed patients photos either on their sites and/or social media as well as success stories. No clinic announced prices and only one offered an exclusive treatment. Success rates were published on 51(32.9%) and only 18(11.6%) used their own data whereas 7 (4.5%) displayed success rates by age. No clinic showed LBR. All clinics offered IVF and 131 explained the procedure to patients. Social fertility preservation was offered by 127(81.9%) and oncofertility by 122 (78.7%). Preimplantation genetic diagnosis was available in 85 (54.8%), oocyte donation in 67(43.25), surrogacy in 51 (32.9%) and semen donation in 44 (28.4%) and only 35 (22.6%) had andrologists.

CONCLUSIONS: Online Information provided by fertility clinics in Brazil is heterogeneous. A significant proportion of the SisEmbrio-registered fertility clinics websites do not follow some aspect of ASRM and CFM guidelines for advertising. As websites and social media are widely used by patients to obtain health information, increased dissemination and awareness of the guidelines is highly recommended.

SUPPORT: None

P-1008 3:30 PM Wednesday, October 21, 2020

PREDICTING PROBABILITY OF CUMULATIVE LIVE BIRTH BASED ON BOTH BASELINE INFORMATION AND PROTOCOLS OF CONTROLLED OVARIAN STIMULATION. Jing Liu, Prof., Qi Wan, Dr., Jihua Huang, Dr., Xingyu Lv, Dr., Xiangqian Meng, Dr., Huan Xu, Dr., Ying Zhong, Prof. Chengdu Xi'nan Gynecology Hospital, Chengdu, China.

OBJECTIVE: To develop a prediction model for the probability of cumulative live birth from one initiated assisted reproductive technology (ART) cycle based on couples' baseline characteristics and controlled ovarian stimulation (COS) protocols. Therefore, we sought to create a clinical prediction model for counseling and COS protocol selection.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: From Jan 2012 to Mar 2016, all women at age of 19-39 years old with at least 5 antral follicle count (AFC) underwent just one complete ART cycle with long GnRH-agonist, depot GnRH-agonist, modified long GnRH agonist and GnRH-antagonist protocols in Chengdu Xi'nan Gynecology Hospital were included, and followed up to Mar 2018. Couples with chromosome abnormality were excluded. Cumulative live birth was defined as first live birth resulting from one initiated ART cycle, including cycles in which fresh and/or frozen embryos were transferred, until one delivery with a live birth occurs or until all embryos are used, whichever occurs first. A multivariate stepwise logistic regression model was used to predict the probability of cumulative live birth. The accuracy of the model was then tested using a receiver operating characteristic curve (ROC).

RESULTS: 6862 patients with 6862 complete ART cycle were enrolled with a 72.89% overall cumulative live birth rate (CLBR), namely 5002 cycles cumulatively had live birth. Predictors in the model were female's age (-0.07, 95% CI:-0.09∼-0.05, P<0.001), height (0.06, 95% CI:0.05∼0.08, P<0.001), weight (-0.01, 95% CI:-0.02∼0.00 , P=0.005), duration of infertility (-0.06, 95% CI:-0.08∼-0.04 , P<0.001), number of previous ART cycle (-0.60, 95% CI:-0.79∼-0.41 , P<0.001), basal AFC (0.08, 95% CI:0.07∼0.09, P<0.001), basal FSH (-0.09, 95% CI:-0.12∼-0.06, P<0.001) and COS protocols [long GnRH-agonist (reference category), depot GnRH-agonist (-0.08, 95% CI:-0.64∼0.48, P=0.785), modified long GnRH agonist (-0.69, 95% CI:-0.96∼-0.43 , P<0.001), GnRH-antagonist protocols (-0.12, 95% CI:-0.71∼0.47, P=0.696)]. The area under the curve (AUC) for ROC was 0.708.

CONCLUSIONS: This model provides a scientific predicting method for probability of cumulative live birth, thus help doctors give patients more accurate counseling and select more suitable COS protocol.

SUPPORT: This study was supported by the China Health Promotion Foundation's ART Research Program of Young and Middle-aged Physicians.

P-1009 3:30 PM Wednesday, October 21, 2020

IS BLASTOCYST DEVELOPMENTAL RATE A GOOD PREDICTOR OF ONGOING PREGNANCY RATE IN EUPLOID BLATOCYSTS? Silvia De Frutos Sánchez, MSC,[1] Marta Ariza Lopez, MSC,[1] Fernando Bronet, PhD,[2] Eva María Martinez, MSC,[1] Maria Gaytan, PhD,[1] Ma Del Carmen Nogales, MSC,[1] Ma José de los Santos, PhD.[3] [1]IVI RMA Madrid, Madrid, Spain; [2]IVI Madrid, Madrid, Spain; [3]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: To determine whether onoing pregnancy rate (OPR) is affected by bastocyst developmental rate (trophoectoderm biopsy on day 5 or on day 6) in euploid embryos with the same morphological quality.

DESIGN: Retrospective, observational and multicenter cohort study.

MATERIALS AND METHODS: Patients who underwent PGT-A or PGT-SR cycles, dated from May 2016 to February 2019, in IVI Madrid, IVI Valencia and IVI Barcelona were included. A total of 5648 euploid embryos (biopsied on day 5 and on day 6) were divided into six different grups according to their morphological quality, wich are further divided acording to the biopsy day. Statistical program SPSS was used to find significant differences in OPR among analized groups (Table 1).

All biopsied blastocysts were hatching or hatched. Blastocysts were divided as followed: 427 in Group 1 (AA), 792 in Group 2 (AB/BA), 2921 in Group 3 (BB), 1477 in Group 4 (BC/CB/CC), 21 in Group 5 (AC) and 10 in Group 6 (CA).

RESULTS:

	OPR DAY 5	OPR DAY 6	p	N (D5+D6)
GROUP 1 BH(i) AA	55,50%	50,48%	ns	427
GROUP 2 BH(i) AB/BA	56,76%	51,28%	ns	792
GROUP 3 BH(i) BB	53,90%	46,23%	**0,0455**	2921
GROUP 4 BH(i) BC/CB/CC	45,26%	34,68%	**< 0,0001**	1477
GROUP 5 BH(i) AC	40%	33,33%	ns	21
GROUP 6 BH(i) CA	50%	33,33%	ns	10

CONCLUSIONS: Excelent and good blastocysts (Groups 1 and 2) have similar OPR, regardless the day of the biopsy. However, average and poor blastocysts (groups 3 and 4) showed lower OPR on Day 6. We can conclude that blastocyst developmental rate can affect OPR only when the morphological embryo qality is average or poor.

*As the number of embryos included in Groups 5 and 6 were too small, they have not been considered for conclusions.

P-1010 3:30 PM Wednesday, October 21, 2020

PROOF OF CONCEPT OF A TREATMENT FOR HUMAN OOCYTE MATURATION ARREST;TRANSVAGINAL OVARIAN NEEDLE INJURY PRECEEDING LETROZOLE PRIMING IN VITRO MATURATION. Safak Hatirnaz, MD,[1] Ebru Hatirnaz, MD,[1] Alper Basbug, MD,[2] Michael H. Dahan, M.D.,[3] Kaan Hatirnaz, LİCENCE STUDENT.[4] [1]Medicana International Hospital, Samsun, Turkey; [2]DÜZCE UNIVERSITY, DÜZCE, Turkey; [3]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Center, Montreal, QC, Canada; [4]ONDOKUZ MAYIS UNİVERSİTY SCHOOL OF SCİENCE, SAMSUN, Turkey.

OBJECTIVE: We aim to present the proof of concept of a novel targeted treatment strategy; transvaginal ovarian needle injury (TVOI) preceeding letrozole priming in vitro oocyte maturation (Letrozole IVM) for women suffering from repeated in vitro fertilization failures due to oocyte maturation arrest (OMA).

DESIGN: This study is designed as a proof of concept study.

MATERIALS AND METHODS: 7 cases were treated with TVOI-Letrozole IVM protocol.

TVOI –Letrozole IVM protocol was desinged to address all mechanisms involved in the maturation arrest process of oocytes.

TVOI is the puncture under mild sedation or anesthesia with a 17 gauge aspiration needle with 10-20 punctures in each ovary.This procedure can be performed 1-6 months before letrozole priming IVM procedure.The aim of TVOI is to activate the follicles from the primordial follicular pool and to distrupt any inhibiting factors if present in the ovary

Letrozole,an aromatase inhibitor induces endogenous FSH secretion secondary to the reduced estrogen levels. The resultant increased androgens may promote follicular/oocyte growth and maturation.

IVM was selected as the treatment of choice in cases with OMA because unknown intrafollicular factors can be hypothesized to either promote apoptosis of the oocytes or may cause oocyte maturation issues.

The combination of these methods was named as TVOI-Letrozole IVM protocol

SPSS 23.0 (IBM Corporation, Armonk, NY, USA) was used for the statistical analysis of the data.The quantitative data were expressed as median and range (minimum–maximum) and categorical variables were expressed as number (%).

RESULTS: Seven out of fifteen women completed their TVOI-Letrozole IVM cycles.

The clinical and laboratory course of all participants(including treated and untreated patients) were shown in Table 1.

One woman with two IVF failures due to OMA a the MI stage gave birth to a healthy baby.

Another women with seven failed IVF attemts due to Mixed OMA(GV,MI and immature MII oocytes) gave birth to a healthy baby.

Embryo transfer was succesfully performed in a woman with mixed OMA who had five times failed IVF history but pregnancy can not be achieved.

In one woman with a history of five failed IVF attempts dueto MI OMA was treated with our protocol but we failed to achive MI-MII transition in this case.

In a woman with a family history of ZP1 mutation,we applied TVOI and letrozole priming IVM for diagnostic purpose and zona free oocytes without any maturation (GV OMA) was determined.

In one woman with Primary amenorrea with normal AMH value our protocol managed to retrieve one GV and one MI oocytes for the first time in her life but failed to mature the eggs.

In one woman with 4 failed IVF attempts due to mixt OMA ,one oocyte was succesfully fertilized for the first time but arrested at PN stage.

CONCLUSIONS: OMA is accepted to be untreatable by autologous oocytes currently .Targeted treatment like TVOI-Letrozole IVM may show in overcoming OMA in selected cases.Studies are warranted to clarify mechanisms of OMA and of how TVOI Letrozole functions.This case series presents the first livebirths with autologous oocytes in OMA.

HP-HMG IN MONOTHERAPY IMPROVES CLINICAL OUTCOMES IN YOUNG WOMEN. María Cruz, PhD, Maria Eugenia Ruiz, PhD. IVIRMA Global Headquarters, Madrid, Spain.

OBJECTIVE: To evaluate the efficacy of HP-hMG ovarian stimulation in young women to tailor ART protocols to meet patient needs and improve the likelihood of a positive outcome in real world setting.

DESIGN: Multicenter retrospective, anonymized cohort analysis performed in 11 Spanish clinics from the IVI group.

MATERIALS AND METHODS: Study population:women < 38 years old receiving monotherapy with HP-hMG (n=1744) or rFSH (n=3316). Patients underwent short GnRH antagonist protocol, 0.25 mg daily doses from day 6 of stimulation. On day cycle 2/3, they received daily rFSH α/β or HP-hMG, with FSH:LH activity ratio 1:1. Initial doses were based on weight and BMI according to the experience of clinicians. . A single dose of 0.1 mg GnRH agonist was used for triggering. Embryo transfer was performed on day 3 or 5 where applicable. ANOVA and Chi-squared statistical analysis was performed.

RESULTS: Assuming the limitations of the study design**,** we observed significant differences in age (33.1±0.1 vs 34.1±0.2 y, p<0.001), AMH levels (3.7±0.4 vs 2.9±0.5 ng/ml, p=0.002) and AFC (14.1±2.0 vs 12.7±1.5 follicles, p=0.031) favoring rFSH vs HP-hMG group. Number of retrieved oocytes was significantly higher with rFSH vs HP-hMG (13.1±0.4 vs 10.0±0.3, p<0.001). as well as MII (9.2±0.5 vs 7.1±0.2, p<0.001). However, despite these poorer biomarkers of ovarian response HP-hMG can improve the efficiency of the cycle since there are no significant differences in the usable blastocyst rate in any of the ratios analyzed. Clinical outcomes are also significantly better for HP-hMG vs rFSH: clinical pregnancy (57.1% vs 54.1% p=0.045) and live birth (45.8% vs 42.1% p=0.043) rates, respectively.

CONCLUSIONS: We can establish the possibility that the LH activity mainly provided by hCG of postmenopausal origin only, might improve the proficiency of the cycle. The HP-hMG group got a more effective MII/oocyte ratio. In addition, the initial differences in the number of oocytes retrieved with rFSH disappeared, as there were no differences in usable blastocyst rate according to the number of retrieved oocytes, MII or fertilized oocytes. We might also assume the hCG-driven LH activity improves embryo quality, since stimulation with HP-hMG significantly increases clinical outcomes not only in clinical pregnancy rate but in live birth rate, which is ultimately the parameter that determines the true success of the treatment. HP-hMG vs rFSH data of well-designed randomized control trials can be here confirmed in antagonist setting in a real-world scenario.

P-1012 3:30 PM Wednesday, October 21, 2020

UTILIZATION OF GONADOTROPIN-RELEASING HORMONE AGONIST (GNRHA) TRIGGER IN GNRH ANTAGONIST CYCLES: DOES THE TIME INTERVAL FROM LAST ANTAGONIST ADMINISTRATION MATTER? Anat Hershko Klement, MD,[1] Efrat Esh Broder, MD,[1] Amy Solnica, RN MSN,[1] Hananel G. E. Holzer, MD,[1] Judith Frei, RN MSN,[2] Jigal Haas, M.D.,[2] Raoul Orvieto, MD.[2] [1]Hadassah Mt. Scopus, the Hebrew university, Jerusalem, Israel; [2]Sheba medical center, Tel Aviv university, Ramat Gan, Israel.

OBJECTIVE: To evaluate the efficiency of GnRHa trigger in GnRH antagonist cycles with regard to the time interval from the last antagonist administration to trigger injection.

DESIGN: A cohort encompassing two IVF clinics was assembled: we included GnRH antagonist IVF cycles in which GnRH agonist (GnRHa) trigger was used alone for final oocyte maturation or GnRHa trigger as a surrogate trigger along with hCG (dual trigger). Oocyte retrieval took place 36 hours after trigger injection. One clinic adhered to a 12-14 hour interval between last antagonist administration and trigger, while the other clinic practiced shorter intervals.

MATERIALS AND METHODS: All cycles were assessed retrospectively and analyzed according to the time interval between the last GnRH antagonist exposure to the triggering injection time. Group1 included patients with a 12-14 hour interval, Group 2 included patients with an 8-10 hour interval and Group 3 included patients with a 4-6 hour interval. LH levels were measured 12 hours post trigger injection. The study was approved by a local Institutional Review Board.

RESULTS: 78 patients were included in Group 1, 164 in Group 2, and 54 in Group 3. Roughly 40% of patients were triggered by the dual trigger and statistical analysis was split according to the triggering modality in order to avoid the bias related to the use of agonist trigger in cases prone to OHSS. For the entire study population, mean and median post-trigger LH levels were 66.7±41.4 mIU/ml, 61.2 4 mIU/ml respectively. No previous data exists regarding post trigger LH level in respect to the antagonist schedule: we found that LH levels were significantly higher in group 2 (55.8±28.5 Group 1, 77.0±49.4 Group 2, 59.2±29.5 Group 3, p= 0.01), but no correlation between the absolute LH level to the number of oocytes retrieved or to the oocyte maturation rate (p= 0.4 and 0.6 respectively) for both triggering modalities. In a multivariate Poissonian model for oocyte number, neither time interval from antagonist, nor absolute LH levels were significant predictors for the outcome, while age, as expected, was (p <0.001).

CONCLUSIONS: GnRH antagonist administration timing before GnRH agonist trigger does not seem to affect the triggering efficiency in intervals between 14 to 4 hours prior to the GnRH agonist utilization. In these time intervals, the conventional 0.2 mg GnRH agonist dose is sufficient for displacing the GnRH antagonist and triggering final follicular maturation. To the best of our knowledge, this is the first study looking into the efficiency of GnRHa trigger in GnRH antagonist cycles, with regard to the time interval from the last antagonist administration to trigger injection. Further prospective randomized controlled studies are warranted to support our conclusion.

WHEN AND WHERE DURING COVID-19: THE EFFECT OF AT-HOME SEMEN COLLECTION ON SPERM PARAMETERS, FERTILIZATION RATE, AND BLASTOCYST RATE. Caitlin R. Sacha, MD, Stylianos Vagios, MD, Karissa C. Hammer, MD, Victoria W. Fitz, MD, MSCR, Irene Souter, MD, Charles L. Bormann, PhD. MGH Fertility Center and Harvard Medical School, Boston, MA.

OBJECTIVE: In order to maintain social distancing and reduce risk of transmission of coronavirus disease 2019 (COVID-19) amongst patients at an academic fertility center, semen collection for semen analyses and treatments such as intrauterine insemination (IUI) and in vitro fertilization (IVF), were converted to "at home." Our aim was to assess whether at-home semen collection altered sperm parameters, fertilization rates, or day 5 usable quality blastocyst rates in patients undergoing IVF.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Semen parameters and embryo outcomes were compared in 42 patients between their IVF cycle prior to COVID-19 (on-site "clinic" collection) and their subsequent cycle after COVID-19 protocols necessitated "at-home" collection. On-site collection was performed in a room adjacent to the andrology laboratory, and processing occurred within approximately 30 minutes. The post-COVID-19 collections were performed at home with the standard specimen cup, delivered to the andrology laboratory within 2 hours of collection, and then processed. Patient demographics, semen parameters, fertilization rate (number of 2 pronuclear embryos/number metaphase II oocytes), and day 5 usable quality blastocyst rate (number transferable and freezable blastocysts/number 2 pronuclear embryos) in fresh transfer cycles were compared between clinic and at-home collections from each patient with a paired T-test. The effect of time between semen production and processing on sperm parameters and embryo outcomes was assessed with linear regression modeling.

RESULTS: Mean male age was 38.1 years in the clinic group and 38.9 years in the at-home group ($p < 0.001$). On average, men were abstinent for 2.9 days (SD 1.3) in the clinic group and 3.3 days (SD 3.6) in the at-home group ($p = 0.576$). Mean time to semen processing was 34.0 minutes (SD 11.4) in the clinic group and 78.7 minutes (SD 28.5) in the at-home group ($p < 0.001$). Semen concentration, percent motility, total motile count, and forward progression score were similar between the clinic and at-home groups. While there was no change in sperm parameters by the amount of time to processing in clinic samples, those collected at home demonstrated an increase in motility of 0.357% ($p = 0.002$), an increase in total motile count by 1.6 million ($p = 0.007$), and an increase in forward progression score of 0.01 ($p = 0.006$) for each extra minute from production to processing. There were no differences in mean fertilization rates (clinic 77.0%, SD 22.5 vs. at-home 77.9%, SD 18.2; $p = 0.813$) or usable day 5 blastocyst rates (clinic 47.2%, SD 21.3 vs. at-home 54.6%, SD 24.8; $p = 0.218$). Longer time between semen production and processing had no effect on fertilization rates or day 5 usable quality blastocyst rates.

CONCLUSIONS: Our data suggest that at-home semen collection within 2 hours of processing does not negatively impact sperm parameters or embryo outcomes within the same patient. Therefore, at-home collection is a reasonable alternative to on-site collection in clinics seeking to encourage increased social distancing of patients during the COVID-19 pandemic.

PATERNAL EXPOSURE TO NON-ESSENTIAL HEAVY METALS AFFECTS EMBRYO EFFICIENCY INDICATORS IN INTRACYTOPLASMIC SPERM INJECTION (ICSI) CYCLES: EVIDENCE IN FAVOR OF A PARADOXICAL EFFECT. Johnny Awwad, M.D., HCLD, Carol Sukhn, PhD, Akram Ghantous, PhD, Nour Assaf, BS, Ghazi Zaatari, MD. American University of Beirut Medical Center, Beirut, Lebanon.

OBJECTIVE: While preconception health remains an essential component of fertility counseling, the association between paternal exposure to pollutants and reproductive endpoints in intracytoplasmic sperm injection (ICSI) cycles remains uncertain and poorly explored. The primary aim of this study was to address this existing data gap and generate hypotheses by identifying associations between paternal levels of non-essential metals in blood and semen, and reproductive endpoints in ICSI cycles.

DESIGN: This is a prospective cohort study of heterosexual couples undergoing ICSI treatment using autologous oocytes at a university fertility center. Ninety-five heterosexual couples undergoing fresh ICSI cycles were evaluated.

MATERIALS AND METHODS: Metal levels (lead Pb, cadmium Cd, arsenic As, mercury Hg, barium Ba, and uranium U) in semen and blood samples from male partners were analyzed using Ion-Coupled Plasma-Mass Spectrometry (ICP-MS; Agilent 7500 ce, Agilent Technologies, Germany) equipped with cell dynamic range. Adjusted associations between paternal concentrations of metals and embryo-level outcomes (embryo quality/fragmentation score, cleavage, and implantation) were evaluated using multiple linear regression models and natural log transformed metal data. Associations between paternal exposure and reproductive endpoints (live births) were investigated using modified Poisson regression employing a sandwich variance estimator after adjusting for co-variates.

RESULTS: High blood Cd, As and U levels in men were associated with significantly lower proportions of cleaved embryos ($\beta = -0.30$; 95% CI: -0.11, -0.02; $P = 0.01$) ($\beta = -0.26$; 95% CI: -0.16, -0.11; $P = 0.02$) ($\beta = -0.22$; 95% CI: -0.24, -0.02; $P = 0.05$), respectively. Counterintuitively, paternal blood and semen Pb concentrations were positively associated with higher embryo implantation ($\beta = 0.26$; 95% CI: 0.01, 0.22; $P = 0.03$) ($\beta = 0.25$; 95% CI: 0.03, 0.14; $P = 0.04$), respectively. Semen U concentrations were also positively associated with embryo implantation ($\beta = 0.27$; 95% CI: 0.01, 0.19; $P = 0.03$). Paternal metal concentrations in both body compartments did not predict the likelihood of livebirth in ICSI treatment cycles.

CONCLUSIONS: These findings highlight the potential effects of sperm metal exposure on embryo efficiency indicators after ICSI, laying support to possible molecular pathways which could impact specific pre- and post-implantation embryonal events. This may point to the likelihood of a transgenerational effect of paternal exposure to pollutants with long-term bearing on obstetrical and postnatal outcomes. These results also underline a paradoxical favorable association between specific metal pollutants at low-exposure levels and some reproductive outcomes, shedding light on different pattern effects through pathophysiologic pathways unique to each trace element. Whereas counseling of women is common practice in fertility care, this study emphasizes the importance of paternal health on reproductive outcomes in ICSI treatment cycles and the need for more male partner inclusive counseling in fertility practice.

P-1015 3:30 PM Wednesday, October 21, 2020

COMPARISON OF THE EMBRYO QUALITY OBTAINED AFTER AN UNSTIMULATED AND STIMULATED CYCLE IN THE SAME INFERTILE PATIENT UNDERGOING *IN VITRO* FERTILIZATION. Elena Labarta, MD PhD,[1] Cristina Rodriguez-Varela, M.Sc,[1] Marcos Meseguer, PhD,[1] Lorena Bori, M.Sc,[1] Arantza Delgado, PhD,[2] Amparo Mercader, PhD,[1] Belén Aparicio-Ruiz, PhD,[1] Ernesto Bosch, MD, PhD.[1] [1]IVI-RMA, Valencia, Spain; [2]Embryologist, Valencia, Spain.

OBJECTIVE: To analyze if ovarian stimulation increases the rate of aneuploidy compared to what occurs in the natural basal state.

We compared the probability of a MII oocyte becoming an euploid blastocyst in a natural and stimulated cycle in the same patient.

DESIGN: Prospective cohort study comparing embryo quality after a modified natural (MNC) and a stimulated cycle (SC) in the same infertile IVF patient. Registration Number: NCT03128580.

MATERIALS AND METHODS: Patients provided written informed consent prior to any procedure. No exogenous gonadotropins were given in the MNC. The requirement to continue in the study was to obtain at least one MII oocyte in the MNC. The SC consisted of a fixed combo GnRH antagonist protocol with a daily dose of 225 IU of rFSH and 75 IU of hp-HMG. In both cycles, ovulation was triggered 36h prior to oocyte retrieval with triptoreline (0.1mg) when at least one (MNC) or 3 follicles (SC) >=17 mm were observed.

Embryo quality was assessed through morphological (following the ASEBIR criteria), morphokinetic (by time-lapse technology) and genetic evaluation (using NGS for the embryo chromosomal analysis).

Student's t tests and ANOVA were used for quantitative variables, for comparisons between 2 or more than 2 groups, respectively. $\chi 2$ was used for categorical variables. Correlation between quantitative variables was evaluated by Pearson's correlation analysis. P-value<0.05 is considered statistically significant.

Sample size was calculated assuming a 5% difference in the % of euploid embryos/ MII in favor of the MNC. Assuming that at least 2 MII oocytes are

obtained in the SC, 70 patients were needed to reach a statistical power of 80% and a 95% confidence level in a single-tailed test where the upper limit of the CI excludes a 10% difference (80 patients considering a 15% loss rate). After an interim analysis, the study was discontinued after a stochastic curtailment analysis.

RESULTS: From 54 recruited patients, 40 obtained MII oocytes in both cycles. Intra-patient comparison showed a similar proportion of euploid embryos per MII oocyte (16.1% in MNC and 18.6% in SC; p>0.05). The number of oocytes needed to obtain one euploid blastocyst was 6.2 MII in MNC and 5.4 MII in SC (p=0.68). Aneuploidy rates were 64.7% vs 52.4%, respectively (p=0.30).

No differences were observed in the morphological classification (p=0.89), whereas morphokinetic evaluation showed that tPNf, t3, t5, t6, t7, t8, t9+,tSC, and t5-t2 were significantly faster in the SC (p<0.05).

The mean number of euploid embryos was significantly higher in the SC (2.4 vs 0.2; p=0.000). A linear relation was found between the number of oocytes and the number of euploid blastocysts obtained (R=0.659; 0=0.00).

CONCLUSIONS: Ovarian stimulation has no negative effect on oocyte and embryo quality. Aneuploidy rate, the number of MII needed to obtain an euploid blastocyst, and embryo quality are comparable between the natural and the stimulated cycle. The implication of the faster division times observed in the SC is yet to be determined.

Ovarian stimulation offers a significantly higher number of euploid embryos without diminishing embryo quality.

REDUCTION OF BACTERIAL COLONY FORMING UNITS IN AN OBSTETRICS OPERATION THEATRE USING COLD-PLASMA BASED DIELECTRIC BARRIER DISCHARGE AIR PURIFICATION SYSTEM. Milind RAMCHANDRA. Ubale, M.D.,[1] Rajvi H. Mehta, Ph.D.[2] [1]Rajiv Gandhi Medical College & Chatrapati Shivaji Maharaj Hospital, Thane, India; [2]Trivector Boimed LLP, Mumbai, India.

OBJECTIVE: To evaluate the effectiveness of the cold-plasma based dielectric barrier discharge (CP-DBD) based air purification system on the number of bacterial colony forming units in an obstetrics operation theatre (OBOT).

DESIGN: Air samples were taken to determine the bacterial load before and 7, 14 and 21 days after the installation of the CP-DBD based air purification system in the OBOT; the unit was switched off on Day 21 and air samples were taken on Day 28. The number of bacterial colony forming units were compared on different days to determine the effect of the CP-DBD air purification system on the bacterial load.

MATERIALS AND METHODS: This study was carried out in the OBOT of a municipal public hospital. Air samples were taken from the OBOT (Pre, Day 0) at 0, 1, 2, and 4 hours. The CP-DBD based air purification system Novaerus-1050 was installed in the OBOT and air samples were taken at 0, 1, 2 and 4 hours on Day 7, 14, 21 days (Post). The Novaerus unit was switched off after taking the samples on Day 21 and 4 air samples at 0, 1, 2 and 4 were taken on Day 28. The number of individuals present in the OBOT on that particular day was also noted. The air samples were cultures on Blood agar and Sabouraud's Dextrose agar plates and incubated at at 37^0 C for 48 hours and 30 days respectively. The number of bacterial colony forming units for each air sample were determined in the Blood agar as well as Sabourauds Dextrose Agar plates. The data for Day 0, 7, 14, 21 and 30 was tabulated and and compared.

RESULTS: There was significant reduction in bacterial colony count /ml in post- I compared to pre-I air sampling. Fluctuation in post- I colony count at 0 ,1, 2, 4 hours was observed during each intervention day that is on 0, 7, 14, 21 days. However in all intervention days the 4 hours CFU showed reduction in bacterial colony counts as compared to 0 hour colony count. At day 28, there was increase in colony counts at every reading (0, 1, 2, 4 hours) as compared readings taken on day 0, 7, 14, 21 days when air purifier was operational. The mean CFU decreased from 21 on Day 0 to 10, 7, 5 on Day 7, 14 and 21 respectively. After switching off the CP-DBD air purification system, the mean CFU increased to 18 on Day 28.

CONCLUSIONS: The results indicate that continuous usage of cold plasma based air purifier system can decrease and consistently maintain low microbial load in the operation theaters. This system would be very useful in OBOTs of public hospitals which work 24 x 7 and therefore are higher risk of microbial contamination.

P-1017 3:30 PM Wednesday, October 21, 2020

INCREASED AVERAGE OF SPERM HEAD AREA (ASHA) IS A NOVEL SPERM PARAMETER ASSOCIATED WITH HIGHER INCIDENCE OF SPERM ANEUPLOIDY. Miguel Ruiz-Jorro, MD, MSc, PhD,[1] Minerva Ferrer-Buitrago, BSc, PhD,[1] Juan Jesús Bataller-Sánchez, BSc, MSc,[1] Antonio Barberá-Alberola, MSc,[1] Xavier Vendrell-Montón, BSc, PhD,[2] Carmen Calatayud-Lliso, MD, MSc, PhD.[1] [1]CREA. Medicina de la Reproducción S.L., Valencia, Spain; [2]Ascires Sistemas Genómicos, Paterna-Valencia, Spain.

OBJECTIVE: To evaluate the association between the average sperm head area (ASHA) and altered sperm aneuploidy rate in male infertility.

DESIGN: A total of 147 patients who showed normal sperm aneuploidy rates were used as a control to determine the cut-off value for ASHA. A retrospective study was further performed to calculate the incidence of sperm aneuploidy in infertile patients with a suspected risk of sperm aneuploidy: Recurrent implantation failure or pregnancy loss (RIF; RPL), or testicular failure (Study Group 1; n=250). The intra-patient variability of ASHA was compared to other sperm parameters: concentration, motility and morphology. Moreover, the sperm aneuploidy rate was prospectively assessed in a total of 22 patients with increased ASHA values, who showed normal testicular function, normal FSH values (4,81±2,83 mUI/ml), and absence of RIF or RPL. Sample size was adjusted to detect at least 30 % difference in sperm aneuploidy rate compared to published data in reference population of infertile men (15.0 %), and for a power calculation of 95.

MATERIALS AND METHODS: All participants signed an informed consent form. ASHA cut-off value was established according to the value at percentile 95. Chi-squared statistic was used to asses frequency distribution. Two semen samples were analyzed per patient according to WHO-V-manual. Sperm concentration, motility, morphology and ASHA were evaluated using the CASMA software ISAS. Samples were stained using the Diff-quick kit. Sperm aneuploidy was determined by FISH analysis (5 chromosomes) using Metafer-4 software.

RESULTS: ASHA cut-off value was established as $\geq$14,8 μm2 in the control group. Group 1 revealed an increased incidence of altered FISH (41.2%) compared to the reference value (15.0%). The mean ASHA value in group 1 was 12.9 $\pm$ 1.3 μm2, whereas the mean ASHA value in the subgroup of patients with altered FISH was 13.2 $\pm$ 1.4 μm2. ASHA values showed lower intra-patient variability (p<0.002) and higher positive predictive value to detect altered FISH (73.9%) than other sperm parameters such as concentration (56.5%), total sperm count (58.8%) and morphology (46.7%). The predictive value of ASHA to detect sperm aneuploidy was further validated in a prospective analysis (Group 2). Sperm parameters in group 2 were: concentration (20.8 $\pm$ 26.5 million sperm/ ml), % total motility (45.0 $\pm$14.6) and % normal morphology (1.6 $\pm$0.7). The mean ASHA value in group 2 was 15.2 $\pm$ 0.6 μm2, and the incidence of sperm aneuploidy was significantly increased compared to the reference value of 15.0% (p<0.05).

CONCLUSIONS: Our study describes ASHA as a sperm parameter with low intra-patient variability. Prospective data revealed that patients presenting with idiopathic infertility, who show ASHA values > 14,8 μm^2 have a high risk to carry chromosomal aberrations in sperm. Our results indicate that altered ASHA is an indicator to request a FISH analysis from the first sperm evaluation.

These findings provide new insights in the field of androgenetics and male infertility, since ASHA might contribute to reduce the time to advise PGT-A, and consequently, the time to conceive in some infertile couples.

P-1018 3:30 PM Wednesday, October 21, 2020

PREGNANCY LOSS RATES AFTER SINGLE, EUPLOID FROZEN-THAWED EMBRYO TRANSFER IN THE COVID-19 ERA. Eric Flisser, MD,[1] Devora Aharon, MD,[2] Dmitry Gounko, MA,[1] Alan B. Copperman, MD.[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: Data on the impact of COVID-19 on early pregnancy is extremely limited, and patients and practitioners remain cautious about initiating pregnancy in areas of high SARS-CoV-2 transmission.[1-4] In April 2020,

during the peak of the pandemic, the prevalence of COVID-19 among New York State residents was estimated to be 22.7%, consisting largely of asymptomatic infection.[5] If SARS-CoV-2 is pathogenic to early pregnancy, an increase in loss might be expected given this high transmission. The objective of this study is to determine if an increase in early pregnancy loss occurred in patients undergoing single euploid frozen embryo transfer (FET) during the height of the COVID-19 pandemic.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study took place at an academic tertiary care center with offices throughout New York City. All single euploid FET cycles performed from January-May of 2017-2020 were included. Cycles with FET in 2017-2019 were compared to those with FET performed in the corresponding time period in 2020. Baseline characteristics included age, oocyte age, AMH, BMI, and endometrial thickness. Pregnancy loss rate (PLR), or loss after the presence of serum βhCG $\geq$2.5 mIU/mL, and clinical pregnancy loss rate (CLR), loss after a gestational sac was seen on ultrasound, were compared between January-May, 2017-2019 and January-May, 2020, in aggregate as well as for each corresponding month individually. Comparative statistics and multivariable logistic regression were used.

RESULTS: 2629 single euploid FET cycles were included in the study: 2070 from Jan-May, 2017-2019 and 559 from Jan-May, 2020. Positive pregnancy rates were 73.7% in January-May, 2017-2019 and 77.6% in January-May, 2020. Baseline characteristics were similar. No differences were seen in PLR or CLR when comparing FET from January-May, 2017-2019 to FET from January-May, 2020. No differences were seen in PLR or CLR when comparing individual months in 2017-2019 to 2020. On multivariable logistic regression, when controlling for oocyte age, AMH, BMI, and endometrial thickness, FET in January-May 2017-2019 was associated with a higher odds of pregnancy loss compared to January-May 2020 (OR 1.32, 95% CI 1.02-1.73, p=.039). No difference was seen in CLR between these groups (OR 1.34, 95% CI 0.92-1.97, p=.13). No differences were seen in PLR or CLR comparing each month individually in the two time periods.

CONCLUSIONS: This data is reassuring that early pregnancy loss rates were not increased during widespread SARS-CoV-2 transmission. A decrease in PLR in January-May 2020 compared to prior years might be attributable to selection against treatment of patients with known risk factors for severe infection. While in the absence of universal screening for SARS-CoV-2, which at the time was neither available nor recommended, this data does not exclude a possible impact of infection on pregnancy loss, it suggests that screening patients for elevated temperature, symptoms, and exposure may be effective in maintaining established early pregnancy success rates. This data may help guide clinics in regions experiencing a surge in virus transmission.

P-1019 3:30 PM Wednesday, October 21, 2020

IS COH /IUI AN EFFECTIVE TREATMENT IN OLDER WOMEN AND MALE PARTNERS WITH DECREASED TOTAL MOTILE SPERM COUNTS?

Einav kadour-Peero, MD,[1] Namaa Steiner, MD,[1] Russell Frank, M.D.,[2] Maryam al Shatti, MD,[1] Jacob Ruiter, MD,[1] Michael H. Dahan, M.D.[1] [1]Division of Reproductive Endocrinology and Infertility, McGill University Health Care Center, Montreal, QC, Canada; [2]McGill University Health Centre, Montreal, QC, Canada.

OBJECTIVE: To assess the effect of the total motile sperm count (TMSC) on the success of controlled ovarian stimulation (COH) and intra uterine insemination (IUI) in women 38-42 years-of-age. Current literature suggests women 35-40 years of age have no pregnancies when TMSC $\leq$5mil at COH/IUI [1, 2].

DESIGN: Retrospective cohort study, included women who underwent IUI with stimulation at a University Reproductive Centre between 2009-2018.

MATERIALS AND METHODS: A database from all women aged 38-42 years old who underwent IUI with stimulation at a University Reproductive Centre between 2009-2018. Including stimulation with clomiphene citrate, letrozole or gonadotropins and divided into TMSC 5.01-10.0 mil and $\leq$5.00 mil. The main outcome was clinical pregnancy rate, defined as fetal heart beat by ultrasound, per stimulation cycle. Statistics were compared with multivariate logistic regression, t-tests or chi-squared tests.

RESULTS: A total of 397 cycles of IUI were included, of which, 190 cycles with TMSC 5.01-10.0 and two hundred and seven cycles with TMSC $\leq$5.00. There were no statistical differences in the basic characteristics between the two groups including: age (P=0.2), gravidity (P=0.7), parity (P=0.6), basal FSH (P=0.2), basal E2 (P=0.4), antral follicular count (P=0.5) and the number of mature follicles stimulated (P=0.2). As designed, TMSC was 7.6$\pm$1.5 mil in the first group and 2.4$\pm$1.6 mil in the second group (P<0.0001). The clinical pregnancy rate per cycle in the 5.01-10.00 TMSC group was 9.5 % vs. 3.4% when TMSC $\leq$5.00 (P=0.01). When evaluating only women 40-42 years of age (99 women in the 5.01-10.00 TMSC group and 95 in the group of TMSC $\leq$5.00); the pregnancy rates were not statistically different between the two groups (7% vs. 7.3%, P= 0.082), nor was the clinical pregnancy rate (5% VS. 5.2%, P=0.7).

CONCLUSIONS: Women 38-39 years-of-age have poorer outcomes at COH/IUI when TMSC $\leq$5 million than if it is greater. Once a woman is 40 years of age this effect is lost. With mild male factor infertility, women 38-39 years of age have respectable outcomes at COH/IUI. Clinical pregnancy rates are just 5% irrelevant of sperm quality in women 40-42 years of age performing COH/IUI with male factor infertility.

GNRH ANTAGONIST PROTOCOL WAS SUPERIOR TO MILD STIMULATION PROTOCOL IN CONTROLLED OVARIAN STIMULATION IN PATIENTS WITH DISCORDANCE BETWEEN ANTI-MÜLLERIAN HORMONE CONCENTRATION AND ANTRAL FOLLICLE COUNT.

Meng Rao, MD., Shuhua Zhao, Ph.D, Li Tang, MD. The First Affiliated Hospital of Kunming Medical University, Kunming, China.

OBJECTIVE: To evaluate the laboratory and clinical outcomes between GnRH antagonist and mild stimulation protocols in patients with discordance between anti-Müllerian hormone (AMH) concentration and antral follicle count (AFC).

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: This study was conducted in the Reproductive Medical Center of the First Affiliated Hospital of Kunming Medical University during Jan 2016 to Dec 2019. This study included 130 infertile couples with female AMH<1.1 ng/mL and AFC$\geq$7 , 65 couples received GnRH antagonist protocol and another 65 age and BMI-matched couples received mild stimulation protocol treatment.Laboratory and clinical outcomes were compared between GnRH antagonist cycles and mild stimulation cycles. The primary outcomes included the no. of aspirated oocytes and cumulative clinical pregnancy rate. The secondary outcomes included the cycle cancellation rate and the no. of good-quality embryos.

RESULTS: During the study period, a total of 220 patients received 303 GnRH antagonist and mild stimulation cycles in our reproductive center. 130 cycles (65 in each group) were enrolled by using propensity score matching with age and BMI. Mean female age in GnRH antagonist and mild stimulation groups were 36.2 and 36.4 years, respectively (p=0.84). Mean male age (37.0 vs. 38.0 years), female BMI (23.5 vs. 23.3 kg/m2), AMH (0.76 vs. 0.74 ng/mL) and AFC (8.8 vs. 8.4) were all similar between these two groups (p=0.37, 0.73, 0.58 and 0.25, respectively). After adjusting for a series of

potential demographical and clinical confounders, we found 2.1 more oocytes were aspirated in GnRH antagonist cycles compared with mild stimulation cycles [adjusted mean (95% CI): 4.7(4.2-5.3) vs. 2.8(2.4-3.2), p<0.001]. Good-quality embryos were also significantly more in GnRH antagonist cycles than mild stimulation cycles [1.6 (1.2-2.2) vs. 1.1(0.8-1.5), p=0.014]. The cycle cancellation rate was non-significantly lower in in GnRH antagonist cycles than mild stimulation cycles (0% vs. 3.1%, p=0.13). The cumulative clinical pregnancy rate in GnRH antagonist cycles was higher than that in mild stimulation cycles [30.0% (20.0%-42.7%) vs. 21.8% (13.8%-33.8%), whereas the difference was non-significant (p=0.29).

CONCLUSIONS: We concluded that GnRH antagonist protocol may be superior to mild stimulation protocols in women with low AMH (<1.1 ng/mL) but moderate AFC (≥7). Due to the retrospective nature and the limited no. of sample size, population and multi-center based study and RCTs are warranted to provide stronger evidence.

SUPPORT: This study was supported by the China Health Promotion Foundation's ART Research Program of Young and Middle-aged Physicians.

RECOMBINANT LUTEINIZING HORMONE (LH) SUPPLEMENTATION IMPROVES CONTROLLED OVARIAN HYPERSTIMULATION OUTCOME IN WOMEN WITH LOW LH CONCENTRATION DURING MID- AND LATE-FOLLICULAR PHASE. Tian Tang, M.D., Yuechao Lu, M.D., Junliang Guo, M.D., Wei Huang, Professor. West China Second Hospital; Key Laboratory of Birth Defects and Related Diseases of Women and Children, Ministry of Education, Sichuan University, Chengdu, China.

OBJECTIVE: To examine the role of rLH supplementation in patients undergoing assisted reproductive technology (ART). We therefore compared the effect of rFSH vs rFSH+rLH on controlled ovarian hyperstimulation (COH) characteristics and ART cycle outcome.

DESIGN: A retrospective cohort study was conducted for all cases on ART cycle outcome with the use of either rFSH or rFSH+rLH.

MATERIALS AND METHODS: From January 2018 to January 2019, 163 patients (52 with rLH and 111 without rLH) were enrolled in this study : 1. Main causes of infertility attributable to tubal, idiopathic, or male factors; Regular menstrual cycle; Normal uterine cavity. 2. Serum levels of LH (Follicle reached 12mm of the ovarian cycle) ≤4 IU/l. 3.Underwent COH utilizing GnRH-antagonist protocol. Propensity score matching (PSM) was used to reduce confounding, baseline characteristics between two groups were matched. The primary outcome measures were number of oocytes retrieved and number of embryos available. The secondary outcome measure is clinical pregnancy rate in fresh embryo transfer cycle.

RESULTS: PSM resulted in 98 patients (49 in each group) for analysis. Baseline characteristics, including age, BMI, AMH, basal FSH, basal LH, LH on day of stimulation start, LH on day of follicle reach 12mm and LH on day of triggering, did not differ significantly between two groups. Women accepted rFSH+rLH for stimulation had significantly higher number of oocytes retrieved (12.24 ± 8.13 vs 8.27 ± 5.98, P=0.007) and higher number of embryos available (4.20 ± 2.75 vs 2.98 ± 2.47, P=0.022) than rFSH alone.

	rFSH alone (n=49)	rFSH+rLH (n=49)	P value
Baseline Characteristics			
AGE	31.67 ± 4.86	31.45 ± 5.22	0.826
BMI	21.78 ± 2.89	21.18 ± 2.46	0.274
AMH	4.71 ± 4.44	4.68 ± 4.86	0.977
LH on day of follicle reach 12mm	1.51 ± 0.83	1.45 ± 0.96	0.745
Basal FSH	5.98 ± 3.12	7.24 ± 4.69	0.123
Basal LH	7.44 ± 10.19	6.17 ± 4.57	0.431
LH on day of stimulation start	4.55 ± 4.14	3.69 ± 2.68	0.237
LH on day of triggering	5.72 ± 29.52	1.93 ± 2.52	0.373
Outcome Measures			
Number of oocytes retrieved	8.27 ± 5.98	12.24 ± 8.13	0.007
Number of embryos available	2.98 ± 2.47	4.20 ± 2.75	0.022
pregnancy rate (%)	32.35 (11/34)	44 (11/25)	0.521

Women in rFSH+rLH group had higher clinical pregnancy rate (44.0% vs 32.4%, P=0.521) but showed no significant difference compared with rFSH group.

CONCLUSIONS: Supplementation of rLH was suggested to bring more oocytes and embryos and it might potentially increase the clinical pregnancy rate. Our data supports rLH supplementation improves controlled ovarian hyperstimulation outcome in women with low LH concentration (≤ 4 IU/l) during mid- and late-follicular phase. Further studies are needed to confirm these findings.

P-1022 3:30 PM Wednesday, October 21, 2020

IN VITRO FERTILIZATION OUTCOMES OF BLACK PATIENTS COMPARED TO WHITE PATIENTS IN A MIDWEST COHORT. Jean-Claire Powe Dillon, MD, MPH,[1] Caitlin Elizabeth Martin, MD, MS,[1] Patricia T. Jimenez, MD,[2] Joan Riley, PhD, HCLD,[3] Kenan Omurtag, MD.[4] [1]Washington University School of Medicine, St. Louis, MO; [2]Washington University in St. Louis, Saint Louis, MO; [3]Washington University in St. Louis, St. Louis, MO; [4]Washington University St Louis School of Medicine, St. Louis, MO.

OBJECTIVE: To identify disparities in IVF cycle outcomes and parameters between black and white patients at a single center.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Data from 2016-2019 was obtained from clinical records at Washington University in St Louis. Women undergoing their first fresh IVF cycle at the clinic were included. All analyses were performed with IBM SPSS Statistics software (version 26). The data was analyzed using chi-square, Fisher's exact test, or student's T-test where appropriate**.** Multinomial logistic regression was used for assessing live birth rate, controlling for body mass index (BMI) and age.

RESULTS: There were 1054 white patients (93.6%) and 72 black patients (6.4%) identified. The mean age was similar for black patients compared to white patients (34.4 years vs. 33.3 years, p = 0.083). The mean BMI was statistically higher for black patients when compared to white patients (31.3 vs. 27.7, p < 0.001). Tubal factor (33.3% vs. 12.2%, p < 0.001) and uterine factor (6.9% vs. 1.1%, p= 0.003) infertility was more common amongst black patients compared to white patients. The stimulation regimens for IVF were similar between groups. Black patients were statistically more likely to use preimplantation genetic testing of their embryos (n=6, 8.3% vs. n=23, 2.2%, p=0.008). Black women were more likely to have more embryos available to freeze compared to white patients (4.36 vs. 3.41 embryos, p = 0.001), however the live birth rate was lower amongst black patients compared to white patients, which persisted when controlling for BMI and age (n=15, 20.8% vs. n=352, 33.4%, AOR 0.510 95% CI 0.279-0.930, p = 0.030). The number of patients whose pregnancies resulted in spontaneous abortions were not statistically different amongst both groups (black n=5, 6.9% vs. white n=65, 6.2%, p=0.799).

CONCLUSIONS: Despite advances in reproductive medicine, disparities exist between black and white patients undergoing IVF. In a midwestern cohort, despite freezing more embryos, the live birth rate was overall lower in black women undergoing their first IVF cycle at our center compared to white women, when controlling for BMI and age. Risk factors for poorer pregnancies outcomes were identified to be higher in our black patients, such as BMI and uterine factor, however additional analysis needs to be completed to identify these relationships further. Black patients were more likely to have embryos to cryopreserve and use preimplantation genetic testing when compared to white patients, which warrants investigation of cumulative live birth rate amongst the groups. A subanalysis of insurance coverage on this new cohort will also provide needed socioeconomic insights related to access and outcomes.

P-1023 3:30 PM Wednesday, October 21, 2020

WHERE DO CRYOPRESERVED EMBRYOS END UP AFTER A POSITIVE PREGNANCY TEST? Edgardo Young, Jr., PhD,[1] Laura Isa, Medical Doctor,[1] Sofia Garcia Argibay, Medical Doctor,[1] María Pía Zappacosta Villarroel, Medical Doctor,[1] Roberto Inza, Medical Doctor,[1] Alberto Valcarcel, PhD.[2] [1]IFER, Ciudad Autonoma de Buenos Aires, Argentina; [2]IFER, Ciudad Autónoma de Buenos Aires, Argentina.

AGE	DESTINATION		LBR	MR	*P*
<35 (n = 93)	Not used Embryos		46/68 (67,6%)	4/25 (16%)	p <0,0001

		Embryo transfer	17/22 (77,3%)	19/21 (90,5%)	p = 0,4121
35-39 (n= 103)	Not used Embryos		43/63 (68,3%)	7/40 (17,5%)	p <0,0001
	Used Embryos	Taken to unknown site	4/20 (20%)	3/33 (9%)	p = 0,4048
		Taken to another center	3/20 (15%)	2/33 (6%)	p = 0,3536
		Donation	1/20 (5%)		
		Embryo transfer	20/12 (60%)	28/33 (84,8%)	p = 0,0541
>40 (n= 49)	Not used Embryos		17/31 (54%)	1/18 (5,5%)	p <0,0006
	Used Embryos	Taken to unknown site	6/14 (42,8%)	1/17 (5,88%)	p = 0,0281
		Embryo transfer	14/8 (57%)	16/17 (94,1%)	p = 0,0281

OBJECTIVE: To report what happens with vitried surplus embryos after IVF in patients with a positive pregnancy test, carrying out an analysis according to age and final evolution of the pregnancy.

DESIGN: Retrospective descriptive study.

MATERIALS AND METHODS: We analyzed 245 embryo transfer cycles, performed between January 2013 to December 2017, in 235 patients with a positive pregnancy test and who vitried surplus embryos. All the patients underwent treatment with their own oocytes. The variables studied were: age, miscarriage rate (MR) and live birth rate (LBR). We compared the destination of the cryopreserved embryos according to the patient's age and pregnancy evolution. Statistical analysis was performed with Fisher's exact test.

RESULTS: 20% of the IVF cycles (n=49) were performed in women older than 40 years, 42% between 35 and 39 (n =103) and 38% in women younger than 35 (n= 94). Average age was 35.8 ± 4.1 years. 859 embryos were cryopreserved (3.5 ± 1.9 cryopreserved embryos/patient). Average search time for surplus embryos was 20.5 ± 17.9 months, rising to 36.9 ± 14.9 months after delivery and decreasing to 8.7 ± 7.8 months after miscarriage (P<0.0001). Up to date there are 118 (48.2%) patients whose cryopreserved embryos have not been transferred yet. Signficant differences were found in the three groups in using the cryopreserved embryos according to whether or not they had delivery.

CONCLUSIONS: Half of the surplus cryopreserved embryos in assisted reproductive technologies are not transferred. Regardless of the age of the patient, all groups showed the same behavior regarding the utilization of the cryopreserved embryos after delivery. It is essential to advise couples who perform assisted reproductive technologies, with a good probability of success (regardless of the patient's age), about the responsibility that embryonic cryopreservation entails. Argentine legislation has limitations regarding the availability of cryopreserved surplus embryos. We believe that Public Health policies related to this issue should be re evaluated based on these results.

NOMOGRAM FOR THE CUMULATIVE LIVE BIRTH RATE IN LOW PROGNOSIS PATIENTS ACCORDING TO POSEIDON CRITERIA: A RETROSPECTIVE COHORT STUDY OF 4494 PATIENTS IN CHINA. Pengfei Qu, Ph.D, Wenhao Shi, M.D. Northwest Women's and Children's Hospital, Xi'an, China.

OBJECTIVE: A small number of prediction model have been previously developed to predict the success of infertility treatment. However, the studies of prediction model for low prognosis patients are limited. The aim of this study was to develop and validate a nomogram for the cumulative live birth rate (CLBR) in low prognosis patients using a single center database in China.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We reviewed the clinical data of 4494 low prognosis patients according to POSEIDON criteria who underwent in vitro fertilization (IVF)/intracytoplasmic sperm injection (ICSI) treatment between 2014 and 2018 at Assisted Reproduction Center of Northwest Women's and Children's Hospital, Northwest China. Of the eligible participants, 70% were randomly assigned to the training set, while the remaining 30% were assigned to the external validation set. Multivariate analysis using the Logistic regression model was performed.

RESULTS: Multivariate analyses revealed that female age, female body mass index (BMI), antral follicle count (AFC), male infertility, uterine factor infertility, and basal serum follicle stimulating hormone (FSH) level were significant factors for CLBR in low prognosis patients. An area under the receiver operating characteristic curve (AUC) in the prediction model was 0.70 (95% CI 0.68 to 0.72) in the training cohort. The validation set showed good discrimination with an AUC of 0.68 (95% CI 0.65 to 0.71). Additionally, Hosmer-Lemeshow chi-square statistic was 5.931 (P = 0.655).

CONCLUSIONS: We developed and validated a nomogram to predict CLBR in low prognosis patients using a single center database in China. The validated nomogram to predict CLBR could be a potential tool for IVF counselling in low prognosis patients.

P-1025 3:30 PM Wednesday, October 21, 2020

APPLICATION OF THE CRYOPIECE SYSTEM FOR CRYOPRESERVATION OF RARE HUMAN SPERMATOZOA. Wenlong Su, MS,[1] Lei Jia, PhD,[2] Shujing He, MM,[3] Zhiqiang Zhang, master's degree,[4] Cong Fang, Ph.D.,[2] Xiao-yan Liang, PhD.[4] [1]Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [3]The Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [4]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the clinical efficacy of cryopiece system for cryopreserving rare human spermatozoa from patients with severe male-factor infertility.

DESIGN: Retrospective study.

MATERIALS AND METHODS: Cryopreservation of small numbers of human spermatozoa with cryopiece system was performed at the Reproductive Medicine Center of the sixth affiliated hospital of Sun Yat-Sen University between August 2019 and July 2020. Cryopreservation procedure was as follows: The liquefied ejaculated semen or testicular tissue which was dissected with two 1 mL-syringe needles, was centrifuged at 300g for 5 min. And the re-suspended deposit was loaded on the micro-strips. Spermatozoa were captured using ICSI injection pipette and added to 0.5μL droplet of cryoprotective solution on a cryopiece. After holding upon liquid nitrogen vapor for 15 min, the cryovial with a cryopiece was plunged into liquid nitrogen. On the day of oocyte retrieval, the cryopiece was placed on the ICSI dish with 37°C immediately. The recovery rate, fertilization rate and clinical outcomes were analyzed to evaluate the clinical efficacy of cryopiece system.

RESULTS: In total, 125 spermatozoa from 7 patients (44% motile) were vitrified. 107 spermatozoa were warmed for ICSI; the sperm recovery was 100%. The motile sperm rate per recovered spermatozoa was 31.4%. The 2PN fertilization rate was 60.9%, the cleavage rate was 85.7% and the rate of transferable embryo on D3 was 60.9%. The clinical pregnancy rate following fresh embryo transfer was 100% (2/2).

CONCLUSIONS: Hence, we draw the conclusion that the cryopiece system was a simple constructed and highly efficient carrier that used for vitrification of small numbers of human spermatozoa in micro-droplets.

P-1026 3:30 PM Wednesday, October 21, 2020

OLEANOLIC ACID INHIBITS PROLIFERATION AND ANGIOGENESIS AND PROMOTES APOPTOSIS IN HUMAN ENDOMETRIOTIC STROMAL CELLS. Jingjie Li, M.D.,[1] Pan Chen, PhD,[2] Xiaoyan Liang, M.D.[1] [1]the Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: Oleanolic acid (OA) is a pentacyclic triterpenoid that has long been used as an effective drug in treating hepatitis, but its role in endometriosis remains unclear, our study aims to investigate the effect of OA in endometriosis progression in vitro.

DESIGN: Pharmacologic interventions in human endometriotic stromal cells.

MATERIALS AND METHODS: Patients with ovarian endometriosis undergoing laparoscopy were recruited at the Sixth affiliated Hospital of Sun Yat-sen University from January 2018 to May 2020. Primary human endometriotic stromal cells that isolated from ectopic endometrium (endometriotic tissue, n=12) were exposed to 20μM, 40μM, 60μM and 80μM of OA for 24 h. MTT assay, BrdU incorporation assay and Caspase-Glo luminescent-based assay were performed to detect cell growth and apoptosis. Enzyme-linked immunosorbent assay was carried out to measure expression of vascular endothelial growth factor (VEGF).

RESULTS: OA reduced the viability of stromal cells in a dose-dependent manner, 60 and 80 μM of UA treatment led to a decrease in the endometriotic stromal cell viability to 64.2% and 53.3%, respectively ($p < 0.05$), as compared to the viability in the vehicle. BrdU assay confirmed that the growth inhibition effect of OA started at 40 μM and increased up to 80 μM (22.5% of that in the vehicle group). Caspase-3 activity was also promoted dose-dependently, and 2.3-, 5.8-, 18.7-, and 89.6-fold of increase were found in the four concentration groups. Besides, OA inhibited the secretion of the proangiogenic factor VEGF in endometriotic stromal cells, 40μM, 60μM and 80μM of OA remarkably downregulated the levels of VEGF in supernatants by 29.5%, 44.7% and 73.6%, respectively.

CONCLUSIONS: OA plays a role in suppressing the survival of human endometriotic stromal cells by inhibiting proliferation and angiogenesis and promoting apoptosis.

ZIKA VIRUS INFECTION AND MALE FERTILITY TWO YEARS AFTER A MAJOR OUTBREAK: PRELIMINARY FINDINGS. Filipe Tenorio Lira Neto, MD MSc,[1] Marina Cadena Matta, PhD,[1] Alexandre de Freitas Cavalcanti Filho, MS,[1] Leuridan Cavalcante Torres, Sr., PhD,[1] Peter N. Schlegel, M.D.,[2] Shuibing Chen, PhD,[2] Gilbert J. Wise, MD.[2] [1]Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil; [2]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: Evaluate the effects of the ZIKV epidemic in the male reproductive function in a cohort of fertile men two years after a major outbreak in Brazil.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: We enrolled 39 fertile men who attended the urology an outpatient clinic at Recife - Brazil for vasectomy. All subjects completed an epidemiological questionnaire, underwent standard semen analysis, sexual hormone levels measurement, and ZIKV serologic tests. Based on their serologic tests results, subjects were divided in two groups, a ZIKV negative (Z-) group and a ZIKV positive group (Z+). Epidemiological, clinical and laboratory variables were compared between both groups.

RESULTS: There were 25 (64%) ZIKV positive subject based on positive serum IgG anti-ZIKV antibodies; no subject showed IgM anti-ZIKV antibodies or viral RNA by PCR in semen samples. There were no significant differences between the groups regarding demographic and clinical data, but a few variables deserve mention. Overall, only 7 subjects reported ZIKV infection symptoms in the last two years, a small number compared to the overall prevalence of ZIKV of positive serologic test. The proportion of participants that reported symptoms was higher in the Z+ group when compared to the Z- group (24% and 7% respectively). Fever, myalgia, headache and cutaneous rash were the symptoms described. There were no known neurologic sequelae in patients or first-degree family members. The Z+ group had a clinically significant higher incidence of mosquito bites than the Z- group, although without statistically significance. In addition, semen analysis parameters and hormone levels showed no differences between the groups.

CONCLUSIONS: The prevalence of serum IgG anti-ZIKV antibodies was high in this cohort of fertile men, despite a low prevalence of ZIKV infection symptoms. There was no statistical difference in semen parameters or hormone between the groups. Screening of all male infertility patients should be considered in areas with high risk of exposure to Zika Virus.

DESCRIPTIVE DIFFERENCES IN FERTILITY TREATMENT USAGE AFTER THE START OF THE COVID-19 PANDEMIC: A PILOT STUDY - FEELINGS ABOUT INFERTILITY IN RESPONSE TO THE COVID-19 EPIDEMIC (FIRE). Ijeoma N. Iko, M.D., Amanda Adeleye, M.D., A. Musa Zamah, M.D., Ph.D. The University of Chicago, Chicago, IL.

OBJECTIVE: Prior research has demonstrated that economic health has an influence on the utilization of assisted reproductive technology (ART). It is indisputable that the United States (US) economy has been negatively impacted by the novel coronavirus (COVID-19) pandemic. However, there is limited data on how the pandemic has affected patient interest in fertility treatment and limited data on how concern about infectious disease and physical health may affect family building decisions. We hypothesized that there would be a decrease in interest in fertility treatments due to the COVID-19 pandemic. The aim of this pilot study was to assess if the experience of COVID-19 in the US has influenced intentions to pursue fertility treatment.

DESIGN: Prospective internet-based survey.

MATERIALS AND METHODS: An internet based survey, administered through Redcap was used to assess demographics, concern about COVID-19, fertility treatment prior to and after statewide lockdowns which became widespread on March 15th 2020. The pilot survey was administered June 1st to July 31st 2020 to infertile participants between the ages of 18-43 years. The CloudResearch platform was used to recruit participants and administer the survey. COVID-19 related questions were derived from the validated COVID concern survey. Summary statistics are presented. Institutional Review Board approval was obtained.

RESULTS: The pilot survey was completed by 55 participants (female =46, 83.6%; male=9, 16.4%) from 23 states. The mean age was 29.6 years (+/- 7.6). The majority were White (78%), non-Hispanic (92.7%), with varying education levels, 45.5% (25/55) with some college education, 20% with a bachelor's degree (11/55) and 14.5% with graduated education (8/55). The majority of participants were "somewhat concerned" that they would lose their current job in the next 12 months (41.4%). While the majority believed that COVID-19 had spread widely in the US (32.7%) and had "inflicted serious damage in the area that" they lived (38.2%), most individuals felt that they could protect themselves from the virus (48.2%).

Prior to the pandemic, 29.1% (n=16) participants sought ovulation induction medications, 16.4% (n=9) sought intrauterine insemination and 9.1% sought (n=5) in vitro fertilization (IVF). The remainder of patients were contemplating treatment. After the pandemic, 13 patients were no longer interested in fertility treatment. The majority of patients, 53% (n=7) stated "I am worried about the coronavirus/COVID-19" as the primary reason they discontinued treatment, compared to several other reasons including spontaneous conception, financial concerns, and lack of partner support.

CONCLUSIONS: COVID-19 is an important consideration for people who discontinue treatment; however, it may not deter the majority of patients who seek care. Data is part of an ongoing larger prospective study.

DIFFERENT TREATMENT MODALITIES FOR MANAGEMENT OF CAESAREAN SCAR ECTOPIC PREGNANCY: A SINGLE-CENTER EXPERIENCE. Dania Al-Jaroudi, MD, MHA,[1] Saeed Marzoq Baradwan, MD, SBOG, ABOG, MRCPI, MRCOG2,[2] Saud Aboudi, MBBS.[3] [1]King Fahad Medical City, Riyadh, Saudi Arabia. Reproductive Endocrine and Infertility Medicine Department, Riyadh, Saudi Arabia; [2]Health Plus Fertility and Women's Health Center, Jeddah, Saudi Arabia; [3]Department of Obstetrics and Gynecology, King Fahad Medical City, Riyadh, Saudi Arabia, Riyadh, Saudi Arabia.

OBJECTIVE: This study aims to evaluate the outcomes of the different treatment modalities used in CSP treatment at a single center.

DESIGN: This is a retrospective case series study that was conducted; all women who diagnosed with CSP between January 2013 and November 2019 in Women's Specialized Hospital, King Fahad Medical City.

MATERIALS AND METHODS: The clinical characteristics, diagnosis, different treatment modalities, and clinical outcomes were analyzed.

RESULTS: Twenty-seven cases of CSP were identified during the study period. The mean maternal age was 36.55 years (range, 23-47 years). The gestational age at diagnosis ranged between 5 weeks and 5 days to 13 weeks and 6 days. All diagnoses were made by ultrasound. Fetal heartbeat was present in 10 cases (37.03%). The most commonly used method for first-line treatment was medical treatment. A total of 14 patients (51.85%) were treated with systemic methotrexate (MTX), Three (11.1 %) intra-sac and systemic MTX, and Two (7.4 %) intra-cardiac potassium chloride (KCl) along with systemic MTX, five (18.51%) cases had expectant management, one case initially treated with Laparotomy Wedge resection, and one case treated with Uterine artery embolization (UAE) and systemic MTX. A total of 20 (74.07%) patients were treated successfully with first-line treatment. Seven (25.92%) patients needed additional second line treatment. Among them, only one case had surgical intervention. None of the women in medical treatment group experienced any side effects. Overall, the mean β -hCG resolution time was 60.85 days (range, 28 - 95 days).

CONCLUSIONS: The treatment of CSP should be individualized based on risk factors. Diagnosis and management of CSP need expertise and a multidisciplinary approach to prevent complications. Early diagnosis and management of cesarean scar ectopic pregnancy remains the mainstay for a successful outcome.
