LIBERTY: LONG-TERM EXTENSION STUDY DEMONSTRATING ONE-YEAR EFFICACY AND SAFETY OF RELUGOLIX COMBINATION THERAPY IN WOMEN WITH SYMPTOMATIC UTERINE FIBROIDS.

Ayman Al-Hendy, MD, PhD,[1] Andrea S. Lukes, MD, MHSc,[2] Alfred Poindexter, III, MD,[3] Roberta Venturella, MD PhD,[4] Claudio Villarroel, MD,[5] Rachel B. Wagman, MD,[6] Yulan Li, PhD,[6] Laura McKain, MD,[6] Elizabeth A. Stewart, MD.[7] [1]Department of Surgery University of Illinois at Chicago, Chicago, IL; [2]Carolina Women's Research and Wellness Center, Durham, NC; [3]Baylor College of Medicine and St. Luke's Episcopal Hospital, Houston, TX; [4]Magna Graecia University of Catanzaro, Catanzaro, Italy; [5]Institute for Mother and Child Research (IDIMI), Faculty of Medicine, University of Chile, Santiago, Chile; [6]Myovant Sciences, Inc., Brisbane, CA; [7]Mayo Clinic Department of OB/GYN, Reproductive Endocrinology and Infertility, Rochester, MN.

OBJECTIVE: In the LIBERTY 1 and 2 trials, once-daily relugolix combination therapy (Rel-CT) reduced menstrual blood loss (MBL) volume and pain in women with uterine fibroids (UF) and was well tolerated, with preservation of bone mineral density (BMD) through 24 weeks (Al Hendy, ASRM 2019). Here we report on the long-term efficacy and safety of Rel-CT for up to 52 weeks of treatment.

DESIGN: Multinational, Phase 3, open-label, long-term extension trial.

MATERIALS AND METHODS: Women with UF-associated heavy menstrual bleeding (HMB) who completed the 24-week, double-blind, placebo-controlled LIBERTY 1 and 2 trials were eligible to enroll in a 28-week extension study. All received once-daily Rel-CT (40 mg relugolix, an oral gonadotropin-releasing hormone receptor antagonist, estradiol 1 mg, norethindrone acetate 0.5 mg). The primary efficacy endpoint was the proportion of women who achieved or maintained an MBL volume < 80 mL and a $\geq 50\%$ reduction from parent study baseline to the last 35 days of treatment, as measured by the alkaline hematin method. Secondary endpoints included mean % MBL reduction, amenorrhea rate, and improvements in anemia. Adverse events (AEs) and BMD changes by dual-energy X-ray absorptiometry were assessed. Outcomes were analyzed by treatment assignment: Rel-CT, delayed Rel-CT (relugolix 40 mg alone for 12 weeks, then Rel-CT for 12 weeks), and placebo, and were reported using descriptive statistics without statistical comparisons between groups. The Rel-CT group has the longest treatment duration (52 weeks): the other groups, where patients transitioned to Rel-CT, are supportive.

RESULTS: Of the 770 randomized LIBERTY patients, 610 completed the primary study; 477 (78%) enrolled in the long-term extension and 363 (76%) completed it. The Rel-CT group demonstrated sustained improvement in HMB through 52 weeks with 87.7% of patients meeting the definition of responder. The mean MBL volume reduction from baseline was 89.9% with most patients (70.6%) achieving amenorrhea. The reductions in MBL led to substantial improvements (> 2 g/dL) in hemoglobin concentrations at Week 52 for most (59.0%) patients with anemia (< 10.5 g/dL) at baseline. Reductions in uterine and UF volume at Week 24 were sustained through Week 52. Consistent with the change observed at Week 24, the Bleeding Pain and Discomfort scale score was reduced by 51.3 points from baseline to Week 52, indicating that reduction in measures of symptom-associated distress were substantial and sustained. There was no disproportionate increase in the incidence of either serious or nonserious AEs in the Rel-CT group through the 52 weeks. The most frequently reported AEs were headache and hot flush. BMD was preserved with a mean % reduction of –0.80% (95% confidence interval: –1.36, –0.25) for lumbar spine BMD at Week 52. Efficacy and safety outcomes for delayed Rel-CT and placebo were consistent.

CONCLUSIONS: Rel-CT showed durability of effect for both HMB and pain through 52 weeks of treatment in women with UF. No new safety concerns were identified, and bone mass was maintained.

AMH HIGHLY CORRELATES WITH ASSISTED REPRODUCTION CUMULATIVE LIVE BIRTH RATE IN WOMEN WITH DIMINISHED OVARIAN RESERVE INDEPENDENT OF AGE: AN ANALYSIS OF 34,540 CYCLES FROM THE SART DATABASE FOR 2014-2016.

Reshef Tal, MD, PhD,[1] David B. Seifer, MD,[2] Renana Tal, MBA,[3] Emily Granger, BS,[1] Oded Tal, PhD.[4] [1]Yale School of Medicine New Haven, CT; [2]Yale University, Orange, CT; [3]Conestoga College, Kitchener, ON, Canada; [4]■ ■ ■.

OBJECTIVE: Serum antimullerian hormone (AMH) is used to predict a woman's response to ovarian stimulation. However, its ability to predict clinical outcomes per embryo transfer such as clinical pregnancy and live birth rate has been considered to be poor. We hypothesized that its association with cumulative live birth rate (CLBR) as reported by Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SARTCORS) from 2014 onward among women with diminished ovarian reserve (DOR) could be more informative as CLBR accounts for all embryos (fresh and frozen) linked to a single identified index retrieval.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: The SARTCORS database was analyzed for CLBR by assessing outcomes of all linked fresh and/or frozen embryo transfer cycles (2014 to 2016) from an index retrieval cycle (between 2014-2015). A total of 34,540 (25.9%) of 133,442 autologous index cycles with DOR (i.e. AMH<1 ng/ml) were included and analyzed. Cycles with preimplantation genetic testing, egg/embryo banking and those with embryo transfer/s from more than one ART index cycle were excluded. Multiple logistic regression (MLR) was performed for the probability of CLBR per index cycle. Data was stratified according to AMH and age and linear regression analysis of AMH and CLBR were calculated for each age strata.

RESULTS: Multiple logistic regression demonstrated that AMH is an independent predictor of CLBR (Odds ratio 1.46, 95% CI 1.28-1.66, P<0.0001) when controlling for age, body mass index, race, total FSH dose and number of embryos transferred. Serum AMH was associated with number of oocytes retrieved, number of embryos cryopreserved and percentage of index cycles that had an embryo transfer, but was not associated with number of embryos transferred. Linear regression analysis demonstrated that AMH highly correlated with CLBR in each age strata of women with DOR (Table 1), and most strongly in women <35 (R=0.95, p<0.001).

	Age				
AMH (ng/ml)	<35 N=8,290	35-37 N=7,507	38-40 N=8,999	41 – 42 N=5,548	43+ N=4,196
0.00 – 0.1	22.1%	18.7%	9.2%	6.1%	1.2%
0.11 – 0.2	29.1%	19.8%	12.5%	6.4%	1.7%
0.21 – 0.3	30.3%	26.1%	16.3%	7.9%	1.9%
0.31 – 0.4	32.0%	26.1%	17.8%	7.4%	2.4%
0.41 – 0.5	35.9%	27.6%	17.7%	7.3%	3.2%
0.51 – 0.6	34.0%	26.7%	19.1%	9.2%	3.9%
0.61 – 0.7	36.7%	30.8%	18.9%	10.1%	2.6%
0.71 – 0.8	38.2%	31.2%	21.8%	11.1%	3.0%
0.81 – 0.9	42.7%	30.2%	19.0%	10.7%	4.1%
0.91 – 1.00	41.2%	34.0%	20.6%	9.5%	4.1%
Mean CLBR	36.1%	25.5%	19.3%	5.7%	1.4%
Linear regression (R)	0.95	0.88	0.87	0.89	0.88
p-value	<0.0001	<0.0001	0.001	0.001	<0.001

CONCLUSIONS: Serum AMH is highly correlated with CLBR in women with DOR independent of age. The addition of AMH to current age-based prognostication counseling would provide more informative and personalized CLBR prediction.

NEW INSIGHTS FROM ONE THOUSAND MOSAIC EMBRYO TRANSFERS: FEATURES OF MOSAICISM DICTATING RATES OF IMPLANTATION, SPONTANEOUS ABORTION, AND NEONATE HEALTH.

Manuel Viotti, PhD,[1] Andrea Victor, MS,[2] Frank Barnes, PhD,[1] Christo Zouves, MD,[2] Andria G. Besser, MS, CGC,[3] James A. Grifo, MD, PhD,[4] En-Hui Cheng, PhD,[5] Maw-Sheng Lee, MD, PhD,[5] Pin-Yao Lin, MD,[6] Laura Corti, MSc,[7] Francesco Fiorentino, PhD,[8] Francesca Spinella, PhD,[9] Maria Giulia Minasi, MSc,[10] Ermanno Greco, MD,[10] Santiago Munné, PhD.[11] [1]Zouves Foundation for Reproductive Medicine Foster City, CA; [2]Zouves Fertility Center, Foster City, CA; [3]New York University Langone Fertility Center, New York, NY;

[4]NYU Langone School of Medicine, New York, NY; [5]Lee Women's Hospital, Taichung, Taiwan; [6]Chung Shan Medical University, Taichung, Taiwan, Taichung, Taiwan; [7]San Raffaele Scientific Institute, Milan, Italy; [8]GENOMA Group, Rome, Italy; [9]Genoma Group, Rome, Italy; [10]European Hospital, Rome, Italy; [11]Overture Life, Madrid, Spain.

OBJECTIVE: To understand how the features of chromosomal mosaicism detected in PGT-A affect implantation rates, pregnancy, and newborn health.

DESIGN: Compiled analysis from multicenter data on transfers of mosaic embryos (n=1,000) and their clinical outcome, with comparison to a euploid control group (n=5,561). Birth characteristics of neonates (n>200) from mosaic embryo transfers are compared to a euploid control group (n>200).

MATERIALS AND METHODS: PGT-A was performed on blastocyst-stage embryos with 24-Chromosome whole genome amplification (WGA)-based Next Generation Sequencing (NGS). In accordance with established guidelines, embryos were categorized as mosaic when PGT-A results indicated 20-80% aneuploid content.

RESULTS: Compared to the euploid group, mosaic embryos had lower rates of implantation (57.2% vs. 46.5%, P<0.05) and lower rates of ongoing pregnancy or birth at the time of analysis (OP/B) (52.3% vs. 37.0%, P<0.05). When only considering embryos with mosaicism involving at least one entire chromosome (no segmental mosaics), implantation and OP/B rates were 41.8% and 31.3%, respectively. Rates of spontaneous abortion for euploids, all mosaics, and non-segmental mosaics were 8.6%, 20.4%, and 25%, respectively. Mosaic embryos with percent aneuploidy ≤50% had more favorable clinical outcomes than those containing >50% aneuploidy (implantation 47.4% vs. 35.8% and OP/B 39.5% vs. 24.1%, P<0.05 for both comparisons, n=848 and n=137, respectively). Mosaics of the segmental type (n=483) had more favorable outcomes than whole chromosome mosaics involving one or two chromosomes (n=392) (implantation 51.6% vs. 43.1%, OP/B 43.1% and 34.7%, P<0.05), while complex mosaics involving three or more chromosomes (n=125) had the least favorable outcomes, experiencing implantation rates of 30.4% and OP/B rates of 20.8%. Evaluation of clinical outcomes when combining mosaic level (low ≤50% aneuploidy or high >50% aneuploidy) and mosaic type (segmental, whole chromosome, or complex) produces the following ranking system from most to least favorable: Low segmental>low whole chromosome>high segmental>low complex->high whole chromosome>high complex. Prenatal testing of >200 pregnancies from mosaic embryo transfers showed no incidence of mosaicism that matched the PGT-A findings, indicating the involvement of self-corrective mechanisms. By and large, the metrics of pregnancy and birth (e.g. length of gestation and birth weight) were similar between babies born from transfers of mosaic embryos and euploid embryos.

CONCLUSIONS: This large dataset of transferred mosaic embryo outcomes confirms that mosaic embryos have lower rates of implantation and higher likelihood of spontaneous abortion compared to euploid embryos. The data reveals that traits of mosaicism (level and type) significantly affect likelihood of positive outcome, and identifies a ranking system for mosaic embryos in the clinic. Pregnancy and obstetric data indicates that mosaic embryos prevailing through gestation and birth have similar chromosomal and physiological health compared to euploid embryos.

WHAT IS THE OPTIMAL TIMING OF INTRACYTOPLASMIC SPERM INJECTION (ICSI) AFTER EGG RETRIEVAL? A RANDOMIZED CONTROLLED TRIAL. Meghan Brooke Smith, MD, Jacqueline Ho, MD MS, Victoria Cortessis, PhD, Irene J. Chen, MS, Kristin A. Bendikson, MD, Richard J. Paulson, MD, Lynda K. McGinnis, PhD, Ali Ahmady, PhD. University of Southern California Los Angeles, CA.

OBJECTIVE: To determine if oocyte denudation/ICSI at 2.5 hours vs 5 hours post retrieval (36.5 vs 39 hours post HCG and/or Lupron trigger) influences fertilization/blastulation rates in good prognosis couples.

DESIGN: Randomized controlled trial (RCT).

MATERIALS AND METHODS: This is a RCT of oocytes obtained at time of IVF. We included couples with: female age ≤ 38 yo; AMH > 1 ng/mL; day 3 FSH < 13.5 mIU/mL; ≥ 10 oocytes retrieved; male partner < 50 years old; no male factor infertility. Oocytes retrieved from each participant were randomized in blocks of 4 to 2 groups for denudation/ICSI: 2.5 hours (Group 1) vs 5 hours (Group 2) post oocyte retrieval after 34 hr trigger. Fertilization a/blastulation was recorded for each oocyte. Regression analyses conditioned on the patient from whom each oocyte had been retrieved was used to estimate relative rates of these events, treating 2.5 hours as the reference value. A total of 200 oocytes was determined by an a priori power calculation to provide 95% power to detect rate ratio of 78% or lower in either outcome at 5% level of nominal significance.

RESULTS: 206 MII oocytes were randomly assigned, 105 to group 1, 101 to group 2. Median parameters for female patients were: age 33 (IQR 31.0-36.5); D3 FSH 5.9 (IQR 4.4-7.5); AMH 4.76 (IQR 3.7-6.5); BMI 20.96 (IQR 18.9 – 24.8); total MII oocytes retrieved 17 (IQR 11.0 – 19.8). All patients underwent controlled ovarian stimulation with antagonist protocols. No difference was observed in fertilization rate, total blastulation rate, or day of blastulation based on timing of denudation and ICSI (all p > 0.05). Fertilization was less frequent among group 2 oocytes (5 hours), estimate of relative fertilization rate 0.81 (95% confidence interval [CI]: 0.40-1.63, p=0.55). However, among women for whom any blastulation event occurred, blastulation was more frequent in group 2 oocytes (5 hours); estimates of relative blastulation rate were 1.42 (95% CI: 0.81-2.49, p=0.22) overall, and 1.76 (95% CI: 0.84-3.71, p=0.14) among women 35 or more years of age at the time of retrieval. No relative rate estimate achieved statistical significance.

CONCLUSIONS: In good prognosis couples, we observed no difference in fertilization/blastulation rates based on timing of ICSI within the currently accepted 2-6 hr window post-retrieval with 34 hr trigger. The oocyte appears to have a physiological tolerance for fertilization during this window of time. Variability in the timing of ICSI during this window is unlikely to have an impact on cycle outcome.

	Group 1	Group 2
Fertilization Rate (#2PN/#MII)	84.8%	81.2%
Total Blastulation Rate, (#Blasts/#2PN)	66.3%	74.4%
Day 5 Blastulation (#D5 Blasts/#2PN)	38.7%	43.9%
Day 6 Blastulation (#D6 Blasts/#2PN)	37.9%	38.7%
Day 7 Blastulation (#D7 Blasts/#2PN)	6.9%	6.5%

NONINVASIVE PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY EXHIBITS HIGH RATES OF DNA AMPLIFICATION FAILURE AND LACKS CONSISTENCY WITH PGT-A USING TROPHOECTODERM BIOPSY. Brent M. Hanson, MD,[1] Xin Tao, Ph.D,[2] Julia G. Kim, MD, MPH,[1] Nola S. Herlihy, MD,[3] Amber M. Klimczak, MD,[3] Ashley W. Tiegs, MD,[1] Emily K. Osman, MD,[1] Kathleen Hong, MD,[3] Emre Seli, M.D.,[1] Richard Thomas Scott, Jr., MD.[1] [1]IVI RMA New Jersey Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVI-RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) is currently performed via analyses of trophectoderm (TE) biopsies. Concerns regarding the safety of TE biopsy and the technical skill required to perform the procedure have led to increased interest in noninvasive preimplantation genetic testing for aneuploidy (niPGT-A). The noninvasive testing modality assesses an embryo's genetic composition indirectly by analyzing spent culture media. This study begins the validation process of a commercially available assay by investigating: 1) the prevalence of DNA amplification failure with niPGT-A compared to TE biopsy; 2) factors affecting amplification failure with niPGT-A, and 3) the frequency of discrepant results between niPGT-A and traditional PGT-A.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: This study was performed at a university-affiliated fertility practice. Patients were enrolled prospectively during in vitro fertilization (IVF) cycles between July and October 2019. Culture media samples were collected at the blastocyst stage immediately prior to TE biopsy. Media samples underwent whole genome amplification using the commercially available NICSInst™ sample preparation kit (Yikon Genomics) followed by NGS with the Illumina HiSeq system. Coordination with Yikon Genomics was undertaken to ensure optimization of the niPGT-A protocol. Standard PGT-A of TE biopsies was performed using targeted NGS, consistent with institutional practices.

RESULTS: A total of 170 individually cultured blastocysts were included in the study. 1) When performing niPGT-A, 62 of the 170 samples (36.47%) failed to amplify. The failure rate following TE biopsy was dramatically

lower at 0 out of 170 (0%) ($p<1*10^{-6}$). 2) Investigation into the factors that may lead to amplification failure revealed that when an aneuploid result was noted on TE biopsy, the DNA amplification failure rate with niPGT-A was 23.46% (n=19). However, when TE biopsy resulted in a euploid embryo, rates of DNA amplification failure with niPGT-A were significantly higher (48.31%, n=43, p<0.01). 3) Finally, among the 108 embryos with results from both niPGT-A and TE biopsy analyses, a discrepancy in diagnosis was noted in 37 cases (34.3%). Twenty of the 37 cases showed aneuploidy on niPGT-A where none was evident in the TE biopsy.

CONCLUSIONS: DNA amplification failures were unacceptably high when using niPGT-A. This dramatically impairs the clinical applicability of niPGT-A based on poor amplification alone. Moreover, when interpretable results were obtained with niPGT-A, results failed to correlate with TE biopsy in over one-third of cases. This study suggests that niPGT-A, in its current state, lacks the precision and accuracy to be a useful diagnostic tool and should be used with caution until prospective non-selection data allow calculation of the "no result" rate and the predictive values of normal and abnormal results.

ASSOCIATIONS BETWEEN POLYCYSTIC OVARY SYNDROME AND ADVERSE OBSTETRICAL, AND NEONATAL OUTCOMES: A POPULATION STUDY OF 9.1 MILLION BIRTHS. Ginevra Mills, MD, FRCSC, Ahmad Badeghiesh, MD, Eva Suarthana, MD, Haitham Baghlaf, MD, MPH, Michael H. Dahan, M.D. McGill University, Montreal, QC, Canada.

OBJECTIVE: The objective of this study is to determine if polycystic ovary syndrome (PCOS) confers an independent risk for adverse delivery and neonatal outcomes.

DESIGN: This retrospective population-based cohort study utilized data from the HCUP-NIS from 2004 to 2014. The HCUP-NIS is an inpatient sample database from the United States, comprised of hospital inpatient stays throughout the entire country. It provides information relating to 7 million inpatient stays per year, includes approximately 20% of admissions, and represents over 96% of the American population.

MATERIALS AND METHODS: A cohort of all deliveries between 2004 and 2014 inclusively was created. Within this group, all deliveries in women with PCOS were identified as part of the study group (n=14,882), and the remaining deliveries were categorized as non-PCOS births and comprised the reference group (n=9,081,906). Initial analysis was performed to identify the prevalence of pregnant women with PCOS over the entire duration of the study. Baseline clinical and demographic characteristics were compared between women with PCOS and those without PCOS. Logistic regression analyses were conducted to explore associations between PCOS, delivery, and neonatal outcomes through the estimation of odds ratio (OR) and 95% confidence intervals (CI). The regression models were adjusted for the potential confounding effects of maternal demographic, preexisting clinical characteristics, and concurrently occurring conditions including hypertension and diabetes. Pregnancy induced hypertension (PIH) and gestational diabetes (GDM) data is presented separately.

RESULTS: Women with PCOS were more likely to experience preterm pre-labour rupture of membranes (aOR1.48, 95%CI 1.20-1.83), preterm delivery (aOR1.37 95%CI1.24-1.53 p<0.001), placental abruption (aOR1.63, 95%CI 1.30-2.05), and cesarean delivery (C/S) (aOR1.50, 95%CI 1.40-1.61 p<0.001). Women with PCOS developed more chorioamnionitis (aOR1.58, 95%CI 1.34-1.86 p<0.001), and maternal infections (aOR1.58, 95%CI 1.36-1.84 p<0.001). With the exception of multiple gestations (aOR1.27, 95% CI1.01-1.62 p=0.04), there was no difference in the number of women who gave birth to small for gestational age infants (aOR 0.97, 95% CI 0.82-1.15 p=0.72). Intrauterine fetal deaths were comparable between the two groups (aOR1.03, 95%CI 0.68-1.59, p=0.88). However, congenital anomalies were more likely to occur in women with PCOS (aOR1.89, 95%CI 1.51-2.38, p<0.001).

CONCLUSIONS: After controlling for all potential confounding effects including PIH and GDM, women with PCOS are at an increased risk of experiencing delivery related complications, C/S, infections, and having a child with congenital anomalies. Increased risk of placental abruptions, infections and congenital anomalies are a novel finding in women with PCOS.

ACCESS TO CARE

O-7 9:55 AM Saturday, October 17, 2020

FRONTERAS Y FERTILIDAD: INSIGHTS ON LATINX INFERTILITY AND ACCESS TO CARE FROM THE ENVIRONMENT, LEIOMYOMAS, LATINAS, AND ADIPOSITY STUDY (ELLAS). Nicholas S. Raja, MD,[1] Anne Waldo, MS,[1] Torie C. Plowden, MD, MPH,[2] Lia Bernardi, MD,[3] Sonia Acosta, PhD,[4] Charo C. Ledon, NA,[5] Anita Malone, MD,[1] Erica E. Marsh, MD, MSCI, FACOG.[1] [1]University of Michigan Ann Arbor, MI; [2]Womack Army Medical Center, Fort Bragg, NC; [3]Northwestern University, Chicago, IL; [4]Centro Multicultural la Familia, Pontiac, MI; [5]Buenos Vecinos, Ann Arbor, MI.

OBJECTIVE: To investigate infertility rates and access to infertility care among Latinx females using data from the Environment, Leiomyomas, Latinas, and Adiposity Study (ELLAS).

DESIGN: Prospective longitudinal cohort study.

MATERIALS AND METHODS: Latinx females between the ages of 21 and 50 were eligible to enroll in this study. All participants were administered questionnaires collecting demographic information as well as reproductive health and fertility histories. Demographic data included age, country of birth, education history, annual household income, acculturation level, health literacy, insurance status, and body mass index (BMI). Outcomes of interest were pregnancy history, including gravidity, live births, and pregnancy loss, as well as rates of infertility and rates of accessing fertility care. The prevalence of infertility was evaluated in the general population, followed by subgroup analyses to compare outcomes of interest among infertile patients based on income, educational level, insurance status, health literacy, and acculturation level using Kruskal-Wallis and Chi-squared tests for comparison.

RESULTS: 633 participants have enrolled in the study and 569 have completed the first study visit. The average age of enrolled females was 37.6 ± 6.97 years. 90% of study participants were born outside the United States (U.S.) and 79.3% of this subgroup entered the U.S. after age 18. 59.8% of participants reported an annual household income of $30,000 or less, 48.2% had not completed high school, and 56.9% did not have health insurance. 25.1% of the participants reported having experienced infertility at some point their lives, but of these ultimately 85.3% reported a live birth. We found that participants that reported a history of infertility had a higher mean BMI (31.3 vs. 29.5, p=0.01), and that rates of infertility did not differ based on income, education level, or insurance status. Infertility was associated with lower gravidity, fewer live births, and a history of polycystic ovarian syndrome but not with a history of pregnancy loss or ectopic pregnancy. In this cohort, females with infertility did not experience differences in their ability to obtain treatment based on annual income, insurance status, educational history, health literacy, or acculturation.

CONCLUSIONS: Strikingly, 25.1% of ELLAS participants reported a history of infertility – a rate nearly four times higher than that reported by the National Survey of Family Growth (6.7%) [1]. Despite robust scientific literature documenting racial disparities in rates of infertility and access to care, studies specifically focused on Latinx females remain rare. Insights from the ELLAS study will contribute to collective knowledge of this understudied population of largely first generation Latinx females as well as inform future research into racial and ethnic disparities in the field of reproductive health and infertility.

JOURNEY LEVEL ANALYSIS OF PROGRESSION TO TREATMENT VERSUS DROP OUT IN A LARGE COHORT OF PATIENTS WITH ACCESS TO A DEFINED FERTILITY BENEFIT. Yishin Yang, BA,[1] Melody Qiu, MSc,[1] Aly Emiola, BA,[1] Dmitry Gounko, MA,[2] Joseph A. Lee, BA,[2] Alan B. Copperman, MD.[3] [1]Progyny Inc., New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: To evaluate variables associated with progression to ART treatment versus with patient drop-out.

DESIGN: Retrospective Multi-Center Study.

MATERIALS AND METHODS: Between January 2018 and July 2019, a total of 8,441 patient journeys were analyzed based on intention to initiate IVF treatment. Data points included factors relating to patient drop-out versus accessing Assisted Reproductive Technologies. Relevant factors in this study include the number of provider locations the patient had access to within their CBSA (Core Based Statistical Area), age at time of appointment, number of calls/emails made before an initial consultation. Further classifications were assumed based on the patient's geographic location, region, and etiology of infertility. Missing CBSA clinic options where substituted with average clinic option counts. Hypothesis tests were performed using Chi Square tests for independence of categorical variables as well a t-tests for continues variables. A multivariable logistic regression was performed in order to model the likelihood of a patient initiating treatment.

RESULTS: Hypothesis testing determined a significant difference between CBSA provider counts (P<.0001), Patient inquiries (P<.0001), male diagnosis (P<.0020), age quartiles (P<.0001) with treatment progression. No univariate significant association was determined when comparing coastal status of patients and treatment status. A multivariable analysis was also examined to adjust for confounding factors. The odds of progressing to treatment was significantly associated with an increase in CBSA clinic options (OR 1, [95% CI 1.001-1.008], p= 0.0047) as well as the number of patient inquiries (OR 1.032, [95% CI 1.020.-1.046], p< .001). Using a third quartile range age group as reference, the odds of treatment progression was significantly different amongst the first age quartiles and the third age quartile ranges (OR .605, [95% CI .526 - .696], p< .0001). For patients with a male infertility diagnosis the odds of treatment progression was determined to be 39.96% lower than other diagnosis (OR .604, [95% CI .425 - .858], p< .0049). Patients living in Coastal states where determined to have an approximately 14% lower likelihood of progressing to treatment (OR .8 63, [95% CI .763 - .976], p< .0186).

CONCLUSIONS: In the largest multi-center study to date analyzing patient drop out, we identified that patients with multiple contacts with patient care advocates were more likely to access treatment, and that patients with male factor were less likely to progress. We plan to use this data to improve support systems of the patient and the partner and increase contact points with couples presenting for fertility treatment.

ASSOCIATION BETWEEN DEMAND FOR FERTILITY SERVICES AND CHANGES IN UNEMPLOYMENT RATE IN THE UNITED STATES.

Leslie B. Ramirez, PhD,[1] Alexis Adler, BS,[1] L. Maslow Bat-Sheva, MD, MSCTR,[1] Joshua U. Klein, MD,[1] Urbano L. Franca, PhD.[2] [1]Extend Fertility New York, NY; [2]Boston Children's Hospital / Harvard Medical School, Boston, MA.

OBJECTIVE: The effect of the economic crises on the demand for fertility services remains to be understood. This is particularly relevant nowadays as fertility centers prepare for the economic impact of the current COVID-19 pandemic. Using the 2008 financial crisis and resulting economic downturn as a proxy, this study describes and quantifies the impact of recessions on the demand for fertility services in the US.

DESIGN: Retrospective study.

MATERIALS AND METHODS: We used the SART dataset (2007-2011) to evaluate demand for fertility services in the period surrounding the 2008 economic crisis. Number of cycles per thousand women (cycles/1k) was standardized using the US Census data on the number of females of reproductive age (20-44 years). States with at least 500 cycles/year were included in the study. The historical unemployment rate was obtained from the US Bureau of Labor and its projection for 2020 from the Congressional Budget Office. Statistical associations were assessed using generalized least squares and significance set at P<.05.

RESULTS: There were 1,119,806 cycles performed in these states during the study period. While the number of cycles increased throughout the period an average of 2.3% per year, the growth significantly decreased during the economic downturn from 4.8% in 2007 to 0.2% in 2009 (Table). The number of cycles in 2009 decreased in more than half of the states, with a median change of -0.4% (Table). The change in the number of cycles/1k was significantly associated with the change in state unemployment rate. On average, an 1% increase in unemployment was associated with a decrease of 0.94% in the number of cycles, accounting for expected growth. A conservative estimate indicates that about 10,000 cycles were forgone in 2008-2010. Under the same assumptions and a projection of 5% additional unemployment in 2020, around 15,000 ART cycles are estimated to be forgone this year.

CONCLUSIONS: We used the recession of 2008 as a framework to estimate the potential impact of the current economic crisis in the demand for fertility services. Our results suggest that while fertility care is not as affected as other industries, changes in unemployment rate are associated with decreases in demand for fertility treatments. Further research is needed to evaluate the additional impact of the unique situation programs and patients are facing in the current COVID-19 pandemic, including temporary halt of fertility services, reduced mobility, and variation in state policies.

ANALYSIS OF STATE MANDATED INSURANCE COVERAGE FOR INFERTILITY TREATMENT AND FERTILITY PRESERVATION IN THE UNITED STATES.

Benjamin J. Peipert, MD,[1] Shelun Tsai, MD,[1] Melissa N. Montoya, MD, MA,[1] Ryan C. Ferrante, JD,[2] Tarun Jain, MD.[3] [1]Duke University Medical Center Durham, NC; [2]The Law Office of Ryan C. Ferrante, Chicago, IL; [3]Northwestern University, Chicago, IL.

OBJECTIVE: To characterize the landscape of state mandated insurance coverage for infertility treatment and fertility preservation in the United States (US). Furthermore, we aimed to identify the political party in power at the time these mandates were passed.

DESIGN: Retrospective analysis of US legislation mandating insurance coverage pertaining to the diagnosis and treatment of infertility and fertility preservation.

MATERIALS AND METHODS: Review of state infertility and fertility preservation insurance mandates was conducted via ASRM's ReproductiveFacts.org, the National Council of State Legislatures (NCSL), and Google search. Initial search was confirmed by primary review of current state legislation (performed April 2020). Mandate eligibility criteria, covered procedures, step-through requirements, lifetime limits, exemptions, and coverage of fertility preservation were analyzed. State political party at time of passage was derived from the NCSL.

RESULTS: Nineteen states (38%) have passed legislation mandating insurers to cover or offer coverage for the diagnosis and treatment of infertility or conditions resulting in infertility. Nine (47%) states require individuals to demonstrate a period of infertility longer than the ASRM definition of infertility to be eligible for assisted reproductive technologies (ART). Four (21%) states have an age limit, after which services are no longer covered. Utah is the only state that mandates coverage for IVF contingent on the presence of a genetic trait associated with a qualifying condition. States vary in the specific services covered, such as IVF (12 [63%]), IUI (9 [47%]), and fertility preservation for patients with cancer or other iatrogenic infertility (10 [53%]). Seven of the 12 states mandating IVF (58%) require patients to attempt less costly methods of ART prior to IVF being covered. Four (21%) states require fertilization to be performed with the spouse's sperm. Seven (37%) states require that the facility providing fertility services conform to the standards developed by ASRM, ACOG, or another governing body. Eleven (58%) states place a lifetime limit on the amount of fertility treatment

provided. Coverage exemptions exist for religious, small employer, and non-health maintenance organizations (8 (42%), 6 (32%), and 3 (16%) states, respectively). Eight (42%), 2 (11%), and 9 (47%) infertility mandates were passed by Democratic, Republican, and split state governments, respectively. Among fertility preservation bills, 6 (60%), 0 (0%) and 4 (40%) bills were passed by Democratic, Republican, and split state governments.

CONCLUSIONS: Across state infertility and fertility preservation insurance mandates, significant heterogeneity exists. Only Colorado, Connecticut, Delaware, Illinois, Maryland, New Hampshire, New Jersey, New York, and Rhode Island mandate coverage for both IVF and fertility preservation. Most states do not have an infertility mandate. Infertility mandates have passed with bipartisan state legislature support; however, no fertility preservation mandates have been passed by Republican-controlled state governments.

DOES SOCIOECONOMIC STATUS PLAY A ROLE IN LONG-TERM REPRODUCTIVE OUTCOMES IN INFERTILE COUPLES? FOLLOW-UP RESULTS FROM THE FAST TRACK AND STANDARD TREATMENT TRIAL (FASTT). Carleigh B. Nesbit, DO,[1] Marlene B. Goldman, ScD,[2] June L. Fung, PhD,[2] Katherine G. Koniares, MD,[3] Denis A. Vaughan, MD,[4] Thomas L. Toth, MD,[5] Richard H. Reindollar, MD.[2] [1]Dartmouth Hitchcock Medical Center Lebanon, NH; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Tufts Medical Center, Boston, MA; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Boston IVF, Waltham, MA.

OBJECTIVE: To investigate long term reproductive outcomes in couples of different socioeconomic groups enrolled in FASTT from 2001-2006.

DESIGN: Long term follow-up of randomized controlled trial (RCT) participants.

MATERIALS AND METHODS: A telephone survey was administered to couples who had been enrolled in FASTT, an RCT which investigated time to conception and cost effectiveness of conventional treatment for unexplained infertility vs a fast track approach in women ages 21-39 years. Statistical analyses were performed using SAS v 9.2. Categorical variables were compared between groups using chi-square and Fisher's exact tests and continuous variables with analysis of variance with $P < 0.05$ as significant.

RESULTS: Of the 503 couples enrolled in FASTT, 311 (61.8%) were able to be contacted of whom 286 (56.9%) consented to participate. The distribution of reported annual household income at the time of FASTT among consenting couples was 32.5% ≥$140,000, 28.3% $100,000-139,999, 31.5% $60,000-99,999, and 5.6% <$60,000. The distribution of highest level of education of female participants at the time of FASTT was 1.8% high school diploma, 7.8% associate's degree, 7.8% some college education but no degree, 44.8% bachelor's degree, 28.3% master's degree, and 9.5% medical degree/doctorate. There were no statistically significant differences in income between those who were able to be contacted and those who were not nor in income or education level between those who consented to participate and those who did not. Women who were able to be contacted were more likely to have a bachelor's or master's degree than those who were not ($P = 0.01$). In terms of outcomes during FASTT, there were no differences in any income group in terms of achievement of live birth but couples with lower income were less likely to achieve a clinical pregnancy ($P = 0.02$.) There were no differences by level of education in achievement of live birth or clinical pregnancy during FASTT. Following FASTT, there were no statistically significant differences by income or level of education in number of couples who attempted conception, achieved a clinical pregnancy or live birth, or who reported ultimate family building satisfaction. For those who were able to conceive, time to conception was not significantly different based on couple's reported income or level of education. There were no statistically significant differences in number of couples who attempted spontaneous conception after FASTT, controlled ovarian hyperstimulation +/- intrauterine insemination, in vitro fertilization with autologous or donor oocytes, or who adopted children between groups of different income or education levels.

CONCLUSIONS: In a long term follow up of infertile couples, annual household income and level of education of female partners did not have an impact on long term reproductive outcomes. These findings reflect the success of insurance coverage for infertility treatments.

O-12 11:10 AM Saturday, October 17, 2020

PATIENT BARRIERS TO DISCONTINUING LONG ACTING REVERSIBLE CONTRACEPTION. Kacie R. Fox, MD, Alyssa M. Kameoka, BA, Bliss Kaneshiro, MD, MPH, Shandhini Raidoo, MD, MPH, Reni Soon, MD, MPH, Tiana Fontanilla, MPH. University of Hawaii Honolulu, HI.

OBJECTIVE: The objective of this study was to determine whether patients face barriers to discontinuing long acting reversible contraception (LARC), and if so, to evaluate if certain patient demographic groups are disproportionately affected. We classified the patient as having a barrier if the patient was unable to remove the device at the time they requested or desired removal.

DESIGN: Prospective online survey.

MATERIALS AND METHODS: We conducted an online survey of individuals ages 18-50 who used and discontinued (or attempted to discontinue) a contraceptive implant or intrauterine device. Estimating that about 20% would have experienced a barrier, we aimed to recruit 500 participants. Participants provided demographic information and answered questions related to their experiences discontinuing LARC, including any challenges they faced, such as, "my provider wouldn't remove it until I started another form of contraception," or "my provider stated there wasn't enough time in that visit." Flyers advertising our online survey were posted at various University of Hawaii faculty practice sites, in the University of Hawaii dormitories, and online via Instagram and Facebook. In addition, an international sample of participants was obtained using Amazon Mturk. Statistical analysis was performed using SPSS.

RESULTS: Of the 133 individuals who completed our Hawaii-based survey, 59% had experience discontinuing LARC, and of those, 21.5% encountered a barrier to discontinuation. Half of those who identified with Hispanic ethnicity experienced a barrier to discontinuation, compared to 17.6% of non-Hispanics ($p=0.03$). Those with no insurance, or government funded insurance were also more likely to face a barrier compared to those with private insurance (100% and 36.8% respectively, versus 13.6%, $p=0.05$). A greater proportion of participants who were high school or college graduates experienced a barrier when compared to those with more than a college degree, though this was not statistically different. Age, other racial groups, or prior pregnancy was not associated with experiencing a barrier in discontinuation.

In our international survey using Mturk (n=448), 29.2% of participants reported a barrier to discontinuation. Characteristics associated with facing barriers included having government-funded insurance ($p=0.005$), lower levels of education ($p=0.005$), younger age ($p<0.001$,) and having previously been pregnant ($p<0.001$). In addition, Hispanics and those of African, Middle Eastern, Asian, American Indian or Alaksa Native decent were statistically more likely to experience a barrier ($p< 0.03$.)

CONCLUSIONS: Results of our study show that patients often face barriers to discontinuing LARC. Demographic characteristics associated with meeting a barrier to discontinuation were different in the Hawaii-based survey and the Mturk international survey, but our findings suggest that insurance-status, race, education, age, and parity could play a role. Providers should remain mindful of these barriers and work towards an unbiased practice where patients have easy access to using and discontinuing LARC.

A NOVEL NON-INVASIVE METABOLOMICS APPROACH TO SCREEN EMBRYOS FOR ANEUPLOIDY. Sara Cabello-Pinedo, Biotechnologist,[1] Hussain A. N. Abdulla, Ph.D.,[2] Michelle Louise Seth-Smith, Master,[1] Maria Escriba, MSc,[3] Juana Crespo, Medical Director,[3] Santiago Munne, PhD,[4] Jose A. Horcajadas, PhD.[4] [1]Overture Life Alcobendas - Madrid, Spain; [2]Texas A&M University Corpus Christi, Corpus Christi, TX; [3]Equipo Juana Crespo, Valencia, Spain; [4]Overture Life, Madrid, Spain.

OBJECTIVE: The aim of this study was to develop a novel non-invasive technique for embryo selection. This was performed by identification of

metabolomics biomarkers of euploidy and aneuploidy in spent culture media after embryo culture.

DESIGN: Samples (n=80) consist of spent culture media collected in IVF clinics after embryo culture from day 3 to day 5. After collection, samples were frozen and shipped to analysis lab. Samples were analyzed using a high-resolution accurate mass (HRAM) mass spectrometer. After appropriate data processing and analysis, several critical biomarkers were identified, leading to the development of a new non-invasive technique for embryo selection based on these specific molecules.

MATERIALS AND METHODS: After embryo culture between days 3 and 5, spent culture media was collected from 80 samples with known PGT results. These samples were processed using an ultrafiltration technique to separate high-molecular weight molecules from the metabolites fraction, the relevant one for this study.

After this step, samples were analyzed using HRAM mass spectrometer. Resulting chromatograms were aligned and processed to identify and quantify different metabolites in the culture media.

Several statistical and machine learning techniques were applied to identify the most important metabolites to use as biomarkers. To test the performance of the model built, half of the samples (50%) were used to build the prediction model and the other half were used in the validation phase.

RESULTS: A total of 7,523 metabolites were detected in spent media samples. Several dimension reduction techniques were applied and, eventually, selection was performed using PLS-DA (Partial Least Squares – Discriminant Analysis), which gave the best results. Sixty (60) metabolomics biomarkers were identified as the most significant ones and a model was built using PLS-DA algorithm.

The model was tested using the other half of the dataset (27 aneuploid and 13 euploid), for validation purposes. The results gave a concordance with PGT results of 97.5% accurate prediction, with only one misclassified instance: one euploid embryo was classified as aneuploid.

CONCLUSIONS: Differences in metabolites concentration in spent culture media between euploid and aneuploid embryos were highlighted, confirming that we are able to infer metabolic status of the embryo by analyzing the compounds in culture media. In addition, a set number of metabolites were identified as potential biomarkers, facilitating its use in clinical practice instead of the total data, which is highly dimensional and difficult to handle.

This research demonstrates the power of metabolomics in IVF as a non-invasive tool for accurate selection of euploid embryos.

MATHEMATICALLY ADJUSTING FOR EMBRYO SIZE IMPROVES THE ACCURACY OF A SPECIFIC GRAVITY DEVICE IN PREDICTING EMBRYO SEX. Samuel D. Prien, PhD,[1] Lindsay L. Penrose, PhD.[2] [1]Texas Tech University Health Sciences Center AND Texas Tech University Lubbock, TX; [2]Texas Tech University Health Sciences Center, Lubbock, TX.

OBJECTIVE: Previous research from this laboratory has demonstrated a Specific Gravity Device (SGD) can be used to noninvasively assess embryo quality across the early stages of embryo development (zygote to blastocyst). Preliminary data also appears to suggest the system might also be useful in predicting embryo sex as embryos enter the blastocyst stage. However, as the SGD calculations assumed embryos of a consistent size, its usefulness was limited in expanding blastocyst. The objective of the current study was to determine if a corrective mathematical algorithm, based on embryo size, could enhance the ability of the SGD to predict embryo sex.

DESIGN: Lab-based trial of the SGD in predicting embryo sex.

MATERIALS AND METHODS: In this preliminary study, a proprietary algorithm was developed to account for embryos of varying sizes based upon the physics of shape and buoyancy. Data from a previous experiment of 463 bovine blastocyst stage embryos that had SGD results correlated to sex determination by Polymerase Chain Reaction (PCR) were used. Data were first corrected for size using the new mathematical algorithm and the embryo's predicted growth (expansion) from the time of blastocyst formation and exposure to the SGD, and then re-analyzed using the SGD prediction for sex. Finally, these new outcomes were compared to the PCR results to determine if correcting for embryo size improved the predictive power of the SGD.

RESULTS: Initial studies without the size correction demonstrate the SGD 65.3-78.4% accuracy selecting for female embryos with no predictive power for male embryos. With the size adjustment, the predictive power for both sexes increased; female embryos were predicted with over 80% accuracy and male embryos with 60% accuracy. While further refinement of the mathematical algorithm may be necessary, these data suggest the SGD could be an effective noninvasive means of predicting the sex of preimplantation embryos.

CONCLUSIONS: Theoretically, the differences in the buoyancy of mammalian blastocyst embryos of similar sizes must be a reflection of differences in the chromosomal weight of X and Y chromosomes or due to developmental differences of male and female embryos. However, while the size of embryos before blastocyst formation is highly conserved, embryos at the blastocyst stage show dynamic shifts in size. Data suggest the SGD can remain an accurate predictor of sex if embryo size is incorporated into the calculations.

EMBRYO DEVELOPMENT ON DAY 7 BY CULTURE MEDIA EXPOSURE: A PROSPECTIVE TRIAL. Iris Insogna, MD, MBE, Andrea Lanes, PhD, Elizabeth S. Ginsburg, MD, Catherine Racowsky, PhD. Brigham and Women's Hospital Boston, MA.

OBJECTIVE: 1) To test the hypothesis that slowly developing embryos on day 6 (D6) will be more likely to develop into good, biopsy-quality embryos when randomized to fresh culture medium on D6, compared to embryos that remain in the same medium until day 7 (D7) and that this is age-dependent; 2) To determine the overall percentage of otherwise discarded D6 embryos that would meet biopsy criteria on D7 in PGT-A cycles.

DESIGN: Prospective randomized trial within an academic IVF clinic.

MATERIALS AND METHODS: Embryos of patients ages 18-44, undergoing fresh autologous or donor cycles, with or without preimplantation genetic testing (PGT) that did not meet criteria for biopsy and/or freeze on D6, were randomized to remain in the culture medium (Global® total; GLBT) used for D3-D5 of culture (C-GLBT) or be moved to fresh medium (F-GLBT) with re-evaluation on D7. Embryos from the same cycle were randomized to the medium groups following a pre-determined algorithm. Cycles with at least 2 randomized embryos were included.

Log binomial regression was used to calculate the relative risk and 95% confidence intervals of embryos achieving good quality on D7 when exposed to fresh versus continuous media. The models accounted for patients contributing embryos from more than one cycle.

RESULTS: 1254 embryos were randomized between 3/2019 – 2/2020, with complete grading available for 603 embryos cultured in F-GLBT and 620 cultured in C-GLBT. The groups were similar for patient age, gravidity, parity, AMH, BMI, infertility diagnosis, stimulation protocol and mature eggs retrieved.

The proportion of good quality D7 blastocysts did not differ between media groups (10.1% (61/603) vs. 9.7% (60/620), F-GLBT vs. C-GLBT, respectively; RR 1.05 [95% CI 0.74 – 1.47]). No significant differences were found between groups when stratified by age (Table).

In PGT cycles, 12.3% (26/211) of embryos in F-GLBT achieved good quality on D7 compared to 10.3% (22/214) in C-GLBT, RR 1.20 (95% CI 0.72 – 2.00). 9.9% of embryos otherwise discarded on D6 met criteria for biopsy and/or freeze on D7.

Relative risk of conversion to good quality blastocysts on D7 after randomization to fresh or continuous media on D6, stratified by age

CONCLUSIONS: Refreshment of medium on D6 did not increase the incidence of D7 good, biopsy quality embryos and this was not influenced by patient age. However, our findings support culturing slow developing

	F-GLBT N (%)	RR (95% CI)	C-GLBT N (%)	RR (95% CI)	Total (F-GLBT + C-GLBT) N (%)	RR (95% CI)
<38 N = 897	50/446 (11.2%)	Ref	41/451 (9.1%)	Ref	91/897 (10.1%)	Ref
≥38 N = 326	11/157 (7.0%)	0.63(0.32–1.23)	19/169 (11.2%)	1.24 (0.69–2.22)	30/326 (9.2%)	0.91 (0.57–1.44)

embryos to D7, rather than discarding them on D6, as a significant number of good quality blastocysts become available for clinical use.

INTRACYTOPLASMIC SPERM INJECTION (ICSI) DOES NOT PROVIDE ANY BENEFIT OVER IN VITRO FERTILIZATION (IVF) ON PLOIDY RATES IN NON-MALE FACTOR INFERTILITY CYCLES UNDERGOING PRE-IMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A). Jessica N. Tozour, MD, PhD, Alyson Brady, MS, Meredith Akerman, MS, Alicia J. Arnott, BS, Linda Sung, MD, Rani Fritz, DO, PhD. NYU Winthrop Hospital Mineola, NY.

OBJECTIVE: Early PGT-A platforms required use of ICSI to eliminate paternal DNA contamination. Advances in genetic testing platforms, such as Next Generation Sequencing (NGS), allow for the use of IVF or ICSI. Despite clinical indication, ICSI is currently the recommended fertilization method for PGT-A cycles [1]. Our objective is to evaluate whether significant differences exist in ploidy rates from PGT-A tested embryos fertilized by IVF compared to ICSI.

DESIGN: Retrospective cohort study at a single academic institution.

MATERIALS AND METHODS: All embryos from ICSI and IVF cycles performed from 1/2016 to 2/2020 that underwent NGS PGT-A from trophectoderm biopsy were evaluated. Exclusion criteria included male factor infertility, embryos tested for PGT for monogenic disorders, structural rearrangements, or HLA-typing, cryopreserved oocytes, blastomere or polar body biopsy, in vitro maturation, rescue ICSI, or split IVF/ICSI cycles. Patient demographics, infertility diagnoses, cycle characteristics, and embryo PGT-A results for euploid, aneuploid, low and high mosaicism, and no call rates were collected. Primary outcome was euploid embryo rates. Secondary outcomes were aneuploid and mosaic rates. Chi-square or Fisher's exact test and Mann-Whiney test were used for categorical and continuous variables, respectively. Outcomes of IVF vs. ICSI groups were compared using generalized linear mixed models, in which euploid and aneuploid rates were adjusted for confounding variables attained during the univariate screen. Continuous variables are reported as median with interquartile range. Outcomes variables are reported as mean (95% CI). Results were considered statistically significant with a p-value <0.05. Analyses were performed using SAS version 9.4

RESULTS: A total of 1517 embryos from 387 cycles met criteria, 789 embryos from IVF (52.0%) and 728 embryos from ICSI (47.9%) cycles. Median age in IVF vs. ICSI group were 38 (35 ,40) and 38.5 (36 ,41) years, respectively. Median AMH in IVF vs. ICSI group was 1.8 ng/ml (1 ,3.7), and 2.1 (1.18 ,2.9) ng/ml, respectively. Average embryos biopsied in IVF vs. ICSI group were 4 (2 ,6) vs. 3 (1 ,5), respectively. Euploid, aneuploid, mosaic, and no call rates demonstrated no significant differences in IVF vs. ICSI inseminated groups (Table 1).

CONCLUSIONS: The use of ICSI in non-male factor infertility cycles undergoing PGT-A does not provide an advantage over IVF for euploid or mosaic rates.

TABLE 1.

	IVF	ICSI	p-value
Euploid	0.43 (0.34, 0.51)	0.42 (0.34, 0.49)	0.76
Aneuploid	0.40 (0.31, 0.49)	0.43 (0.37, 0.52)	0.37
No call	0.02 (0.005, 0.03)	0.03 (0.01, 0.04)	0.35
Mosaic	0.15 (0.11, 0.19)	0.13 (0.09, 0.17)	0.39
Low Mosaic	0.07 (0.04, 0.09)	0.06 (0.04, 0.09)	0.79
High Mosaic	0.08 (0.053, 0.11)	0.07 (0.04, 0.09)	0.41

REDUCING THE STRESS OF CULTURE? LOW LACTATE EMBRYO CULTURE MEDIUM INCREASES USABLE BLASTOCYST RATE FOR WOMEN OF ADVANCED MATERNAL AGE. Elizabeth R. Hammond, PhD, Dean E. Morbeck, Ph.D., M.B.A. Fertility Associates, Auckland, New Zealand.

OBJECTIVE: to determine the impact of low-lactate concentration in continuous embryo culture media on useable blastocyst rates and clinical pregnancy rates.

DESIGN: prospective validation of embryology and clinical outcomes for standard-lactate (Continuous Single Culture Complete; CSCM-C) compared to low-lactate continuous culture media (Continuous Single Culture-NX; CSCM-NX, Irvine Scientific).

MATERIALS AND METHODS: from 2019 to 2020, 1673 IVF or ICSI cycles had embryos cultured in either CSCM-C or CSCM-NX at a multicentre clinic (5 clinics) during a prospective culture media validation. CSCM-NX contains a lower concentration of lactate compared to traditional culture media (6-fold lower compared to CSCM-C) enabling direct assessment of whether a reduced concentration of the energy substrate lactate is biologically relevant in human embryos. Day 5 useable blastocyst rate (D5BUR), total useable blastocyst rate (TBUR) and clinical pregnancy rate (CPR) after first fresh or frozen transfer (primary outcome) were compared using two-tailed t-Tests or Pearson Chi-squared test. A p-value of <0.05 was statistically significant.

RESULTS: low-lactate continuous media, CSCM-NX, resulted in a 7% increase in TBUR (52.8%) compared to CSCM-C (46.1%) for exclusively older patients ($\geq$ 38 years; $p=0.0186$). Young patient ($\leq$ 37 years) had a comparable TBUR for the two media (53.2% for CSCM-C and 53.6% for CSCM-NX). There was no difference in the D5BUR between CSCM-C and CSCM-NX according to female age group (40.9% and 41.9 % for $\leq$ 37 years; 32.4% and 37.3% for $\geq$ 38 years, respectively). Similarly, there was no difference in the primary outcome clinical pregnancy rate (44.4% and 47.6% for $\leq$ 37 years; 25.8% and 26.6% for $\geq$ 38 years, respectively).

CONCLUSIONS: results from this large prospective media validation provide evidence that comparatively lower levels of lactate in continuous embryo culture media provide a beneficial metabolic environment for blastocyst development in older patients. The fact that the effect was confined to older patients may reflect higher levels of metabolic stress occurring within their embryos and therefore indicate lower lactate concentrations throughout culture improve metabolic conditions.

IS MTDNA CONTENT ASSESSMENT AN INDICATOR OF THE AMOUNT OF MITOCHONDRIA (TOTAL AND ACTIVE ONES) IN THE HUMAN BLASTOCYST?: A CONFOCAL MICROSCOPY APPROACH. Marta Pérez, phD student,[1] Amparo Mercader, PhD,[2] Amparo Mifsud, PhD,[2] Diana Beltrán, Master,[2] Carmen Vidal, M.D., Ph.D.,[2] Elena Labarta, MD PhD,[3] Antonio Pellicer, MD,[4] Ma José de los Santos, PhD.[2] [1]IVI foundation Valencia, Spain; [2]IVIRMA Valencia, Valencia, Spain; [3]IVI-RMA, Valencia, Spain; [4]IVI Foundation Innovation, Valencia, Spain.

OBJECTIVE: to assess if mitochondrial DNA (mtDNA) content per trophectoderm (TE) cell (Mitoscore®) could serve as a predictor of total mitochondrial mass and activity in the human blastocyst.

DESIGN: A prospective cohort study was performed in 51 vitrified aneuploid blastocysts with known Mitoscore® data. Blastocysts were warmed, maintained 6 hours under in vitro culture conditions and stained with mitochondrial dyes. Nonyl acridine orange was used for staining the total mitochondrial content, Mitotracker Deep Red was used for staining the active mitochondrial content and Dapi was used for staining the nucleus.

MATERIALS AND METHODS: Confocal microscopy was used to take three photos of the focal plane of each blastocyst. The analysis was performed with two different methods: Adjusting a fluorescence value for each mitochondrial dye and evaluating the differences in gains values required (N=17) between embryos and setting the same gain values for each dye and calculating the differences in fluorescence emitted between embryos using the image analysis software Image J (N=34). Data was statistically analysed by linear regression and analysis of variance ratios.

RESULTS: We observed that there was no correlation ($p>0.05$) between the mtDNA content either with the number of mitochondria per cell or with the number of active mitochondria per cell using both methods of analysis (fixed fluorescence, N=17 and fixed gains values, N=34).

Most importantly, when we analyzed the variance ratios (variance of a subsample divided by variance of the global population) of the total embryos fluorescence for each dye (mitochondrial mass variance ratio=0,99 and active mitochondria variance ratio=1,89) within a group of embryos with the same Mitoscore® (Mitoscore® variance ratio=0,0096) we observed differences in terms of Mitoscore®' emitted fluorescence and vice versa (mitochondrial mass variance ratio =0,11 and Mitoscore® variance ratio = 0,79; active mitochondria variance ratio=0,007 and Mitoscore® variance ratio= 0,97).

CONCLUSIONS: Confocal approach showed that no correlation could be established between Mitoscore® and total and active mitochondrial content in human blastocysts.

The lack of correlation observed can be due to random distribution of mtDNA content in TE during embryo culture, indicating that mtDNA copy number in the TE is not a good surrogate marker of the mitochondrial mass and the metabolic state of the trophoblast and suggesting a lack of utility of mtDNA measurement as a marker of embryo implantation. Another possibility is that the confocal approach is not accurate enough for doing such correlation.

MENSTRUAL CYCLE CHARACTERISTICS THROUGHOUT THE LIFE COURSE IN RELATION TO CANCER RISK.

Siwen Wang, BS,[1] Janet Rich-Edwards, PhD,[2] Edward Giovannucci, MD, Sc.D.,[3] Jorge E. Chavarro, MD, Sc.D.[1] [1]Harvard School of Public Health, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard T.H. Chan School of Public Health, Boston, MA.

OBJECTIVE: Long and irregular cycles have been associated with lower risk of breast cancer and higher risk of endometrial cancer, but associations with other malignancies are less clear. Therefore, we comprehensively assessed the relation of menstrual cycle length or regularity throughout the reproductive lifespan with risk of cancer.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Between 1993 and 2015, we followed 78,947 premenopausal women in the Nurses' Health Study II without a history of cancer and who reported the usual length and regularity of their menstrual cycles at ages of 14-17, 18-22, and 28-48 years. Self-reports of newly diagnosed cancer were subsequently confirmed through review of medical records and pathology reports. Cancer was categorized into obesity-related cancer (colorectal, gallbladder, kidney, multiple myeloma, thyroid, pancreatic, esophageal, gastric, liver, endometrial, ovarian, and post-menopausal breast cancer) and non-obesity-related cancer, based on the classification from the International Agency for Research on Cancer. We fitted Cox proportional hazard models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) of the association between menstrual cycle characteristics and cancer incidence, adjusting for updated body mass index (BMI) and other known cancer risk factors.

RESULTS: We documented 6,661 incident cancer cases during 1,646,310 person-years of follow up. After adjusting for potential confounders, women who reported irregular cycles at age 28-48y had a 9% higher risk (95% CI, 0%-18%) of cancer than women reporting very regular cycles in the same age range. This association was limited to obesity-related cancers, with a 22% (95% CI, 9%-36%) higher risk, while no relation was found with non-obesity-related cancers (HR, 0.94; 95% CI, 0.83-1.07). Similarly, cycles longer than 40 days were associated with increased risk of total cancer and obesity-related cancer compared to a usual cycle length of 26-31 days [HRs=1.19 (95% CI, 1.07-1.32) and 1.30 (95% CI, 1.12-1.51), respectively]. These associations were not modified by BMI, clinical signs of excess androgens, smoking status, or family history of cancer.

CONCLUSIONS: Women with irregular or long menstrual cycles in adolescence and adulthood have a significantly higher risk of developing cancer, especially obesity-related cancers, independent of obesity. Our findings suggest that obesity-related cancers may need to be added to the spectrum of long-term health consequences of long/irregular cycles, possibly warranting targeted screening among women who experience long or irregular cycles in mid-adulthood.

LOWER SERUM FSH LEVELS IN RESPONSE TO IV RECOMBINANT FSH IN OBESE WOMEN IS NOT EXPLAINED BY GNRH ANTAGONIST (CETRORELIX) PHARMACODYNAMICS.

Katherine Kuhn, MS,[1] Thanh Ha Luu, MD,[1] Andrew P. Bradford, PhD,[1] Luke Wittenburg, DVM, PhD, DACVCP,[2] Nne-Omoji Nwobodo, PharmD,[3] Michael F. Wempe, PhD,[4] Alex J. Polotsky, M.D., M.S.[5] [1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]University of California-Davis School of Veterinary Medicine, Davis, CA; [3]University of Colorado Hospital, Aurora, CO; [4]University of Colorado, Aurora, CO; [5]University of Colorado, Denver, CO.

OBJECTIVE: ART employs GnRH suppression and FSH stimulation to induce follicular development. Obese women are known to require higher FSH doses during ART as compared to normal weight (NW) women. It remains unclear whether this higher exogenous FSH requirement for ART is related to abnormal hypothalamic-pituitary dynamics, abnormal ovarian environment or GnRH antagonist or FSH pharmacodynamics/ pharmacokinetics.

DESIGN: We have developed a model to examine IV recombinant (r)FSH levels after GnRH antagonist (cetrorelix) suppression due to the fact there is a need for higher FSH levels in obese women undergoing ART remains unexplained.

MATERIALS AND METHODS: 23 NW and 17 obese women, with regular menstrual cycles, underwent early follicular phase frequent blood sampling (q10min) for 10hrs. At 10hrs cetrorelix acetate (3 mg) was given followed by a secondary dose (0.25mg) 6hrs later. At this time, hourly IV rFSH (30IU) was initiated and frequent blood sampling continued for 10hrs. LH and FSH were measured by immunoassay (Centaur XP, Siemens). Baseline adjusted serum FSH values were used in non-compartmental analysis (WinNonlin) to assess clearance (CLss), steady state volume of distribution (Vss) and total FSH exposure. Pharmacokinetics were compared by two-tailed, unpaired t test. Cetrorelix was measured by tandem gas chromatography and mass spectrometry.

RESULTS: Baseline FSH levels were significantly lower in obese compared to NW subjects. Cetrorelix suppressed FSH by 30% in both groups. Serum cetrorelix concentrations trended lower in obese subjects but were not significantly different (see Table). Despite equivalent IV dosing and correction for baseline levels, the rate of FSH accumulation in serum and total overall FSH exposure concentration was significantly lower in obese women ($p=0.01$, for both). No differences in clearance or volume of distribution were observed.

CONCLUSIONS: FSH pharmacokinetics and Cetrorelix concentrations and efficacy were similar, implying that another factor or pharmacodynamic effect underlies the disparate endogenous post-suppression FSH profiles. This model of pulsatile, IV rFSH reveals a novel and clinically relevant, difference in pharmacodynamics between NW and obese women, which has not been previously observed. Repeated IV boluses of rFSH, after GnRH blockade, mimics endogenous FSH secretion but yields significantly lower serum FSH levels in women with obesity.

Cetrorelix Levels	Minimum (ng/mL)	Maximum (ng/mL)	Area Under the Curve (ng*min/mL)
Normal Weight	3.2	8.0	2655.9
Obese	1.75	4.75	924.4
p Value	0.3	0.27	0.26

THE PHARMACOKINETICS OF FOLLICLE STIMULATING HORMONE IN WOMEN WITH POLYCYSTIC OVARY SYNDROME AND MATCHED CONTROLS ACROSS A WIDE BMI SPECTRUM. Malinda S. Lee, MD, MBA,[1] Andrea Lanes, PhD,[1] Andrey V. Dolinko, MD,[2] Alexandra Bailin, MD,[3] Elizabeth S. Ginsburg, MD.[1] [1]Brigham and Women's Hospital Boston, MA; [2]Women and Infants Hospital and Warren Alpert Medical School of Brown University, Providence, RI; [3]Children's Hospital Los Angeles, Los Angeles, CA.

OBJECTIVE: Women with polycystic ovary syndrome (PCO) have an increased ovarian responsiveness to exogenous recombinant follicle stimulating hormone (rFSH); it is unknown how obesity may affect FSH absorption and response in the context of PCO. The objective of this study was to compare pharmacokinetic and pharmacodynamic responses to rFSH between lean and overweight/obese PCO subjects and age and BMI-matched normo-ovulatory controls.

DESIGN: Prospective pilot study conducted in the clinical research center of an academic hospital.

MATERIALS AND METHODS: Fourteen women with PCO by Rotterdam criteria aged 18-42y with BMI of 18.5-24.9 kg/m^2 (normal) or 25.0-40.0 kg/m^2 (overweight/obese) and eleven normo-ovulatory controls matched by age (+/- 3y) and BMI (+/- 2.5 kg/m^2) were included. After an initial hormone washout period of at least one month, participants were initiated on combined oral contraceptive pills (COCPs) for 2-3 weeks. Following a withdrawal from COCPs, participants were administered a single subcutaneous injection of 225IU rFSH and underwent serial blood draws over the next 72 hours. The main outcome measures were the changes in serum FSH and estradiol following rFSH injection.

RESULTS: Lean women exhibited significantly higher peak serum concentration of change in FSH from baseline (Cmax) when compared to overweight/obese women (p=0.01). Lean PCO subjects exhibited a significantly higher area under the curve (AUC) of change in FSH when compared to overweight/obese PCO subjects (183.3 vs 139.8 IU*h/L, p=0.0002), and lean, normo-ovulatory women had a significantly higher AUC of change in FSH when compared to overweight/obese, normo-ovulatory women (193.3 vs 93.8 IU*h/L, p<0.0001). Lean PCO subjects similarly had the highest AUC of change in estradiol (6,095 pg*h/mL), compared to lean normo-ovulatory subjects (1,931 pg*h/mL, p<0.0001) and overweight/obese PCO subjects (2,337 pg*h/mL, p<0.0001).

CONCLUSIONS: As previous studies similarly have shown, FSH absorption and maximum circulating concentrations are mediated by BMI, with overweight/obese women having significantly lower Cmax FSH than women with a normal BMI. In our study, which was able to compare the pharmacokinetics and pharmacokdynamics of FSH between ovulatory and PCO subjects across a wide BMI spectrum, overweight/obese PCO subjects exhibited significantly higher FSH and estradiol levels following rFSH injection when compared to matched normo-ovulatory controls, but significantly lower responses when compared to lean PCO subjects. These findings suggest that PCO itself, in addition to BMI, also appears to mediate FSH absorption and metabolism.

LETROZOLE "STAIR-STEP" PROTOCOL VERSUS TRADITIONAL PROTOCOL IN PATIENTS WITH POLYCYSTIC OVARY SYNDROME. Anna Claire Reynolds, M.D.,[1] Heather R. Burks, MD,[1] Sarah Z. Gavrizi, MD,[2] Katherine Boecking, B.S.[1] [1]University of Oklahoma Health Sciences Center, Department of Obstetrics and Gynecology, Oklahoma City, OK; [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK.

OBJECTIVE: Polycystic ovarian syndrome (PCOS) is the most common cause of anovulatory infertility. Prior studies have shown that increasing clomiphene citrate dosing in a "stair-step" fashion shortens time to ovulation. Although it is an off-label use, patients with PCOS have improved fertility outcomes with letrozole as compared with clomiphene citrate for ovulation induction[1]. Stair-step dosing increase using letrozole is common in clinical practice but not well studied[2].

Primary: To evaluate time to ovulation using a letrozole stair-step protocol versus traditional protocol in patients with anovulation secondary to PCOS. *Secondary*: To evaluate time to pregnancy using a letrozole stair-step protocol versus traditional protocol in patients with anovulation secondary to PCOS.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Patients with anovulation and previously diagnosed PCOS by Rotterdam criteria who underwent ovulation induction with letrozole were included from both the Reproductive Medicine Network (RMN) database of patients in the PPCOSII study and our academic REI clinic. Patients were separated into two groups: traditional (progestin-induced withdrawal bleed between cycles if no ovulation with initial letrozole dose) and stair-step (no withdrawal bleed). Interval between the first day of letrozole administration and the date of ovulation was measured and compared in both groups. For patients who conceived, the time from initiating letrozole treatment to positive pregnancy test was also measured and compared.

Patient demographic data and the time to ovulation were evaluated using Student's t-test. Chi-squared test was used to compare the rate of ovulation and pregnancy between groups.

RESULTS: 143 patients were included in this study: 35 patients in the traditional protocol group and 108 in the stair-step protocol group. There were no significant differences in patient demographics or pregnancy rates. A significant difference in time to ovulation was noted, see table below.

	Traditional Protocol n = 35	Stair-step Protocol n=108	p-value
Ovulation (Y/N)	85.7% yes (n=30) 14.3% no (n=5)	83.3% yes (n=90) 16.7% no (n=18)	0.74
Time to ovulation (days)	**75.2**	**37.2**	**< 0.01**
Clinical pregnancy (Y/N)	34.3% yes (n=13) 65.7% no (n=22)	30.6% yes (n=33) 69.4% no (n=75)	0.47
Time to pregnancy (days)	111.4	87.3	0.15

CONCLUSIONS: To expedite ovulation in PCOS patients, with the goal of expediting pregnancy, letrozole is often prescribed in a stair-step fashion. Our findings suggest there is decreased time to ovulation with a letrozole stair-step protocol, of 38 days on average, with similar pregnancy rates. In conclusion, the dose of letrozole may be increased as soon as nonresponse is noted, and menses is not required between cycles in PCOS patients.

HIGH LIVE BIRTH RATES WITH LOW MULTIPLE BIRTH RATES: OVER TWO DECADES' EXPERIENCE OF PULSATILE GNRH PUMP USE FOR OVULATION INDUCTION IN PATIENTS WITH FUNCTIONAL HYPOTHALAMIC AMENORRHEA (FHA). Philipp Quaas, MD,[1] Alexander M. Quaas, MD, PhD,[2] Manuel Fischer, PhD,[1] Christian De Geyter, MD.[1] [1]University Hospital Basel Basel, Switzerland; [2]University of California San Diego, San Diego, CA.

OBJECTIVE: To analyze the experience of treating patients with FHA (functional hypothalamic amenorrhea) over the last 25 years using a subcutaneous pulsatile gonadotropin releasing hormone (GnRH) pump at a Swiss university-based tertiary referral center.

DESIGN: Retrospective cohort study of all patients with FHA undergoing ovulation induction using the GnRH pump between 1996 and 2020.

MATERIALS AND METHODS: Inclusion criteria for the study were a diagnosis of FHA and treatment using a subcutaneous pump delivering pulsatile gonadorelin acetate during the study period. Baseline characteristics including age, BMI, smoking status, AMH, AFC, endocrine profiles, and

lifestyle parameters including exercise were recorded. The primary outcome was live birth rate (LBR) per treatment. Secondary outcomes included the number of dominant follicles per cycle and ovulation rate per cycle attempt (data available for 2014-2020), biochemical pregnancy rate (BPR), clinical pregnancy rate (CPR), miscarriage rates and multiple pregnancy rates.

RESULTS: During the study period, 66 patients with FHA underwent a total of 82 separate treatment episodes involving 208 ovulation induction attempts using the pulsatile GnRH pump. Baseline characteristics of the study population included a mean age of 31.6 years, mean BMI of 20.2 kg/m^2, and a mean serum AMH concentration of 35.2 pmol/l, equivalent to 4.93 ng/ml. The ovulation rate per cycle attempt was 96% and monofollicular ovulation (one follicle of $\geq$14 mm size at time of ovulation) was observed in 67% of cycle attempts. In patients who conceived, the median number of cycles necessary to achieve a clinical pregnancy was 2. The cumulative CPR per treatment episode was 62/82 (76%) and the overall LBR per treatment was 50/82 (61%)*. The miscarriage rate was 7/62 (11%). There was one dizygotic twin pregnancy (multiple pregnancy rate 1/62 = 1.6%). The mean infant birth weight in the cohort was 3249 g. No significant adverse effects were reported by any of the patients in the study.

CONCLUSIONS: In patients with FHA, monofollicular ovulation can be achieved in the majority of patients using the subcutaneous pulsatile GnRH pump. The high observed cumulative live birth rates, with multiple pregnancy rates comparable to those in the general population suggest that the pulsatile GnRH pump represents a safer, more physiologic alternative to ovulation induction using injectable gonadotropins.

TABLE. Treatment outcomes in the study population

Clinical parameter	Outcome (n / %)
Monofollicular ovulation	31/46 (67%)
BPR per cycle	67/208 (32%)
CPR per cycle	62/208 (30%)
LBR per cycle	50/208 (24%)*
LBR per treatment episode	50/82 (61%)*
miscarriage rate	7/62 (11%)
Multiple pregnancy rate	1/62 (1.6 %)

*5 pregnancies ongoing at time of submission.

POSITIVE EFFECTS OF THYROID REPLACEMENT THERAPY ON ART OUTCOMES IN WOMEN WITH SUBCLINICAL HYPOTHYROIDISM WITH TPO^{+VE} ANTIBODIES.

Maria Bustillo, M.D,[1] Ineabelle Collazo, BS,[2] Katherine L. Palmerola, BS, MD,[2] Sabrina A. Gerkowicz, MD,[2] Juergen Eisermann, M.D,[1] Nicholas Hendon, BS,[2] Himanshu Arora, PhD.[3] [1]IVFMD South Florida Institute for Reproductive Medicine, MIAMI, FL; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [3]University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: Thyroid function is critical to optimal reproductive function in women; and thyroid disease may exert negative effects on ovulation, menstrual function, and pregnancy success. Thyroid-stimulating hormone (TSH) is the primary marker for thyroid function, stimulates the release of thyroxine (T4) and tri-iodothyronine (T3) from the thyroid gland, exerting the metabolic effects of the thyroid gland throughout the body. Serum TSH levels and antithyroid antibodies are routinely screened in women with infertility. In a previous study, we have shown that thyroid replacement therapy (TRT) has significant effect on pregnancy outcomes in women with subclinical hypothyroidism (TSH levels > 2.5 uIU/mL and </= 4.2 uIU/mL; SCH). Whether antithyroid antibodies on thyroid replacement therapy in women with SCH remains largely unexplored. In the current study we evaluated whether TRT can overcome the adverse effects of antithyroid antibodies on pregnancy outcome in women with SCH.

DESIGN: Retrospective study of 707 patients undergoing IVF.

MATERIALS AND METHODS: Patients were categorized into 3 groups. Group 1, euthyroid, consisted of women who had pre-IVF TSH levels <2.5 uIU/mL. Patients with SCH were divided into two groups (Group 2 and 3) based on whether or not they were given low dose thyroid supplementation (treatment): group 2 included women with SCH who were not treated, and group 3 included women with SCH who were treated. Additionally, all three groups were classified into two subgroups based on thyroid peroxidase (TPO) antibody levels: TPO negative (<11ng/ml) or TPO positive (>11ng/ml). All women underwent standard IVF protocols following usual individualized practice in our practice. IVF outcomes were compared between the three groups using three-way ANOVA. GraphPad Prism (GraphPad Software) was used for statistical analysis, with $p<0.05$ considered statistically significant.

RESULTS: A total of 707 patients were included in the analysis. Group 1 (euthyroid) included 526 women: 454 patients were TPO negative (359 pregnant (P), 95 not pregnant (NP)) and 72 patients were TPO positive (54 P, 18 NP). Group 2 included 50 women: 42 patients were TPO negative (28 P, 14 NP) and 8 patients were TPO positive (3 P, 5 NP). Group 3 included 131 women: 87 patients were TPO negative (64 P, 23 NP) and 44 patients were TPO positive (37 P, 7 NP). Three-way ANOVA analyses demonstrated that women with SCH and TPO positive had significantly fewer pregnancies compared to women with SCH who were TPO negative ($p<0.001$). However, thyroid replacement therapy significantly improved the pregnancy outcomes in patients with SCH that are TPO positive ($p<0.0001$). Importantly, the difference between pregnancy outcomes between patients in Group 1 versus Group 3 is non-significant ($p>0.05$).

CONCLUSIONS: Our findings suggest that thyroid replacement therapy has significant positive effects on ART outcomes in SCH women with positive TPO antibodies. Further in-depth studies are ongoing considering parameters such as the AMH, patient's BMI etc and additional specific treatment strategies which may have an additional effect on successful IVF outcomes.

CONTRACEPTION AND COMPLEX FAMILY PLANNING

O-25 9:55 AM Saturday, October 17, 2020

POLIDOCANOL/DOXYCYCLINE FOAM FOR NONSURGICAL PERMANENT FEMALE CONTRACEPTION BABOON CONTRACEPTION STUDY: 18 MONTH DATA.

Jeffrey T. Jensen, MD, MPH,[1] Carol B. Hanna, Ph.D.,[2] Shan Yao, M.D.,[3] Philberta Y. Leung, Ph.D.,[3] Nicholas M. Kiulia, MS,[4] Ov D. Slayden, PhD.[5] [1]Oregon Health & Science University Portland, OR; [2]Oregon National Primate Research Center, Beaverton, OR; [3]Oregon National Primate Research Center, BEAVERTON, OR; [4]Department of Reproductive Health and Biology, Institute of Primate Research, Nairobi, Kenya; [5]Professor, Beaverton, OR.

OBJECTIVE: The addition of doxycycline to polidocanol foam increases the rate of tubal occlusion. We sought to determine if a single transcervical administration of polidocanol/doxycycline foam (PDF) would prevent pregnancy in female baboons and assess safety of treatment.

DESIGN: Controlled nonhuman primate cohort study.

MATERIALS AND METHODS: Healthy regularly cycling female baboons underwent laparoscopy with chromopertubation for evaluation of tubal patency and pelvic adhesions followed by transcervical infusion of either 20 mL of 5% PDF (each 5 mL of foam contains 25 mg doxycycline; n=12, 8 nulliparous, 4 parous), 20 mL of 1% control methylcellulose foam (MC; n = 6, 5 nulliparous, 1 parous), or no additional treatment (Control; n=6, all nulliparous). All of the females received an intramuscular injection of depomedroxyprogesterone acetate (DMPA, 2 mg/kg) after the treatment. After recovery, females were socially-housed with males of proven fertility, and observed for resumption of menstrual cyclicity and evidence of mating. The primary outcomes was pregnancy through 18 months of follow-up. Secondary outcomes included histologic evaluation of the fallopian tube, and peritoneal adhesions assessed at necropsy (PDF group only).

RESULTS: All females resumed normal menstrual cycles and mating activity within 3 months of treatment. After 15 months of regular cycles, 11/12

(92%) of control females became pregnant (6/6 MC control, 5/6 untreated control). Significantly fewer (2/12, 16%) pregnancies occurred in PDF-treated females ($p < .001$, Fisher's exact test). All of the pregnancies were intrauterine. Both pregnancies in PDF-treated females occurred in nulliparous females considered high-risk for failure; one progressed normally to term and one underwent spontaneous abortion. Histologic evidence of bilateral tubal occlusion (de-epithelialization, collagen obliteration of lumen) developed in all of the PDF-treated females except for the two that became pregnant (each with unilateral occlusion). New pelvic adhesions developed in 11/12 of the PDF-treated females; of these 4/11 (36%) were dense. In contrast, we found no new adhesions in a subset of control females (n=3) evaluated at necropsy.

CONCLUSIONS: A single transcervical treatment with PDF prevented pregnancy in most baboons, and resulted in histologic tubal occlusion that appears permanent at 18 months. The new onset of pelvic adhesions appears related to the addition of doxycycline, as these occurred uncommonly in a prior baboon contraception study with polidocanol foam alone [Contraception. 2016;94(5):527-33].

BLEEDING PATTERNS FROM MONTHS 60 TO 72 WITH USE OF A LEVONORGESTREL 52 MG INTRAUTERINE SYSTEM. Jeffrey T. Jensen, MD, MPH,[1] Bruce R. Carr, MD,[2] Thomas D. Kimble, MD,[3] Michael A. Thomas, MD,[4] Andrea I. Olariu, MD, PhD,[5] Mitchell D. Creinin, MD.[6] [1]Oregon Health & Science University Portland, OR; [2]UT Southwestern Medical Center, Dallas, TX; [3]Eastern Virginia Medical School, Norfolk, VA; [4]University of Cincinnati, Cincinnati, OH; [5]Medicines360, San Francisco, CA; [6]University of California, Davis, Sacramento, CA.

OBJECTIVE: Evaluate bleeding patterns during levonorgestrel (LNG) 52 mg intrauterine system (IUS) use beyond 5 years.

DESIGN: Prospective clinical trial.

MATERIALS AND METHODS: Nulliparous and parous women 16-45 years old received the Liletta® LNG 52 mg IUS in an IRB-approved multicenter trial to evaluate efficacy and safety for up to 10 years. Bleeding assessments after 24 months of IUS use occurred every 3 months, including subjective flow evaluation and how the bleeding compared to pre-insertion frequency or flow. For this analysis, we evaluated reported bleeding patterns (none, "just spotting," irregular or regular), comparison of frequency or flow to baseline, and discontinuation for bleeding complaints over 3-month intervals beginning at 60 months (5 years) and then for the following year (months 63 to 72). We performed chi-square test for trend to evaluate changes in patterns over time.

RESULTS: The dataset included 707, 645, 563, 477 and 349 women with bleeding pattern reports for months 58-60, 61-63, 64-66, 67-69, and 70-72 at the time of the data cut. The heaviest flow in the prior 3 months is reported in the Table. Amenorrhea rates remained around 40%, ranging from 39.1-43.2% (p=0.75). Most women reported their heaviest flow as none (amenorrhea) or spotting during each interval (69.8-72.6%, p=0.30). Approximately 90% of women (87.2-90.4%, p=0.58) reported their heaviest bleeding as none (amenorrhea), spotting, or light bleeding per interval. Among women with any bleeding, most reported spotting as the main pattern, ranging from 29.8-35.3% (p=0.41); the remainder reported the main pattern as irregular (6.4-7.7%, p=0.84) or regular (16.6-19.5%, p=0.52) during each interval. Approximately 1-1.5% of users reported frequency or flow worse than pre-insertion patterns and only 1 woman during months 58-60 and 1 during months 70-72 discontinued for a bleeding complaint considered an adverse event. Additionally, beginning after month 60, 1-2 persons per 3-month period discontinued because of reduced menstrual suppression.

CONCLUSIONS: Bleeding patterns remain consistent in LNG 52 mg IUS users from months 60 through 72 of use, with most women experiencing amenorrhea, spotting or light bleeding. Discontinuation for a bleeding complaint occurred in only 2/707 (0.3%) women during this period, and another 6 (0.9%) discontinued for reduced menstrual suppression. Providers and patients can be informed by this data that bleeding patterns remain favorable with use beyond 5 years.

	Heaviest flow in prior 3 months

COMPARING THE CARDIOVASCULAR RISK OF NORETHINDRONE ACETATE- AND LEVONORGESTREL-CONTAINING ORAL CONTRACEPTIVES: IS THERE A DIFFERENCE? Clare Barnett, MBBS (Hons), MPH, Sophia von Stockum, PhD, Anja Bauerfeind, PhD, Klaas Heinemann, MD, PhD, MBA. ZEG Berlin GmbH Berlin, Germany.

OBJECTIVE: Norethisterone acetate (NETA) and levonorgestrel (LNG) were two of the first progestins to be introduced for medical use. From a research perspective, LNG is the first-choice progestin and it is accepted by regulators as the gold-standard since it has been shown to not increase the thromboembolic risks derived from the estrogen component. Combined oral contraceptives containing norethindrone acetate (NETA) are widely used in the US, and globally, and are recommended as first-line therapy alongside LNG-containing pills. No robust data is currently available directly comparing the cardiovascular risk profiles of LNG and NET/NETA.

DESIGN: A pooled analysis to directly compare the safety of NETA and LNG in pills containing ethinyl estradiol (EE) $\leq$30 mcg.

MATERIALS AND METHODS: We pooled cohorts of NETA (EE $\leq$30 mcg) and LNG (EE $\leq$30 mcg) users from four large prospective, controlled, non-interventional, cohort studies in 14 European countries, US and Canada. Baseline characteristics, including reproductive, contraceptive and medical history, were summarized using descriptive statistics. Propensity score sub-classification was applied to balance baseline characteristics between cohorts. Time-to-event analysis of venous and arterial thromboembolic events was carried out based on the extended Cox model to calculate crude and adjusted hazard ratios with 95% confidence intervals.

RESULTS: Overall, 235,437 study participants who were followed up for a total of 571,163 WY of exposure were included in the pooled dataset. Among these, 40,142 women were users of NET/NETA (EE$\leq$30μg) and 39,098 women were users of LNG (EE$\leq$30μg), contributing 61,976 and 84,816 WY of observation, respectively. The prevalence of prognostic factors at baseline showed typical characteristics of US and European COC user populations regarding age structure, socioeconomic and life-style factors and cardiovascular risk factor. In total, 43 validated VTE events in 61,976 WY occurred in the NET/NETA (EE$\leq$30μg) user cohort, and 75 VTE events during an observation time of 84,816 WY in the LNG (EE$\leq$30μg) user cohort. Study participants taking NET/NETA (EE$\leq$30μg) had a similar risk of encountering a VTE (IR: 6.9; 95% CI, 5.0-9.3 per 10,000 WY) to study participants taking LNG (EE$\leq$30μg) (IR: 8.8; 95% CI, 7.0-11.1 per 10,000 WY). A time-to-event analysis of the VTE data was carried out based on the extended Cox model. Validity of the model was demonstrated by the standardized differences summarized over strata as weighted average yielded upon PS sub-classification, which were consistently <0.25 and mostly <0.1. A comparison between NETA vs LNG showed no significant difference in the risk of venous thromboembolism: adjusted hazard ratio 0.73 (95% CI 0.48-1.11). A similar result was observed considering the risk of arterial thromboembolism (adjusted hazard ratio 0.89 [95% CI 0.42-1.89]).

CONCLUSIONS: Low-dose oral contraceptives containing NETA and LNG are associated with similar low risks of venous and arterial disease. This analysis provides reassurance for both women and clinicians regarding the safety of contemporary oral contraceptives.

SUPPORT: Analysis of pooled dataset was supported by a grant from Myovant Sciences. Dataset is owned by ZEG Berlin GmbH.

DURATION OF CONTRACEPTIVE USE IS NOT ASSOCIATED WITH AMH LEVELS. Sharon Briggs, PhD, Talia Shirazi, MA, Avner Hershlag, MD. Modern Fertility San Francisco, CA.

OBJECTIVE: To estimate the effect of length of contraceptive use on anti-Mullerian hormone (AMH) levels in reproductive-age women.

DESIGN: Prospective analysis of serum AMH levels and survey data.

MATERIALS AND METHODS: The study included a subset of customers who used an at-home fertility hormone test between June 2018 and April 2020 ($n = 2,358$). Participants were between 21 and 46, consented to research, had not reported a previous diagnosis of polycystic ovary syndrome or primary ovarian insufficiency, and were currently using either the levonorgestrel IUD (LNG-IUD), implant, combined oral contraceptive (COC), or vaginal ring. The duration of contraceptive use was self-reported and ranged from 1-3 months up to more than 20 years.

We performed three linear regressions per contraceptive method to evaluate the relationship between the length of contraceptive use and log-transformed AMH levels. Since three regressions were run per contraceptive group, the threshold for statistical significance ($\alpha = 0.05$) was set to 0.017 to adjust for multiple comparisons. We subsequently grouped short-term use and long-term use participants into binary categories or bins and compared mean AMH levels for each contraceptive use group.

RESULTS: Our cohort included 807 women using the LNG-IUD, 112 using the implant, 1,109 using a COC, and 165 using the vaginal ring. There were no statistically significant associations between length of contraceptive use and adjusted AMH levels for any contraceptive method. This was true in regressions of the entire sample and when we limited the sample to just short-term users or just long-term users.

When the length of contraceptive use was treated as a binary variable (short-term <1 year or long-term 1+ years) or was grouped into categories spanning approximately 5 years, no statistically significant effects were observed for any contraceptive method.

CONCLUSIONS: It is known that AMH levels are lower in women using hormonal contraceptives when compared to women who aren't. However, this study shows that the duration of contraceptive use is not associated with any additional variation in AMH levels. We observe no impact of either long or short term usage on AMH levels for any of the contraceptive methods included in this study. These results are reassuring since it is still widely believed among physicians and patients alike that long term contraceptive use suppresses ovarian reserve more than short term use, particularly in users of COC.

Women are increasingly seeking testing of their ovarian reserve while remaining on contraceptives to prevent pregnancy. Reasons for getting tested for AMH while on contraceptives are varied and include seeking proactive hormone assessments, getting information about time to menopause, egg freezing, or donating eggs. Having to stop contraception to test ovarian reserve may be unwanted or inconvenient. By better understanding the effects of contraceptives on AMH, women will have more options when pursuing this testing, and physicians will be better equipped to interpret the results.

MENORRHAGIA AND RISK OF INTRAUTERINE DEVICE (IUD) EXPULSION AND UTERINE PERFORATION: RESULTS FROM THE APEX IUD STUDY. Susan D. Reed, MD, MPH, MS,[1] Catherine W. Saltus, MPH, MA,[2] Darios Getahun, MD, MPH, PhD,[3] Juliane Schoendorf, MD,[4] Mary Anne Armstrong, MA,[5] Jeffrey F. Peipert, MD, PhD,[6] Tina R. Raine-Bennett, MD, MPH,[5] Mary E. Ritchey, PhD,[7] Laura E. Ichikawa, MS,[8] Xiaolei Zhou, PhD,[9] Michael J. Fassett, MD,[10] Amy Alabaster, MPH, MS,[5] Fagen Xie, PhD,[3] Maqdooda Merchant, MSc, MA,[5] Vicki Y. Chiu, MS,[3] Jiaxiao M. Shi, PhD,[3] Ann-Kathrin Frenz, MSc,[11] Theresa M. Im, MPH,[3] Harpreet S. Takhar, MPH,[3] Richard Lynen, MD,[12] Alex Asiimwe, PhD,[13] Mary S. Anthony, PhD.[9] [1]University of Washington Seattle Seattle, WA; [2]RTI Health Solutions, Waltham, MA; [3]Kaiser Permanente Southern California, Pasadena, CA; [4]Bayer OY, Espoo, Finland; [5]Kaiser Permanente Northern California, Oakland, CA; [6]Indiana University, Indianapolis, IN; [7]Med Tech Epi, LLC, Philadelphia, PA; [8]Kaiser Permanente Washington, Seattle, WA; [9]RTI Health Solutions, Research Triangle Park, NC; [10]Kaiser Permanente Southern California, Los Angeles, CA; [11]Bayer AG, Wuppertal, Germany; [12]None, Richboro, PA; [13]Bayer AG, Berlin, Germany.

OBJECTIVE: IUDs are an effective form of contraception, and the most common levonorgestrel (LNG) IUD has an FDA indication for heavy menstrual bleeding. We assessed the risk of IUD expulsion and uterine perforation in women with and without a recent diagnosis of menorrhagia.

DESIGN: APEX IUD was a retrospective cohort study that used electronic health records from three Kaiser Permanente sites (Northern California, Southern California, Washington) and Regenstrief Institute (Indiana).

MATERIALS AND METHODS: This study included 228,834 women aged ≤50 years with an IUD inserted from 2001–2018 without a delivery in the prior 52 weeks (including nulliparous women). Diagnosis of menorrhagia was identified via ICD code within 12 months before IUD insertion. Expulsion included complete and partial (IUD in cervical canal). Perforation was defined as complete (in pelvis or abdomen) or partial (embedded in myometrium). Crude incidence rates, hazard ratios adjusted for confounding with propensity scores via Cox regression, and 95% confidence intervals (CI) were estimated.

RESULTS: Expulsions occurred more often among women with a menorrhagia diagnosis. Among 31,600 women with menorrhagia, 2% of IUD insertions were copper; and among 197,234 women without menorrhagia, 20% were copper. The expulsion rate among those without menorrhagia was lower for those with LNG versus copper IUDs. For those with menorrhagia, expulsion was lower in the few with copper IUDs. Perforation rates were higher among women with menorrhagia but low in all groups. After adjusting for confounding, women with menorrhagia had a 2.84-fold increased risk of expulsion and a 1.53-fold increased risk of perforation over women without.

	Person-Years	# Events	Incidence, Per 1,000 Person-Years (95% CI)	Adjusted Hazard Ratio (95% CI)
IUD Expulsion				
Menorrhagia	**62,405**	**2,497**	**40.0 (38.5, 41.6)**	**2.84 (2.66, 3.03)**
LNG	60,053	2,450	40.8 (39.2, 42.5)	–
Copper	1,505	32	21.3 (14.5, 30.0)	–
No menorrhagia	**390,598**	**4,265**	**10.9 (10.6, 11.3)**	**Ref**
LNG	306,268	3,031	9.9 (9.6, 10.3)	–
Copper	79,930	1,197	15.0 (14.1, 15.9)	–
Uterine Perforation				
Menorrhagia	**62,405**	**61**	**0.98 (0.75, 1.26)**	**1.53 (1.10, 2.13)**
LNG	60,053	58	0.97 (0.73, 1.25)	–
Copper	1,505	2	1.33 (0.16, 4.80)	–
No menorrhagia	**390,598**	**248**	**0.63 (0.56, 0.72)**	**Ref**
LNG	306,268	185	0.60 (0.52, 0.70)	–
Copper	79,930	59	0.74 (0.56, 0.95)	–

CONCLUSIONS: Increased rates of expulsion and perforation with menorrhagia may be due to physiological differences related to menorrhagia including adenomyosis and uterine fibroids. Providers should be aware of these risks for patient counseling and exercise caution at the time of insertion. We recommend informing women regarding the higher risk of IUD expulsion and the importance of recognizing expulsion in prevention of unwanted pregnancy.

SEXUAL SATISFACTION WITH A VAGINAL PH REGULATOR (EVO100): RESULTS FROM THE AMPREVENCE CLINICAL TRIAL. Michael A. Thomas, MD,[1] Kelly R. Culwell, MD, MPH,[2] Scott G. Mollan, MS, MBA,[3] Brandon Howard, PhD.[2] [1]University of Cincinnati Cincinnati, OH; [2]Evofem Biosciences, Inc., San Diego, CA; [3]ICON Clinical Research LLC, Durham, NC.

OBJECTIVE: EVO100 is an investigational antimicrobial vaginal pH regulator that is a non-hormonal, woman-controlled, water-based vaginal gel for prevention of sexually transmitted infection. To better understand the effects of use on sexual satisfaction and function, questionnaires were administered to women receiving EVO100 in the phase 2B/3 AMPREVENCE trial (NCT03107377) at each study visit.

DESIGN: AMPREVENCE was a randomized, multicenter, US-based, double-blinded, placebo-controlled trial conducted over 16 weeks in women aged 18–45 years who had been treated for chlamydia or gonorrhea $\leq$16 weeks before enrollment. Women were randomized to receive EVO100 or placebo vaginal gel. Primary and secondary efficacy endpoints were prevention of urogenital chlamydia and gonorrhea, respectively. Women's sexual satisfaction and function with EVO100 was an exploratory endpoint.

MATERIALS AND METHODS: To assess sexual satisfaction/function, questionnaires were administered at enrollment and at Visit 5. Women reported how EVO100 use impacted their sex life since their last study visit and provided responses on the Sexual Function Questionnaire (SFQ) and for item 10 on the Female Sexual Function Index (FSFI). All results were summarized using frequency and percentage.

RESULTS: AMPREVENCE enrolled 860 women randomized 1:1 to EVO100 (n=426) or placebo (n=434). At Visit 5, most of the women receiving EVO100 (51%, 140/273) reported a positive impact on their sex life or "no difference" (45%, 124/273) since their last study visit. With EVO100, more women reported no difficulty maintaining lubrication until completion of intercourse (74%, 203/274) at Visit 5 compared with baseline (68%, 239/350). Most women receiving EVO100 surveyed at Visit 5 reported improvements in various sexual function measures compared with baseline and reported no vaginal dryness during sexual activity (67% [181/272] vs 53% [184/349]); no pain during intercourse (71% [192/272] vs 58% [204/350]); no vaginal tightness (49% [133/272] vs 37% [131/350]); and ability to orgasm in the past month (67% [181/272] vs 57% [200/350]). Overall, 91 of 426 women randomized to EVO100 discontinued the study early; of these, 25 provided responses to the sexual impact question and to FSFI, and 24 provided responses to the SFQ. Of women who terminated the study early and reported an impact of EVO100 on their sex life, 44% (11/25) and 48% (12/25) reported a positive impact or no difference in their sex life, respectively, since their last study visit. Women who terminated the study early also described improvements in sexual function measures and reported no vaginal dryness during sexual activity (79%, 19/24); no pain during intercourse (67%, 16/24); ability to orgasm (63%, 15/24); and no vaginal tightness (42%, 10/24) in the past month.

CONCLUSIONS: In AMPREVENCE, healthy women receiving EVO100 reported positive impact on their sexual satisfaction, maintained lubrication, and reported improvement in many sexual function measures.

FRESH EMBRYO TRANSFER FOLLOWING IN VITRO INSEMINATION OF FRESH VERSUS CRYOPRESERVED ANONYMOUS DONOR OOCYTES- WHICH HAS A BETTER LIVE BIRTH RATE? A SART CORS ANALYSIS.

Rachel M. Whynott, M.D.,[1] Karen M. Summers, MPH CHES,[2] G. David Ball, PhD,[3] Bradley J. Van Voorhis, MD,[2] Amy E. Sparks, PhD.[4] [1]University of Iowa Hospitals and Clinics Iowa City, IA; [2]University of Iowa, Iowa City, IA; [3]Seattle Reproductive Medicine Center, Seattle, WA; [4]University of Iowa Center for Advanced Reproductive Care, Iowa City, IA.

OBJECTIVE: To determine if transfer of fresh embryos derived from fresh anonymous donor oocytes yields a higher live birth rate compared with cryopreserved (cryo) oocytes.

DESIGN: Historical cohort study.

MATERIALS AND METHODS: All anonymous donor oocyte recipient cycles undergoing fresh embryo transfer on day 5 in the United States from 2014-2016 using the SART CORS database were included. Demographics were analyzed using t-test or Chi-square as appropriate. Generalized estimating equations were used for modeling to determine predictors of live birth, using Bayesian Information Criterion (BIC) to select the best model.

RESULTS: 24,663 transfers met inclusion criteria. 16,073 were transfers from fresh embryos created from fresh oocytes, and 8,590 were fresh embryos from cryo oocytes. Age, body mass index (BMI), gravidity, and parity were clinically similar between recipients using fresh oocytes compared with cryo oocytes. Most patients using donor oocytes identified as white non-Hispanic (66.9%), followed by Asian (13.7%), then black non-Hispanic (9.3%), and Hispanic (7.2%). When compared to other races, a larger proportion of black non-Hispanic women used cryo oocytes (37.2%), whereas a smaller proportion of women of Asian descent used cryo oocytes (19.9%) (p< .001). Intended parents using gestational carriers were more likely to use fresh oocytes than those not using gestational carriers (75.5% vs 64.6%, p<0.001). Cryo oocyte cycles were more likely to have only one embryo for transfer (9.5% vs 3.1%), while fresh oocyte cycle were more likely to utilize elective single embryo transfer (42.5% vs 37.8%) and cryo oocyte cycles were more likely to involve transfer of more than 2 embryos (2.2% vs 1.2%)(p<0.001). Fresh oocyte cycles resulted in more surplus embryos available for cryopreservation after completion of fresh embryo transfer (4.55 vs 1.16, p<0.001).

The live birth rate using fresh oocytes was 58.3% versus 49.9% using cryo oocytes (p<0.001). Negative predictors of live birth included utilization of cryo oocytes (OR 0.744, 95% CI 0.674-0.821, p<0.001), black non-Hispanic race (OR 0.597, 95% CI 0.509-0.700, p<0.001), Asian race (OR 0.752, 95% CI 0.653-0.867, p<0.001), and increasing oocyte recipient BMI (OR 0.913, 95% CI 0.876-0.952, p<0.001). Other factors in the model included age, Hispanic ethnicity, multiracial status, number of embryos transferred on day 5, and unexplained infertility diagnosis. For cycles utilizing fresh oocytes, number of live born was 1.28 ± 0.46, versus 1.21 ± 0.42 for cryo oocytes (mean difference 0.07 (CI 0.05-0.09), p<0.001).

CONCLUSIONS: Live birth rate is higher with use of fresh oocytes versus cryo oocytes in fresh embryo transfer cycles in anonymous donor oocyte recipients. Negative predictors of live birth include black non-Hispanic or Asian race, and increasing BMI.

STATE-MANDATED INSURANCE AND PREIMPLANTATION GENETIC TESTING (PGT) INDICATION IN THE UNITED STATES.

Bronwyn S. Bedrick, MD, MSCI,[1] Andrew D. Tipping, MA,[2] Katelin B. Nickel, MPH,[3] Joan Riley, PhD, HCLD,[4] Tarun Jain, MD,[5] Emily S. Jungheim, MD, MSCI.[6] [1]Johns Hopkins University Baltimore, MD; [2]Center for Administrative Data Research, St. Louis, MO; [3]Washington University School of Medicine, St. Louis, MO; [4]Washinton University School of Medicine, St. Louis, MO; [5]Northwestern University, Chicago, IL; [6]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: To assess associations between insurance mandates for fertility care and indications for PGT over time.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Fresh autologous IVF cycles from the 2007-2016 SART registry were analyzed in two time periods due to changes in SART cycle definitions in 2013. Given the introduction of "other" indication for PGT in 2009, we limited our analysis to 2009-2016. Frozen, cancelled, and banking cycles were excluded. Fertility clinics were categorized by level of insurance coverage mandated in their state: comprehensive, partial, and no coverage. Indications for PGT were categorized hierarchically as follows: genetic, balanced translocation, HLA typing, elective sex selection, aneuploidy, and other. Log binominal regression was used to analyze change in indication for PGT over time relative to mandate type.

RESULTS: 99,726 cycles were included. The median age of women utilizing PGT remained fairly constant over time (37 years), and median ages by mandate were comparable. The most common indication for PGT across all years was aneuploidy. For most indications, state mandate impacted the rate of change in indication. No coverage states had a greater decline in proportion of genetic cycles, and there were no statistically significant differences between comprehensive and no coverage states for HLA typing. For both periods, elective sex selection was more commonly used in states with no coverage (p<0.0001). Additionally, the yearly proportion of cycles for elective sex selection decreased significantly over both periods (β = -0.24, SE = 0.01, p<0.0001 and β = -0.18, SE = 0.02, p<0.0001), although the number of elective sex selection cycles increased.

CONCLUSIONS: This is the first study to examine differences in PGT indication by insurance mandate and the first to examine trends over a period longer than two years. Our findings suggest indications for PGT have changed over time and vary by level of insurance coverage for fertility. As

Period	1					2		
Year	2009	2010	2011	2012	2013	2014	2015	2016
Aneuploidy	1331 (36.8)	1480 (38.4)	1537 (35.5)	1522 (34.5)	1657 (33.7)	8297 (51.7)	15183 (59.0)	20029 (54.4)
Elective Sex	833 (23.0)	875 (22.7)	930 (21.5)	625 (14.2)	518 (10.5)	1312 (8.2)	1837 (7.1)	2170 (5.9)
Genetic	861 (23.8)	893 (23.2)	980 (22.6)	1061 (24.1)	938 (19.1)	1576 (9.8)	1804 (7.0)	1844 (5.0)
Translocation	331 (9.2)	325 (8.4)	516 (11.9)	816 (18.5)	1116 (22.7)	2694 (16.8)	2585 (10.0)	3703 (10.1)
HLA Typing	50 (1.4)	54 (1.4)	61 (1.4)	33 (0.7)	18 (0.4)	57 (0.4)	91 (0.4)	110 (0.3)
Other	208 (5.8)	228 (5.9)	307 (7.1)	350 (7.9)	674 (13.7)	2122 (13.2)	4243 (16.5)	8941 (24.3)

Legend: Values are n (% of PGT cycles that year).

PGT utilization increases, it is vital we understand how and why PGT is applied in order to better understand outcomes.

PULSATILE GONADOTROPIN RELEASING HORMONE (GNRH) VIA SUBCUTANEOUS PUMP FOR THE TREATMENT OF PRIMARY AMENORRHEA ASSOCIATED WITH HYPOGONADOTROPIC HYPOGONADISM.

James H. Liu, M.D.,[1] Masakazu Ando, PhD,[2] Patrick W. Heiser, PhD.[2] [1]UH MacDonald Women's Hospital Cleveland, OH; [2]Ferring Pharmaceuticals, Inc, Parsippany, NJ.

OBJECTIVE: To compare the ovulation rate in women with primary amenorrhea, hypogonadotropic hypogonadism (HH) randomized to three GnRH doses (10, 15, 20 μg per pulse) delivered subcutaneous every 90 minutes with the LutrePulse OmniPod Pump versus a placebo control.

DESIGN: Multicenter, double-blind, randomized, placebo-controlled trial.

MATERIALS AND METHODS: Reproductive-aged women with primary amenorrhea, hypogonadotropic hypogonadism and a negative progestin challenge test were randomized to receive one of three GnRH doses or placebo. Baseline serum FSH and LH were $<$5 IU/L. Follicular and endometrial development were monitored by transvaginal ultrasound until a dominant follicle of $\geq$18 mm mean diameter and normal endometrium (thickness and pattern) were confirmed. If a dominant follicle was not observed after 21 days or if menses occurred, treatment was discontinued. Urine luteinizing hormone tests were used to time sexual intercourse. The primary endpoint was ovulation rate, defined as either a serum progesterone $\geq$6 ng/mL, positive β-hCG, or presence of a gestational sac. An adaptive design included interim analyses that allowed for trial continuation, early success, or stop for futility by utilizing pooled 15 and 20 μg efficacy versus placebo as the primary analysis.

RESULTS: Across 24 trial sites, 39 subjects were randomized (N: 10, placebo; 10, 10 μg; 9, 15 μg; 10, 20 μg per pulse) and is one of the largest trials in this rare patient population. Demographics were similar across treatment arms with mean age 30.2 years and BMI 25.9 kg/m^2. Mean treatment duration days were 21.1, 23.8, 34.4, and 32.0 for the placebo, 10, 15, and 20 μg doses, respectively. The pooled ovulation rate with LutrePulse 15 μg and 20 μg was 50.0% compared to 0% with placebo with p-value for the comparison of 0.0120, i.e. below a pre-defined success threshold of 0.0130 allowing for early trial termination for efficacy success at the first interim analysis with 37 subjects (N: 10, placebo; 9, 10 μg; 9, 15 μg; 9, 20 μg). One subject who did not complete 14-day pituitary priming in the 10 μg group was excluded from the efficacy analysis. A significant difference in the number of follicles with mean diameter $\geq$14 mm was seen on treatment day 18 for 15 μg versus placebo (p = 0.0143), and 20 μg versus placebo (p = 0.0060). Biochemical pregnancy was achieved in 8 subjects (3 in the 15 μg group and 5 in the 20 μg group), of these, 7 subjects (2 in the 15 μg group [22.2%] and all 5 in the 20 μg group [50.0%]) achieved a live birth in the final efficacy dataset (N=38). The most frequently reported adverse events were breast tenderness (2 events reported by 2 subjects in the 15 μg group and 2 events reported by 2 subjects in the 20 μg group) and hot flush reported by 3 subjects (2 events reported by 1 subject in the 15 μg group and 2 events reported by 2 subjects in the 20 μg group).

CONCLUSIONS: LutrePulse administered as subcutaneous pulsatile injections with the OmniPod pump in doses of 10 μg, 15 μg, and 20 μg was well-tolerated, the pooled 15 and 20 μg doses were superior to placebo for the primary endpoint, ovulation rate, and the highest live birth rate was observed in subjects treated with the 20 μg dose.

SELF-CORRECTION OF MOSAICISM IN HUMAN SELF-ORGANIZING GASTRULOIDS AS POTENTIAL EXPLANATION FOR NORMAL BIRTHS AFTER TRANSFER OF CHROMOSOMAL-ABNORMAL EMBRYOS.

Min Yang, PHD,[1] Tiago Rito, PhD,[1] Jeffrey Naftaly, BA,[1] Jianjun Hu, MD,[2] David F. Albertini, PhD, MS,[2] David H. Barad, MD, MS,[2] Ali H. Brivanlou, PhD,[1] Norbert Gleicher, MD.[3] [1]Rockefeller University New York, NY; [2]Center for Human Reproduction, New York, NY; [3]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY.

OBJECTIVE: To recapitulate in *in vitro*in self-organizing human "*gastruloids*"the consequences of aneuploidy in cell fate determination during early human development and investigate a putative aneuploidy-correcting mechanism, suggested by birth of normal offspring following transfer of chromosomal-abnormal embryos.

DESIGN: Experimental study.

MATERIALS AND METHODS: We induced aneuploidy in the human embryonic stem cell line (RUES2) by reversion (0.5μM) treatment for 48 h. Both, induced aneuploid RUES2 and control euploid RUES, were used to generate gastruloids. To induce gastruloid differentiation, the cells grown on a micropattern in culture dishes were cultured with 2 ml induction medium (MEF-CM supplemented with 20 ng/ml bFGF, 100 μg/ml normocin, and 50 ng/ml BMP4) for 48 h. To generate mosaic human gastruloids, we treated fluorescence-tagged RUES2 line (VENUS-H2B) with reversine to generate aneuploidy line and mixed the cells at different ratios with the parental non-tagged RUES2. We used three mixing ratios: 1:3 (25% of aneuploid cells), 1:1(50%), and 3:1(75%) of reversine-treated RUES2 (VENUS-H2B). After immunofluorescent staining, quantification of VENUS-H2B line for different cell fates was performed in ImageJ.

RESULTS: In response to BMP4, euploid RUES2 cells differentiated and generate embryonic and extraembryonic fates that patterned in radially symmetrical domains with ectoderm (SOX2+) at the center, extraembryonic (GATA3+) and mesoderm (BRA+) in between. However, when aneuploid RUES2 cells were used to generate gastruloids, almost all cells were GATA3+, suggesting global conversion to extraembryonic tissue. SOX2 and BRA domains were largely absent.Strikingly, mixture with euploid cell were able to rescue the self-organization of aneuploid gastruloids. When aneuploid cells comprised 25% of the cell population, the gastruloids exhibited self-organization of completely normal spatial patterning. The mosaic micropatterned colonies containing 50% and 75% of aneuploid cells were also able to form gastruloids with normal self-organization of all lineages. However, the higher the aneuploidy ratio, the smaller the SOX2 territory became. Compared with euploid cells, a significantly lower percentage of aneuploid SOX2+ cells (18.32 %, 15.79%, 27.16% lower for 1:3, 1:1, 3:1 ratio, respectively) and significantly higher percentage of aneuploid GATA3+ cells (16.90 %, 17.22%, 30.02% higher for 1:3, 1:1, 3:1 ratio, respectively) were found in the mosaic gastruloids.

CONCLUSIONS: Results of this first analysis of aneuploid cell fate in humans demonstrate that aneuploidy exhibits a lineage preference during early specification. A small fraction of euploid cells in the mosaic gastruloid is sufficient to generate a normal self-organizing circular patterns, with aneuploid cells preferentially allocated to the trophectodermal layer. These findings offer a putative explanation for delivery of chromosomal-normal pregnancies after transfer of chromosomal-abnormal embryos, diagnosed by trophectoderm biopsy.

RISK OF CARDIOVASCULAR DISEASE AFTER MENOPAUSE AMONG WOMEN WITH POLYCYSTIC OVARY SYNDROME (PCOS).

Jacob Christ, MD,[1] Genevieve S. Neal-Perry, M.D., Ph.D.[2] [1]University of Washington, Seattle, WA; [2]University of North Carolina, Chapel Hill, NC.

OBJECTIVE: Women with PCOS have increased rates of premenopausal cardiometabolic dysregulation, however it is not clear if this baseline dysfunction results in increased risk of cardiovascular disease (CVD) after menopause. This study sought to prospectively assess risk of cardiovascular disease after menopause among women with and without PCOS using a validated prospective multicenter cohort.

DESIGN: A secondary analysis of data from the prospective cohort study, Study of Women's Health Across the Nation (SWAN).

MATERIALS AND METHODS: Enrollment criteria included age 42-52, presence of a uterus, at least one ovary and a spontaneous menstrual period within the past three months. Inclusion criteria for secondary analysis included complete data on baseline menstrual status and total testosterone, and at least one follow-up visit after menopause. Menopause was defined as date of final menstrual period. Among those without a recorded final menstrual period, 51 years of age (or 1 year after enrollment if 51 years or older at time of inclusion) was used to impute date of menopause. Postmenopausal outcomes included self-reported postmenopausal cardiovascular disease events as well as calculated Framingham 10-year risk score, Atherosclerotic cardiovascular disease (ASCVD) risk score and General cardiovascular risk score. PCOS cases were defined as presence of both biochemical hyperandrogenism and a history of irregular menses and non-PCOS cases were defined as a lack of both features. Between groups comparisons were completed using Student's t-test and Chi-squared test. Associations between PCOS diagnosis and CVD events as well as calculated CVD risk scores were assessed using a multivariable Cox proportional hazards model and linear regression models respectively.

RESULTS: 174 women with PCOS and 1166 women without PCOS met criteria for inclusion. At baseline women with PCOS more frequently smoked cigarettes (22.0% vs 12.7%), had higher body mass index (BMI) (31.3±8.6 vs 26.7±6.5 kg/m^2), systolic blood pressure (120.7±19.7 vs 115.8±16.3 mmHg), total cholesterol (202±38 vs 192±33 mg/dl), and fasting blood glucose (103.7±44.6 vs 89.2±21.8 mg/dl) $p < 0.01$ for all comparisons. Independent of age at enrollment, baseline BMI, smoking status and race, women with PCOS had a significantly greater odds of a CVD event after menopause (odds ratio (95% CI), 1.6 (1.1-2.4)). Independent of age at enrollment, baseline BMI, smoking status, race and age at follow up, PCOS diagnosis significantly associated with General cardiovascular risk score (β (95% CI)) (1.1 (0.3-2.0)) and ASCVD risk score (0.01 (0.0-0.2)), but not Framingham 10-year risk score (0.19 (-0.2-0.6)).

CONCLUSIONS: PCOS diagnosis prior to menopause appears to confer an increased risk of cardiovascular disease after menopause. Women with PCOS should have increased monitoring to help reduce risk of long-term disease even after the menopausal transition.

PRIMARY OVARIAN INSUFFICIENCY HAS STRONG HERITABILITY, EVEN AMONG DISTANT RELATIVES; RESULTS OF A MULTIGENERATIONAL GENEALOGICAL OBSERVATIONAL STUDY.

Lauren Elizabeth Verrilli, MD, Erica Johnstone, MD, Corrine K. Welt, MD, Kristina Allen-Brady, Ph.D., MSPH. University of Utah Salt Lake City, UT.

OBJECTIVE: To determine the heritability of primary ovarian insufficiency (POI) on a population level through examination of multigenerational genealogical information linked to electronic medical records.

DESIGN: Case Control Study.

MATERIALS AND METHODS: POI cases were identified from 1995 to 2019 using electronic medical records from the two major healthcare systems in Utah (University of Utah Health and Intermountain Healthcare), which provide approximately 80% of all healthcare to Utahns. POI cases were identified using ICD9 256.31, 256.39 and ICD10 E28.31, E28.39, and elevated FSH > 20 IU/L or AMH <0.08 ng/mL before the age of 40 years. We excluded women who had a hysterectomy, oophorectomy, endometriosis with pelvic surgery, pelvic radiation or chemotherapy before the diagnosis of POI and those with systemic lupus erythematosus or other disorders treated with cyclophosphamide using ICD codes, lab results, medication lists, cancer treatment and surgical data (using CPT codes). All medical records at the University of Utah were then examined to ensure that each subject fulfills the POI diagnosis. These cases were then linked to genealogy information extending back to the 1700s using the Utah Population Database (UPDB). All POI cases were required to have genealogy information available for 12 of 14 immediate ancestors (parents, 4 grandparents, and 6/8 great grandparents). Expected number of affected relatives were calculated based on matched (by age, sex, and birthplace) population rates of POI. Consanguinity rates in the Utah population have been determined to be the same as, or lower than, United States rates.

RESULTS: A total of 857 POI cases were identified. The table below reports number of relatives of a specific type, observed and expected number of affected relatives, p-value, relative risk (RR) and 95% confidence interval (CI). We observed a significantly increased risk of POI among first, second, and third-degree relatives.

CONCLUSIONS: We observed a strong heritability for POI, even in distant relatives, suggesting a genetic component to the ovarian lifecycle and ovarian insufficiency. While a few causative genes for POI have been identified mostly in consanguineous families, there is an opportunity to study POI genetics in non-consanguineous families.

Familial POI Cases Observed in Utah Population Database

Relationship	# Relatives	Observed	Expected	p-value	RR	95% CI
1st Degree	4632	14	4.67	<0.0004	3.00	1.64-5.03
2nd Degree	10612	12	5.53	<0.011	2.17	1.12-3.79
3rd Degree	23270	27	16.65	<0.015	1.62	1.07-2.36

URINARY PHTHALATE METABOLITE CONCENTRATIONS ARE INVERSELY ASSOCIATED WITH FOLLICULAR FLUID ANTI-MÜLLERIAN HORMONE CONCENTRATIONS IN WOMEN UNDERGOING FERTILITY TREATMENT.

Caitlin R. Sacha, MD,[1] Irene Souter, MD,[1] Jorge E. Chavarro, MD, Sc.D.,[2] Jennifer B. Ford, RN,[2] Paige L. Williams, PhD.,[2] Shruthi Mahalingaiah, M.D.,[2] Patricia K. Donahoe, MD,[3] Russ Hauser, MD, MPH, Sc.D.,[2] David Pépin, PhD,[3] Lidia Mínguez-Alarcón, PhD.[2] [1]MGH Fertility Center Harvard Medical School, Boston, MA; [2]Harvard T.H. Chan School of Public Health, Boston, MA; [3]MGH Pediatric Surgical Research Laboratories, Boston, MA.

OBJECTIVE: We previously showed that anti-müllerian hormone (AMH) concentrations in pre-ovulatory follicular fluid (FF) positively correlated with serum AMH, a commonly used marker of ovarian reserve, and associated with improved pregnancy outcomes among women undergoing fertility treatment. Thus, identifying modifiable lifestyles, such as environmental exposures, which are associated with FF AMH has become a public health matter and is understudied. In particular, exposure to phthalates, endocrine-disrupting chemicals commonly used as plasticizers, has been associated with infertility and premature ovarian failure. Our objective was to investigate whether urinary phthalate metabolite concentrations are associated

with pre-ovulatory FF AMH concentrations in women undergoing fertility treatment.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: FF was collected from 2-3 pre-ovulatory follicles in 162 women contributing 217 in vitro fertilization (IVF) cycles (range=1-3) enrolled in the Environment and Reproductive Health (EARTH) Study at Massachusetts General Hospital Fertility Center (2010-2016). AMH concentrations were quantified using a sandwich enzyme-linked immunosorbent assay (ELISA) in FF samples and corrected for volume. We also quantified 8 phthalate metabolite concentrations using tandem mass spectrometry in 1-2 urine samples/cycle, calculated the cycle-specific geometric mean for each metabolite, and the molar sum of di-2-ethylhexyl phthalate ($\sum$DEHP) metabolites. Linear regression models adjusted for age, body mass index (BMI), race, fertility treatment protocol, and urinary dilution were used to estimate the association between urinary phthalate metabolite concentrations, in quartiles, and FF AMH concentrations.

RESULTS: The 162 women studied had mean age of 34.0 years (+/- SD), 83% were white, and mean BMI of 22.7 kg/m^2 (+/- SD). The following stimulation protocols were used: luteal phase agonist (69%), antagonist (16%), or flare (15%). We found lower FF AMH concentrations across quartiles of urinary $\sum$DEHP (p-trend=0.07). Specifically, women in the highest quartile of urinary $\sum$DEHP (range 0.23-0.33) had, on average, 0.2 (95% CI=0.1, 0.6) ng/mL FF AMH, compared to women in the lowest $\sum$DEHP quartile (range 0.01-0.06), who had 0.7 (95% CI=0.1-0.7) ng/mL FF AMH (p=0.04). This negative association was non-linear, as mean FF AMH was similar in the second, third and fourth quartiles, and was mainly driven by individual negative associations between urinary concentrations of two DEHP metabolites, mono(2-ethyl-5-oxohexyl) phthalate and mono(2-ethyl-5-carboxypentyl) phthalate, with FF AMH. No other urinary phthalate metabolites were associated with FF AMH.

CONCLUSIONS: We observed that urinary concentrations of certain phthalate metabolites are negatively associated with FF AMH concentrations, which may have implications for fertility treatment.

POLY AROMATIC HYDROCARBONS (PAHS) IN SEMEN OF INFERTILE MEN REVEAL DISTINCT SIGNATURES OF OXIDATIVE STRESS AND PROTEIN TRAFFICKING AS MODULATORS OF SPERM FUNCTION: A PROTEOMIC INSIGHT THROUGH SEMINAL EXTRACELLULAR VESICLES.

Soumya Ranjan Jena, M.Phil,[1] Luna Samanta, Ph.D,[2] Smriti Sanchita, B.S.[3] [1]Redox Biology Laboratory, Center of Excellence in Environment and Public Health, Ravenshaw University, Cuttack-753003, India, Cuttack, India; [2]Redox Biology Laboratory, Department of Zoology, Ravenshaw University, Cuttack, Odisha, India; [3]UCLA, Los Angeles, CA, India.

OBJECTIVE: To evaluate the cut off levels of seminal poly aromatic hydrocarbons (PAHs) and its correlation with sperm function in infertile men by comparative proteomic analysis of seminal extracellular vesicles (EVs).

DESIGN: Perspective case-control study involving 42 fertile donors and 113 infertile patients. Infertile patients having PAH level above cut off (n=57) were included in the experimental group and compared with fertile donors.

MATERIALS AND METHODS: PAH levels in semen were determined by HPLC and receiver operator curve (ROC) analysis was carried out to find the cut off limits of different PAHs. Seminal EVs were isolated in both groups by ultracentrifugation and characterized by western blot, transmission electron microscopy, and nanoparticle tracking analysis followed by label free liquid chromatography mass spectroscopy (LC-MS/MS) and bioinformatics analysis.

RESULTS: A total of 13 PAHs were detected (Table 1) where Benzo (a) pyrene was exclusively detected in infertile group. A total of the 1120 proteins were detected (Control:724 and PAH:1041). Of the 272 differentially expressed proteins 210 were underexpressed and 62 overexpressed in PAH ($\log_2$ fold change ≥ 2, $p \leq 0.001$) while 79 and 396 proteins were exclusive to control and PAH, respectively. STRING-PPI and Cytoscape analysis revealed oxidoreductase activity (p value=7.5292E-5), carbonyl reductase activity (p value=1.2657E-3) and transfer of alkyl and aryl activity (p value=5.740E-3) were overexpressed in PAH while antioxidant activity (p value=4.9436E-3) was underexpressed. Ingenuity pathway analysis (IPA) showed signaling by Rho family GTPases, NRF2-mediated oxidative stress response, protein trafficking, cellular function and maintenance, molecular transport were deregulated in PAH group.

TABLE 1. Receiver Operating Characteristic (ROC) optimal cut points and operating characteristics for semen PAH metabolites.

PAH	Area Under Curve	Cut-off Value (ppm)	p Value
Benzo (A) Pyrene	0.817460	6	<0.0001
Anthracene	0.815789	62	<0.0001
Benzo (B) Fluoranthene	0.811821	40	<0.0001
Fluoranthene	0.758981	17	<0.0001
Pyrene	0.738304	32	<0.0001
Indo (123 CD) Pyrene	0.737260	8	<0.0001
Benzo(A) Anthracene	0.728488	333	<0.0001
Napthalene	0.707602	868	<0.0001
Dibenzo (AH) Anthracene	0.694653	7	<0.0001
Fluorene	0.692565	831	<0.0001
Chrysene	0.687552	6	<0.0001
2Bromonapthalene	0.682957	188	<0.0001
Benzo (GH1) Perylene	0.671053	107	<0.0001

CONCLUSIONS: Seminal EVs are reported to protect and maintain sperm function by trafficking RNA and proteins to spermatozoa. Our data indicate that PAH exposure above cut off is associated with male infertility due to impaired protein trafficking by seminal EVs resulting in oxidative damage and declined antioxidant defense.

O-39 2:30 PM Saturday, October 17, 2020

REDUCED OOCYTE QUALITY JUSTIFIES POOR ICSI OUTCOMES AMONG SMOKERS AND SUGAR CONSUMERS.

Gabriela Halpern, MSc,[1] Amanda Souza Setti, MSc,[2] Daniela Paes de Almeida Ferreira Braga, PhD,[2] Assumpto Iaconelli, Jr., MD,[2] Edson Borges, Jr., PhD.[2] [1]Fertility Medical Group São Paulo, Brazil; [2]Fertility Medical Group / Sapientiae Institute, Sao Paulo, Brazil.

OBJECTIVE: Considering that the human fertility rate has declined over time, it could be argued that maternal lifestyle factors, including eating, smoking and physical exercise habits, may affect fertility potential. Growing evidences link maternal lifestyle and prenatal factors with serious health consequences later in life. To date, studies have shown that both female and male germline development follow distinct paths of epigenetic events and both gametes possess their own unique epigenomes. Lifestyle factors can be adapted to enhance well-being and are ultimately under one's own control; therefore, adjusting for their influence may yield valuable information for counselling couples undergoing ICSI. Therefore, the goal for the present study was to evaluate the influence of maternal lifestyle factors on oocyte morphology.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: The study included 561 female patients undergoing ICSI cycles, in a private university-affiliated in vitro fertilization center, from January/2015 to December/2018. Prior to start of the treatment, participants were asked to complete a detailed non-validated questionnaire regarding cigarette smoking habit, consumption of items such as refined sugar, soft drinks, alcoholic beverages, milk and dairy, and white and red meat, and exercise frequency over the past 3 months. Oocyte morphology was evaluated before sperm injection and intra and extra-cytoplasmic dimorphisms were recorded. The influences of maternal lifestyle factors on oocyte morphology were evaluated by multiple multivariate regression analyses, adjusted for maternal age and body mass index, FSH dose and number of retrieved oocytes.

RESULTS: Cigarette smoking positively influenced the incidence of zona pellucida dimorphisms (B: 14.9, CI: 3.9 – 25.9, p=0.009), fragmented first polar body (PB) (B: 32.4, CI: 7.9 – 57.0, p=0.011), and oocyte shape dimorphisms (B: 14.2, CI: 4.6 – 23.8, p=0.004). The consumption of refined sugar positively influenced the incidence of centrally located granular cytoplasm (B: 19.5, CI: 0.5 – 38.4, p=0.044) and perivitelline space granulation (B: 21.6, CI: 2.6 – 40.6, p=0.027). The consumption of milk and dairy was inversely correlated with the incidence of fragmented PB (B: -26.4, CI: -51.2 - -1.5, p=0.038), and the consumption of fish was inversely correlated

with the incidence of membrane resistance (B: -8.7, CI: -16.4 - -1.0, p=0.027). There were no significant influences of other investigated maternal lifestyle factors on oocyte dimorphisms.

CONCLUSIONS: Cigarette smoking and the consumption of refined sugar appear to reduce oocyte quality. Therefore, it would be wise to advise female partners undergoing assisted reproduction treatments to abstain from smoking and consuming sugar to avoid decreased in vitro reproduction outcomes.

SUPPORT: None.

O-40 2:45 PM Saturday, October 17, 2020

INFERTILITY AND ENVIRONMENTAL, CHEMICAL, AND HAZARDOUS EXPOSURES AMONG UNITED STATES VETERANS. Abigail C. Mancuso, MD,[1] Andrea Holcombe, MS, PhD,[2] Michelle A. Mengeling, MS, PhD,[2] Ginny L. Ryan, MD, MA.[3] [1]University of Iowa Hospitals and Clinics Iowa City, IA; [2]Iowa City VA Health Care System, Iowa City, IA; [3]University of Iowa Carver College of Medicine, Iowa City, IA.

OBJECTIVE: To assess the association between infertility and environmental, chemical, or hazardous material exposures among United States Veterans.

DESIGN: Cross-sectional survey study.

MATERIALS AND METHODS: A national sample of female and male US Veterans aged 20-45 completed a computer-assisted telephone interview lasting an average of 1 hour 27 minutes assessing demographics, general and reproductive health, and lifetime and military exposures.

Infertility was defined as unprotected intercourse with a member of the opposite sex, with or without trying to conceive, for >12 months without pregnancy over a lifetime. Participants reporting never having had unprotected intercourse were excluded from analysis.

Logistic regression analysis was used to compare exposures among infertile and non-infertile groups. Odds ratios (OR) with 95% confidence intervals are reported.

RESULTS: 3,018 Veterans participated in this study. After excluding participants never reporting unprotected intercourse (216 women and 201 men), 1,194 women and 1,407 men were included in this analysis with 592 (50%) women and 727 (52%) men meeting the definition of infertility.

Exposures reported to be higher among both women and men meeting the definition of infertility than among those not meeting this definition included polychlorinated biphenyl (PCBs) (4.7% vs. 2.3% exposed in the infertile and non-infertile groups respectively; OR 2.09 (1.09-4.00) for women; 9.5% vs 6.2%; OR 1.59 (1.07-2.37) for men) and sulfur fires (2.2% vs. 0.5%; OR 4.48 (1.27-15.81) for women; 4.0% vs 2.1%; OR 1.98 (1.04-3.77) for men).

Exposures reported to be higher only among women meeting the definition of infertility than among women not meeting this definition were extreme heat (66.3% vs 59.0%; OR 1.37 (1.08-1.74)), chemical weapons (e.g., Sarin gas) (10.7% vs 6.8%; OR 1.63 (1.08-2.46)) and anthrax vaccine (54.2% vs. 45.9%; OR 1.40 (1.11-1.75)).

Exposures reported to be higher only among men meeting the definition of infertility than among men not meeting this definition included exposure to oil well fires (16.8% vs. 11.5%; OR 1.56 (1.15-2.11)), petrochemicals (71.4% vs 64.9%; OR 1.35 (1.08-1.69)), other chemicals (such as solvents, degreasers) (55.3% vs. 49.4%; OR 1.27 (1.03-1.56)), and asbestos (35.4% vs. 28.2%; OR 1.39 (1.11-1.74)).

There were no queried exposures self-reported at higher rates in the non-infertile group.

CONCLUSIONS: During their military service, Veterans commonly experience exposure to chemical, physical, and environmental hazards that may have negative effects on their future reproductive health. Our study found that Veterans reporting at least one episode of 12 months or more of unprotected intercourse without conception over their lifetime were more likely to report exposure to such hazards, especially PCBs and sulfur fires. These data provide evidence of an association between exposures encountered during military service and infertility, and thereby support recent efforts to improve coverage of fertility preservation and fertility treatment for Veterans.

UNIVERSAL SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS 2 (SARS-COV-2) TESTING IN A NEW YORK CITY REPRODUCTIVE MEDICINE PRACTICE. Pietro Bortoletto, MD, Phillip A. Romanski, MD, Joshua Stewart, M.D., Glenn Schattman, MD, Zev Rosenwaks, M.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To describe our single-center experience and results of universal SARS-CoV-2 testing in asymptomatic patients undergoing controlled ovarian hyperstimulation (COH).

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: On March 21, 2020, New York-Presbyterian Hospital, where our retrieval suite is located, instituted a policy of universal SARS-CoV-2 testing prior to surgical procedures requiring anesthesia. As a result, we began testing all patients undergoing COH for SARS-CoV-2 using reverse transcription-polymerase chain reaction via nasopharyngeal swabs (Roche Cobas 6800). Tests were performed on the morning of cycle start and repeated 24 hours before oocyte retrieval. A positive test at either time point excluded patients from continuing with treatment. During the testing period, all patients and staff were required to wear surgical masks at all times when at our center and consented to symptom and temperature screening at every monitoring visit.

RESULTS: Between March 21 and May 20, 2020, 169 asymptomatic patients underwent nasopharyngeal swabs at cycle start, four of which returned positive for SARS-CoV-2 for a center prevalence of 2.4%. All four patients were asymptomatic at the time of cycle start and were not permitted to begin their COH cycle. One of these patients had previously had a positive PCR swab over 60 days prior and had been symptom-free during this interval. One patient with a negative PCR swab on cycle start subsequently converted to positive 15 days later on her PCR swab prior to retrieval, despite the absence of COVID-19 symptoms. Per our hospital policy, she was not allowed to proceed with oocyte retrieval and was started on a course of daily GnRH antagonist and asked to abstain from intercourse for 14 days. None of the 5 patients went on to develop COVID-19 symptoms following their positive test result. All patients were referred to follow-up with their primary care provider. Prior to returning for further COH treatment, all patients will be required to undergo repeat PCR testing with a negative result.

CONCLUSIONS: While rare, asymptomatic carriers of the SARS-CoV-2 virus were identified for a center prevalence of 2.4% in patients undergoing COH. Despite initial negative PCR testing, patients may convert to positive over the course of a COH cycle and not demonstrate symptoms. Strict personal protective equipment and social distancing use is essential to protect patients and staff alike.

EFFECT OF THE EXPOSURE TO FINE INHALABLE PARTICULATE MATTER ($PM_{2.5}$) ON SPERM FUNCTIONAL QUALITY OF MICE. Paula Intasqui, PhD,[1] Letícia Kaory Tamashiro, BSc.,[1] Victor Yuji Yariwake, BSc.,[2] Rosana Xavier Souza, BSc.,[1] Camila Matie Kanashiro, BSc.,[1] Mariana Matera Veras, PhD.[2] [1]Sao Paulo Federal University São Paulo, Brazil; [2]Laboratory of Experimental Air Pollution (LIM05), São Paulo, Brazil.

OBJECTIVE: To evaluate the effect of exposure to pollution (fine inhalable particulate matter - $PM_{2.5}$) from the city of São Paulo on sperm functional quality.

DESIGN: Male isogenic BALB/c mice were used, distributed in two groups, control (n=6) and polluted air (n=8). For the polluted air group, after weaning (21 days), animals were daily exposed to 600 $\mu g/m^3$ of $PM_{2.5}$ for 96 days in an Ambient Particle Concentrator (APC). Control group was simultaneously exposed to filtered air in the APC. On postnatal day 118, animals were sacrificed (isoflurane overdose), body was weighted and the epididymis were collected.

MATERIALS AND METHODS: Sperm obtained from the cauda epididymis were used for the evaluation of motility, mitochondrial activity (DAB staining), acrosome integrity (PNA staining), DNA fragmentation (alkaline comet assay), oxidative stress (DHE staining) and cell viability (PI staining). Groups were compared using an unpaired Student's t test ($p<0.05$).

RESULTS: Groups did not differ regarding body weight, and sperm motility. Furthermore, air pollution did not alter sperm functional quality (Table 1).

CONCLUSIONS: Exposure to high concentrations of $PM_{2.5}$ does not affect sperm motility and functional parameters.

TABLE 1. Body weight and sperm functional quality of mice from the control and polluted air groups. Data are presented as Mean ± Standard Deviation. Groups were compared using an unpaired Student's t test.

	Control (n=6)	Polluted air (n=8)	p
Body weight	29.46 ± 4.82	28.01 ± 0.82	0.50
Motility (%)	51.67 ± 13.66	55.62 ± 18.41	0.67
Intact acrosome (%)	85.33 ± 7.65	81.94 ± 9.08	0.48
Mitochondrial activity			
DAB I (%)	7.08 ± 4.53	9.81 ± 10.19	0.56
DAB II (%)	71.75 ± 11.16	68.44 ± 61.75	0.53
DAB III (%)	20.83 ± 9.31	21.06 ± 11.55	0.97
DAB IV (%)	0.33 ± 0.61	0.75 ± 0.96	0.37
DNA fragmentation			
Comet I (%)	29.83 ± 23.17	35.07 ± 23.16	0.69
Comet II (%)	45.83 ± 10.81	36.36 ± 12.90	0.18
Comet III (%)	17.92 ± 10.88	16.36 ± 9.70	0.79
Comet IV (%)	6.58 ± 9.11	12.14 ± 11.70	0.37
Tail DNA (%)	14.11 ± 12.67	19.82 ± 15.38	0.49
Olive Tail Moment (a.u.)	5.41 ± 5.91	7.27 ± 6.60	0.61

EXPERIENCE WITH CARRIER SCREENING FOR X-LINKED CONDITIONS. Dana Neitzel, MS, CGC, Jocelyn Leahey, MS, CGC, Sienna Aguilar, MS, CGC, Nicole Faulkner, PhD, FACMG, Swaroop Aradhya, PhD, FACMG. Invitae San Francisco, CA.

OBJECTIVE: Current ACOG carrier screening guidelines do not support routine inclusion of X-linked (XL) conditions. There are over 100 known XL conditions. Clinical presentation depends on many variables and males are typically affected while females may show varying symptoms. Despite high *de novo* mutation rates, the identification of carriers for XL conditions is important as females have a 50% chance of transmitting a disease-causing variant. The aim of this study was to determine the carrier frequency of XL conditions identified through routine carrier screening for the purpose of reproductive planning.

DESIGN: Retrospective cohort study of patients undergoing routine carrier screening to determine carrier rates of a subset of XL conditions.

MATERIALS AND METHODS: Carrier screening was performed by next-generation sequencing with full coding sequence and deletion and duplication analysis for up to 301 genes as ordered on 68,100 patients. Twenty-two of the 301 genes were XL. Pathogenic and likely pathogenic variants were reported. Ordering patterns and positive rates for XL conditions were assessed.

RESULTS: Of 68,100 patients, 68% were female and 32% were male. Most orders (87.9%; 59,865) included at least one XL condition, though female orders included XL conditions more often than male orders (91.9% vs 79.4%).

Of the 59,865 orders that include XL conditions, the overall positive rate was 60.9% and of these positives, 1.98% were for XL conditions, giving an overall positive rate for XL conditions of 1.2%. In this dataset, at least one carrier was identified for each of the 22 XL conditions tested.

When stratified by patient sex, 1.3% of females (557/42,572) tested positive for an XL condition, most frequently *G6PD*, *FMR1*, *DMD*, *COL4A5*, and *ABCD1*; 0.95% of males (165/17,293) were positive for an XL condition, most frequently *G6PD*, *FMR1*, *COL4A5*, *DMD*, and *GLA*.

CONCLUSIONS: In this cohort, 88% of all orders included at least one XL condition, indicating that clinicians are regularly ordering XL conditions as part of their routine carrier screening for both male and female patients. One point two percent of individuals were positive for at least one XL condition, and XL conditions together accounted for 2% of all positive results.

The inclusion of XL conditions on a carrier screen is controversial: ACOG does not support it; the line between carrier screening and diagnostic testing may be crossed for male patients who screen positive for variants in XL conditions; and the high *de novo* rate in many of XL conditions may lead to false reassurance after a negative carrier screening result.

However, inclusion of XL conditions in routine carrier screening is common practice. Screening for XL conditions allows patients the opportunity to make informed reproductive decisions about these often severe conditions with high reproductive risks. Additional studies are needed to determine the phenotypes and potential impact associated with males identified with XL conditions in this study.

FAVORABLE OUTCOMES IN A SUBSEQUENT PGT-A CYCLE FOLLOWING ALL ANEUPLOID BLASTOCYST COHORT. Alyssa Schickedanz, M.S, C.G.C, Diane Klepacka, MS, Annette Matts, MS, Amy Bartoli, MS, Emily Anderson, BS, Mary E. Haywood, PhD, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD. Colorado Center for Reproductive Medicine Lone Tree, CO.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) has been shown to improve the likelihood of live birth per embryo transfer. However, oocyte aneuploidy is significantly associated with reproductive aging, and the probability of an IVF cycle resulting in a lack of euploid embryos becomes more significant for women of advanced maternal age (>38 years). The aim of this study was to review patient's treatment decisions following an all aneuploid PGT-A cycle to assist in future clinical management and counseling practices.

DESIGN: Retrospective cohort analysis.

MATERIALS AND METHODS: Consecutive, autologous PGT-A cycles that resulted in all aneuploid blastocysts between January 2016 and December 2019 (n=550) were included in this analysis. Individual variable analysis was performed using Wilcoxon rank sum test. Step-wise logistic regression models evaluated whether 12 clinical parameters were predictive of patient treatment decisions including parental ages, prior live birth, BMI, ovarian reserve variables and IVF cycle characteristics. Significance determined at $p<0.05$.

RESULTS: Nearly half of the couples (47.6%) decided to terminate treatment following an all aneuploid IVF cycle. Only a small number of couples pursued donor oocytes for future treatment (7.6%) and a handful naturally conceived (1.5%). The remaining couples (43.3%) pursued a second autologous PGT-A cycle, with 50.4% obtaining ≥ 1 euploid blastocyst. Interestingly, women who chose to stop treatment had significantly more oocytes retrieved ($p<0.05$) but trended towards being less likely to have had prior live births ($p = 0.07$) than women who continued infertility treatment. Other variables, including maternal age, AMH and resting antral follicle count (AFC), were not significantly different. Women with euploid blastocysts following their second IVF cycle were significantly younger ($p<0.001$, OR = 0.84) and had higher AMH ($p<0.05$, OR = 1.25) than women with a consecutive second all aneuploid cycle. Stratification of subsequent euploid frozen blastocyst transfers demonstrated the trend of lower maternal age ($p = 0.06$, OR=0.89), higher AFC ($p<0.05$, OR = 1.06) and more mature autologous oocytes ($p<0.05$, OR = 1.12) in association with a positive pregnancy outcome.

CONCLUSIONS: Following a PGT-A cycle resulting in all aneuploid blastocysts, nearly half of all couples chose to cease pursing infertility treatment. Maternal age, ovarian reserve and other clinical parameters were not significantly associated with this decision. This indicates that external variables such as, stresses of the procedure and financial burden, may be more significant in patient treatment decisions. For those couples that did pursue further treatment over half went on to have a euploid embryo transfer. This encouraging information will be useful during patient counseling for future clinical decisions following an all-aneuploid PGT-A cycle.

EMBRYO TRANSFER BASED ON PREIMPLANTATION GENETIC TESTING: A CRITICAL ASSESSMENT OF CURRENT PRACTICE AND POLICY GUIDELINES. Christina Ren, BS,[1] Andria G. Besser, MS, CGC,[2] Jon Weil, PhD,[1] Rachel Hull, BS,[3] Janey Youngblom, PhD, MS.[1] [1]California State University Stanislaus, Turlock, CA; [2]New York University Langone Fertility Center, New York, NY; [3]University of California, Davis, Davis, CA.

OBJECTIVE: To investigate the status of policies and practice of IVF clinics regarding transfer of embryos with positive or abnormal results following preimplantation genetic testing for aneuploidy and for monogenic disorders (PGT-A and PGT-M).

DESIGN: Mixed methods study, using a survey and semi-structured interviews.

MATERIALS AND METHODS: An online survey was emailed to 394 IVF clinics across the United States. In-depth interviews were conducted with a subset of 11 survey respondents. Descriptive statistics and chi-square were used to analyze survey data. Interviews were transcribed verbatim and independently analyzed by two coders using thematic analysis. Abnormal PGT-A results only included non-mosaic aneuploidies. Unaffected carriers of autosomal recessive disorders were not included in the definition of positive PGT-M results.

RESULTS: A total of 97 clinics completed a survey (25% valid response rate). 37% of clinics had written policies on transferring embryos with positive or abnormal results which they discuss with patients before testing and 54% handled patient requests on a case-by-case basis. 9% did not have a policy because they did not transfer abnormal embryos or were in the process of creating a policy. Clinics with policies were less likely to consider transfer of embryos with non-viable aneuploidy (11%) and partial aneuploidies (22%) than clinics without policies (31% and 43%, respectively; $p<0.05$). A minority of clinics reported having previously transferred one or more embryos with a non-viable aneuploidy (12%), partial aneuploidy (12%), or viable aneuploidy (7%). No clinics have transferred embryos positive for a monogenic childhood-onset life-limiting disorder. However, most clinics (69%) would consider transferring embryos positive for reduced penetrance, variable-onset monogenic disorders, and 16% of all clinics have transferred such embryos. 78% would require genetic counseling before transfer of embryos with abnormal PGT-A or positive PGT-M results.

The qualitative interviews suggested that the decision to create clinic policies was shaped by previous/anticipated patient requests and desire for either standardized or discretionary practice. Factors contributing to provider considerations for transfer of positive or abnormal embryos include individual patient circumstances and limited reproductive options, clinical uncertainty/variability of outcomes, interpretation and reliability of PGT results, liability and financial concerns, and balance of ethical perspectives.

CONCLUSIONS: Patient requests to transfer embryos with abnormal or positive PGT-A/PGT-M results do occur and there is variability in practice policies for such situations among U.S. IVF clinics. The majority of clinics do not have a policy in place regarding transfer of abnormal or positive embryos, preferring to handle these requests on a case-by-case basis. Ongoing discussion of establishing practice guidelines is critical as PGT-A results become increasingly complex, the scope of indications for PGT-M use expands, and providers increasingly encounter these requests more frequently.

GENETIC SCREENING IN REPRODUCTIVE AGE WOMEN IDENTIFIES A HIGH POSITIVE RATE OF ACTIONABLE RESULTS. Sienna Aguilar, MS, CGC,[1] Eden Haverfield, DPhil, FACMG,[1] Edward Esplin, MD, PhD, FACMG,[1] Robert L. Nussbaum, MD,[2] Swaroop Aradhya, PhD, FACMG.[1] [1]Invitae San Francisco, CA; [2]1400 16th Street, San Francisco, CA.

OBJECTIVE: Personal risk for actionable Mendelian genetic disease has been identified in 2-16% of the general population.[1-5] Early identification of individuals at risk allows for proactive screening and prevention to reduce morbidity. Current genetic testing guidelines designed to identify those most likely to have a genetic risk appear to miss a significant portion of at-risk individuals.[6-8] The aim of this study was to determine the frequency of pathogenic variants found in a medically actionable genetic screening panel in a cohort of reproductive age women.

DESIGN: Retrospective cohort study of reproductive age women undergoing proactive genetic screening to determine rates of medically actionable findings.

MATERIALS AND METHODS: Under an IRB-approved protocol, we analyzed de-identified data from 1,305 women of reproductive age (18-45 years) who underwent genetic screening with a panel of up to 147 genes for actionable disorders.

RESULTS: Pathogenic/likely pathogenic variants were observed in 15.6% (204 of 1,305) of individuals. Among these, 55.4% had at least one finding in a cancer-related gene, 36.8% in a cardiovascular-related gene, and 12.3% in genes causing other medically actionable disorders. At least 8.3% of positive individuals had two or more findings. Even when individuals with moderate risk (variants in F2 and F5, APC I1307K, biallelic HFE variants, and heterozygous variants in MUTYH) are excluded, one in 13 women still had a positive actionable test result.

CONCLUSIONS: Our data show that 15.6% of women of reproductive age may have risks for hereditary disease. Incorporating genetic screening for personal risk of actionable disorders in the course of preconception evaluations may be an opportunity to identify individuals at high genetic risk prior to disease onset. Outcomes-focused longitudinal data are needed to fully understand the benefits of genetic risk information identified in this population.

PATIENT EXPERIENCE WITH EXPANDED-CARRIER SCREENING: ADEQUACY OF PROVIDER COUNSELING, ECONOMIC BURDEN AND DECISION-MAKING REGARDING PARTNER TESTING. Alice J. Shapiro, M.D., Molly M. Quinn, MD. David Geffen School of Medicine University of California, Los Angeles, Los Angeles, CA.

OBJECTIVE: Expanded carrier screening (ECS) is a method for identifying individuals who are carriers for recessively-inherited genetic disorders. When couples are screened sequentially, many positively-screened individuals choose not to test their reproductive partners despite provider recommendations.[1] The patent experience with ECS and factors contributing to decision-making regarding partner testing have not been explored. The goal of this study was to evaluate the patient experience with ECS by

assessing the efficacy of provider counseling, the economic burden imposed by ECS, and the reasons some positively-screened individuals do not have their partners tested.

DESIGN: Cross-sectional patient survey.

MATERIALS AND METHODS: All individuals presenting to a university-affiliated reproductive endocrinology and infertility clinic who underwent ECS with a single test provider between 9/1/13 and 2/1/20 were contacted via e-mail to complete a confidential and anonymized online survey. All survey questions were in multiple-choice format with an optional free text response.

RESULTS: The survey response rate was 11.9% (189/1586). The cost of ECS was not covered by insurance for 54.5% (103/189) of patients and most paid over $300 out-of-pocket for testing (47.6%). ECS was covered by insurance for 34.4% (65/189) of patients. Among those who had insurance coverage, 38.5% had no co-pay. Nearly half (49.2%, 93/189) of patients were found to be carriers of at least one disorder. Among carriers, 16.1% (15/93) did not have their reproductive partners screened. The most common reason positively-screened individuals cited for not testing their partners was that the results would not alter their course when seeking conception (33.3%). Nevertheless, 73.9% (139/188) of patients knew that the largest benefit of ECS comes from knowing a partner's results as well as their own. If presented with the option again, 82.6% would choose to undergo ECS screening.

CONCLUSIONS: A significant number of patients who are found to be carriers of a recessively-inherited disorder did not have their partners screened because the results would not change what they would do when seeking conception. For many patients, ECS testing is not covered by insurance and this test may impose a significant economic burden. Providers should evaluate whether a patient's ECS result would change their treatment course prior to testing.

O-48 3:15 PM Saturday, October 17, 2020

EGG DONORS ARE NOT GOLDEN: ABNORMAL RESULTS AFTER PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY, PRODUCTS OF CONCEPTION ANALYSIS OR NONINVASIVE PRENATAL TESTING WITH USE OF SNP-BASED METHODOLOGIES.

Katherine L. Howard, MS,[1] Wendy DiNonno, MS,[1] Melissa K. Maisenbacher, M.S.,[2] Katrina Merrion, MS.[1] [1]Natera Inc., San Carlos, CA; [2]Natera, San Carlos, CA.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A), products of conception (POC) and noninvasive prenatal testing (NIPT) are not routinely indicated for pregnancies conceived with in vitro fertilization (IVF) and donor oocytes, as lower aneuploidy rates are anticipated due to lower maternal age.[1] This study compared rates of chromosome abnormalities for IVF cycles with and without the use of donor oocytes via PGT-A, POC and NIPT.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: Trophectoderm biopsy samples for PGT-A, fresh POC samples and NIPT samples were sent to a single reference laboratory. Inconclusive results and POC results showing maternal cell contamination (MCC) were excluded. For PGT-A and POC analysis, genotyping was performed using Illumina Cyto12 SNP-based microarrays with informatics. For NIPT, cell-free DNA was isolated and amplified by massively-multiplexed PCR targeting >13,000 SNPs covering chromosomes 13, 18, 21, X and Y. Oocyte donor age is defined as ≤30 years.

RESULTS: Abnormal PGT-A and POC results had monosomy, tri/polysomy, haploidy, triploidy, deletions/duplications, and/or uniparental disomy reported. High-risk NIPT results indicated trisomy 13, 18 or 21, sex chromosome abnormality, triploidy versus suspected multiple gestation, microdeletions, or high risk Fetal-Fraction-Based Risk (FFBR) calls. The FFBR model is validated to assess SNP-based NIPT no-call low fetal fraction pregnancies given specific clinical information to determine pregnancies at an increased risk for trisomies 13, 18, and triploidy.[2]

CONCLUSIONS: In cycles that used donor oocytes, high-risk results were observed in ~30% of PGT-A cases and ~20% of POC tests. For NIPT cases, high-risk results were observed in 1.0% of cases with donor and 2.2% for those without donor oocytes. Screening and diagnostic options to detect chromosome abnormalities should still be considered for donor oocyte recipients. These results may be beneficial for counseling intended parents about the rates of chromosome abnormalities following IVF with donor oocytes.

INFERTILITY AND CANCER

O-49 2:00 PM Saturday, October 17, 2020

DEVELOPMENT OF A FERTILITY RISK CALCULATOR TO PREDICT INDIVIDUALIZED CHANCES OF OVARIAN FAILURE AFTER CHEMOTHERAPY.

Esther H. Chung, MD,[1] Chaitanya R. Acharya, PSM, PhD,[2] Benjamin S. Harris, MD, MPH,[3] Kelly S. Acharya, MD[3] [1]Duke University Medical Center, Durham, NC; [2]Duke Center for Applied Therapeutics, Department of Surgery, Durham, NC; [3]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC.

OBJECTIVE: Individualized prediction of a patient's risk of premature ovarian insufficiency (POI) after chemotherapy is challenging. Currently, chemotherapy regimens are stratified as "minimally increased" risk of POI (<20% risk), "intermediate" (30-70%) or "high" risk (>80%). Given the wide range of possible effects, it is challenging to counsel a patient with "intermediate" risk. Our study sought to use individual patient and treatment factors to develop a model that predicts personalized risk of POI after chemotherapy for reproductive-aged women. The eventual goal is to create a user-friendly, web-based fertility risk calculator to be made publicly accessible for oncofertility counseling.

DESIGN: Retrospective analysis of existing studies

MATERIALS AND METHODS: Candidate studies that followed patients for resumption of menses or POI after gonadotoxic therapy were identified and narrowed to randomized controlled trials and cohort studies that assessed the use of GnRH agonists in various cancer patients (breast, lymphoma, leukemia, etc.). By May 2020, 5 authors shared their data for a total N of 532 patients (111 records excluded for missing outcomes). A composite outcome for POI was determined for each patient and validated by 3 separate authors. Random Forest (RF) regression classifiers for POI were trained on 75% of the

	PGT-A	POC	NIPT
Overall Sample Total (n)	138,391	63,261	1,061,540
Donor Oocytes			
Total Samples, n (%)	15,889 (11.5)	1625 (2.6)	7314 (0.7)
Excluded (Inconclusive/MCC) , n (%)	435 (2.7)	206 (12.7)	724 (9.9)
Abnormal/High Risk Result, n (%)	5109 (33.1)	300 (21.1)	76 (1.0)
Non- Donor Oocytes			
Total Samples, n (%)	122,502 (88.5)	61,636 (97.4)	1,054,226 (99.3)
Average Maternal Age (years)	37.1	33.9	31.3
Excluded (Inconclusive/MCC/Test Not Performed) , n (%)	3455 (2.8)	8603 (14.0)	48,273 (4.6)
Abnormal/High-Risk Result, n (%)	60,170 (50.5)	23,915 (45.1)	23,684 (2.2)

data, while the remaining 25% was used as a validation set. For every RF classifier, we optimized the number of variables randomly sampled at every tree split and the number of trees until maximum possible POI prediction accuracy in the test dataset was achieved. Prediction scores for each patient sample are computed as the mean predicted class probabilities of the trees in the forest. To reduce overfitting, each classifier was validated using 10-fold cross-validation procedure.

RESULTS: A prediction score of >0.5 indicated a higher probability of POI. Our classifier predicted individualized risk of POI with an accuracy of 80% (area under the ROC 0.78, 95% CI: 0.67-0.88; p <0.001). The mean prediction scores for patients who developed POI and those who did not were 0.50 and 0.27 (t-test p < 0.001), respectively. Variables weighted most highly in our model included age, chemotherapy dose, prior chemotherapy, smoking status, and presence of baseline diminished ovarian reserve.

CONCLUSIONS: Using machine learning, we developed a predictive model to estimate patient-specific risks of POI after chemotherapy. We were able to assign an individualized risk score to each patient, refining the currently-used wide ranges of risk. Ongoing work involves validating the model with institutional data and other shared data from collaborators, as well as comparing our model's outcomes with the current risk stratification system. In the move towards personalized medicine, our web-based calculator will be a useful decision aid for providers and patients, thereby improving the quality and individualization of risk prediction in oncofertility consultations.

SUPPORT: None

O-50 2:15 PM Saturday, October 17, 2020

TOWARD TARGETING COUNSELING: ASSOCIATION BETWEEN CANCER TYPE AND ADVERSE PREGNANCY OUTCOMES.

Beth Zhou, MD,[1] Milli Desai, MHS,[1] Vinit Nalawade, MS,[1] James D. Murphy, MD,[1] Brian W. Whitcomb, PhD,[2] H. Irene Su, M.D., M.S.C.E.[1] [1]University of California San Diego, La Jolla, CA; [2]University of Massachusetts, Amherst, Amherst, MA.

OBJECTIVE: At higher risk of infertility, female adolescent and young adult (AYA) cancer survivors seek care of fertility specialists, who need information on cancer-specific pregnancy risks to inform treatment decisions. Limited studies on pregnancy and perinatal outcomes in AYA cancer survivors lack data on low-incidence cancers. Hypothesizing that adverse pregnancy outcomes differ by cancer type, the objective was to estimate the association between cancer type and live birth, preterm birth, and severe maternal morbidity.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: We used OptumLabs® Data Warehouse, a longitudinal, real-world data asset with de-identified administrative claims data to identify females with pregnancies from 1/1/2001 to 6/30/2019. Primary exposures were AYA cancer type, i.e. bone, brain, breast, cervical, gastrointestinal, leukemia, lung, lymphomas, melanoma, ovarian, renal, sarcoma, thyroid, and uterine. Primary outcomes: live birth, preterm birth, maternal morbidity in pregnancy measured by the Bateman Obstetrics Comorbidity Index, and CDC-defined severe maternal morbidity. Exposures, outcomes, and covariates were defined using ICD, CPT, DRG codes, and validated algorithms. Log-binomial generalized estimating equation models estimated associations of outcomes by cancer type. Counts <11 were suppressed.

RESULTS: There were 2,220,026 pregnancy episodes, 1,549,494 singleton live births in 1,286,922 women without cancer and 5,956 pregnancy episodes, 3,708 singleton live births in 3,150 women with history of cancer diagnosed between ages 15 and 39 prior to pregnancy. In all pregnancies, 70% were live birth, 12% preterm. Compared to women without cancer, several cancer types had lower likelihood of live births: brain (relative risk [RR] 0.8, 95% CI 0.7-0.9), breast (RR 0.9, 95% CI 0.9, 0.95), renal (RR 0.8, 95% CI 0.6, 0.99), sarcoma (RR 0.8, 95% CI 0.7, 0.99), and uterine (RR 0.6, 95% CI 0.5, 0.8). Preterm birth was also increased in survivors of gastrointestinal cancers, leukemia, and thyroid cancers with relative risks of 1.8 (95% CI 1.2, 2.7), 1.6 (95% CI 1.2, 2.0) and 1.3 (95% CI 1.1, 1.5) respectively.

Severe maternal morbidity occurred at a higher rate in several cancers. Compared to a 1.8% risk in women without cancer, leukemia (RR 2.9, 95% CI 1.8, 4.7), Non-Hodgkins lymphoma (RR 3.5, 95% CI 2.0, 6.1), and sarcoma (RR 3.9, 95% CI 1.5, 9.9) survivors experienced significantly higher rates of morbidities such as eclampsia, acute heart failure, and embolisms.

CONCLUSIONS: Leveraging a large administrative claims dataset to build a sizeable AYA cancer survivor cohort, this study presents novel data on cancer types at highest risks of adverse outcomes. While impact on preterm births and live births were modest, severe maternal morbidity had increased magnitude of risk that warrants further investigation. These findings by cancer type can aid in counseling of AYA cancer survivors as they present for fertility care and prompt further investigation of the pathophysiology and prevention of these outcomes.

SYSTEMATIC REVIEW OF REPRODUCTIVE OUTCOMES FOR WOMEN UNDERGOING FERTILITY-SPARING THERAPY WITH PROGESTIN AND METFORMIN FOR ATYPICAL ENDOMETRIAL HYPERPLASIA AND EARLY ENDOMETRIAL CANCER.

Jennifer Chae-Kim, MD,[1] Gunjal Garg, MD,[1] Larisa Gavrilova-Jordan, MD,[2] Lindsay E. Blake, MLIS, AHIP,[3] Tongil T. I. Kim, PhD,[4] Clifford Cal Hayslip, Jr., MD.[1] [1]East Carolina University Greenville, NC; [2]Medical College of Georgia at Augusta University, Augusta, GA; [3]University of Arkansas for Medical Sciences, Little Rock, AR; [4]Emory University, Goizueta Business School, Atlanta, GA.

OBJECTIVE: High potency progestin is a common fertility-sparing management of atypical endometrial hyperplasia (AEH) or early stage endometrial cancer (EC) in reproductive-aged women (1). Addition of metformin has been shown to have a synergistic effect in the suppression of endometrial proliferation (1, 2). Reproductive outcomes for therapies using progestin or metformin have been reported. The outcomes of progestin and metformin combined therapy (Prog+M) in comparison to progestin (Prog) alone have not yet been evaluated systematically. The aim of this study was to conduct a systematic review of the reproductive outcomes for fertility-sparing management of AEH/EC with Prog+M versus Prog therapy.

DESIGN: Systematic review and meta-analysis.

MATERIALS AND METHODS: An extensive literature search was conducted to identify studies reporting outcomes in reproductive-aged women who underwent Prog+M versus Prog therapy. Primary outcomes were clinical pregnancy and live birth rates, hyperplasia or cancer remission, as well as relapse. Databases (MEDLINE, Web of Science, Cochrane Library, CINAHL, LILACS, clinicaltrials.gov) were searched from inception through April 2020 using key terms and subject headings where available. Inclusion criteria were as follows: reproductive-aged women with a histologically confirmed diagnosis of AEH or EC, who met criteria for fertility-sparing management, and received Prog+M or Prog; and studies reporting on at least one of the primary outcomes. Data were presented as proportions and odds ratio (OR) (95% confidence interval [CI]) with fixed- or random-effects meta-analysis.

RESULTS: In total, 251 reports were identified, and 10 studies (250 Prog+M and 226 Prog comparators) met the inclusion criteria. Mean age and body mass index for Prog+M were 35.8 years and 31 kg/m^2, compared to 36.4 years and 27 kg/m^2 in the Prog group. Both Prog+M and Prog had a high percentage of nulliparous women, at 74% and 77% respectively. Results showed a pooled remission rate of 78% (95% CI 64%-91%) for Prog+M and 70% (95% CI 51%-89%) for Prog, and the odds ratio for both treatments was not statistically significant (pooled OR 1.35, 95% CI 0.86-2.12, P = 0.26). Relapse rates for AEH/EC were statistically lower for Prog+M (pooled OR 0.49, 95% CI 0.25-0.95, P = 0.035). Interestingly, while clinical pregnancy rates were not different, live birth rates were significantly lower for Prog+M (pooled OR 0.39, 95% CI 0.17-0.89, P = 0.025).

CONCLUSIONS: Reproductive-aged women with AEH/EC have similar clinical pregnancy rates and lower cancer relapse after Prog+M compared to Prog therapy alone. Prog+M therapy was associated with a lower live birth rate. Further evaluation of the optimal window between discontinuation of Prog+M and onset of pregnancy is necessary to investigate possible improvements in the live birth rates in these women.

OVARIAN RESERVE AND RESPONSE TO STIMULATION AMONG PATIENTS UNDERGOING FERTILITY PRESERVATION FOR CANCER (ONCOFERTILITY) COMPARED TO THOSE PATIENTS WITHOUT A CANCER DIAGNOSIS. Devora Aharon, MD,[1] Sydney Chang, MD,[1] Dmitry Gounko, MA,[2] Joseph A. Lee, BA,[2] Alan B. Copperman, MD,[1] Erkan Buyuk, MD.[1] [1]Icahn School of Medicine at Mount Sinai New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Whether malignancy has a harmful effect on ovarian function is currently unknown, with studies demonstrating conflicting results regarding ovarian reserve and response to stimulation among cancer patients.[1-2] The objective of this study is to determine whether oncofertility patients undergoing fertility preservation have reduced ovarian reserve and cycle outcomes compared to oocyte cryopreservation patients without cancer.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients who underwent fertility preservation prior to undergoing chemotherapy and/or radiation for cancer treatment from February 2006 through May 2020 were included. Controls were other fertility preservation patients matched by age (within 2 years) and cycle year in a 2:1 ratio. Patients with a prior oophorectomy or prior chemotherapy or radiation were excluded. Age, BMI, AMH, basal antral follicle count (bAFC), basal estradiol (bE2) and follicle stimulating hormone (bFSH) values, number of oocytes and mature oocytes (MII) retrieved, and ratio of MII to oocytes retrieved were compared between the groups using comparative statistics. Linear regression was used to compare cycle outcomes and control for confounders.

RESULTS: A total of 187 cancer patients who underwent fertility preservation were identified and included in the analysis, matched to 374 controls. 146 patients had breast cancer (75.4%), 19 had hematologic cancers (10.2%), 14 had endometrial or cervical cancers (7.5%), and 13 had other cancers (6.9%). Oncofertility patients were similar to patients without cancer in terms of age, BMI, AMH, bAFC, and bFSH. Oncofertility patients had significantly higher bE2 (62.4 ±56.1 vs. 46.0 ±33.0, p=0.001). Number of oocytes retrieved was similar between oncofertility patients and egg freezers without cancer (15.5 ±11.7 vs. 13.6 ±8.8, respectively, p=0.41). Oncofertility patients had a significantly lower number of MIIs retrieved (9.44 ±9.37 vs. 9.71 ±7.06, p=0.03) and MII/oocyte ratio (0.59 ±0.29 vs. 0.70 ±0.22, p=<0.0001). After adjusting for age, BMI, AMH, bAFC, bE2, and bFSH, egg freezing in patients without cancer was not associated with number of MIIs retrieved (β=-0.733, p=0.30) but was significantly associated with a higher MII/oocyte ratio (β=0.075, p=0.007).

CONCLUSIONS: Oncofertility patients had similar ovarian reserve testing and oocytes retrieved, however the ratio of mature oocytes to total number of oocytes retrieved was lower when compared to egg freezing patients without cancer. This may be due to the effect of the underlying disease process on oocyte maturation, a shorter time frame to start and complete a cycle, or a physician bias in either the stimulation protocol or retrieval process to maximize oocyte yield in cancer patients who face potentially sterilizing treatment. Clinicians should counsel patients that while outcomes may not be identical in patients with cancer, fertility preservation with oocyte freezing can result in a satisfactory yield of mature oocytes for future use.

IS FERTILITY PRESERVATION A PART OF COMPREHENSIVE CANCER CARE IN THE UNITED STATES? Adriana Nicholson Vest, PhD, Nelson T. Kuete, B.Sc., Akanksha Mehta, M.D., M.S. Emory University School of Medicine, GA.

OBJECTIVE: Although fertility preservation is important to young cancer survivors of reproductive age, the delivery of oncofertility care remains challenging, and utilization of fertility preservation remains low. Cancer patients increasingly utilize online health information to fill knowledge gaps in their fertility care. The purpose of this study was to evaluate the website content of NCI designated cancer centers to assess the quantity and quality of patient-oriented information pertaining to pre-treatment fertility preservation.

DESIGN: A cross-sectional review of National Cancer Center (NCI) designated Cancer Center websites.

MATERIALS AND METHODS: Cancer Centers (CC) and Comprehensive Cancer Centers (CCC) were identified based on the NCI list of designated institutions. Laboratories were excluded and centers that shared a website were counted once. Each center's website was evaluated for the presence of terms related to the etiology and treatment of cancer related infertility. The frequency with which websites included information pertaining to fertility preservation was calculated and the differences between CC and CCC were compared with Fischer's exact test using Matlab R2020a. Statistical significance was set as $p<0.05$.

RESULTS: Of the 72 identified CC and CCCs, 64 patient-facing websites were eligible for analysis. Overall, 72% of websites mentioned any effect of cancer or cancer therapy on fertility potential. Only 56% of websites had a page devoted solely to the effect of cancer on fertility; information for female patients was more common than for male patients (59% vs 50%). Sperm banking (66% of websites), embryo banking (67%), and oocyte banking (69%) were the most commonly mentioned options for fertility preservation. The least mentioned options for fertility preservation were radiation shielding of gonads (19%) and radical trachelectomy (27%). Referral information that directed a patient to a fertility provider was provided on 63% of websites.

When comparing CC vs. CCC websites, the latter were more likely to include information about the effects of cancer and cancer treatments on fertility and the option for fertility preservation ($p< .001$). CCCs were more likely to include details for fertility preservation methods, including sperm banking, surgical sperm extraction, embryo banking, oocyte banking, ovarian tissue banking, ovarian transposition and ovarian suppression ($p < .05$). CCCs were also more likely to have referral information on their website to a fertility specialist ($p < .05$).

CONCLUSIONS: Patient-directed information pertaining to oncofertility and fertility preservation is absent on greater than 25% of NCI-designated cancer center websites, and represents a gap in comprehensive cancer care and survivorship planning. Patients who rely primarily on internet-based information regarding oncofertility may not be well-informed about fertility preservation options in the critical period between cancer diagnosis and treatment.

ADVERSE PERINATAL OUTCOMES IN ADOLESCENT AND YOUNG ADULT CANCER SURVIVORS AND IMPACT OF ART. Milli Desai, MHS,[1] Beth Zhou, MD,[1] Vinit Nalawade, MS,[1] James Murphy, MD, MS,[1] Brian W. Whitcomb, PhD,[2] H. Irene Su, M.D., M.S.C.E.[1] [1]University of California San Diego, La Jolla, CA; [2]University of Massachusetts, Amherst, Amherst, MA.

OBJECTIVE: Little is known about use of assisted reproductive technology (ART) and adverse perinatal outcomes following ART in female survivors of adolescent and young adult (AYA) cancers. The magnitude of risks for preterm birth and maternal morbidity and whether these risks are moderated by ART use are unknown. We hypothesized that prior AYA cancer is associated with these outcomes, and the effect of AYA cancer differs by ART use.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: We used OptumLabs® Data Warehouse, a longitudinal, real-world data asset with de-identified administrative claims data. Eligibility criteria: female and live birth from 1/1/2001 to 6/30/2019. Primary exposures: AYA cancer preceding pregnancy, and ART. Primary outcomes: preterm birth and CDC-defined severe maternal morbidity. Exposures, outcomes and covariates were defined using ICD, CPT, DRG codes and validated algorithms. Generalized estimating equation log-binomial models estimated associations to account for repeated pregnancy episodes, and control for maternal age. We tested for effect modification of ART on the association between AYA cancer and outcomes, and stratified by birth plurality.

RESULTS: We identified 3,708 singleton and 137 multiple live births after cancer in 3,265 females with prior cancer. The most common cancer types were thyroid (22%), melanoma (21%), and breast (15%). For cancer survivors, mean age at pregnancy was 33.5 (SD 4.7). Cancer survivors used ART more than women without cancer (6% vs. 3% of singleton births, 34% vs. 21% of multiple births). The incidence of preterm birth and severe maternal morbidity in cancer survivors were 15% and 2.5%, respectively, in singleton births and 61% and 18% in multiple births.

In singleton births, compared to women without cancer, cancer survivors had a 1.2-fold higher risk of preterm birth (95% CI 1.1, 1.3) and 1.3-fold higher risk of severe maternal morbidity (1.1, 1.6) after adjusting for age. In multiple births, cancer survivors did not have significantly higher risks of these outcomes.

Cancer survivors had a higher Bateman maternal comorbidity index score than women without cancer. Adjusting for age and comorbidity index, the effect of cancer on outcomes was attenuated, suggesting mediation.

In singleton births, controlling for cancer and age, ART was associated with 1.4-fold higher risk of preterm birth and 1.6-fold higher risk of severe maternal morbidity; in multiple births, the relative risks of each outcome with ART were 1.3 and 1.5, respectively. The interaction between AYA cancer and ART was not significant for any outcomes.

CONCLUSIONS: For AYA cancer survivors, preterm birth and severe maternal morbidity risks are increased and appear to be mediated through more maternal comorbidities. ART independently increased perinatal risks, but the magnitude of increase was no higher than in women without cancer. As adverse perinatal outcomes were increased in multiples, the goal of singleton pregnancies remains paramount. AYA cancer survivors desire healthy pregnancies; ART use presents an important clinical opportunity to modify risks through singleton pregnancies.

MALE REPRODUCTION AND UROLOGY: TRAVELING SCHOLARS

O-55 2:00 PM Saturday, October 17, 2020

THE PROVIDER LANDSCAPE OF MALE INFERTILITY CARE IN THE UNITED STATES. Richard Jacob Fantus, MD,[1] Cecilia Chang, MS,[2] James Wren, MD,[3] Nelson E. Bennett, Jr., MD,[3] Robert E. Brannigan, MD,[3] Joshua A. Halpern, MD, MS.[3] [1]University of Chicago Chicago, IL; [2]NorthShore University HealthSystem, Evanston, IL; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: Recent studies have demonstrated that reproductive endocrinologists perform sperm extraction procedures for male infertility, yet the overall proportion of male infertility care provided by non-urologists is unknown. Using a nationally representative cohort, we sought to assess male infertility visits to examine provider specialization and patient characteristics across the United States.

DESIGN: Retrospective cohort review.

MATERIALS AND METHODS: We examined all male patient visits in the National Ambulatory Medical Care Survey (NAMCS) between 2006-2016, a Center for Disease Control and Prevention (CDC) sponsored dataset designed to characterize ambulatory medical care in the US. The diagnosis of infertility was made using the International Classification of Disease (ICD) 9 codes 606.x for the years 2006-2015 and ICD 10 codes N46.x for the year 2016. Chi-squared tests were used to compare demographic and clinical information of men with and without infertility.

RESULTS: A total of 3,410,129 weighted visits were analyzed of which 1513 (0.04%) were for infertility. Men seen with a diagnosis of infertility compared to those without were on average younger (35 years vs. 58 years, $p<0.05$) and more likely to have private insurance (89.2% vs 50.4%, $p<0.05$). Urologists were responsible for the majority (N=957, 64.6%) of visits for infertility, followed by gynecologists (N=205, 13.6%). When examining the primary diagnosis for each encounter, gynecologists represented 69.4% of infertility diagnoses among non-urologists. Compared to men seen for infertility by urologists, those seen by non-urologists were more likely to be younger (31 years vs. 36 years, $p<0.05$) and Black (18.2% vs. 10.0%, $p=0.04$).

CONCLUSIONS: Over a third (35.4%) of office visits for male infertility were performed by non-urologists, primarily gynecologists. Given the high prevalence of medical comorbidity and treatable etiologies of male infertility among male partners of infertile couples, it is critical that these men undergo evaluation by a reproductive urologist. As models for delivery of care in reproductive medicine continue evolve, further studies are needed to examine referral patterns and integration of care between reproductive endocrinologists and urologists. This will aid in the optimization of access to reproductive urologic evaluation.

PERCEPTIONS OF INFERTILITY AND SEMEN ANALYSIS TESTING AMONG MEN WITHOUT CHILDREN. Matthew Hudnall, MD, MPH, Mary Kate Keeter, MPH, James Wren, MD, Nelson E. Bennett, Jr., MD, Robert E. Brannigan, MD, Joshua A. Halpern, MD, MS. Northwestern University Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: Adult men, particularly those in the millennial generation (age 25-40) and younger, are increasingly targeted by direct-to-consumer (DTC) companies offering diagnosis and treatment of men's health conditions, including home semen testing. However, perceptions of infertility among adult men not actively attempting to conceive and their willingness to undergo semen analysis are not well understood. We hypothesized that men proactive about their health are more likely to be concerned about infertility and undergo semen analysis without a healthcare provider recommendation.

DESIGN: Online survey study conducted via ResearchMatch.com.

MATERIALS AND METHODS: We surveyed men age 18 and older without children (n=634). Sociodemographic data (age, education, income, insurance, relationship status) were collected. Survey questions included 5-point Likert items assessing level of concern and likelihood of performing a particular action, such as discussing infertility with a physician or conducting a semen analysis test without a physician recommendation. Responses were dichotomized and logistic regression estimated the association between participant characteristics and outcomes of interest.

RESULTS: The majority of men (54.7%) were aged 18-39 and in a romantic relationship (55.2%). Only 186 (29.3%) men expressed concern about infertility, whereas 391 (62%) expressed concern about low testosterone. Among men concerned about infertility, 23.4% were unlikely to discuss infertility concerns with a health care provider. On multivariable analysis, factors associated with infertility concern included younger age (age 18-39: OR 4.48, 95% CI 2.23-9.03, $p<0.001$), being single (OR 0.65, 95% CI 0.43-0.97, $p=0.037$), and concern about low testosterone (OR 5.28, 95% CI 3.32-8.40, $p<0.001$).

Of all respondents, 10.4% would obtain a semen analysis without a health care provider recommendation. This increased to 14.2% if the test could be performed at home ($p=0.04$). Factors associated with likelihood to pursue semen analysis included post-graduate degree (OR 0.28, 95% CI 0.11-0.72, $p=0.009$), frequency of doctor visits (1-2 in last year: OR 4.05, 95% CI 1.11-14.83, $p=0.034$), concern about low testosterone (OR 2.30, 95% CI 1.12-4.74, $p=0.023$), and concern about infertility (OR 3.91, 95% CI 2.14-7.15, $p<0.001$). Regular exercise, fitness tracker use, and use of DTC services such as Hims®, Roman®, or 23andMe® were not associated with increased likelihood.

CONCLUSIONS: Millennial and younger men were more concerned about infertility than older men, but many were unlikely to discuss infertility concerns with a healthcare provider. These men were not more inclined to pursue a semen analysis without a health care provider recommendation, even after accounting for use of other DTC health care services. Concerns about low testosterone were pervasive and are strongly associated with both infertility concern and likelihood of self-initiating a semen analysis.

O-57 2:30 PM Saturday, October 17, 2020

WALNUTS IMPROVE SEMEN QUALITY IN INFERTILE MEN: A RANDOMIZED CONTROL DIETARY INTERVENTION TRIAL. John Michael Masterson, MD,[1] Howard H. Kim, MD,[1] Wendie A. Robbins, PhD.[2] [1]Cedars Sinai Medical Center Los Angeles, CA; [2]University of California Los Angeles, Los Angeles, CA.

OBJECTIVE: Walnut-enriched diets have been shown to improve semen parameters in healthy men. The objective of the present study was to measure the impact of walnut consumption on semen parameters in a clinic population diagnosed with male factor infertility.

DESIGN: A randomized, parallel two-group dietary intervention trial with single-blind masking of outcome assessors was conducted with infertility

patients at a major university. The primary outcome was improvement in conventional semen parameters from baseline to 12 weeks.

MATERIALS AND METHODS: Eligible participants were males diagnosed with male factor infertility. Men were ineligible if they had a known food allergy, were smokers, were taking medications for chronic illness, or consumed multivitamins, supplements or walnuts within the prior six months. Participants were randomly assigned to one of two parallel groups: group one received usual care but added ≥45 grams/day of whole-shelled walnuts to their diet, while group two received usual care but added a daily fertility vitamin and avoided consumption of tree nuts. Blood fatty acid/nutrient profiles, 24 hour ASA dietary recalls, and semen parameters were measured at baseline and 12 weeks. Fertility outcomes were tracked for one year.

RESULTS: A total of 75 infertile men, age 27 to 61 completed the study. The group consuming walnuts experienced improvement in sperm motility ($p = 0.02$) and progressive motility ($p = 0.08$) from baseline to 12 weeks (table 1). Both groups saw improvement in percent normal morphology from baseline to 12 weeks with the control group reaching statistical significance ($p = 0.02$), group x time interaction $p = 0.02$ (table 1). The walnut intervention group also experienced a non-significant improvement in sperm concentration (table 1).

CONCLUSIONS: Dietary modification is a safe and cost-effective method of improving semen parameters. Adding dietary walnuts can improve sperm motility for some patients. Whether increased walnut consumption alone will improve fertility outcomes remains to be proven. This is the first walnut dietary intervention randomized control trial (RCT) conducted with male factor infertility patients, however, findings are consistent with two previous RCTs showing improved motility for healthy men of unknown fertility (1,2).

	Baseline mean (SE)	Post-intervention mean (SE)	p
Concentration million/ml			
Control	41.9 (6.81)	45.9 (9.76)	NS
Walnuts	41.9 (8.08)	52.4 (8.32)	NS
Motility %*			
Control	38.3 (6.82)	32.8 (5.76)	NS
Walnuts	35.5 (5.4)	44.6 (6.64)	0.02
Progressive Motility %			
Control	23.2 (4.08)	22 (4.03)	NS
Walnuts	20.4 (3.6)	25.2 (4.49)	0.08
Morphology % Normal			
Control	4.3 (0.86)	5.7 (1.11)	0.02
Walnuts	3.4 (0.76)	4.1 (1.03)	0.09

*ANOVA time x group interaction, $p = 0.02$.

O-58 2:45 PM Saturday, October 17, 2020

AN ANALYTICAL MODEL TO DEFINE THE PROBABILITY OF AZOOSPERMIA FROM SERUM FOLLICLE STIMULATING HORMONE.

Michael B. Tradewell, MD, MS, Andrew Hany Rezk, BA, Elie Nwefo, MS, Emad Ibrahim, MD, HCLD(ABB), Ranjith Ramasamy, M.D. University of Miami Miller School of Medicine Miami, FL.

OBJECTIVE: To develop and internally validate a model to predict the probability of azoospermia from serum follicle stimulating hormone (FSH) in men with infertility.

DESIGN: We reviewed a prospectively maintained database from a male infertility clinic between 01/2016 and 03/2020. Age at semen collection, sperm concentration, FSH, LH, total testosterone, bilateral testis volume (estimated by Prader orchidometer) were extracted from the database. Only pared sperm concentration and clinical data collected within +/-90 days of semen analysis were included. Data from men using medications clomiphene, anastrozole, or human chorionic gonadotropin and from men with diagnoses of Klinefelter Syndrome or Y Chromosome Microdeletion (YCM) AZFc were included. Men with history of vasectomy, solitary testis, recent testosterone or steroid use, and YCM AZFa or AZFb microdeletion were excluded.

MATERIALS AND METHODS: Probability of azoospermia was determined from the quotient of binned FSH data (Number of Azoospermic Samples / Total Number of Samples). A quadratic model predicting probability of azoospermia from FSH was fit to these data. Logistic regression from continuous gonadotropin, testosterone, and testis volume data was used as a comparator. Accuracy and internal validity of each model were assessed via correlation, discrimination (after exclusion of men with obstructive azoospermia) and calibration. All modeling and statistical analysis was computed in *R*.

RESULTS: A total of 946 pared sperm concentration and hormone data sets from 749 men were analyzed. The quadratic FSH model (Probability of Azoospermia = $0.133[FSH]^2 - 0.965[FSH] + 10.1$) fit with a high R^2 (0.95). The model showed an undetectable FSH (<0.2 IU/mL) confers a 10% chance of azoospermia, the probability of azoospermia is least when FSH is 3.6 IU/L. Most interesting was that all men with FSH >30 IU/L were uniformly azoospermic.

On internal validation, the Pearson Correlation Coefficient between the quadratic FSH model and the logistic regression model is 0.93, suggesting excellent agreement. The logistic regression and quadratic FSH models both demonstrated good discrimination with AUCs of 0.86 and 0.84, respectively. Finally, each model is well calibrated with near ideal probabilities throughout the entire range of predictions however the quadratic FSH model's calibration is closer to ideal at higher, more clinically relevant, predicted probabilities of azoospermia.

CONCLUSIONS: Based on a single serum FSH level, our model provides an infertility specialist the ability to predict with a high degree of confidence the probability of azoospermia, especially at high levels suggesting production defect. The utility of this study presents itself during the initial infertility encounter with a male who is apprehensive about performing a semen analysis. Future work will be necessary to externally validate the model.

SUPPORT: None.

CHANGES IN SEMEN ANALYSIS IN UNTREATED NON-AZOOSPERMIC PATIENTS OVER TIME: A TEMPORAL TREND ASSESSMENT OF 23 YEARS.

Nahid Punjani, MD MPH,[1] Omar Al Hussein Alawamlh, MD,[1] Soo Jeong Kim, MD,[2] Carolyn A. Salter, MD,[3] Gal Wald, BA,[1] Miriam Feliciano, BSc,[1] Vanessa L. Dudley, MSHS,[1] Philip S. Li, M.D.,[4] Marc Goldstein, M.D.[5] [1]Weill Cornell Medicine, New York, NY; [2]New York Presbyterian - Weill Cornell Medical Center, New York, NY; [3]Memorial Sloan-Kettering Cancer Center, New York, NY; [4]Weill Cornell Medical College, New York, NY; [5]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To examine trends of population-level semen quality over a 23-year period at a single high-volume institution with a heterogenous patient population.

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: We assessed a total of 12,883 consecutively collected semen samples over 23 years (1997-2019) at Weill Cornell in New York City. We included samples that had an available corresponding date of collection. To remove confounding due to patients with post-vasectomy semen samples, we excluded all patients with sperm concentrations of zero. We examined yearly trends in concentration (million/ml), total sperm count (million), pH, volume (mL), motility (%) and progressive motility (grade 1-4), and morphology (%). To determine trends in semen parameters over time in men presenting for fertility assessment restricted cubic spines were used to model the data due to its non-linearity. Furthermore, differences in estimated average outcomes at the beginning and end of the study period were assessed.

RESULTS: After exclusions, a total of 10,505 semen samples were assessed over our study period. A total of 23-time intervals were included. Semen volume decreased over time and estimate average at the beginning and end were statistically different ($p<0.001$). Similarly sperm morphology decreased overtime, with a statistically significant difference between estimated averages from start to finish ($p<0.001$). Semen pH appeared to be increasing over time, with significant differences between estimated average outcomes at the beginning and end ($p<0.001$). Sperm concentration and count displayed an increase around 2003-2005 but otherwise remained fairly constant over time ($p=0.215$ and $p=0.409$, respectively). Sperm motility appeared to remain relatively similar over time ($p=0.654$).

CONCLUSIONS: In a large subset of patients presenting to a single institution for fertility assessment at a single lab, semen volume and sperm morphology significantly worsened over more than two decades. The etiologies and driving forces changing semen parameters over time remains to be determined.

VIDEO VISITS ALLOW FOR MANAGEMENT OF MALE INFERTILITY ACROSS A BROAD SPECTRUM OF DIAGNOSES. Juan J. Andino, MD, MBA, Alex Zhu, DO, Stephanie Daignault-Newton, MS, Chad Ellimoottil, MD, MS, James M. Dupree, IV, MD, MPH. Michigan Medicine Ann Arbor, MI.

OBJECTIVE: While the COVID-19 pandemic has resulted in a rapid expansion of telehealth services, it remains unknown how video visits, a form of telehealth, can be used to treat male infertility. We sought to evaluate what infertility diagnoses were see and how they were managed through telehealth. Herein we summarize a single institution's experience with video visits for male infertility prior to COVID-19.

DESIGN: Retrospective case series of patients with male infertility managed via video visits.

MATERIALS AND METHODS: We identified video visits completed at our institution between August 21, 2017 and March 17, 2020 for male infertility. All men had a previous in-person examination. We collected patient demographic and referral information, grouped primary diagnoses, categorize what management steps were taken, and determined whether in-person examinations were needed within 90 days.

RESULTS: 70 video visits were completed by 56 men. The median age was 36 years (interquartile range 32 - 40), 78.5% were white, and most patients were referred by their primary care provider or their partner's reproductive endocrinologist (47% and 33%, respectively). Most men were diagnosed with endocrinologic (29%) or anatomic (21%) contributors to infertility. See Table1A for full diagnostic categories.

73% of video visits involved reviewing results such as semen analysis and hormonal testing. 30% of visits involved counseling for assistive reproductive technologies (ART) and, in 25% of visits, hormonally active medications were prescribed. See Table1B for all management categories. There were only two in-person visits within 90 days after a video visit, both of which were planned post-operative visits.

TABLE 1. Diagnostic categories of and management through video visits

A. Diagnostic categories	Proportion
Endocrinologic (hypothalamic-pituitary-gonadal axis)	29%
Anatomic (e.g., varicocele, vasectomy, CBAV)	21%
Idiopathic	16%
Treatment-related concerns (e.g. cancer therapy or medication impact)	9%
Concurrent partner evaluation	9%
Genetic abnormalities	7%
Ejaculatory failure	6%
DNA integrity	4%
Total	100%
B. Male infertility management	Proportion*
Review of results	73%
ART counseling	30%
Medication management	25%
Sperm extraction counseling	14%
Varicocelectomy counseling	13%
Cryopreservation counseling	4%
Referral to other specialists (REI, genetics)	3%

*Visits included multiple management categories; totals do not equal 100%.

CONCLUSIONS: Video visits can be used with established patients to manage a broad spectrum of diagnoses that contribute to male infertility. In the short-term, these visits are serve as substitutes for clinic visits without resulting in additional in-person encounters.

MILITARY SERVICE AND MEDICAL ASSOCIATIONS WITH INFERTILITY IN U.S. VETERANS. Ginny L. Ryan, MD, MA,[1] Marie E. Thoma, PhD, MHS,[2] Andrea Holcombe, MS, PhD,[3] Anne Sadler, PhD, MS,[3] Bradley J. Van Voorhis, MD,[4] Alicia Y. Christy, MD,[5] Michelle A. Mengeling, MS, PhD.[3] [1]Center for Access and Delivery Research and Evaluation Iowa City, IA; [2]University of Maryland, College Park, MD; [3]Iowa City VA Health Care System, Iowa City, IA; [4]University of Iowa, Iowa City, IA; [5]Veterans Administration, Kensington, MD.

OBJECTIVE: Studies suggest U.S. military Veterans have higher rates of poor reproductive outcomes due to unique exposures and complex health challenges. Our objective was to identify associations between lifetime infertility measures and key military service/medical characteristics in Veterans.

DESIGN: Cross-sectional survey study of 1407 female and 1601 male U.S. Veterans aged 20-45.

MATERIALS AND METHODS: Data were collected using computer-assisted telephone interviews. Infertility prevalence and key military service/medical characteristics were analyzed by sex. Lifetime infertility was defined as: 1) twelve or more consecutive months of unprotected intercourse without pregnancy (UI), 2) twelve or more months of trying before any pregnancy (TTP), and 3) ever diagnosis of infertility in participant and/or partner (DX). For depression, eating disorder, and PTSD, Veterans were screened for current disease and self-reported ever diagnosis.

RESULTS: 84.9% reported ever unprotected intercourse and of those 49.6% reported having twelve or more consecutive months without pregnancy. Among those ever pregnant (65.3%; n=919), 45.3% (n=416) reported twelve or months of TTP. Overall, 11.7% (n=165) reported ever being diagnosed with infertility. There were no statistically significant associations between age of enlistment, ever deployed or duration of deployment and any of the 3 infertility measures for female or male Veterans.

Ever deployed male Veterans with infertility were more likely to have been under enemy fire or at risk of IED injury than ever deployed male Veterans without infertility (UI measure, p=0.04). Ever PTSD diagnosis was associated with the DX infertility measure for women (p=0.01) and with UI (p=0.003) and DX (p=0.04) infertility measures for men. Female Veterans with infertility (UI measure) were also more likely to screen positive for current PTSD (p=0.02).

Female Veterans with lifetime infertility (UI measure) were more likely to have ever smoked than female Veterans without infertility (p=0.046). Higher BMI was associated with infertility in female Veterans by all 3 infertility measures (p=0.02-0.0003). Neither of these associations was seen in male Veterans.

Ever diagnosis of depression was more likely in female Veterans with lifetime infertility (by TTC p=0.03 and DX p=0.0002) but not in their infertile male counterparts. Current depression, ever diagnosis of anxiety disorder, and ever diagnosis of or current eating disorder were not significantly associated with any infertility measure in female or male Veterans.

CONCLUSIONS: Consistent with general population studies, several general health-related factors were found to be associated with infertility in women Veterans but not in men. More research is needed regarding the role of traumatic deployment experiences in male Veteran infertility. The role of PTSD as a mediator or moderator, or alternatively an outcome, of infertility for both male and female Veterans also requires additional research to examine the timing of this association. Our results provide evidence to help inform Veteran- and sex-specific infertility care.

SUPPORT: The research reported here was supported by the Department of Veterans Affairs, Veterans Health Administration, Health Services Research and Development (HSR&D) Service grant HSR&D IIR 13-294. THE IMPACT OF AN INTERACTIVE E-LEARNING PLATFORM ON PATIENT COMPREHENSION REGARDING INFERTILITY TREATMENT: A RANDOMIZED CLINICAL TRIAL. Ashley K. Barbour, MPhys,[1] Abigail L. Bernard, MD,[2] Jody L. Madeira, Ph.D., J.D.,[3] Steven R. Lindheim, M.D.,[4] Linnea R. Goodman, MD.[2] [1]Brody School of Medicine at East Carolina University Greenville, NC; [2]University of North

Carolina, Raleigh, NC; [3]Professor of Law, Bloomington, IN; [4]Wright State University, Dayton, OH.

OBJECTIVE: To determine the impact of a multi-media e-learning platform regarding patient comprehension of fertility pathophysiology and treatment.

DESIGN: Prospective randomized controlled trial.

MATERIALS AND METHODS: Consecutive female patients aged 18-43 years undergoing their first intrauterine insemination (IUI) or in-vitro fertilization (IVF) cycle were randomized to receive either standard fertility counseling with their physician and nursing team (Conventional group) or to standard counseling plus an interactive online learning platform (EngagedMD) before and during their first treatment cycle (EMD group). A 15-question online assessment was administered to both groups after completion of their MD consultation/nursing teaching at the start of their treatment cycle (T1) and again at the conclusion of that same treatment cycle (T2) to quantitatively evaluate initial fertility treatment comprehension and whether knowledge was learned and retained over the course of the cycle. Physicians and nurses involved in patient care during the study were also surveyed to determine if a difference in fertility comprehension between groups was noted. A power analysis was performed to determine a sample size adequate to detect a difference of four more questions answered correctly in comprehension between groups and Chi-square and Student's t-test were used as appropriate.

RESULTS: To date, a total of 77 patients have been recruited, 35 undergoing IUI and 42 undergoing IVF, with 52 completing both assessments. The average age of the cohort was 35.2 +/- 4.4 (mean +/- SD) years and the most common reason for fertility treatment was unexplained (50.7%) followed by male factor (29.9%). For both IUI and IVF patients, demographics including age, duration of infertility and education level were similar between groups. Overall, the average scores in the EMD group (n=23) were significantly higher than the conventional group (n=29) at T1 (13.7 +/- 1.6 vs. 11.76 +/- 2.05; $p<0.01$), but were similar at T2 (13.1 +/- 2.1 vs. 12.3 +/- 1.6; $p = 0.11$). When comparing IUI and IVF patients, this difference remained with the EMD group scoring higher at start of treatment in both IUI (13.2 +/- 1.8 vs. 11.0 +/- 3.4; $p = 0.01$) and IVF (14.3 +/- 1.4 vs. 12.4 +/- 1.9; $p = 0.01$) groups and at the conclusion of the IVF cycle (14.1 +/- 1.9 vs. 12.7 +/- 1.3; $p = 0.04$). The IUI group did not score higher at the conclusion of the cycle (12.2 +/- 2.0 vs. 11.8 +/- 1.7; $p = 0.52$). All physicians surveyed ($n = 6$) could not determine a difference in fertility comprehension between groups. However, all nurses (n=4) reported an improvement in comprehension, shorter teaching visits and fewer questions in the EMD group.

CONCLUSIONS: The addition of an online learning platform significantly improved patients' knowledge base at the initiation of first IUI or IVF cycles and at the conclusion of IVF cycles. These results suggest that having access to such resources improve patient understanding of their diagnosis and treatment prior to undergoing fertility therapy.

O-63 10:10 AM Sunday, October 18, 2020

READING LEVEL OF PATIENT EDUCATION MATERIAL ON INFERTILITY CLINIC WEBSITES IS ABOVE NATIONAL RECOMMENDATIONS. Holly Mehr, MD MSEd,[1] Victoria Lee, BS,[1] Tia Jackson-Bey, MD MPH,[2] Christopher Herndon, MD,[3] Molly M. Quinn, MD.[1] [1]University of California Los Angeles, Los Angeles, CA; [2]University of Illinois at Chicago, College of Medicine, Chicago, IL; [3]University of Washington, Seattle, WA.

OBJECTIVE: Patients are increasingly using the internet to answer medically related questions. Most fertility clinics offer patient educational materials (PEMs) via a practice website. The National Institutes of Health (NIH) and the American Medical Association (AMA) recommend that PEMs are written between a 6th and 8th grade reading level. In this study, we assess the reading level of PEMs on fertility clinic websites.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: Between 4/2020 and 5/2020, SART affiliated fertility clinic websites were reviewed for PEMs, defined as content intended to inform patients about the etiology, diagnosis or treatment of a specific disease beyond the purpose of advertising a service performed by the clinic. Clinic characteristics including size, type of practice, and location were collected from SART. To improve reliability of results, only sites with content on hysterosalpingogram (HSG) or intrauterine insemination (IUI) of at least 100 words in length were analyzed. Using 5 validated readability metrics: Flesch-Kincaid Grade Level, Gunning Fog Index, SMOG formula, Coleman-Liau Index and Automated Readability Index, an average reading level was calculated for each PEM. To ensure HSG and IUI were interchangeable and representative of website reading level, the reading levels of HSG were compared to IUI in 15 websites containing both topics using paired t-test. Readability levels were compared across clinic characteristics using one-way ANOVA and chi squared analyses where appropriate.

RESULTS: Of the 382 SART affiliated clinics, 355 had an active, unique website. While most (n=309, 92%) websites had some form of patient education, fewer (n=266/355, 75%) had at least 100 words of PEM on either HSG or IUI and were included in the readability analysis. Analysis of websites with both HSG and IUI material found reading levels between the two to be similar ($p=0.348$). It was more common to find PEMs for analysis in private practices than academic practices (79% vs 60%, $p=0.001$) and in practices with >1000 cycles a year than <200 cycles a year (95% vs 53%, $p<0.001$). Websites with PEM also differed by geographic region, with 62% of midwestern versus 84% southern websites containing PEMs ($p=0.014$).

The average reading level of all PEMs was 12.3 +/- 1.78 grade level (range 6.5-17.3). Only 2.2% (n=6) of PEMs were written at the AMA/NIH recommended grade level. Website reading level was similar between private and academic practices ($p=0.34$), and was not associated with practice size ($p=0.33$). The 15 most readable PEMs included 8 practices in the Western US and all (n=2) SART affiliated clinics in Puerto Rico.

CONCLUSIONS: Most fertility clinics in the United States offer patient education on their websites. However, content is written well above the NIH and AMA recommended 6th to 8th grade reading level. Patients with lower educational attainment have greater need for PEM, but patients of all levels of educational attainment prefer medical information presented in plain, easy to understand language. All infertility patients may be better served with more readable patient education material.

WHAT DO WOMEN NEED TO KNOW TO MAKE INFORMED DECISIONS ABOUT FERTILITY PRESERVATION? A DELPHI ANALYSIS OF PROVIDER-RECOMMENDED KEY FACTS. Sukhkamal Campbell, MD,[1] Aubri S. Hoffman, PhD,[2] Robert Volk, PhD,[2] Terri L. Woodard, M.D.[2] [1]Fellow, Baylor College of Medicine, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.

OBJECTIVE: To support national guidelines that all reproductive-age women should be offered fertility counseling prior to starting cancer treatment, this study sought to identify the key facts newly-diagnosed female cancer patients should know to make an informed decision about fertility-preservation.

DESIGN: Pilot Study.

MATERIALS AND METHODS: *Challenging Choices*: *Understanding the Specific Fertility Needs of Providers and Newly Diagnosed Female Cancer Patients in High and Low Resource Settings* was a clinical pilot study completed at MD Anderson Cancer Center and the Harris County Health System to understand and address gaps in fertility preservation counseling. A portion of the study involved engaging oncologists (medical, pediatric, young adult, and gynecologic) and reproductive endocrinologists in a Delphi survey. Providers completed three rounds of online questionnaires, with anonymized results that were reviewed and revised between rounds. Round 1: provider perception of fertility preservation counseling in a low resource setting. Round 2: A) a fertility facts quiz and B) ranking of facts in order of importance. Facts with more than 5 providers choosing "strongly agree" were retained for round 3. Round 3: provider ranking of most important final "key facts" (6 total).

RESULTS: The majority of the 33 providers were female (73%) with mean age of 51 years old. Overall, 34 reproductive endocrinologists and 25 oncologists were polled. The majority (80%) of providers agreed that

newly diagnosed female cancer patients of reproductive age should be counseled on fertility preservation options regardless of parity, partnership or financial status, or literacy level. The top ranked key-facts were: 1) Many cancer treatments can lead to infertility (the inability to get pregnant), 2) Fertility preservation should be done before starting cancer treatment, 3) Freezing eggs takes about 2 weeks, 4) If your insurance does not fully cover fertility preservation, there may be funds available through your employer (eg Johnson and Johnson, Starbucks) or other organizations (i.e. LIVESTRONG Fertility or Walgreens/Ferring Heart Beat Program) 5) Fertility preservation does not increase the risk of cancer recurrence in the future, and 6) If you choose not to do fertility preservation before cancer treatment, you can consider other family building strategies (i.e. adoption, fostering, third-party options) later.

CONCLUSIONS: Providers confirmed the importance of fertility preservation counseling for all reproductive-age women with cancer prior to initiation of treatment. Before deciding about fertility preservation, women should understand these key facts – infertility is a risk, preserve before cancer treatment (takes 2 weeks) if possible, confirm insurance coverage (or apply for funding), no increase in future cancer risk, and there are alternatives for family building. These facts may be used to guide shared decision making discussions, develop measures (knowledge tests, decision quality indices), design tools (patient decision aids), and inform reimbursement policies for high quality comprehensive cancer care.

DESIRE FOR TWIN OR TRIPLET PREGNANCY IN INFERTILITY PATIENTS AND PATIENTS PRESENTING FOR PLANNED FERTILITY PRESERVATION (FP). Anne P. Hutchinson, M.D.,[1] Rafael Confino, BS,[2] Angela K. Lawson, Ph.D.,[1] Seth Barishansky, M.D.,[1] Mary Ellen Pavone, MD, MSCI.[1] [1]Northwestern University Feinberg School of Medicine Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [2]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: To assess the desire for future twin or triplet pregnancy in patients presenting for planned FP and infertility.

DESIGN: Survey study.

MATERIALS AND METHODS: We designed a 40-question digital survey based on a validated survey developed at University of Iowa and approved by our IRB. Between February 2019 and May 2020, patients presenting to the clinic were asked to participate in a survey study. Those who agreed were routed to our survey which collected de-identified patient demographic information as well as treatment outcomes ranked in order of preference, specifically "no child", "singleton pregnancy, "twin pregnancy", "triplet pregnancy", obstetrical history, openness to multifetal reduction, and understanding of maternal and neonatal risks associated with twin and triplet pregnancies.

Chi-squared analysis was used to compare characteristics of planned FP who prefer twin or triplet pregnancy to those who prefer singleton pregnancy and infertility patients who prefer twin or triplet pregnancy to those who prefer singleton pregnancy.

RESULTS: 337 patients completed our survey, 14% undergoing planned FP and 86% presenting for infertility. 30% of the patients undergoing planned FP and 31% of the patients presenting with infertility identified twin or triplet pregnancy as their ideal pregnancy outcome. In the infertility population, patients who desired twin or triplet pregnancies were less likely to be open to multifetal reduction (p=0.012), had a lower annual household income (p=0.003), and had a larger ideal family size (p=0.004). Importantly, they were also less likely to understand the maternal and neonatal risks that came with twin and triplet pregnancy. While there was no significant effect of parity noted, those who received fertility treatments to conceive a previous child were less likely to desire twin or triplet pregnancy (p=0.036). There was no difference in age between the two groups.

In patients undergoing planned FP, those who desired twin or triplet pregnancy were more likely to be open to multifetal reduction (p=0.027). These patients showed similar understanding of maternal and neonatal risk of twin and triplet pregnancy as their counterparts desiring singleton pregnancy. No other parameters were noted to be significantly different between the groups.

CONCLUSIONS: Nearly one third of our patients desire twin or triplet pregnancy as their ideal outcome. This finding is consistent between our planned FP patients and our patients undergoing treatment for infertility. Our goal as providers is to help our patients achieve the healthiest possible pregnancy and baby, which is most effectively done through singleton pregnancy. While it can be helpful to recognize motivators for these desires, these findings highlight the importance of providing patient education to better align provider and patient goals.

OPTIMIZING PROVIDER AND PATIENT EXPERIENCE: AN ANALYSIS OF AN ONLINE TOOL FOR PRE-IMPLANTATION GENETIC TESTING (PGT) PRE-TEST EDUCATION. Stephanie Sehnert, B.A.,[1] Sarah Yarnall, MSc,[1] Syed U. Abdul Aziz, B.S.,[1] Paul C. Lin, M.D.,[2] Maria Saketos, M.D.,[3] Dina Nusblat, MS, CGC.[4] [1]EngagedMD Washington DC, DC; [2]Seattle Reproductive Medicine, Seattle, WA; [3]NYU Langone Reproductive Specialists of New York, Mineola, NY; [4]CooperGenomics, Livingston, NJ.

OBJECTIVE: Evaluate the patient experience and utility of a digital tool for pre-test PGT education.

DESIGN: There is increased demand for PGT during in vitro fertilization (IVF) treatment, but clinician time to educate patients about testing is limited and pre-test genetic counseling is rare. This study assesses the ability of digital tools to facilitate patient education, support informed consent, and impact overall patient care.

MATERIALS AND METHODS: Patients considering PGT were provided a 15 minute video module consisting of 5 sections. Following each section, patients were required to answer comprehension questions. After completion, an optional survey was provided to assess their experience.

RESULTS: Between July 2018 and November 2019, 1562 patients completed the module and answered all comprehension questions. 246 patients completed the survey. Before the module, 50% (115/230) agreed or strongly agreed they knew what to expect before, during, and after their treatment. Afterwards, 88% (203/230) agreed or strongly agreed. 97% (224/230) felt the module was a helpful addition to the care provided by their medical team and 167/226 were more satisfied with their care after the module. Of 192 respondents, 83% felt the module made them more prepared to sign consent forms. For 92% (211/230), the module answered at least one question the respondent would have asked their medical team.

CONCLUSIONS: As fertility providers struggle to manage increased patient load and the complexities of genetic testing, digital tools can play an important role in the patient education and informed consent process. The results of this survey demonstrate the ability of digital tools to enhance patient education and improve the patient experience, with more than 70% of respondents (73.8%) reporting increased satisfaction with their overall care after completion of the modules. The average comprehension score for patients was 92%, which is evidence of patients' ability to absorb and retain the information. Digital platforms like the one studied here may be an effective way to improve the patient experience while reducing provider burden and time constraints. Further investigation of their utility for topics beyond PGT is warranted.

INCREASED RISK FOR CONGENITAL MALFORMATIONS IN RELATIVES OF MEN WITH POOR SEMEN QUALITY: EVIDENCE FROM THE UTAH POPULATION DATABASE (UPDB). Darshan P. Patel, MD,[1] Joshua J. Horns, PhD,[1] Stevie Kinnear, BS,[2] Heidi A. Hanson, PHD, MS,[1] Kelli X. Gross, MD,[1] Alexander W. Pastuszak, MD, PhD,[1] Ken R. Smith, PhD,[3] James Hotaling, MD.[4] [1]University of Utah Health Salt Lake City, UT; [2]Huntsman Cancer Institute, Salt Lake City, UT; [3]University of Utah, Salt Lake City, UT; [4]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT.

OBJECTIVE: Male reproductive health is a marker of individual somatic health and more recently has been associated with familial health. Familial studies offer a unique opportunity to quantity the effect of genetic and shared environmental exposures on male subfertility and birth outcomes. We have previously shown an increased risk of death from congenital malformations (CM) in relatives of men with lower semen parameters. We examine the association between markers of poor semen quality in men presenting for

infertility workup and any CM in their relatives, within the Utah Population Database (UPDB).

DESIGN: This is a retrospective, population-based, cohort analysis of subfertile men who underwent semen analysis (SA) at our centers for infertility workup (cases). Their clinical records have been linked to the UPDB as part of the Subfertility, Health, and Assisted Reproduction (SHARE) study and with age-matched, fertile male controls drawn from the UPDB (5:1 ratio).

MATERIALS AND METHODS: Relatives of cases and controls were identified using the familial relationship data in the UPDB. CMs were identified using diagnosis data from the Utah Birth Defects Network, birth certificate data, statewide inpatient and ambulatory surgery records, and electronic medical records. Presence of a CM in first-degree relatives (FDR), second-degree relatives (SDR), and first-cousins (FC) were identified through logistic regression analyses among men presenting for SA as part of infertility work-up compared to age-matched, fertile controls. Total motile count (TMC) was categorized by quartiles and sperm concentration and sperm count were each categorized by World Health Organization reference criteria. Separate logistic regression models were estimated for each semen parameter and relative type (FDR, SDR, and FC) to test the association between case-control status and CMs in relatives.

RESULTS: We identified 13,628 men with SA who presented for infertility evaluation, who were matched to 68,140 age-matched, fertile controls. Male relatives had excess risk of a CM compared to female relatives among cases and controls. FDR of men with low TMC (1st quartile), oligospermic for sperm count, or oligospermic for sperm concentration, had an elevated risk of a CM (OR: 1.28 (95%CI: 1.11-1.47); OR: 1.31 (95%CI: 1.10-1.56); OR: 1.25 (1.04-1.49), respectively when compared to fertile controls. There was no significant risk difference for a CM between relatives of azoospermic, normospermic, or hyperzoospermic men or of men in the 2nd, 3rd, or 4th quartiles for TMC and relatives of fertile population controls.

CONCLUSIONS: We found that FDR of men with poor semen quality had a higher risk of CM. This suggests that genetic and epigenetic factors leading to subfertility, in addition to shared environmental exposures, may increase the risk for adverse birth outcomes.

O-68 9:55 AM Sunday, October 18, 2020

MALE INFERTILITY TESTING AND DIAGNOSES REMAIN INFREQUENT FOR INFERTILE COUPLES. Jesse Benjamin Persily, BA,[1] Sameer Thakker, BA,[1] Paxton E. Voigt, BA,[1] Bobby B. Najari, MD MSc.[2] [1]NYU Langone School of Medicine New York, NY; [2]New York University School of Medicine, New York, NY.

OBJECTIVE: To characterize the population of men specifically undergoing infertility testing using a nationally representative survey of the US male population, with a focus on the burden of male infertility diagnoses.

DESIGN: Secondary analysis of the 2011-2017 male responses of the National Survey for Family Growth (NSFG).

MATERIALS AND METHODS: We used the provided sample weights and the complex sample analysis required by the NSFG survey design. All men who sought any medical advice to conceive were included. We looked at the proportion of men who specifically underwent infertility testing. We then looked at the demographic and healthcare utilization characteristics of the men who had received a specific infertility diagnosis, which included low sperm count, varicocele, genetic disorders that alter sperm production, low testosterone, and other infertility diagnosis. We compared men who received a fertility diagnosis to the general population of men who had fathered at least one child using univariate and multivariate logistic regression. Significance was set at $p < 0.05$.

RESULTS: Of the 13,861 men surveyed, 643 sought medical help with their partner to have a baby. In 305 cases, the male underwent infertility testing. Applying the NSFG sample weights, 3,486,602.9 couples (95% Confidence Interval: 3,026,890.3-3,946,315.6), or 6.6% (95%CI: 5.9-7.4) of the population sought medical advice to have a baby, but of these couples, only 53.1% (95%CI: 47.6-58.4) of the men received infertility testing. Of the men who received testing, 30.5% (95%CI: 23.5-38.5) were given at least one specific infertility diagnosis. 25.8% (95%CI: 19.1-32.4) were diagnosed with low sperm count, 3.7% (95%CI: 1.0-13.3) were diagnosed with varicocele, 0.6% (95%CI: 0.0-3.8) were diagnosed with a genetic disorder affecting sperm production, and 3.5% (95%CI: 0.8-9.9) were diagnosed with low testosterone. Comparing men who received an infertility diagnosis to men who had completed a pregnancy, income, marital status, race, education level, whether or not they had a usual place for healthcare, and insurance status were significantly different between the groups. However, on multivariate analysis, only income ($p<0.001$) and marital status ($p=0.001$) remained significantly difference. The men who had received infertility diagnoses had a higher income and were 6.67 times more likely to have been married than not married.

CONCLUSIONS: Despite the fact that male-factor infertility has been implicated in up to 50% of infertile couples, only half the men seeking help to have a child undergo infertility testing. Very few men are being diagnosed with conditions that are quite common in the infertile male, such as varicocele. The men who ultimately receive infertility diagnoses are wealthier and more likely to be married, and thus, analyses that look at men who have presented to an infertility specialist may not be representative of the national infertile population.

O-69 10:10 AM Sunday, October 18, 2020

ICSI OUTCOMES USING SPERMATOZOA WITH OPTIMAL GENOMIC INTEGRITY. Alessandra Parrella, M.Sc., Danielle Rebecca Tavares, B.A., June Wang, B.A., Mounia Haddad, M.D., Philip Xie, B.S., Derek Keating, B.A., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To test whether selecting spermatozoa with an intact genome enhances implantation and pregnancy rates in couples undergoing ICSI.

DESIGN: During the past 3 years, semen specimens from consenting men with prior ICSI failure were screened for sperm chromatin fragmentation (SCF) and double-stranded DNA breaks (DSBs). These tests were performed on raw specimens that were processed by density gradient centrifugation (DGC) and microfluidic sperm selection (MFSS). Couples underwent subsequent ICSI cycles with MFSS processing in order to select spermatozoa with the highest genomic integrity. Embryological and pregnancy outcomes were recorded in the study groups and compared to the historical cycles.

MATERIALS AND METHODS: Consenting men underwent standard semen analysis according to WHO 2010 criteria. DGC and MFSS were used to select spermatozoa with the highest portion of progressively motile spermatozoa. SCF was assessed by terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) on at least 500 spermatozoa utilizing a threshold of $\leq$15%. DSBs were measured by a neutral Comet assay using a modified in-house protocol which assessed at least 200 spermatozoa per patient considering a normal threshold of $\leq$3%. ICSI was performed in the standard fashion.

RESULTS: A total of 63 men with an average age of 41$\pm$10 years had the following average semen parameters: concentration of 26$\pm$31 x 10^6/mL, 33$\pm$14 motility, and 2$\pm$1% morphology. After DGC and MFSS, the sperm concentration was 18$\pm$23 and 8$\pm$13 x10^6/mL, with 55$\pm$33% and 97$\pm$9% motility ($P<0.0001$), respectively. The morphology remained 2$\pm$1% after DGC, and improved to 3.2$\pm$1% after MFSS ($P<0.001$). The SCF decreased from 24$\pm$8% in the raw samples to 19$\pm$10% following DGC, and fell to 1.7$\pm$1% after MFSS processing ($P<0.0001$). DSB rates were 4.1$\pm$1% in the raw samples, 3.3$\pm$2% after DGC, and only 0.3$\pm$0.1% after MFSS ($P<0.0001$). Men (n=39; 42$\pm$7 years) who underwent ICSI with their female partners (38$\pm$3 years) had an average SCF and DSB rate in their raw sample of 23$\pm$9% and 3.9$\pm$1.5%, respectively, which fell to 19$\pm$2% and 3.2$\pm$3% after DCG selection, and dropped to only 1.4$\pm$1% and 0.2$\pm$0.1% after MFSS ($P < 0.0001$). These couples underwent 25 reference ICSI cycles with DGC sperm selection and achieved a fertilization rate of 60.5% (98/162). The implantation rate was only 2.1% (1/47) with a clinical pregnancy rate of 5.0% (1/20), resulting in a pregnancy loss. These couples subsequently underwent 48 ICSI cycles with MFSS and achieved a fertilization rate of 73.1% (333/455; $P<0.01$). The implantation rate rose to 27.3% (26/95; $P<0.001$) and the clinical pregnancy rate increased to 53.3% (24/45; $P<0.001$), resulting in 46.6% (21/45) ($P<0.0001$) of deliveries/ongoing pregnancies.The pregnancy loss rate was 12.5% (3/24).

CONCLUSIONS: According to our study, SCF is strongly correlated with sperm motility. MFSS is the only device capable of yielding the highest portion of progressively motile spermatozoa that therefore have the least amount of DNA damage. Spermatozoa with an intact genome are associated with improved embryonic development and implantation rates in couples undergoing ICSI.

SUPPORT: None

O-70 10:25 AM Sunday, October 18, 2020

MALE FACTOR INFERTILITY AND PLACENTAL PATHOLOGY IN LIVE BIRTHS CONCEIVED WITH IN VITRO FERTILIZATION. Roisin Ryan, MB BCH BAO,[1] Caitlin R. Sacha, MD,[2] Kaitlyn E. James, PhD,[3] Drucilla J. Roberts, MD,[1] Charles L. Bormann, PhD,[3] Irene Souter, MD.[2] [1]Massachusetts General Hospital Boston, MA; [2]MGH Fertility Center, Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: Recent research has highlighted the role of paternal genetics in the makeup of the trophoblast. However, there is little data available on whether male factor infertility affects placental pathology. This study aimed to analyze the effect of male infertility status on placental pathology from live births arising from in vitro fertilization.

DESIGN: This was a retrospective cohort study of 1035 live births with placental pathology arising from autologous in vitro fertilization cycles performed at MGH Fertility Centre between 2004 and 2017.

MATERIALS AND METHODS: Placental pathology was reported as anatomic, infectious, inflammatory, or vascular/thrombotic. Primary outcomes were differences in placental pathology between live births arising from cycles of couples with and without male factor infertility. Male factor infertility was defined as having a total motile count of less than 15 million, with severe cases less than 5 million, in a pre-IVF semen analysis. Demographic, cycle and placental outcomes were compared with chi square tests, Student's t-tests or non-parametric tests, as appropriate. Multivariate logistic regression models were used to compare placental pathology between groups, adjusting for maternal age, race, BMI, gestational age at delivery, number of fetuses born, number of embryos transferred, transfer type, fertilization method

RESULTS: 1035 cycles were included in this analysis, 145 of which were from couples with a diagnosis of mild male factor infertility and 192 from couples with a diagnosis of severe male factor infertility. There were no differences in maternal age (p=0.083), maternal race (p=0.35) or ethnicity (p=0.37), nulliparity status (p=0.31), hormone measurements (D3 FSH (p=0.67), AMH (p=0.32) or peak estradiol (p=0.81) levels) across groups. There were no significant differences in IVF stimulation protocols (p=0.07) or numbers of embryos transferred per cycle (p=0.73) between groups. Mild and severe male factor infertility groups were significantly more likely to have ICSI as part of their fertilization method (p<0.001). Gestational age at delivery (p=0.07) and median birthweight (p=0.94) did not differ significantly between groups. Measured obstetric outcomes including mode of delivery (p=0.16), postpartum hemorrhage (p=0.38) and hypertensive disorders (p=0.63) were not significantly different between groups. There was no difference in placental pathology outcomes between couples with or without a male factor infertility diagnosis.

CONCLUSIONS: Male factor infertility status was not significantly associated with placental outcomes amongst this cohort. In the setting of an increasing prevalence of male-factor infertility, further prospective research is needed to reproduce and validate this finding.

RELATIONSHIP BETWEEN SEMEN PARAMETERS AND PATERNAL ORIGIN OF ANEUPLOIDY. Marissa L. Luck, MD,[1] Dana B. McQueen, MD, MAS,[1] Rachel Ruderman, MD, MPH,[1] Lydia Hughes, MD,[1] Melissa K. Maisenbacher, M.S.,[2] Christina E. Boots, MD, MSCI,[1] Eve C. Feinberg, M.D.[1] [1]Northwestern University, Chicago, IL; [2]Natera, San Carlos, CA.

OBJECTIVE: To evaluate the relationship between semen analysis parameters and embryonic aneuploidy of paternal origin.

DESIGN: Retrospective Cohort Study.

MATERIALS AND METHODS: Institutional Review Board approval was obtained. All in vitro fertilization (IVF) cycles utilizing preimplantation genetic testing for aneuploidy between 1/2015 and 1/2020 were reviewed. The World Health Organization 2010 criteria were used to evaluate semen parameters. The paternal aneuploidy rate was the number of embryos with paternal aneuploidy or mixed aneuploidy (maternal and paternal aneuploidy) divided by the total number of embryos tested. Continuous variables were compared with a student's t-test and categorical variables with a Chi-square.

RESULTS: A total of 1,245 IVF cycles were included; 617 cycles in men with normal semen parameters and 628 cycles in men with abnormal semen parameters. The parental origin of aneuploidy was available for 453 cycles and 1,720 embryos. The mean paternal age (38 years, SD 4.9), maternal age (36.6 years, SD 3.8), maternal body mass index (24.8 kg/m^2, SD 5.0), number of oocytes retrieved (15.8, SD 9.1), and number of blastocysts biopsied (3.8, SD 2.9) were not different between the two groups. Neither embryonic aneuploidy rates (50.3% vs 50.1%, P=0.48) nor paternal origin of aneuploidy (8.8% vs. 8.0%, P=0.54) were different between groups. Furthermore, there was no difference in the paternal aneuploidy rate between men with normal and abnormal sperm concentration, total count, motility or morphology (Table). There was also no difference in mean sperm concentration, total count, or morphology among cycles resulting in ≥50% (N=31) or cycles with 100% paternal aneuploidy (N=10), compared to cycles with 0% paternal aneuploidy (N=332). Male partners with cycles resulting in 50% or 100% paternal aneuploidy had a higher mean motility (60.5% and 66.8%), compared to cycles with 0% paternal aneuploidy (53.2%).

CONCLUSIONS: There was no association between semen analysis parameters and paternal aneuploidy rates. Couples with male factor infertility can be reassured that abnormal semen parameters are not associated with increased aneuploidy rates due to the male contribution.

Semen analysis parameters	Paternal aneuploidy rates per embryo tested		
	Normal	Abnormal	p-value
Semen analysis (any parameter)	8.8% (75/854)	8.0% (69/866)	0.54
Concentration (15 mil/ml)	8.7% (121/1390)	7.0% (23/330)	0.20
Total count (39 million)	8.5% (105/1238)	8.1% (39/482)	0.85
Motility (40%)	8.8% (127/1438)	6.0% (17/282)	0.13
Progressive motility (32%)	8.7% (122/1401)	6.9% (22/319)	0.32
Morphology (4%)	9.0% (88/979)	7.8% (40/515)	0.44
Severe oligo/ azoospermia (5 mil/mL)	8.6% (134/1567)	6.5% (10/153)	0.45

THE RELATIONSHIP BETWEEN PATERNAL BODY MASS INDEX (BMI) AND PATERNAL ANEUPLOIDY RATES. Lydia Hughes, MD,[1] Dana B. McQueen, M.D., M.A.S.,[1] Rachel Ruderman, MD, MPH,[1] Marissa Luck, M.D.,[1] Melissa K. Maisenbacher, M.S.,[2] Eve C. Feinberg, M.D.,[1] Christina E. Boots, MD, MSCI.[1] [1]Northwestern University Chicago, IL; [2]Natera, San Carlos, CA.

OBJECTIVE: To examine the association between paternal BMI and embryonic aneuploidy of paternal origin.

DESIGN: Retrospective Cohort.

MATERIALS AND METHODS: Institutional Review Board approval was obtained. All in vitro fertilization (IVF) cycles utilizing preimplantation genetic testing between 1/2015 and 1/2020 were reviewed. Obesity was defined as a BMI ≥30 kg/m^2. Embryonic aneuploidy and paternal aneuploidy rates were compared between non-obese and obese male partners. Continuous variables were compared with a student's t-test and categorical variables with a Chi-square. Multivariable regression analysis was used to control for potential cofounders.

RESULTS: A total of 1089 IVF cycles were included; 855 cycles in men with a BMI < 30 and 234 cycles in men with a BMI ≥30. There was no significant difference in female age, anti-mullerian hormone (AMH), or number of blastocysts biopsied between groups. The non-obese group did have a significantly lower paternal age, lower maternal BMI, and a greater number of oocytes retrieved (Table). The embryonic aneuploidy rate was not different between non-obese and obese men, 50.1% versus 51.9%, P=0.37. The parental origin of aneuploidy was available for 399 cycles. The paternal aneuploidy rate was not different between non-obese and obese men, 7.9% versus 9.1%, P=0.5. In addition, there was no difference in paternal BMI among cycles with ≥50% (N=27) or 100% (N=9) paternal aneuploidy, compared to 0% (N=288) paternal aneuploidy,

All values in: Result (SD)	Paternal BMI < 30 (N=855 IVF cycles, 3292 embryos tested)	Paternal BMI > 30 (N= 234 IVF cycles, 835 embryos tested)	P-value
Paternal Age, yr	38.4 (5.1)	39.4 (5.4)	0.009*
Paternal BMI, kg/m^2	25.7 (2.5)	33.4 (3.5)	< 0.0001*
Maternal Age, yr	36.5 (3.9)	36.9 (3.4)	0.15
Maternal BMI, kg/m^2	24.1 (4.6)	27.0 (6.3)	< 0.0001*
AMH, ng/mL	3.0 (2.6)	2.8 (2.5)	0.29
Day 3 FSH, mIU/ml	8.0 (7.6)	8.1 (2.6)	0.84
Days of Stimulation	10.6 (1.6)	10.5 (1.5)	0.39
Peak E2, pg/ml	2466.9 (1463.4)	2177.6 (1215.3)	0.006*
Oocytes Retrieved	16.2 (9.5)	14.7 (7.6)	0.03*
Mature Oocytes	10.9 (7.5)	10.3 (6.4)	0.26
Fertilized Oocytes	9.1 (6.3)	8.8 (5.4)	0.51
Blastocysts Biopsied	3.9 (2.9)	3.6 (2.7)	0.16
Aneuploidy Rate per Embryo	50.1% (1649/3292)	51.9% (433/835)	0.37
Paternal Aneuploidy Rate per Embryo	7.9% (96/1209)	9.1% (30/328)	0.50

BMI 28.6 kg/m^2 ± 5.3 and 27.5 kg/m^2 ± 4.5 versus 27.5 kg/m^2 ± 4.1, respectively. After a multivariable linear regression to control for paternal age, maternal BMI and oocyte number; paternal BMI was not associated with paternal aneuploidy.

CONCLUSIONS: There was no significant difference in overall aneuploidy or paternal aneuploidy between non-obese and obese men. Thus, our findings are reassuring that paternal obesity is not associated with paternal aneuploidy rates.

PREIMPLANTATION GENETIC TESTING

O-73 9:40 AM Sunday, October 18, 2020

A MULTI-CENTER, PROSPECTIVE, BLINDED, NON-SELECTION STUDY EVALUATING THE PREDICTIVE VALUE (PV) OF AN ANEUPLOID DIAGNOSIS WITH PGT-A AND THE IMPACT OF BIOPSY. Ashley W. Tiegs, MD,[1] Xin Tao, Ph.D,[2] Yiping Zhan, Ph.D,[3] Christine V. Whitehead, BSN, RN,[4] Emre Seli, MD,[1] George Patounakis, MD, PhD,[5] Jacqueline Gutmann, MD,[6] Arthur J. Castelbaum, MD,[7] Thomas Kim, MD,[8] Chaim Jalas, N/A,[2] Richard Thomas Scott, Jr., MD.[1] [1]IVI RMA New Jersey Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]The Foundation for Embryonic Competence, Basking Ridge, NJ; [4]IVI-RMA New Jersey, Basking Ridge, NJ; [5]IVI-RMA, Florida, Lake Mary, FL; [6]IVI-RMA, Philadelphia, Philadelphia, PA; [7]IVI-RMA Philadelphia, Philadelphia, PA; [8]IVI-RMA Southern California, Los Angeles, CA.

OBJECTIVE: Two concerns regarding PGT-A are: 1) embryos labeled aneuploid may be reproductively competent and thus may be wrongfully discarded, and 2) trophectoderm (TE) biopsy may have an adverse effect on embryo reproductive potential. This study addresses these concerns by 1) directly measuring the predictive value (PV) of an aneuploid PGT-A diagnosis, and 2) comparing sustained implantation rates (SIR) of the study group to a control group, in which biopsy/ PGT-A were not utilized.

DESIGN: Prospective, blinded, multi-center non-selection study.

MATERIALS AND METHODS: 1) We first conducted a prospective, blinded, multi-center non-selection study in which all participants (n=402) underwent ICSI and blastocyst culture. Blastocysts underwent TE biopsy followed by vitrification. In the next cycle, patients underwent single embryo transfer (SET) of the best embryo selected solely on morphology. PGT-A analysis (targeted amplification, NGS-based) was performed only after the clinical outcome was known. Clinical outcomes were compared to PGT-A results to calculate the PV of an "aneuploidy" diagnosis. 2) To determine the impact of the biopsy, the SIR of the patients in the non-selection study (n=484 transfers) was compared to that of a control group (n=1208) undergoing cryo-SET not using PGT-A. As neither had access to PGT-A results, the groups differed only in that embryos in the study group had undergone TE biopsy.

RESULTS: 1) In the non-selection study, PGT-A analysis of the TE samples diagnosed 102 (out of 484 transferred) as "aneuploidy." The SIR of embryos diagnosed as aneuploidy was 0% (0/102) (binomial proportion 95% CI 0-2.4%); therefore, the PV of an aneuploidy result for failure to deliver was 100%. The PV for a euploid result to predict SIR was 64.7% (p<0.001). 2) When compared to the control group (n=1208) who underwent cryo-SET without biopsy or PGT-A, the mean SIR of all patients in the non-selection study group (including all euploid and aneuploid transfers) was not different (47.9% versus 45.8% (OR 1.17 (95% CI 0.93-1.46)); p=0.17), demonstrating no detectable detrimental effect of the TE biopsy.

CONCLUSIONS: The PGT-A assay evaluated does not result in the discard of embryos with significant reproductive potential. Additionally, the TE biopsy has no detectable adverse impact on sustained implantation. Overall, these data support the safety and benefit of utilization of this PGT-A assay.

PGT-A Diagnosis	Ongoing Pregnancy/ Delivered	Failed or No Pregnancy	Total	Sustained Implantation (%)
Aneuploid	0	102	102	0.0%
Euploid	202	110	312	64.7%

IDENTITY MARKER ANALYSIS DEMONSTRATES THAT MOST INITIAL AND RE-BIOPSY PAIRS ARE CONCORDANT. Lauren Walters-Sen, PhD, FACMG, Dana Neitzel, MS, CGC, Sara L. Bristow, PhD, Asia D. Mitchell, PhD, Charlene A. Alouf, PhD HCLD, Swaroop Aradhya, PhD, FACMG. Invitae San Francisco, CA.

OBJECTIVE: To determine the identity marker concordance rate between initial embryo biopsies and re-biopsies in the context of preimplantation genetic testing for aneuploidy (PGT-A).

DESIGN: Failure to obtain an actionable result is one limitation of PGT-A independent of the testing platform. "No-results" can be categorized into two groups, 1) those with failed amplification (FA) or 2) indeterminate (IND) samples for which data from the amplified DNA is uninterpretable. An alternative to discarding or transferring no-result embryos is to re-biopsy for repeat screening. Since the process from biopsy to PGT result is not fully automated, the potential for labeling error exists due to the multiple steps involved. To determine the rate of error, we retrospectively compared single nucleotide polymorphisms (SNPs) between initial biopsy and re-biopsy material to determine identity concordance rates.

MATERIALS AND METHODS: In total, 2350 trophectoderm biopsies from previous no-result embryos from 106 IVF centers were submitted for re-analysis. Samples were analyzed using FAST-SeqS, an NGS-based assay enhanced with genome-wide SNPs (>10,000). For 2079 biopsy pairs, SNP genotypes were compared between the rebiopsy sample and all samples submitted in the initial case to determine concordance rates; data were then stratified into three categories: full match, sibling, or unrelated.

RESULTS: Actionable results were obtained in >95% of all re-biopsies (2246 of 2350). There was no apparent difference in the ability to obtain results when broken down by result type (FA or IND) or biopsy day. With an average egg age of 35 years, more than half (58%; 1317/2246) of re-biopsies with results were euploid.

Identity marker concordance analysis was performed for 2079 biopsy pairs (FA=1118; IND=961). The majority of initial IND samples had ample SNP data to determine full matches; 98.44% of biopsy pairs were full matches (946/961). For initial FA samples with limited SNP data, full matches between biopsy pairs could not be determined; 98.57% were consistent with a sibling match (1102/1118).

Of the 31 discordant re-biopsy pairs, 16 were unrelated, while 15 were identical matches to a different embryo number from the original biopsy set (sibling).

CONCLUSIONS: Ninety-five percent of re-biopsies yielded actionable results and despite the additional work and expense for the clinic, it is important that these embryos be identified as no-results, rather than be potentially resulted as abnormal, to avoid discarding embryos that may lead to a normal live birth.

As expected, our analysis confirmed that the majority of re-biopsies are in fact taken from the same embryo as the original biopsy. However, it is important to note that ~2% indicate a sample swap, thus identifying room for labeling and workflow improvement on both the IVF lab and PGT-A lab to reduce the likelihood of incorrect embryo assignment. The incorporation of SNPs into a PGT-A assay has many utilities including the ability to identify polyploidy, uniparental isodisomy, as well as to confirm sample identity matches.

DO WE STILL NEED TO DEPRIORITIZE THE TRANSFER OF 'LOW GRADE MOSAIC EMBRYOS'?

Tih Tan, MS,[1] Luca Pagliardini, Bs,[2] Xia Li, PHD,[3] Michel Chaires, MS,[3] Jennifer Lew, BS,[3] Paul Sinogaya, BS,[3] Bradford Kolb, MD, FACOG,[1] Jeffrey R. Nelson, DO FACOOG,[1] John M. Norian, MD FACOG,[1] John Wilcox, MD, FACOG,[1] Patrizia Rubino, MS.[1] [1]HRC Pasadena Pasadena, CA; [2]IRCCS San Raffaele Scientific Institute, Milano, Italy; [3]Nexgenomics LLC, Pasadena, CA.

OBJECTIVE: The efficiency of PGT-A is currently the subject of great debate for possible embryo wastage associated with the technique. Thus, the establishment of evidence-based guidelines for transferring mosaic embryos has become a priority. In this study, we compared the clinical outcomes of over a hundred embryos diagnosed as low grade (<50%) mosaic with embryos diagnosed as euploid by Next Generation Sequencing (NGS). At the time of transfer, no prioritization of euploid embryos versus low grade mosaic embryos were applied.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Up to April 2019, our policy was to classify embryos as euploid when the percentage of normal cells in the TE biopsies was determined to be $\geq$ 50%. The genetic profiles of 896 embryos transferred in single frozen embryo transfers cycles (Jan 2018-Dec 2018) were retrospectively analyzed in order to identify those that would have been classified as mosaic if the Preimplantation Genetic Diagnosis International Society guidelines were applied. Logistic and linear regression analysis were conducted to correct the results for use of day 5 blastocyst, egg donors and gestational carriers.

RESULTS: Out of the 896 embryo transferred, 784 were euploid and 112 were mosaic (range 20-50%). Live birth rates (LBRs) were similar between euploid (58.0%) and mosaic (56.3%) blastocysts. After correction for confounders, the Odds Ratio (OR) for LBR in the mosaic group was 0.88 (95%CI 0.59-1.33, p=0.56). In the mosaic group, after stratifying by the number of chromosomes involved, the adjusted OR for LBR was 1.04 (95%CI 0.65-1.67, p=0.87) when only one chromosome was involved (n=82), and 0.65 (95%CI: 0.30-1.40) when more chromosomes (n=30) were involved, however, the difference was not significant (p=0.27). LBR was higher when a day 5 blastocyst was transferred (OR 1.61, 95%CI 1.15-2.24, p=0.005) and a gestational carrier was involved (OR 1.66, 95% CI 1.21-2.28, p=0.002). The abortion rate (ABR) in the mosaic group was not higher than the ABR in the euploid group, either when one (OR 1.11, 95%CI 0.50-2.48, p=0.79) or more chromosomes were involved (OR 1.07, 95%CI 0.23-4.9, p=0.93). The biochemical pregnancies were higher, but not statistically different, when more than one chromosome was involved (OR 2.74, 95%CI 0.87-8.69, p=0.08). Finally, the birth weights (BW) were similar between euploid (7.1 $\pm$ 1.2 lb) and mosaic (7.0 $\pm$ 1.4 lb) embryos; the adjusted BW differences in the stratified population were -0.10 lb (95%CI -0.48 to 0.29, p=0.62) when one chromosome was involved and -0.23 (95%CI -0.95 to 0.48, p=0.65) when more chromosomes were involved. One therapeutic abortion was reported for each group.

CONCLUSIONS: Our results show that low grade mosaic embryos give the same results in term of LBR, AR and BW as euploid embryos. Excluding "low grade mosaic embryos" may result in a depletion of the pool of embryos to transfer, reducing the chance for the patient to take home a baby. Due to increasing evidence, the current guidelines that advise to initiate a further PGT-A cycle before considering transferring a mosaic embryo should be loosen at least for the "low grade mosaic embryos".

IVF PGT-M VERSUS NATURAL CONCEPTION WITH PRENATAL DIAGNOSIS FOR HUNTINGTON'S DISEASE: A COST-EFFECTIVENESS ANALYSIS.

Alicia A. Christensen, B.A.,[1] Alyssa R. Hersh, M.D., M.P.H.,[1] Pamela B. Parker, M.D., M.P.H.,[1] Aaron B. Caughey, M.D., Ph.D.,[1] Sacha A. Krieg, M.D., Ph.D.[2] [1]Oregon Health & Science University, Portland, OR; [2]Oregon Health and Science University, Portland, OR.

OBJECTIVE: In 2018 The American Society of Reproductive Medicine (ASRM) published an ethics committee opinion regarding the use of Preimplantation Genetic Testing for Monogenic Disease (PGT-M) for adult-onset conditions, such as Huntington's Disease (HD). We aimed to investigate if IVF PGT-M is cost-effective for heterozygous individuals with HD versus natural conception with prenatal diagnosis (PND).

DESIGN: Cost-effectiveness analysis from a societal perspective of couples, where one individual is heterozygous for HD, undergoing IVF PGT-M compared to natural conception with PND.

MATERIALS AND METHODS: A decision-analytic model using TreeAge Pro software was developed with a theoretical cohort composed of 3,851 couples which contain one individual who is heterozygous for HD and one unaffected individual. Outcomes included procedure-related loss, spontaneous abortion (SAB), termination of pregnancy (TOP), early/normal/late onset HD in addition to cost and quality-adjusted life years (QALYs) for both parents. A willingness-to-pay threshold was set at $100,000/QALY.

RESULTS: IVF PGT-M is both lower in cost and higher in effectiveness compared to natural conception with PND among couples with one heterozygous HD individual, making it the dominant strategy. All measured outcomes were lower in the IVF PGT-M strategy including 39 fewer procedure-related losses, 116 fewer SABs, 462 fewer TOPs. Most notably, in our theoretical cohort of couples, IVF PGT-M resulted in 1,079 fewer HD-affected offspring. IVF PGT-M was also associated with 45 more QALYs and a cost saving of $65,334.757. Our results were robust over a wide range of assumptions.

CONCLUSIONS: We found IVF PGT-M to be a cost-effective strategy compared to natural conception with PND when one of the individuals is heterozygous for HD. Not only can morbidity and mortality incurred by HD be mitigated for the offspring by using IVF PGT-M, this study is the first to demonstrate the cost effectiveness of utilizing IVF PGT-M for those with HD.

TABLE 1.

	IVF PGT-M	Natural Conception	Difference
Procedure-related loss*	0	39	-39

TRANSFER OUTCOMES OF EMBRYOS WITH PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A) DIAGNOSES OF UNDETERMINED REPRODUCTIVE POTENTIAL: RESULTS FROM A PROSPECTIVE, BLINDED, MULTI-CENTER NON-SELECTION STUDY.

Ashley W. Tiegs, MD,[1] Xin Tao, Ph.D,[2] Yiping Zhan, Ph.D,[3] Christine V. Whitehead, BSN, RN,[4] Brent M. Hanson, MD,[1] Julia G. Kim, MD, MPH,[1] Emily K. Osman, MD,[1] Emre Seli, MD,[1] George Patounakis, MD, PhD,[5] Jacqueline Gutmann, MD,[6] Arthur J. Castelbaum, MD,[7] Thomas Kim, MD,[8] Chaim Jalas, N/A,[2] Richard Thomas Scott, Jr., MD.[1] [1]IVI RMA New Jersey Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]The Foundation for Embryonic Competence, Basking Ridge, NJ; [4]IVI-RMA New Jersey, Basking Ridge, NJ; [5]IVI-RMA, Florida, Lake Mary, FL; [6]IVI-RMA, Philadelphia, Philadelphia, PA; [7]IVI-RMA Philadelphia, Philadelphia, PA; [8]IVI-RMA Southern California, Los Angeles, CA.

OBJECTIVE: In reports describing outcomes associated with transfer of whole chromosome mosaicism (MOS) and segmental abnormality (SEG) PGT-A embryos, such embryos are typically the only available for transfer. Therefore, patients in these series likely have reduced prognosis. To truly assess the reproductive potential of PGT-A MOS and SEG embryos, transfer must be performed in a non-selected manner. The present study aimed to report clinical outcomes associated with PGT-A MOS and SEG embryos after transfer in a prospective, blinded non-selection study.

DESIGN: Subset evaluation within a larger prospective, blinded, multicenter, non-selection study.

MATERIALS AND METHODS: This was a prospective, blinded, multicenter, non-selection study including couples undergoing their first in vitro fertilization (IVF) cycle. Couples with endometrial insufficiency or antral follicle count < 8 were excluded. Routine procedures included ICSI and blastocyst culture. All usable blastocysts underwent trophectoderm (TE) biopsy but transferred prior to biopsy analysis. Targeted NGS-based PGT-A was performed only once the clinical outcome of the transfer was determined. Clinical outcomes were then compared to PGT-A results. Specifically, outcomes associated with the transfer of PGT-A MOS and SEG results were evaluated.

RESULTS: In total, 402 patients underwent 484 single, frozen, blastocyst transfers (Jan 2014 - Dec 2019). Of all embryos transferred, 3.3% (n=16) were diagnosed as MOS and 8.1% (n=39) as SEG once PGT-A results were un-blinded. Clinical outcomes are described in Table 1. Outcomes associated with PGT-A euploid and aneuploid diagnoses are provided for comparison only.

CONCLUSIONS: Transfer of embryos with PGT-A diagnosis of MOS appear to result in outcomes similar to that of euploid embryos, while those with a diagnosis of SEG appear to have lower sustained implantation and live birth rates. However, due to the low incidence of MOS and SEG PGT-A results with this NGS-based assay and the resultant limited sample size, there is insufficient power to calculate predictive values associated with such diagnoses. Further research is needed.

SEGMENTAL ANEUPLOIDY RATES OBSERVED IN ~192,000 BLASTOCYSTS BY FAST-SEQS SUPPORT INCLUSION IN PGT-A ASSAYS.

Lauren Walters-Sen, PhD, FACMG, Dana Neitzel, MS, CGC, Sara L. Bristow, PhD, Asia D. Mitchell, PhD, Nicole Faulkner, PhD, FACMG, Swaroop Aradhya, PhD, FACMG. Invitae San Francisco, CA.

OBJECTIVE: Assessing clinical impact of transferring embryos with segmental aneuploidies (SAs) identified through preimplantation genetic testing for aneuploidy (PGT-A) is difficult as not all SAs lead to miscarriage and/or birth defects. In order to support the inclusion of SAs in PGT-A assays, we analyzed the incidence and types of SAs across all chromosomes in our cohort.

DESIGN: Retrospective cohort study of PGT-A biopsy results.

MATERIALS AND METHODS: Trophectoderm biopsies were analyzed using our modified FAST-SeqS method and bioinformatics pipeline, which detects whole chromosome and segmental aneuploidies (≥10Mb), most types of polyploidy, and many instances of single chromosome uniparental isodisomy. [1-3] Similar to other PGT-A platforms, the p arms of the acrocentric chromosomes were not analyzed. SAs derived from known rearrangement carriers and complex abnormalities (gains and losses within a chromosome) were excluded. SA rates were stratified by type (deletion [del], duplication [dup]) and location, and egg age.

RESULTS: The dataset consisted of 191,855 embryos from 40,439 cycles. Mean egg age was 35 years (range 18-55 years). Of all resulted samples, 51.3% were euploid. SAs were detected in 11.2% of biopsies, of which 4.0% were observed along with at least one whole chromosome abnormality. SAs were observed across all ages including donor eggs and had no correlation with clinical indication. Dels/dups were detected on all analyzed chromosome arms and frequency was roughly correlated with size. Among individual SAs (n=26,707), whole-arm abnormalities were more common than partial-arm abnormalities, comprising 23-25% of all SAs. Of the 10 most common SAs (n=2,363), 87% were whole-arm changes primarily involving chr9, chr1, and chr7. The most common partial-arm SAs involved 7q21-q36, 11q14-q25, and Xq21-q28.

CONCLUSIONS: To our knowledge, this is the largest study reporting SA rates in blastocysts. Our data supports the observed rates of SAs reported in the literature (8-15%[4]) and demonstrates consistency across all age groups, unlike whole chromosome aneuploidy. As expected, most dels/dups involved whole chromosome arms, with larger chromosomes having more segmental events. While it is known that whole-arm dels/dups have dire clinical consequences, the field remains divided on the utility of assessing embryos for partial-arm SAs. Of the most frequent partial-arm SAs seen in our cohort, many are associated with known syndromes that cause birth defects and intellectual disability. Additionally, the most frequently observed SAs in our dataset were not only similar to those reported in blastocysts but also miscarriage tissue.[5-7] Despite the fear of discarding embryos that may result in a healthy child, the potential to cause miscarriage and/or an affected child warrants the inclusion of SA analysis in PGT-A assays.

INSULIN-LIKE GROWTH FACTOR 2 PROMOTES DEVELOPMENT AND FUNCTION OF MACAQUE PREANTRAL FOLLICLES DURING THREE-DIMENSIONAL CULTURE. Shally N. Wolf, B.S., Maralee Lawson, B.S., Olena Y. Tkachenko, Ph.D., Jing Xu, Ph.D. Oregon Health & Science University, Beaverton, OR.

OBJECTIVE: This study was to investigate the direct action of insulin-like growth factor 2 (IGF2) on growth and function of primate preantral follicles in vitro.

DESIGN: Rhesus macaque (Macaca mulatta) follicles were studied individually during matrix-free three-dimensional culture.

MATERIALS AND METHODS: Ovaries were obtained from adult rhesus macaques (6-9 years old; n = 3) through an institutional tissue distribution program. Preantral follicles (diameter = 140-180 um) were mechanically isolated and cultured individually in the ultra-low-attachment plate containing alpha minimum essential medium supplemented with follicle-stimulating hormone and insulin at 20% O2 for 2 weeks. Follicles were randomly assigned to two groups (12 follicles/animal/group), including (a) control media only and (b) 50 ng/mL recombinant human IGF2 supplementation. Follicle survival was assessed and follicle diameters were measured weekly by microscopy. Media samples collected at culture week 2 were assayed for anti-Mullerian hormone and inhibin B concentrations by ELISA. Data were analyzed using mixed models.

RESULTS: IGF2 addition increased preantral follicle survival rates compared with controls at week 2 (85 $\pm$ 6 versus 68 $\pm$ 3%; $P < 0.05$). Although follicle diameters were comparable between culture groups at week 1 (control versus IGF2: 181 $\pm$ 4 versus 174 $\pm$ 3 um), follicles exposed to IGF2 had greater diameters than those of controls at week 2 (248 $\pm$ 10 vs. 210 $\pm$ 7 um; $P < 0.05$). While media concentrations of anti-Mullerian hormone were not altered by IGF2 supplementation (control versus IGF2: 7 $\pm$ 1 versus 6 $\pm$ 1 ng/ml), IGF2-treated follicles produced higher levels of inhibin B relative to control follicles at week 2 (1.4 $\pm$ 0.2 versus 0.9 $\pm$ 0.2 ng/ml; $P < 0.05$).

CONCLUSIONS: These data demonstrate that IGF2 promotes survival and growth of primate preantral follicles with increased inhibin B production. IGF2 is the predominant circulating form of insulin-like growth factors in primate species, which plays a key role during antral follicle maturation by stimulating granulosa cell proliferation and theca cell differentiation. IGF2 is also produced locally by antral follicles, which can induce paracrine signaling in the primate ovary. There is evidence that preantral follicles express the type I insulin-like growth factor receptor, which mediates most of the somatomedin-like actions of IGF2. However, data on IGF2-regulated preantral follicle development are limited. Given the fact that rodents only have trace amounts of circulating IGF2, and IGF2 expression is slight and diffuse in the rodent ovary, IGF2 action on preantral follicles appears to be species-specific. The rhesus macaque model is an adequate surrogate for understanding IGF2-regulated follicular development and function in women. The study was supported by NIH/NICHD R01HD082208, P50HD071836, and NIH/OD P51OD011092.

SUPPORT: NIH/NICHD R01HD082208, P50HD071836, and NIH/OD P51OD011092.

O-80 9:55 AM Sunday, October 18, 2020

LOSS OF EXPRESSION OF THE NONCODING RNA *H19* PROMOTES SUSCEPTIBILITY TO GONADOTOXIN-INDUCED OVARIAN DNA DAMAGE. Wang Jing, MD, PhD,[1] Lu Pingping, PhD,[2] Johnson Joshua, PhD,[3] Amanda Nicole Kallen, MD.[4] [1]Beijing Friendship Hospital Capital Medical University, Beijing, China; [2]Women's Hospital, School of Medicine, Zhejiang University, Hangzhou, Hangzhou, China; [3]University of Colorado Denver, Aurora, CO; [4]Yale School of Medicine, New Haven, CT.

OBJECTIVE: Ovarian DNA damage occurs naturally with age and is exposure to gonadotoxic agents such as chemotherapylet-7 is a negative regulator of target genes and is recognized for its importance in the regulation of DNA damage genes. We have shown that let-7 is itself regulated by the long noncoding RNA *H19*; that is, *H19* binds and antagonizes let-7, releasing its targets from suppression. We therefore hypothesized that loss of ovarian *H19* can increase ovarian susceptibility to DNA damage in mice, potentially via a let-7 intermediary.

DESIGN: Basic science research.

MATERIALS AND METHODS: We first induced DNA damage with the chemotherapeutic agent doxorubicin (DXR). 8wk *H19* knockout (*H19*KO) and wild type (WT) mice (n=5) were injected with DXR or saline and ovaries isolated 48h later. Key genes involved in detection and repair of DNA damage were evaluated pre- and post-DXR. Apoptosis was evaluated with TUNEL. Timed matings were done (n=5 mice) 2m post-DXR to determine whether recovery of fertility was impaired in *H19KO* mice. We used bioinformatic analysis to predict let-7 binding sites in DNA damage genes, and transfected a human granulosa cell (GC) line with let-7 to determine whether gene expression was decreased in the presence of let-7. Results were analyzed via t-test.

RESULTS: Expression of *ATM* and *RAD51* was decreased in H1KO at baseline as compared to WT ($p<0.05$, Student's t-test). 48 hours after DXR, gH2AX protein level was increased in both KO and WT ovaries; however, the increase was significantly larger in *H19*KO mouse ovaries ($p>0.05$). Apoptosis was detected in ovarian sections with the ApopTag Fluorescein Apoptosis Detection Kit, ovaries were counterstained with DAPI. After DXR, *H19*KO ovaries exhibited increased apoptosis (as measured by TUNEL) as compared to WT. At 8 weeks, additional H19KO and WT mice were mated and litter sizes evaluated. After DXR, *H19*KO mice were infertile, with no litters born after 8 weeks (Fig.2). By comparison, WT mice exhibited reduced litter numbers and sizes but were still fertile (n=0 pups for *H19*KO vs 5 pups for WT, $p<0.05$). After bioinformatic prediction of let-7 target sites in DNA damage genes and transfection of GCs with let-7, we observed decreased *ATM, RAD51,* and *RPA2* mRNA and protein compared to control ($p<0.05$).

CONCLUSIONS: We have discovered an important role for *H19* and let-7 in ovarian aging via regulation of DNA repair. Our findings of increased ovarian DNA damage and apoptosis and complete fertility loss in *H19* null mice after DXR, along with our observation that transfection of GCs with the *H19*-regulated miRNA let-7 decreased expression of key DNA damage mediators, suggests that loss of *H19* renders the ovary more susceptible to DXR. The *H19*/let-7 pair appears to represent a novel regulatory pathway by which ncRNAs can govern the follicular response to DNA damage. Further mechanistic studies will determine whether differential ncRNA expression in the follicle microenvironment can serve as an important regulator of ovarian sensitivity to gonadotoxins.

NON-INVASIVE METABOLIC IMAGING OF CUMULUS CELLS TO DETECT OOCYTE MATURITY AND FERTILIZATION. Marta Venturas, M.Sc.,[1] Kishlay Kumar, PhD,[2] Xingbo Yang, PhD,[3] Dagan Wells, Ph.D.,[4] Catherine Racowsky, PhD,[5] Dan Needleman, Ph.D.[3] [1]Universitat Autònoma de Barcelona, Cerdanyola, Spain; [2]University of Oxford, Oxford, United Kingdom; [3]Harvard University, Cambridge, MA; [4]Juno Genetics, Oxford, United Kingdom; [5]Brigham and Women's Hospital, Boston, MA.

OBJECTIVE: To investigate the association between Fluorescence Lifetime Imaging Microscopy (FLIM) of metabolic function in cumulus cells and 1) oocyte maturity; and 2) fertilization potential. The over-arching objective of this work is to determine whether metabolic function of cumulus cells can non-invasively detect maturity and fertilization of the corresponding oocytes. And to determine whether these metabolic parameters are correlated with maternal age and BMI.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: Cumulus cell clusters (n=422 from 212 patients; mean age 35.9 y, mean BMI 26.9 kg/m^2) were dissected from the

cumulus oocyte complexes prior to assisted reproduction treatments. Maturity and fertilization status of the corresponding enclosed oocytes were tracked. 60 samples were associated with immature oocytes and 362 with mature oocytes. 282 oocytes resulted in 2 pronuclei zygotes and 36 oocytes did not fertilize. Cumulus cell metabolic function was assessed non-invasively using FLIM to measure the autofluorescence of NADH and FAD+, endogenous coenzymes essential for cellular respiration and glycolysis. Quantitative information was obtained on 1) metabolite concentrations from fluorescence intensity; and 2) metabolite enzyme engagement from fluorescence lifetimes. Each FLIM measurement provides a total of 9 quantitative metabolic parameters (4 for NADH, 4 for FAD+ and Redox Ratio: NADH intensity /FAD+ intensity). These cumulus cell metabolic parameters were compared with oocyte maturity, oocyte fertilization status and patient age and BMI using multi-level generalized linear models providing information of cumulus variance within and between patients.

RESULTS: We found statistically significant correlations regarding both cumulus cell NADH metabolic parameters ($p<0.05$) and the Redox Ratio ($p=0.001$) and oocyte maturity. FAD+ intensity and fraction bound to enzyme displayed significant variation between cumulus cells associated with fertilized compared to unfertilized oocytes ($p<0.05$). All metabolic parameters of cumulus cells were significantly correlated with maternal age ($p<0.05$), but not with BMI.

CONCLUSIONS: Metabolic imaging can non-invasively detect significant metabolic variations in cumulus cells between mature and immature oocytes, suggesting the potential utility of this technique in a clinical setting. These metabolic parameters were also associated with oocyte fertilization potential and clinically relevant factors, such as maternal age, but not BMI. Moreover, we are in the process of developing machine learning based algorithms combining patient characteristics and cumulus cell FLIM data to predict the maturity of the corresponding oocyte.

SUPPORT: NIH RO1 (5R01HD092550-02).Â Becker and Hickl GmbH, and Boston Electronics sponsored research with the loaning of equipment for FLIM.

ENDOMETRIAL MITOCHONDRIAL DNA SECRETED IN EXTRACELLULAR VESICLES: A NOVEL MATERNAL MECHANISM MODULATING EMBRYO BIOENERGETICS.

David Bolumar Recuero, BSc MSc,[1] Alicia Amadoz, PhD,[2] Inmaculada Moreno, PhD,[1] Carlos Marín, MSc,[1] Antonio D. Juan, PhD,[3] Carlos Simon, MD, PhD,[4] Felipe Vilella, PhD.[5] [1]Igenomix Foundation / INCLIVA Valencia, Paterna, Spain; [2]Igenomix, Paterna, Spain; [3]Ronda Narciso Monturiol, 11B., Paterna, Spain; [4]Igenomix Foundation, INCLIVA, Valencia, Spain; Department of Obstetrics and Gynecology, Valencia University, valencia, Spain; Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Valencia, Spain; [5]Igenomix Foundation/INCLIVA, Valencia, Spain; Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Paterna, Spain.

OBJECTIVE: To investigate endometrial extracellular vesicles (EV) mitochondrial DNA (mtDNA) cargo internalization by the embryo as a potential mechanism by which the maternal endometrium modulates embryo bioenergetics.

DESIGN: Secreted EVs [apoptotic bodies (ABs), microvesicles (MVs) and exosomes (EXOs)] were isolated and characterized from endometrial fluid (EF) from fertile donors (n = 10) in their receptive phase. EVs populations originating from the same EF sample were evaluated in a paired design. The potential for EVs to transfer DNA from the mother to the embryo and to modify embryo energetics through ATP modulation was also investigated.

MATERIALS AND METHODS: MtDNA copy number was quantified in receptive endometrium by qPCR ratio of *β-ACTIN* (nuclear) to *ATP8* (mitochondrial) genes, and changes in metabolic gene set were studied using targeted RNAseq (Ion AmpliSeq Transcriptome Human Gene Expression Core Panel). Maternal endometrial EV DNA cargo tagged with 5-ethynyl-2'-deoxyuridine was followed by confocal imaging after co-incubation of EVs with murine embryos (n = 600). In the presence or absence of maternal EVs, embryo ATP levels was assessed by FLASC luciferase reporter system (n = 250 embryos).

RESULTS: Receptive-phase endometrium had lower mtDNA content (92 +/- 31 mtDNA relative to nuclear DNA content, versus 219.37 +/- 56 in pre-receptive phase) together with an upregulation of genes that promote mitophagy in vesicular compartments. The sequencing of EVs isolated from human EF revealed that MVs were 11.12 ± 0.53-fold enriched in the 13 mtDNA-encoded genes for electron transport chain complexes, and 7.1–26.7-fold enriched in transcription factor binding sites (TFBSs). Most TFBSs mapped to the mitochondrial genome associated with transcription factors (*SRF, GABP, E2F4, TR4, FOXA2, FOXA1, CTCF, GATA2, PAX5*) with roles in early embryo development, mitochondrial function and biogenesis. DNA transfer was demonstrated from EVs to embryos by internalization in the cytoplasm and nuclei of trophectoderm cells. Murine embryos incubated with EVs from human EF reduced their ATP content, being more dramatically with EXOs ($p < 0.001$). Since cellular ATP can't be stored, our results suggest a novel maternal mechanism stimulating ATP consumption by the embryo.

CONCLUSIONS: During the preconception period, endometrial mtDNA content is reduced through mitophagy. Processed mtDNA, both coding and regulatory are secreted through EVs to the EF and taken up by the embryo, where it modulates embryo energetics inducing ATP consumption by the embryo. Our results support a novel maternal mechanism modulating embryo bioenergetics in preparation for implantation.

ALTERED BLASTOCYST METHYLOME AND IMPRINTING DYSREGULATION ASSOCIATED WITH THE PROLONGED DISEASE STATE OF INFERTILITY.

Michelle M. Denomme Tignanelli, PhD, Mary E. Haywood, PhD, Blair R. McCallie, BS, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD. Colorado Center for Reproductive Medicine Lone Tree, CO.

OBJECTIVE: The increased incidence of rare imprinting disorders in children born following infertility treatments has led to questions regarding the origin of this observed epigenetic dysregulation. Epidemiological studies suggest that the underlying disease state and severity of infertility plays a significant role. Imprinting disorders frequently arise from DNA methylation errors at imprinting control regions (ICRs), leading to our investigation of the euploid blastocyst methylome in association with duration of infertility (time to pregnancy; TTP).

DESIGN: Research study.

MATERIALS AND METHODS: Surplus cryopreserved euploid blastocysts of transferrable quality (grade $\geq$3BB; n=104) were donated with IRB approval and patient consent. Blastocysts were grouped based on TTP; months of reported primary infertility prior to oocyte retrieval that resulted in a live birth (Fertile Control: 0 months, donor oocyte/donor sperm; Infertile Short: 12-24 months; Infertile Intermediate: 36-48 months; Infertile Long: $\geq$60 months). Patient demographics and total gonadotropin doses were comparable between groups. Individual blastocyst DNA underwent whole genome bisulfite sequencing (Methyl-MaxiSeq; Zymo Research) with significant methylated CpGs determined by Student's t-test adjusted using Benjamini-Hochberg FDR; $q<0.05$. Methylation validation of ICRs was performed by pyrosequencing (PyroMark Q24 Advanced; Qiagen) with significance determined by Student's t-test and one-way ANOVA where appropriate; $p<0.05$. Quantitative RT-PCR was utilized on individual blastocysts for gene expression analysis with REST 2009 Software (Qiagen) and significance determined by a pairwise fixed reallocation randomization test; $p<0.05$.

RESULTS: Prolonged TTP (Infertile Long $\geq$60 months) resulted in 6,609 significantly altered CpGs compared with blastocysts from Fertile Controls (0 months; $q<0.05$). Significant CpGs were situated at five ICRs, including *KvDMR* and *MEST*, and 36 imprinted genes, with NFAT signaling identified as the top canonical pathway (62/221 genes, q=1.28E-08). Overall, extended TTP $\geq$36 months (mean=65 months) exhibited significant hypomethylation compared to shorter TTP $\leq$24 months (mean=10 months) for *KvDMR* (39% Extended vs. 48% Shorter; $p<0.05$), *MEST* (40% Extended vs. 49% Shorter; $p<0.05$), and *H19* (29% Extended vs. 41% Shorter; $p<0.05$) while *SNRPN* trended downward without significance. Significant decreases in expression were observed for maternally imprinted genes (*KCNQ1OT1, MEST, COPG2, DNMT1*; $p<0.05$), and significant increases in expression for paternally imprinted genes (*H19*, *CDKN1C*; $p<0.05$).

CONCLUSIONS: This novel study is the first to report evidence that an extended duration of infertility correlates with altered methylation in euploid blastocysts, with a particular emphasis on genomic imprinting. Our results provide evidence to support an association between imprinting dysregulation and infertility as a prolonged disease.

O-84 10:55 AM Sunday, October 18, 2020

GENE CONVERSION IN HUMAN EMBRYOS INDUCED BY GENE EDITING. Nuria Marti-Gutierrez, PhD,[1] Dan Liang, PhD,[1] Tailai Chen, PhD,[2] Yeonmi Lee, PhD,[3] Hong Ma, PhD,[1] Amy Koski, BA,[1] Aleksei Mikhalchenko, PhD,[1] Stephen B. Heitner, PhD,[4] Eunju Kang, PhD,[5] Paula Amato, MD,[1] Shoukhrat Mitalipov, PhD.[1] [1]Oregon Health & Science University Portland, OR; [2]Shandong University, Jinan, China; [3]ASAN Institute for Life Sciences, ASAN Medical Center, Seoul, Korea, Republic of (South); [4]Oregon Health &Science University, Portland, OR; [5]ASAN Medical Center, Seoul, Korea, Republic of (South).

OBJECTIVE: Double strand breaks (DSBs) at specific loci can be efficiently induced by genome editing tools. It is believed that most DSBs are repaired by either non-homologous end joining (NHEJ) or homology directed repair (HDR) using synthetic DNA templates. Our study aims to evaluate if DNA DSBs in human preimplantation embryos also repaired by an alternative mechanism known as gene conversion (GC).

DESIGN: Pre-tested sgRNAs and Cas9 protein were co-injected into human MII oocytes or zygotes to target heterozygous *MYH7* (g.15819 C>T; NG_007884.1) and homozygous wild-type (WT) *MYBPC3* (g.9836, NC_000011.10) loci. Injected embryos were cultured for 3 days and then individual blastomeres of cleaving embryos were isolated and analyzed by sequencing at a single-cell level.

MATERIALS AND METHODS: DNA from each individual blastomere was amplified and the target region was sequenced by Sanger. Since gene conversion results in loss of heterozygosity (LOH) around target region, we evaluated the presence or loss of single-nucleotide polymorphisms (SNPs) adjacent to the target region.

RESULTS: As expected, most DSBs at the heterozygous *MYH7* locus were repaired by NHEJ (58.3%; 70/120) resulting in additional indel mutations on the mutant allele. However, remaining 41.7% (50/120) of blastomeres lost the mutant allele and were presented by the WT allele. We excluded possibility of deletions in these samples abut showed LOH at adjacent loci. When targeting both alleles at homozygous *MYBPC3* locus, we found that 40.2% (129/321) blastomeres appeared with identical indel mutations on both parental alleles, indicating that GC and NHEJ compete and interplay with each other within the same cell. In contrast, frequency of HDR via exogenous synthetic DNA templates is limited.

CONCLUSIONS: We report here that in addition to NHEJ and HDR, human embryos frequently employ an alternative repair mechanism known as gene conversion where intact endogenous homologous sequences are used as templates. While gene conversion could be applicable for gene correction, extensive LOH presents a safety concern.

ULTRASONOGRAPHIC PARAMETERS PREDICT THE IMPROVEMENT OF POSTMENSTRUAL SPOTTING IN PATIENTS UNDERGOING HYSTEROSCOPIC TREATMENT OF ISTHMOCELE. Simone Ferrero, MD PhD,[1] Franco Alessandri, MD,[2] Michele Altieri, MD,[1] Giulio Evangelisti, MD,[1] Maria Grazia Centurioni, MD,[2] Fabio Barra, MD.[1] [1]IRCCS Ospedale Policlinico San Martino Genova, Italy; [2]IRCCS Ospedale Policlinico San Martino, Genoa, Italy.

OBJECTIVE: Current literature supports a role for hysteroscopic isthmoplasty in treating isthmocele-related abnormal uterine bleeding. However, limited data is available on preoperative factors predicting successful hysteroscopic treatment. The objective of this study is to investigate the performance of bidimensional ultrasonography (TVS) and three-dimensional saline contrast sonohysterography (3D-SCSH) in predicting the improvement of symptoms in patients undergoing hysteroscopic treatment of cesarean scar isthmocele.

DESIGN: Prospective study.

MATERIALS AND METHODS: This prospective study included patients with cesarean scar isthmocele requesting hysteroscopic treatment because of postmenstrual spotting. Exclusion criteria for the study were: residual myometrium over the isthmocele (< 2.5 mm), other potential causes of abnormal uterine bleeding, previous surgical treatment of the cesarean scar defect. 3D-SCSH was performed by introducing a 5-Fr balloon catheter into the cervical canal and gently injecting saline solution into the cervical canal, niche and uterine cavity. The following parameters were assessed by TVS and 3D-SCSH: length, depth, width, residual myometrial thickness, adjacent myometrial thickness, distance between the niche and the vesicovaginal fold, distance between the niche and the external os, volume of the niche (calculated by length × depth × width × 0.52 at TVS and assessed by virtual organ computer-aided analysis at 3D-SCSH), shape of the uterine niche (assessed only by 3D-SCSH). A score number from 1 to 4 was assigned to each variable, and, for each patient, a total score was calculated for TVS and 3D-SCSH. The hysteroscopic correction of the isthmocele was performed under general anesthesia by resection of the superior and inferior edges of the defect using a resectoscopic loop and pure cutting current until reaching the muscular layer; ablation of the isthmocele base was performed. At 3-month from surgery, patient satisfaction was assessed using a 5-point Likert scale.

RESULTS: 102 patients were included in the study. The mean (± SD) age of the study population was 39.1 (± 4.3) years. The median number of previous cesarean section was 2 (range, 1-4). At 3-month follow-up, 59 patients (82.4%) were very satisfied or satisfied with the surgery. The 3D-SCSH score was superior to the TVS score in predicting patient satisfaction after surgery ($p < 0.001$). Linear regression analysis showed that patient satisfaction was significantly correlated with width ($p=0.004$), shape of the uterine niche assesed by 3D-SCSH ($p<0.001$), and the volume of the niche assesed by 3D-SCSH ($p=0.007$).

CONCLUSIONS: 3D-SCSH is superior to TVS in predicting the improvement of postmenstrual spotting following hysteroscopic treatment of isthmocele. The width, shape, and volume of the niche are associated with amelioration of the symptoms.

O-86 9:55 AM Sunday, October 18, 2020

PERSPECTIVES OF 281 PATIENTS WITH MAYER-ROKITANSKY-KÜSTER-HAUSER SYNDROME ON UTERINE TRANSPLANTATION. Nicole Mercado Fischer, MPH,[1] Helen Xun, BS,[2] Bhuchitra Singh, MD, MPH, MS,[3] James Segars, MD.[1] [1]Johns Hopkins University School of Medicine Division of Reproductive Endocrinology and Infertility, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD.

OBJECTIVE: The aim of this study was to investigate the personal, ethical, and financial perspectives of individuals with Mayer-Rokitansky-Küster-Hauser syndrome (MRKH), a congenital uterine factor infertility condition, towards uterine transplantation (UTx).

DESIGN: Cross-sectional quantitative survey analysis.

MATERIALS AND METHODS: A 60-item anonymous electronic questionnaire was advertised to international members of the Beautiful You MRKH Foundation via social media sites (Facebook, Instagram, and Twitter). The survey contained UTx educational materials followed by questions assessing participants' baseline knowledge, global perceptions, financial concerns, and ethical considerations regarding UTx.

RESULTS: We received 281 responses (88% completion rate), with a mean participant age of 28.2 ± 9.8 years. After reviewing the UTx education material, the majority of participants considered receiving a uterine transplant (73%), felt it should be an option for all women with uterine factor infertility (86%), and believed it should be covered by health insurance (78%). Respondents perceived the benefits of the procedure to outweigh the risks (67%) and considered it to be an ethical procedure (82%). Although the majority of participants have or would consider adoption (85%) and gestational surrogacy (81%) to have children, a large percentage indicated they would prefer to give birth to their own child (79%). Almost half of participants (49%) reported a willingness to spend over $10,000 out of pocket to receive a UTx procedure. When asked to rank the risk of UTx to self, donor, and fetus in order of personal importance, (21%) ranked their own safety last.

CONCLUSIONS: The results of this analysis have important implications for the future of UTx. There is a profound desire in the MRKH community for UTx to become more widely available and affordable. MRKH patients may represent a vulnerable population requiring special considerations for informed consent and rigorous evaluation for UTx. Providers caring for MRKH patients should be prepared to educate about UTx and thoughtfully engage with news and media outlets to communicate evidence-supported information.

QUANTIFYING HETEROGENEITY OF TESTICULAR HISTOPATHOLOGY IN NON-OBSTRUCTIVE AZOOSPERMIC MEN. Nahid Punjani, MD MPH,[1] Ryan Flannigan, MD,[2] Kathleen Hart, BSN RN MA,[1] Peter N. Schlegel, M.D.[3] [1]Weill Cornell Medicine, New York, NY; [2]University of British Columbia, Vancouver, BC, Canada; [3]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To quantify the histopathologic heterogeneity of testicular biopsies from non-obstructive azoospermic (NOA) men undergoing microsurgical testicular sperm extraction (mTESE).

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: All patients undergoing mTESE by a high-volume surgeon at Weill Cornell in New York City between 2010 and 2019 were evaluated. Testicular histopathology from all men were reviewed. Men were included if testicular biopsy histopathology reported by the pathologist described the percentage breakdown of respective histopathologies. Men who had pathology reports without a percentage breakdown were excluded. Descriptive reports of pathology totals were reported.

RESULTS: A total of 971 men were included. The median age was 34 (IQR 30-39). Mean pathological components (Table 1) were 57.9 ± 42.9% Sertoli-Cell Only (SCO), 16.3 ± 32.6% maturation arrest (MA), 14.6 ± 25.28% tubular atrophy (TA), 8.0 ± 24.2% full spermatogenesis (SG), and 1.54 ± 8.6% germ cells (GC). A total of 411 (42.5%) had only one pathology on biopsy, 384 (39.8%) two different pathologies on biopsy, 171 (17.7%) had three or more different pathologies. Sperm retrieval rates for first time retrieval was 135/395 (34.2%) for one pathology in comparison to 246/486 (50.6%) with mixed patterns, with increasing rates of success with increasing pathologic variety. Of those with two pathologies, the most common pairs included SCO and TA (n=270, 74.7%) of which mean SCO component was 71.08 ± 29.10% and 28.26 ± 28.60% was TA, followed by MA and TA (n=26, 6.8%). Of those with three different pathologies, the most common combinations include SCO, MA and TA (n=37, 36.3%), of which mean SCO was 35.19 ± 28.38%, mean MA was 32.30 ± 31.20% and TA was 30.78 ± 24.51%, followed by MA, SG, and TA (n=23, 22.5%). Among men with KS (n=107), pathological components were 56.8 ± 48.3% Sertoli-Cell Only, 0.4 ± 2.3% maturation arrest, 0.6 ± 3.2% spermatogenesis, 33.6 ± 35.8% tubular atrophy, 0.52 ± 2.9% germ cells. For those with AZF mutations (n=17) pathological components were 53.2 ± 49.5% Sertoli-Cell Only, 38.8 ± 48.1% maturation arrest, 0.0 ± 0.0% spermatogenesis, 1.5 ± 3.4% tubular atrophy, and 6.5 ± 24.2% germ cells.

CONCLUSIONS: To the best of our knowledge, this is the first report describing the pathological breakdown of testicular histopathology in a large subset of NOA men. The most common overall pathology is SCO in our cohort, which was also the most common in KS and AZF deleted men.

O-88 10:25 AM Sunday, October 18, 2020

EVALUATING THE QUALITY OF REPORTING IN OUTCOMES OF MICROSURGICAL-TESE IN MEN WITH NON-OBSTRUCTIVE AZOOSPERMIA (NOA): A METHODOLOGICAL ANALYSIS. Brittany D. Berk, MD, John Joseph Ernandez, Jr., BA, Tracy X. Han, MD, MBA, Martin Kathrins, MD. Brigham and Women's Hospital and Harvard University Boston, MA.

OBJECTIVE: Microsurgical testicular sperm extraction (micro-TESE), since its introduction in 1999, has been demonstrated to be the optimal approach to surgical sperm retrieval for men with NOA. However, there is heterogeneity in the methodological quality of published micro-TESE approaches and outcomes.

DESIGN: We conducted a systematic methodological analysis of all published literature on the use of micro-TESE in men with NOA from 1999 to the present.

MATERIALS AND METHODS: A PubMed search was performed using the search terms "microdissection TESE" or "microsurgical TESE". Only studies on NOA patients were considered. Studies on obstructive azoospermia, case studies, and review articles were excluded. We included only the most recent publication from a given academic medical center's cohort. Adapted from previously published quality reporting criteria for prospective trials (CONSORT), we evaluated publications on their reporting of preoperative factors, intraoperative techniques, surgical and clinical outcomes, and adverse events. Two reviewers evaluated each publication for inclusion.

RESULTS: 182 articles were identified in our initial search, of which 55 met inclusion criteria. Specific reporting criteria are listed in Table 1. Surgical technique and sperm retrieval rates were the most commonly reported criteria. Reporting on the presence of an embryologist intraoperatively was observed in approximately 25% of articles, while other procedural details including method of sperm quantification, quantity retrieved, and number of cryopreserved vials were observed in fewer than 10% of articles. Clinical outcomes, including surgical complications, pregnancy rates, and live birth rates were reported in fewer than half of the articles. Fetal outcomes were rarely reported.

CONCLUSIONS: There are many inconsistencies in reporting quality of micro-TESE outcomes, specifically a lack of information on the quantity of sperm retrieved, the role of embryology intraoperatively, and clinical and fetal outcomes. Development of a reporting guideline may help standardize reported results to better assess clinical outcomes across institutions.

EFFECTS OF PREOPERATIVE MEDICAL TREATMENT ON SPERM RETRIEVAL RATES IN PRIMARY AND IN RECURRENT MICRO TESE CASES. Murad M. Basar, PROF. MD,[1] Hakan Kadir Yelke, MsC,[2] Gönül Özer, MD,[3] Melike Kaya-Bahcecitapar, PhD,[4] Yesim Kumtepe-Colakoglu, Msc,[2] Semra Kahraman, Prof. MD.[2] [1]MEMORIAL SISLI HOSPITAL ISTANBUL, Turkey; [2]Istanbul Memorial Hospital, Istanbul, Turkey; [3]Istanbul Memorial Hospital, İstanbul, Turkey; [4]HACETTEPE UNIVERSITY FACULTY OF SCIENCE, Ankara, Turkey.

OBJECTIVE: The aim of the present study was to evaluate the efficacy of different medical treatments in azoospermic males through comparison of the effects on sperm retrieval rate in primary and recurrent micro TESE (m-TESE).

DESIGN: This is a prospective study. A total of 1048 non-obstructive azoospermic (NOA) males were included.

MATERIALS AND METHODS: The patients were divided into two groups: Group I: Patients undergoing their first micro TESE operation (n=466) and Group II: Patients undergoing repeated m-TESE operations (n=582). A total of 623 cases were given hormone treatment, HT(+) and a total of 425 did not receive hormone treatment HT(-).
In the HT(+) group, all patients received gonadotrophine replacement, hCG, 5.000U-10,000U per week for 3 months. After 3 months, if the FSH level was suppressed, hMG, 150-225 units per week was added; if not, treatment continued with hCG. In addition, if TT/E2 ratio was less than 0.10, aromatase inhibitor of 1 mg per day was added. If, however, the patient's TT/E2 ratio was higher than 0.10, clomiphene citrate 50 mg was given daily. In all treatment groups, medication was administered for 6 to 9 months until the patients reached eugonadotropic state. Mann-Whitney U test, two sample t-test, paired-t test and Pearson's $\chi 2$ tests were used to determine the effect of medical treatment on m-TESE results. The phi correlation coefficient ($r\varphi$) is used as a measure of association for two categorical variables.

RESULTS: There was a statistically significant relationship between treatment and m-TESE variables ($\chi^2=13.19$, $p<0.001$). Spermatozoa was retrieved in 234 (55.1%) patients who had not received any treatment and in 277 (44.5%) patients who had received treatment. However, while there was no statistically significant difference in sperm retrieval between primary micro-TESE cases who had received or not received hormone treatment ($\chi^2=0.033$, $p>0.001$), there was a significantly higher sperm retrieval rate in HT(-) cases with recurrent micro-TESE. ($\chi^2=22.36$, $p<0.001$). There was no statistically significant difference between hormonal treatment types in terms of the outcome of m-TESE variable ($\chi^2=5.87$, $p> 0.05$).

CONCLUSIONS: Our results show that hormone treatment had no positive effect on sperm retrieval in NOA cases with primary and recurrent micro-TESE. Underlying etiopathologic factors and previous micro-TESE outcomes in recurrent cases are the main determinant factors.

FLUOROSCOPIC-GUIDED HYSTEROSCOPIC TUBAL CANNULATION RESULTS IN HIGH TECHNICAL SUCCESS, HIGH SPONTANEOUS PREGNANCY RATES, AND SIMILAR TIME TO PREGNANCY WHEN COMPARED TO LAPAROSCOPIC GUIDANCE. May-Tal Sauerbrun-Cutler, MD,[1] Emma Charlotte Brown, BA,[2] Gary N. Frishman, MD,[3] Phinnara Has, MS,[4] Martin D. Keltz, MD.[5] [1]Warren Alpert Medical School of Brown University; Women & Infants Hospital Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Providence, RI; [2]Brown University, Providence, RI; [3]Brown University; Women & Infants Hospital, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Providence, RI; [4]Warren Alpert Medical School of Brown University; Women & Infants Hospital, Department of Obstetrics and Gynecology, Division of Research, Providence, RI; [5]WESTMED Reproductive Services, Associate Professor at Icahn School of Medicine at Mt. Sinai, Purchase, NY.

OBJECTIVE: Tubal cannulation for proximal tubal obstruction (PTO) has historically used fluoroscopy for visualization and guidance or hysteroscopic visualization with laparoscopic guidance. This study compared women with PTO undergoing hysteroscopic tubal cannulation with fluoroscopic guidance versus laparoscopic guidance.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Infertile women with unilateral or bilateral PTO on hysterosalpingography who failed selective salpingography in the Radiology suite and had a planned hysteroscopy in the operating room for defects seen on sonohysterography were studied. All women had a Novy Catheter system® positioned hysteroscopically to cannulate the occluded fallopian tube(s). Women undergoing Fluoroscopically Guided Hysteroscopic Tubal Cannulation (FHTC) which utilized contrast and C-arm pelvic imaging at an ambulatory center were compared to those undergoing hospital based Hysteroscopic Tubal Cannulation (LHTC) with laparoscopic chromotubation. Procedural success, perforation rates, pregnancy rates and time to intra-uterine pregnancy were analyzed. T-test, Wilcoxon rank sum analysis were used to compare continuous variables and a Fisher's exact test was used for categorical variables. Kaplan Meier analysis was used to compare times to pregnancy.

RESULTS: 79 infertile women undergoing either FHTC (37 women) or LHTC (42 women) between 2017 and 2019 were included. Demographic variables were similar, though the FHTC group was older (age 37.6 vs 35.4, P =0.03). 34/37 (92%) of FHTC and 36/42 (86%) of LHTC patients had at least one tube successfully cannulated (P=0.49) and 29/37 (78%) of FHTC patients and 33/42 (79%) of LHTC patients had all occluded tubes successfully cannulated (P=0.52). Tubal perforation occurred in 2/37 (5%) FHTC cases vs. 3/42(7%) LHTC cases (p=1.0). A similar percentage of non-IVF intrauterine pregnancies were achieved in the FHTC and LHTC groups (12/37 32% and 12/42 29%, p=0.42). Two ectopics occurred in the LHTC group. Among patients who conceived without IVF, days from procedure to pregnancy was reduced in the fluoroscopically guided group compared to the laparoscopically guided group (102.9 +/-118.6 vs. 228.2 +/-216 p= .01). However, there was no significant difference in time to pregnancy when all subjects regardless of pregnancy were analyzed (hazard ratio 1.08 (95% CI 0.45, 2.57).

CONCLUSIONS: FHTC is a safe, effective, incision free procedure that results in a comparable rate of tubal patency and intrauterine pregnancies as LHTC, and may shorten the time to conception likely due to a quicker recovery. This technique should be considered in women undergoing treatment of PTO when operative laparoscopy is not otherwise indicated.

CRYOPRESERVATION AND FROZEN EMBRYO TRANSFER

O-91 1:50 PM Sunday, October 18, 2020

SUCCESSFUL PRODUCTION OF NORMAL EUPLOID HUMAN BLASTOCYSTS DERIVED FROM SPERM AFTER PARTIAL FREEZE DRYING, REHYDRATION AND ICSI: TOWARDS DEVELOPING A NOVEL METHOD FOR SAFE STORAGE OF BIOLOGICAL SAMPLES. Stoyana Alexandrova, PhD,[1] Amir Arav, PhD,[2] Kristy Hood, M.Sc,[1] Yehudit Natan, M.Sc,[2] John J. Zhang, MD, PhD,[1] Patrizio Pasquale, MD, MBE, HCLD.[3] [1]Darwin Life INC New York City, NY; [2]FertileSafe, Ltd, Ness Tziona, Israel; [3]Yale Fertility Center, Orange, CT.

OBJECTIVE: Current cryopreservation and storage methodologies have many unresolved issues including impact of cryoprotectants (CP) on cell survival, Liquid Nitrogen (LN) tank failures which may jeopardize samples integrity during storage, cumbersome and costly sample shipping. Here we aimed at replacing LN storage with ordinary freezers (-80℃) after partial sperm freeze/drying (pFD) with a CP-free solution. Rehydrated sperm were evaluated for motility and embryo competence following ICSI.

DESIGN: Prospective, experimental basic research.

MATERIALS AND METHODS: Donor sperm cryovials (n=12) were thawed and motile sperm recovered using the ESep device (FertileSafe Ltd, Israel). The separated motile sperm fractions were washed with a solution (Lyo4) containing 0.25M Trehalose and 0.25M Sorbitol in 10mL sperm wash (SW) and diluted 2:1 with SW. Volumes of 100 μL were pipetted into cooled glass vials (-25° C). Five samples were placed in the -80℃ freezer for 1 hour (frozen samples) and the other 7 samples underwent partial freeze drying (pFD). pFD was done with a lyophilizer device (Darya, FertileSafe Ltd, Israel) having preset shelf temperature at -25℃ and operated at a vacuum of <500 mTorr for 10-20 minutes. Samples were then stored at -80℃ for various time lengths (1 to 8 days). Then pFD samples were rehydrated, assessed for motility and used for ICSI with donor MII oocytes.

Thawing of frozen samples was obtained by plunging the vials in a 37℃ water bath (1 min) and sperm suspension diluted with same volume of SW.

Rehydration after pFD, was done by adding pre-warmed Sperm Wash solution (volume 1:1) at 37C to the sperm pellet.

Sperm motility was evaluated (i) at the baseline thawing after ESep preparation of the donor sperm cryovials; (ii) after Lyo4 addition and freezing/thawing and (iii) after pFD after different storage-times.

Both immotile and motile sperm after freezing/thawing and pFD were selected for ICSI of donor MII oocytes. Embryo aneuploidy screening was conducted via Non-Invasive Chromosome Screening (NICS) with DNA obtained from embryo culture media utilizing previously validated NICS platform.

RESULTS: ESep processed sperm cryopreserved at -80ºC in CP-free Lyo4 maintained had high post thaw motility (94%) at 1 hour, supporting the choice of Lyo4 as the optimal SW protocol for sperm pFD. Preliminary work (data not shown) had demonstrated that pFD-sperm without Lyo4 had no survival. Upon thawing and rehydration pFD-sperm had the following motility: 69% at 24 hrs; 43% at 7 days and 6% at 8 days.

After ICSI with immotile sperm (n=6), there were 0 fertilized oocytes and 0 blastocysts; after ICSI with motile PFD-sperm (n=13) there were 8 correctly fertilized oocytes, 6 blastocysts, 3 euploid (46XX).

CONCLUSIONS: This experiment demonstrated that sperm selected by ESep after partial freeze drying with CP-free solution maintains motility during storage at -80ºC for various lengths of time. To our knowledge this is the first report that using rehydrated motile sperm for ICSI produces human euploid blastocysts.

O-92 2:05 PM Sunday, October 18, 2020

EMBRYO VITRIFICATION IN SUPER COOLED SLUSH NITROGEN RESULTS IN SUPERIOR POST-THAW SURVIVAL COMPARED TO CONVENTIONAL LIQUID NITROGEN: A BLINDED, RANDOMIZED CONTROLLED TRIAL. Emily K. Osman, MD,[1] Marga Esbert, PhD,[2] Brent M. Hanson, MD,[1] Ayesha D. Winslow, MS,[3] Emre Seli, MD,[1] Richard Thomas Scott, Jr., MD.[1] [1]IVI RMA New Jersey Basking Ridge, NJ; [2]IVI RMA Barcelona, Barcelona, Spain; [3]IVI-RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Slush nitrogen (N_2) is a mixture of solid and liquid N_2 and has a lower temperature compared to conventional liquid N_2, leading to an accelerated cooling rate. The study aim was to assess if slush N_2 for embryo vitrification is a less damaging alternative to liquid N_2 as determined by post-warming survival.

DESIGN: Blinded, randomized controlled trial.

MATERIALS AND METHODS: This study was conducted at a large infertility center from October 2019-March 2020. High quality blastocysts donated to research with a single autosomal aneuploidy, expansion grade of 4 or 5, and modified Gardner grade of BB or better were eligible. Fifty embryos were randomized to the control group and 50 to the study group. Embryos underwent repetitive vitrification-warming cycles in liquid N_2 at -196°C or slush N_2 at -210°C until deemed to have demised. One embryologist performed all cycles while a separate embryologist who was blinded to vitrification method graded embryo survival. Primary outcome was embryo survival, or the proportion of embryos surviving in good condition after each cycle. Student's *t*-test analyzed differences in oocyte age of blastocysts in each group. Chi-squared testing compared day of cryopreservation between groups. Differences in probability of survival after each freeze-thaw cycle were determined with Cox regression. Wilcoxon-rank sum testing compared the median number of survived cycles.

RESULTS: Of the 50 embryos in the liquid N_2 group, 238 vitrification-thaw cycles were performed compared to 513 cycles on 50 embryos in the slush N_2 group. Oocyte age (35.8 yrs. liquid N_2 vs 36.4 yrs. slush N_2, p =0.38) and day of cryopreservation were equivalent between groups (p =0.84). After each cycle, embryos vitrified in slush N_2 were significantly more likely to survive versus those in liquid N_2 (p <0.0001). The median number of survived cycles in the control group was 3.0 (Quartile(Q)1 1.0, Q3 3.0), compared to 7.5 in the study group (Q1 5.0, Q3 10.0), p <0.0001.

CONCLUSIONS: Blastocyst cryopreservation in slush N_2 results in superior post-thaw survival due to reduced vitrification-associated toxicity compared to liquid N_2. Use of slush N_2 for embryo cryopreservation is a promising intervention for optimization of IVF outcomes.

TABLE 1. Survival data for vitrification-warming cycles 1-10.

	Liquid N_2		Slush N_2	
Vitrification Cycle	# Survived Embryos	Survival % (95% CI)	# Survived Embryos	Survival % (95% CI)
1	41	82 (68.2-90.2)	50	100
2	31	62 (47.1-73.8)	50	100
3	24	48 (33.7-60.9)	50	100
4	12	24 (13.3-36.4)	46	92 (80.1-97.0)
5	10	20 (10.3-32.0)	40	80 (66.0-88.7)
6	8	16 (7.5-27.4)	34	68 (53.2-79.0)
7	6	12 (4.8-22.6)	27	54 (39.3-66.6)
8	3	6 (1.6-14.9)	25	50 (35.6-62.8)
9	2	4 (0.7-12.1)	23	46 (31.9-59.0)
10	1	2 (0.2-9.2)	17	34 (21.4-47.0)

p <0.0001.

UPRIGHT, UPSIDE DOWN, SIDEWAYS - EFFECTS OF ORIENTATION OF VAPOR SHIPPERS AND DATA LOGGERS ON HOLD TIME. William Brent Hazelrigg, M.S., Amy Suzanne Erickson Hagen, M.S. ReproTech, Ltd., Columbia, MO.

OBJECTIVE: Cryoshippers are essential for the movement of embryos. Manufacturers may sell their cryoshipper with a protective mushroom to ensure upright shipping. Labs are at the mercy of commercial transport carriers to ensure the package is kept upright. Our study presents what happens when the cryoshippers are not kept upright.

DESIGN: Prospective Experimental Design.

MATERIALS AND METHODS: In preparation for this experiment each cryoshipper (MVE Vapor Series SC4/2V; SC4/3V) was tested per MVE's annual maintenance to determine the normal evaporation rate (NER; Liters) and calculated hold time (days). Shippers from 2013 to 2015 and 2017 to 2019 were selected, fifteen SC4/2V cryoshippers and fifteen SC4/3V cryoshippers were then placed upright, horizontally or inverted. The cryoshippers were weighed daily in the respective position; temperature at the top position of the cane was continually measured using a temperature probe and wireless transmitter (Vaisala, HMT143) until the temperature reached -135 °C or 7 days*. The NER and hold time were calculated based on the weight loss of the nitrogen.

RESULTS:

	NER (Liters/Day)	Hold Time (Days)	Days to -135 °C
SC4/3V Manufacturer Stated NER (vertical)	0.20	21.00	
SC4/3V Vertical with no data logger	0.14	27.35	N\A
SC4/3V Vertical	0.29	13.79	>7*
SC4/3V Horizontal	0.47	8.45	8.13
SC4/3V Inverted	0.57	7.47	7.00
SC4/2V Manufacturer Stated NER (vertical)	0.26	13.00	
SC4/2V Vertical with no data logger	0.20	15.96	N\A
SC4/2V Vertical	0.37	8.63	>7*
SC4/2V Horizontal	0.46	6.80	6.27
SC4/2V Inverted	0.58	6.03	5.40

CONCLUSIONS: Orientation of dry shippers in transit, while important, allows for a tank to be tipped over or even set upside down for periods of time without jeopardizing the viability of the embryos. Hold times are reduced while in the horizontal or inverted positions.

We show that shipments completed within one calendar week should maintain temperatures below glass transition phase even when in the inverted position for the entire duration. The mushroom case should prevent any extended exposure of the tank to an inverted position and decrease the time the shipper may spend on its side.

The NER increased when comparing our Annual Preventative Maintenance (vertical with no logger) calculated NER to the NER calculated during this study for the tank (vertical with a data logger). While we knew that data loggers decrease the hold time of tanks in shipment, we were surprised at the severity of the decrease caused by the "heat wick" effect of the wiring between the probe within the tank and the transmitter outside of the tank. We witnessed a statistically significant ($p<0.05$) doubling of the NER in the SC4/3V model and a near doubling in the SC4/2V model when the data logger was added. This cut the hold times of the tanks essentially in half.

A NOVEL ORGAN CULTURE SYSTEM SUPPORTED GERM CELL SURVIVAL IN PRIMATES AND SPERMATOGENESIS IN MICE. Kien Tran, BS,[1] Wenbo Li, MS,[2] Sung Kwon Cho, PhD,[2] Kyle E. Orwig, PhD.[1] [1]University of Pittsburgh School of Medicine Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA.

OBJECTIVE: The goal of this study is to develop a simplified, efficient culture system to induce *in vitro* spermatogenesis from fresh and cryopreserved immature testicular tissues, and translate this technology from mouse to monkeys to humans to test safety and feasibility for future clinical applications.

DESIGN: Spermatogonial stem cells (SSCs) have a tremendous capacity to regenerate spermatogenesis under proper conditions. Testicular tissue organ culture, utilizing the potency of SSCs to differentiate them into sperm outside of the body, may become a potential therapy to restore fertility in the future for pre-pubertal male patients, who encounter a permanent infertility risk as a side effect of gonadotoxic treatments. Takehiko Ogawa lab produced mouse sperm and offspring from cultures of neonatal testes in the pump-driven microfluidic (MF) device. To overcome its bulkiness and electrical-dependency, they later invented the pumpless microfluidic (PL) device. However, mouse sperm and offspring have not been produced and spermatogenesis was not reported from cryopreserved tissues or from any other species using the PL devices. This study aims to fill the gaps in knowledge on generating mouse sperm and offspring using the PL devices and translate this technology to non-human primate and/or human testicular tissues. In addition, we developed and tested a novel PDMS-roof transwell (PRT) culture system, comprised of a polycarbonate-membrane-transwell and a polydimethylsiloxane roof, to improve ease of device production and simplify the sample seeding and maintenance of cultures compared to the PL devices.

MATERIALS AND METHODS: Cultures of testicular tissues were maintained in MEM-alpha medium and 10% knock-out serum replacement at 34C with or without additional growth factors or hormones essential for in vitro germ cell development of mouse, Rhesus monkey, and human pre-pubertal tissues, respectively.

RESULTS: The efficiency of *in vitro* spermatogenesis using the PRT device was similar to PL device in cultures of fresh neonatal mouse testes (>70% tubules showed active spermatogenesis at 1 month). In the PRT system, our immunofluorescence results confirmed VASA+ germ cells in 81.6±6.63% of tubules, SALL4+ undifferentiated spermatogonia in 70.1±10.21%, STRA8+ differentiating spermatogonia in 50.0±14.01%, SYCP3+ spermatocytes in 75.9±9.2%, and SOX9+ Sertoli cells in 99.08±0.9% of tubules. A similar experiment using cryopreserved neonatal mouse testes in both culture systems also showed differentiated germ cells but with more delayed spermatogenesis. When culturing a fresh Rhesus testis tissue in the PRT for 3 months, 90.3% of tubules showed presence of VASA+ germ cells. In addition, a 2-month culture of a fresh Rhesus testis tissue under the same condition showed 74.3% of tubules with VASA+ cells, 65.52% tubules with Ki67+ proliferating cells, and 63.04% of tubules with SYCP3+ cells.

CONCLUSIONS: The PRT system could become an alternative testicular tissue culture system with simple design and equivalent efficiency compared with the PL devices to enhance in vitro tissue viability and development.

SUPPORT: This work was supported by anonymous donor funds; the *Eunice Kennedy Shriver* National Institute for Child Health and Human Development grant HD092084 and the National Institute of Biomedical Imaging and Bioengineering of the National Institutes of Health grant 5T32EB001026-15.

O-95 2:50 PM Sunday, October 18, 2020

OOCYTE VITRIFICATION HAS A DISADVANTAGEOUS EFFECT ON EMBRYO QUALITY: A PROPENSITY SCORE MATCHING-BASED STUDY. Jingwei Yang, M.D,[■] Xiaodong Zhang, M.D,[2] Guoning Huang, M.D.[2] [1]ChongQing Health Center for Women and Children; [2]■■■.

OBJECTIVE: To find the evidence of the effect of oocyte vitrification and warming procedures on embryos by comparing embryos developed from vitrified–warmed oocytes with those developed from fresh oocyte cycles.

DESIGN: This was a retrospective analysis of 1360 cycles of intracytoplasmic sperm injection (ICSI) involving 1293 fresh oocytes and 67 vitrified–warmed oocytes in a reproductive institude during January 2016–2019.

MATERIALS AND METHODS: Propensity score matching (PSM) was used for sampling to compare implantation rates, embryo morphological quality on days 2 and 3, and clinical outcomes between the two groups. A confocal microscope was used for imaging of the donated oocytes after ICSI.The primary outcome measure was implantation rate after embryo transfer. The secondary outcome measures included morphological quality of embryos on days 2 and 3. Confocal images were obtained to observe the alternations in vitrified–warmed oocytes.

RESULTS: A 1:1 PSM revealed significantly lower cleavage and implantation rates among the vitrified–warmed oocytes than among the fresh oocytes (97.3% vs 99.5% and 35.0% vs 48.3%, respectively; $P < 0.01$ for both) but similar clinical pregnancy rates. The rates of four-cell embryos on day 2 and eight-cell embryos on day 3 were lower among the vitrified–warmed oocytes than among the fresh oocytes (55.9% vs 63.1% and 34.1% vs 41.7%, respectively; $P < 0.05$). Lower cleavage and implantation rates were observed in the vitrified–warmed oocyte group ($P < 0.05$). In patients who accepted re-vitrification embryo/frozen-thawed embryo transfer after the failure of the first attempt, implantation and pregnancy rates were lower among the vitrified–warmed oocytes than among the fresh oocytes (16.00% vs 50.00% and 23.08% vs 72.73%, respectively; $P < 0.05$). Through confocal analysis, the first mitosis with chromosome separation failure was recorded.

CONCLUSIONS: Clinical data and image observations suggest that oocyte vitrification has a disadvantageous effect on chromosome segregation. We assume that abnormal embryo development might be related to the damage to the spindle, actin, or tubulin owing to vitrification and warming; more evidence should be accumulated on this topic.

DOES TROPHECTODERM BIOPSY AFFECT BLASTOCYST'S EXPANSION RATE POST THAWING? Samar Gamal El qassby, Bachelor and Samar Gamal el qassby, Manar Hozyen, Abdul ghafaar, Hana elkhader, Hosam zaki, FRCOG. Ganin fertility center Giza, Egypt.

OBJECTIVE: The expansion of blastocyst post thawing is one of an important indicator of embryo viability and affects it's implantation potential . Previous research found that there is correlation between rate of expansion and number of trophectoderm cells.Embryo biopsy involves reducing the number of trophectoderm cells . So this study looks into the trophectoderm biopsy would affect post thawing embryo expansion as a proxy of viability.

DESIGN: retrospective comparative study.

MATERIALS AND METHODS: A total of 406 vitrified/thawed blastocysts were observed from May 2019 to April 2020. Blastocysts were divided into two groups: biopsied blastocysts (n=195) and non biopsied blastocysts

(n=204).Biopsy was done using flicking technique of pre-herniated blastocysts. All vitrified blastocysts were of good quality at least 4BB according to Gardner's criteria 1999, and vitrification was done using cryotop kitazato method. We assessed the expansion rates (%) immediately post thawing (t0), after one hour (t1), and at time of transfer (t2). Data was recorded and analyzed using SPSS version -23 statistical software.

RESULTS: There is no significant difference in the female age between the non biopsed blastocyst group (29.5 years) and the biopsed blastocyst group (30.3 years). We found no significant differences between the expansion rates of the biopsied and non biopsied blastocysts at the t(0), .t(1), and t(2).

	Non biopsied blastocyst n=209	Biopsied blastocyst n=197	P-values
Expansion t(0) (%)	8.6±14	6.9±11.2	0.37
Expansion t(1) (%)	27±24.7	26.4±22.3	0.81
Expansion t(3)(%)	64±37.7	63.9±39	0.84

Data presented as mean ± standard deviation, Data are considered significant if p value $\leq$ 0.05.

CONCLUSIONS: This study suggests that embryo biopsy does not seem to affect the rate of expansion of blastocyst post thawing.

O-97 1:50 PM Sunday, October 18, 2020

WORKING HARD OR HARDLY WORKING: DOES PCOS IMPACT THE MITOCHONDRIAL DNA CONTENT OF THE EMBRYO. Lauren Grimm, M.A.,[1] Zoran J. Pavlovic, M.D.,[2] Jessi Anderson, MPH,[1] Christy Oso, B.A.,[1] Emma Radley, M.A.,[1] Nepheli Raptis, B.A., M.A.,[1] Hanna Mandell, M.A.,[1] Shawn Zimmerman, PhD, HCLD,[3] Angeline Beltsos, MD,[1] Amber R. Cooper, MD,[4] Roohi Jeelani, MD.[1] [1]Vios Fertility Institute Chicago, IL; [2]Rush University Medical Center, Chicago, IL; [3]Vios Fertility Institute, Swansea, SC; [4]Vios Fertility Institute St Louis, St. Louis, MO.

OBJECTIVE: This study sought to compare the mitochondrial DNA (mtDNA) content of age-matched controlled, euploid embryos in patients with Polycystic Ovary Syndrome (PCOS) compared to other infertility diagnoses.

DESIGN: Retrospective chart review at a private, multi-site fertility clinic.

MATERIALS AND METHODS: All euploid embryos from patients 35yo and younger who underwent in-vitro fertilization (IVF) with PGT-A from January to February 2020 utilizing a PGT lab that reports mtDNA (MitoScore; Igenomix) were included. Patients were divided into two groups: those whose embryos were derived from patients with a diagnosis of PCOS and those that did not. A PCOS diagnosis was defined according to the Rotterdam Criteria. Baseline patient characteristics were measured and IVF cycle statistics recorded. Two sample t-tests and chi square analysis were used to analyze the data using SPSS (SPSS Inc., Chicago, IL, USA).

RESULTS: A total of 412 embryos were analyzed. Baseline characteristics, including age and BMI, were similar between the PCOS and non-PCOS patient populations ($p>0.05$). There were a total of 202 embryos included in the PCOS group and 212 embryos in the age-matched control group. There was no statistical significance in the number of oocytes retrieved, maturation rate, fertilization rate, and blastocyst rate between the two groups ($p>0.05$). Interestingly, the average mtDNA score was also statistically similar, where the PCOS group had an average score of 22.9 (SD:6.25), compared to the non-PCOS group with an average score of 23.2 (SD:5.7) ($p>0.05$).

CONCLUSIONS: As one of the most common endocrine disorders, PCOS occurs in 5-10% of reproductive age women, and is a leading cause of infertility. It is well established that reactive oxygen species (ROS) are significantly increased in patients with PCOS compared to the average population, where elevated intracellular levels of nitric oxide (NO) and advanced glycation end products (AGE) have been found. This increase in ROS is thought to result in the inducement of PCOS pathogenesis, where accumulating evidence suggests that increased AGEs may play a role in the abnormal steroidogenesis seen in PCOS patients by affecting enzyme function and inflammatory responses during steroid biosynthesis. Similarly, this ROS excess is also thought to result in poor oocyte health. For women undergoing IVF, there are a limited number of ways to appropriately assess oocyte/embryo quality for optimal success. Yet, the quantification of mtDNA may offer a promising new parameter in assisted reproductive technologies (ART). Increased mtDNA have been linked to decreased pregnancy rates and is thought to be indicative of poor embryo quality due to oxidative stress; while lower mtDNA scores have been associated with improved outcomes. Our results show that while women diagnosed with PCOS may have increased rates of oxidative stress, this does not seem to significantly impact blastocyst quality or metabolic health. Further investigation into the underlying biological causes associated with elevated levels of embryonic mtDNA is warranted.

A NOVEL DIAGNOSTIC APPROACH FOR POLYCYSTIC OVARY SYNDROME DIAGNOSIS USING GONADOTROPIN RELEASING HORMONE RECEPTOR AUTOANTIBODY ACTIVITY AND ANTIMULLERIAN HORMONE. Elizabeth A. Weedin, DO, MS,[1] Heather R. Burks, MD,[1] Xichun Yu, MD,[2] Hong Liang Li, MD, PhD,[2] Christopher E. Aston, PhD,[3] David C. Kem, MD,[2] LaTasha B. Craig, MD.[3] [1]University of Oklahoma Health Sciences Center Department of Obstetrics and Gynecology, Oklahoma City, OK; [2]University of Oklahoma Health Sciences Center, Oklahoma Cty, OK; [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK.

OBJECTIVE: Despite being the most common endocrinological disorder of reproductive aged women, polycystic ovary syndrome (PCOS) remains a complex disease of unknown etiology. Patients spend an average of two years of clinical evaluation with at least three health professionals before diagnosis. As PCOS remains a diagnosis of exclusion, there is room for improvement in diagnostic classification. Although the use of Antimullerian hormone (AMH) as a diagnostic test has shown promise, it has limitations. Our laboratory has identifiedvariation in levels of activating autoantibody (AAb) to the second extracellular loop of the gonadotropin-releasing hormone receptor (GnRHR) associated with PCOS in infertile patients. This AAb and its activity level has shown promise as a diagnostic test for PCOS that could be used in conjunction with AMH to provide a direct diagnosis of PCOS. We evaluated the diagnostic capability of GnRHR AAb activity level and its response to a GnRH antagonist, together with age and AMH, to directly discriminate a diagnosis of PCOS using a sample of PCOS patients and unexplained, infertile controls.

DESIGN: Cross-sectional, matched case-control design.

MATERIALS AND METHODS: Sera from 200 patients with PCOS from the Pregnancy in Polycystic Ovary Syndrome II (PPCOS II) trial and from 200 race, parity, age, and body mass index matched ovulatory, unexplained infertile control patients from the Assessment of Multiple Intrauterine Gestations from Ovarian Stimulation (AMIGOS) trial were obtained. GnRHR AAb activity was measured with and without GnRH antagonist (cetrorelix) in all samples using the GeneBLAzer cell-based fluorescence resonance energy transfer (FRET) assay. These activity levels, along with age and AMH levels, were analyzed using logistic regression to develop a prediction model for PCOS. Receiver-operating characteristic (ROC) analyses were used to evaluate the accuracy of prediction of PCOS by this model. This diagnostic algorithm was then applied to a smaller, independent sample of 65 infertile women from an academic infertility practice.

RESULTS: The initial decision point assigned all patients with AMH >13.3 ng/ml as having PCOS. Those with AMH <13.3ng/ml were divided into those above and below 30 years of age; each age group then had its own series of AMH, GnRHR activity and GnRHR activity response decision points. Using ROC analysis, this diagnostic algorithm was estimated to have a sensitivity of 76% and specificity of 87% for PCOS in this sample of infertile women. When applied to the independent sample, the algorithm showed similar sensitivity (73%) and specificity (84%).

CONCLUSIONS: This new diagnostic algorithm incorporating AMH and GnRHR AAb cell activity and response to a GnRH antagonist performs well to diagnose PCOS, with an overall sensitivity of 76% and specificity of 87%; it fills a void in direct diagnosis of PCOS. Additional application studies will aid in identifying feasibility of this testing algorithm with the goal of streamlining and improving efficiency of diagnosis for patients with PCOS.

POLYCYSTIC OVARY SYNDROME COMORBIDITY PATTERNS DIFFER BETWEEN RACIALLY AND ETHNICALLY DIVERSE PATIENTS. Ky'Era V. Actkins, BS,[1] Melinda Aldrich, PhD,[2] Digna R. Velez Edwards, PhD,[2] Lea K. Davis, PhD.[2] [1]Meharry Medical College Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.

OBJECTIVE: To evaluate the comorbidity patterns of polycystic ovary syndrome (PCOS) in White, African American, Hispanic, and Non-Hispanic women. This study aims to understand which comorbidities are caused by the effects of a PCOS clinical diagnosis or influenced by the genetic risk of the disease.

DESIGN: A case-control study using a hospital electronic health record database and biobank.

MATERIALS AND METHODS: A total of 5,526 PCOS cases between the ages of 11 and 44 were identified using a validated algorithm that required the presence of ICD-9/10 codes for polycystic ovaries or irregular menstruation and hirsutism and excluded any other diagnosis whose symptoms mirrored PCOS characteristics. Women not identified by the algorithm were included as controls (n=394,202). Cases and controls were then stratified based on EHR-reported race and ethnicity. Women who identified as White (n=3,606 cases; 328,194 controls), African American (n=882 cases; 58,165 controls), Hispanic (n=234 cases; 15,291 controls), and Non-Hispanic

(n=4,459 cases; 382,462 controls) were used for this analysis. To determine comorbidity patterns of PCOS diagnosis, a logistic regression model adjusted for median age was performed on PCOS cases and controls for each stratified racial and ethnic group against 1,858 phenotypes in the medical database. To evaluate the effects of genetic susceptibility of PCOS on health outcomes, a logistic regression model adjusted for median age and genetic ancestry was performed on a measurement of PCOS genetic liability, genetic risk scores, and the medical database. Genetic risk scores were generated using summary statistics from a PCOS genome-wide association study[1].

RESULTS: Among Hispanic women almost half of all significant comorbidities were endocrine and metabolic disorders. Dermatologic disorders and genitourinary diseases were the second and third most common comorbidities, respectively. The most common comorbidities for White, African American, and Non-Hispanic patients were also endocrine and metabolic disorders. However, for these three cohorts, genitourinary comorbidities and pregnancy complications comprised the second and third largest comorbidity categories. African American patients had higher rates of polyp of corpus uteri (OR = 5.15, p = 6.04e-09) compared to White patients (OR = 2.70, p = 2.06e-06). Conversely, we found that Hispanic patients had higher odds of having chronic liver disease and cirrhosis (OR = 4.87, p = 1.49e-09) compared to Non-Hispanic patients (OR = 2.61, p = 9.93e-29). We also found that a genetic risk score for PCOS was associated with type 2 diabetes (OR = 1.11, p = 8.75e-08) in addition to polycystic ovaries (OR = 1.11, p = 1.91e-07) and ovarian dysfunction (OR = 1.24, p = 9.18-06) among White women.

CONCLUSIONS: Endocrine and metabolic diseases are the top comorbid conditions experienced by PCOS patients regardless of race or ethnicity. However, different racial and ethnic groups have a greater risk of developing specific PCOS comorbidities. Additionally, females with a greater genetic susceptibility to PCOS share an underlying genetic risk for type 2 diabetes.

SUBCUTANEOUS ABDOMINAL STEM CELL ADIPOGENESIS PREDICTS METABOLIC IMPROVEMENTS IN NORMAL-WEIGHT POLYCYSTIC OVARY SYNDROME WOMEN.

Daniel A. Dumesic, M.D.,[1] Ayli Tulberg, student,[1] Karen L. Leung, B.S.,[1] Sam C. Fisch, B.S.,[1] Tristan R. Grogan, M.S.,[1] David H. Abbott, Ph.D,[2] Rajanigandha Naik, M.D.,[1] Gregorio D. Chazenbalk, Ph.D.[1] [1]UCLA, Los Angeles, CA; [2]University of Wisconsin, Madison, WI.

OBJECTIVE: Normal-weight polycystic ovary syndrome (PCOS) women have exaggerated subcutaneous (SC) abdominal adipose stem cell (ASC) differentiation into adipocytes that may be programmed. This study examines whether SC abdominal ASC differentiation into adipocytes *in vitro* correlates with endocrine-metabolic functions in normal-weight PCOS women versus age- and body mass index (BMI)-matched normoandrogenic ovulatory (control) women.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Eight normal-weight PCOS women and 8 age- and BMI-matched controls underwent circulating hormone/metabolic determinations, frequently-sampled intravenous glucose tolerance testing, total-body dual-energy x-ray absorptiometry and SC abdominal fat biopsy. PPARγ and *CEBPa* gene expression and lipid content of adipocytes matured *in vitro* were compared between PCOS and control women and correlated with clinical outcomes, including insulin sensitivity (Si), acute insulin responsiveness to glucose (AIRg) and adipose insulin resistance (adipose-IR). Unpaired Student's *t*-tests, two-way ANOVA, Pearson correlation coefficients and partial correlation coefficients adjusting for serum free testosterone (T) levels were performed as appropriate.

RESULTS: PPARγ and *CEBPa* gene expression in ASCs increased to maximal levels by day 12 ($P<0.001$) without a female type effect, when *PPAR*γ levels positively correlated with total body mass in PCOS alone (control, $P=0.097$; PCOS, $P=0.032$). In control ASCs, gene expression positively correlated with fasting serum insulin ($P=0.047$, *PPAR*γ*;* $P=0.006$, *CEBPa*), AIRg ($P=0.023$, *PPAR*γ) and adipose-IR ($P=0.032$, *CEBPa*) and negatively correlated with Si ($P=0.001$, *CEBPa*). In PCOS ASCs, conversely, *CEBPa* gene expression negatively correlated with serum free fatty acid (FFA) ($P=0.002$), adipose-IR ($P=0.033$) and serum free T ($P=0.016$). Moreover, exaggerated lipid content in PCOS ASCs positively correlated with Si ($P=0.041$) and negatively correlated with serum FFA ($P=0.021$). Adjusting for serum free T levels, significant female type differences remained in the correlations of log *CEBPa* gene expression with fasting serum FFA levels ($P=0.010$) and Si ($P=0.010$); and of lipid content on day 12 with adipose-IR ($P=0.034$) and fasting serum FFA levels ($P=0.044$).

CONCLUSIONS: In normal-weight PCOS women compared to age- and BMI-matched controls, exaggerated SC abdominal ASC differentiation into adipocytes *in vitro* accompanies a normal rise in *PPAR*γ and *CEBPa* gene expression and predicts improved insulin sensitivity *in vivo*. The ability of SC abdominal ASCs of normal-weight PCOS to retain their unique cellular and molecular properties of exaggerated SC abdominal ASC differentiation into adipocytes may be programmed in early life by epigenetic events.

AN AMH-BASED SCREENING TOOL IS BOTH SENSITIVE AND SPECIFIC FOR PREDICTING A DIAGNOSIS OF PCOS BY ROTTERDAM CRITERIA.

Eduardo Hariton, MD, MBA,[1] Jerrine R. Morris, MD, MPH,[1] Chia-Ning Kao, MS,[1] Eleni Greenwood Jaswa, MD, MSc,[1] Molly M. Quinn, MD,[2] Marcelle I. Cedars, MD,[1] Heather G. Huddleston, MD.[1] [1]University of California San Francisco School of Medicine, San Francisco, CA; [2]University of California, Los Angeles, Los Angeles, CA.

OBJECTIVE: To understand whether a polycystic ovary syndrome (PCOS) screening tool using anti-Mullerian Hormone (AMH) in lieu of polycystic ovarian morphology (PCOM) is predictive of patients meeting Rotterdam criteria for PCOS.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: Women with PCOS were diagnosed by ultrasound-based Rotterdam criteria and included 253 subjects from the multisite PPCOS II trial and 111 patients from a tertiary academic centre's multidisciplinary PCOS clinic. Controls included 245 participants in the ovarian aging (OVA) study, a community-based cohort of ovulatory women not seeking treatment for fertility. Received operator curves were used to ascertain the accuracy of AMH thresholds for predicting PCOM. These age-stratified AMH thresholds from women 25-<30, 30-<35, and 35-<40 were used as one of the three criteria for diagnosis of PCOS, in addition to oligomenorrhea (<8 menstrual cycles per year) and biochemical hyperandrogenism (total testosterone >76.5 ng/dL). This modified criteria was applied to all 609 patients; the sensitivity and specificity for diagnosis of PCOS using this AMH-based screening tool was calculated using the Rotterdam criteria as gold standard. All AMH samples were run using an ELISA Ansh Labs AMH assay at a central laboratory, the Ligand Assay and Analysis Core Laboratory at the University of Virginia (UVA).

RESULTS: The optimal thresholds of AMH to predict PCOM were 10ng/dL (ages 25-<30), 6ng/dL (ages 30-<35), and 4.75ng/dL (ages 35-<40). Using these, the screening tool accurately predicted PCOS in 323 out of the 364 patients with diagnosed PCOS by Rotterdam criteria. Conversely, when applied to the control population, it accurately predicted the absence of PCOS in 243 out of 245 patients. This corresponds to a sensitivity of 88.7% and specificity of 99.2%, respectively. Using only oligomenorrhea and hyperandrogenism as diagnostic criteria, the sensitivity decreases to 39.7% (144 out of 364) patients, which is an absolute decrease of 49.1%. We were unable to accurately calculate specificity in this subgroup as our control cohort was ovulatory.

CONCLUSIONS: The PCOS screening tool is both sensitive and specific for predicting a diagnosis of PCOS by Rotterdam criteria. Ultrasonographic assessments of PCOM are subjective, expensive, and invasive. This tool offers a non-invasive, objective alternative to screen patients for PCOS. Further research is necessary to understand how the screening tool would perform prospectively or with a heterogeneous population with varied AMH assays.

POLYCYSTIC OVARY SYNDROME IS ASSOCIATED WITH INCREASED ANEUPLOIDY RATE.

Pamela B. Parker, M.D., M.P.H., Molly Siegel, MD, Wes Urian, MD, Bharti Garg, MBBS, MPH, Diana Wu, MD, Paula Amato, MD, David Lee, MD, Thomas O'Leary, PhD, Sacha A. Krieg, M.D., Ph.D. Oregon Health & Science University, Portland, OR.

OBJECTIVE: To determine if aneuploidy rates and average embryonic mitochondrial content scores differ among an infertile population with polycystic ovary syndrome (PCOS) undergoing in vitro fertilization (IVF) with preimplantation genetic testing for aneuploidy (PGT-A) compared to non-PCOS controls. PCOS is the most common cause of ovulatory dysfunction among reproductive aged women. While poor oocyte and embryo quality are associated with increased aneuploidy, little is known about the effect of PCOS on aneuploidy rates or mitochondrial DNA content, which has become increasingly reported along with embryonic ploidy status. Lower mitochondrial scores have been correlated with early blastulation and higher chances of euploidy.

DESIGN: IRB-approved retrospective cohort study.

MATERIALS AND METHODS: Data from all IVF cycles conducted at an academic center from January 2016 to June 2018 was collected. We excluded cycles utilizing donor egg, preimplantation for genetic testing for mutations or structural rearrangements, and cycles without any euploid embryos or reported mitochondrial scores (Igenomix, Los Angeles, CA). PCOS was diagnosed using the Rotterdam criteria. Baseline characteristics and outcome measures were analyzed using chi square/Fisher exact tests for categorical data and two-sample t-tests for continuous variables. Multiple linear regression models were used to examine the association of PCOS with primary outcomes of aneuploidy rate and average mitochondrial score.

RESULTS: Of the 256 subjects included in the analysis, fifty (19.5%) had PCOS. There were no differences in baseline demographic information such as age, parity, or smoking status, while body mass index (BMI) was significantly different between the PCOS and non-PCOS controls. PCOS patients had a statistically significant increased number of oocytes retrieved (19.18 vs 14.36, $p<0.001$), increased number of oocytes fertilized with ICSI (15.34 vs 12.08, $p=0.0004$), increased numbers of 2PN embryos (12.62 vs 9.5, $p=0.0001$), and increased number of blastocysts biopsied (6.12 vs 4.85, $p=0.0039$). There were no differences in fertilization or blastulation rates between the two groups. There were no differences in average mitochondrial content score (23.5 vs 25.02, $p=0.14$), however, there were statistically significant differences in aneuploidy rates among those with and without PCOS (0.49 vs 0.40, $p=0.03$, respectively). We found after controlling for age, BMI, and blastulation rate, women with PCOS have a 9.6% higher aneuploidy rate ($p=0.027$) than those without PCOS. There were no differences in clinical pregnancy rates, live birth rates, or miscarriage rates between the two groups.

CONCLUSIONS: While patients with PCOS have similar fertilization and blastulation rates compared to controls, these women have aneuploidy rates that are significantly higher, by 9.6%. This highlights one aspect of PCOS that impacts fertility success rates and the need for extensive counseling on expected outcomes in those undergoing IVF.

CLINICAL IMPLEMENTATION OF ALGORITHM-BASED EMBRYO SELECTION USING MULTI-DIMENSIONAL ANALYSIS OF 'BIG DATA' IMPROVES PREGNANCY OUTCOMES IN SINGLE THAWED EUPLOID EMBRYO TRANSFERS (EUPLOID SETS).

Jenna Friedenthal, MD,[1] Rose Marie Roth, MSc, TS(ABB), CLT (NYS),[2] Richard Slifkin, BA, TS(ABB), CLT(NYS),[2] Christine Briton-Jones, PhD, HCLD,[2] Taraneh Gharib Nazem, MD,[2] Dmitry Gounko, MA,[2] Joseph A. Lee, BA,[2] Alan B. Copperman, MD.[1] [1]Icahn School of Medicine at Mount Sinai New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) enables modern assisted reproductive technology treatment centers to better identify and select embryos for transfer. However, even among euploid embryos, morphologic grading remains a significant metric for transfer selection, especially for patients who have >1 euploid embryo available (1,2). Previous work has attempted to determine the accuracy of mathematical models in predicting outcomes using transfer cycles with known clinical results (3). However, there has yet to be a study to evaluate the clinical utilization of an algorithm-based (AB) system for embryo transfer selection. We sought to assess whether AB embryo selection improves clinical outcomes in euploid SETs.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study included patients who underwent euploid SETs at an academic center from September 2016 to February 2020. Controls included euploid SETs in which a senior embryologist selected the embryo for transfer based on modified Gardner grading (traditional). Cases included euploid SETs in which the embryo was selected using an automated AB approach. Exclusion criteria were euploid SETs from July 2017 to January 2018, in which a mixture of traditional and AB selection were used. The algorithm created a weighted ranking system of each embryonic parameter (expansion, inner cell mass grade, trophectoderm grade) and formulated a composite score. The embryo with the highest score was transferred. Our primary outcome was implantation rate (IR). Secondary outcomes were ongoing pregnancy/live birth rate (OP/LBR), biochemical pregnancy rate (BPR) and clinical loss rate (CLR). Baseline demographics were obtained: age, body mass index (BMI), ovarian reserve testing, obstetric history, endometrial thickness (EnT) and progesterone level (PL) at time of transfer, and embryo grade. Data were analyzed using Student's t-test, chi-squared test, and logistic multivariable generalized estimating equation regression models, with $P<0.05$ considered significant.

RESULTS: 4,521 SETs were performed in the study period and met inclusion criteria (traditional: n=1,119; AB: n=3,402). Patients in the traditional group were older and had a lower BMI, PL, and EnT at time of transfer ($P<0.05$ for all); demographic data was otherwise similar. The IR and OP/LBR were significantly higher in the AB group compared to the traditional group (63.52% vs 56.93%, $P<0.0001$ and 53.13% vs 47.18%, $P=0.006$, respectively). After adjusting for age, BMI, AMH, obstetric history, EnT and PL at time of transfer, and embryo grade, use of the algorithm remained significantly associated with improved IR (OR 1.25, 95% CI 1.07-1.47) and OP/LBR (OR 1.24, 95% CI 1.06-1.45). We saw no differences in BPR or CLR.

CONCLUSIONS: This is the first study to clinically implement AB embryo selection in euploid SETs. Our results demonstrate that utilization of a mathematical model for embryo selection improves clinical outcomes. Future studies implementing the algorithm in prospective, randomized trials are warranted and would better delineate the role of our model in embryo selection.

EUPLOIDY RATES AND PREGNANCY OUTCOMES USING THE *ZYMŌT*™ DEVICE FOR SPERM PREPARATION.

Anthony R. Anderson, D.HSc, Elisabeta Kasa, BA in Bioloy, Darleen Taylor, B.Sc., Donna Covington, B.Sc., Elizabeth Williams, B.Sc., Sonam Alissa Bhakta, B.Sc., Ursula Balthazar, M.D. Aspire Fertility San Antonio, San Antonio, TX.

OBJECTIVE: To compare gradient sperm and *ZyMōt*™ sperm preparation and its impact on euploidy and pregnancy outcomes.

DESIGN: Prospective Cohort study.

MATERIALS AND METHODS: Between April 2019 and April 2020 a total of 1219 embryos were available for analysis for PGT-A from 2825 oocytes fertilized with intracytoplasmic sperm injection. Two methods of sperm preparation are evaluated. A single 90% layer gradient preparation of sperm with a 10 minute centrifugation at 300g followed by a 10 minute wash with a HEPES buffered medium/10 mg per ml of human sera albumin. The second method was using the *ZyMōt*™ 850 μl device where 850 μl of raw semen is

loaded into the devices and covered with 750 μl of HEPES/HSA solution. The device is placed in to a 37◦C incubator for 30 minutes. Removal of 0.5 ml of the HEPES solution completes the preparation. Initial counts and motilities were evaluated before and after the two preparation methods. Embryos were evaluated on day 3 and assisted hatched for via laser ablation. Embryos on day 5 and day 6 with a distinct inner cell mass and multiple cells herniating form the zona pellucida were biopsied for PGS aneuploidy testing. Embryo biopsy consisted of laser removal of 5 to 7 cells from the trophectoderm juxtaposed to the inner cell mass. The biopsied cells were treated according to the reference laboratory protocol for off site aneuploidy screening. Embryos available for testing were vitrified and stored under liquid nitrogen until results were obtained from the reference laboratory.

RESULTS: A significant higher euploidy rate from day 5 embryos was noted with the *ZyMōt*™ prepared sperm as compared to the gradient prepared sperm. A total of 358 day 5 embryos were biopsied with the *ZyMōt*™prepared sperm resulting in 63% euploidy compared to 56% euploidy in 383 embryos from the gradient prepared sperm ($P<0.05$). There was not significant difference in euploidy rates with day 6 embryos in the two subgroups where 51% were euploid from the 245 *ZyMōt*™ embryos and 48% of the 233 embryos from gradient prepared sperm (not significant). There was not significant difference in ongoing pregnancies between the two subgroups, where *ZyMōt*™ prepared sperm resulted in 70% ongoing pregnancies 58% implantation rate as compared to 77% ongoing and 64% implantation with gradient prepared sperm (not signicant).

CONCLUSIONS: This study shows that although there was not a significant difference in pregnancy outcomes, there are higher euploidy rates with the *ZyMōt*™ prepared sperm. Overall resulting in more embryos available for transfer and possibly more available pregnancies. With very little changes in the way sperm is prepared in the ART industry in the past 30 years this study demonstrates the *ZyMōt*™ device provides an alternative to sperm preparation with fewer steps in the process.

O-105 2:20 PM Sunday, October 18, 2020

ACCURATE MEASUREMENT OF SPERM DNA FRAGMENTATION EFFECT ON REPRODUCTIVE OUTCOMES BY CUMULATIVE LIVEBIRTH RATES (CLBR) PER EMBRYO TRANSFERRED AND OOCYTE UTILIZED REVEALS ITS LACK OF RELEVANCE IN OOCYTE DONATION FOR UNSELECTED MALES. Irene Hervas, MSc,[1] Nicolas Garrido, PhD,[1] Rocio Rivera-Egea, PhD,[2] Cristina Gonzalez-Ravina, PhD,[3] David Amoros, PhD,[4] Fernando Quintana, Sr., PhD,[5] Maria Gil Julia, MSc, MRes,[1] Alberto Pacheco, PhD.[6] [1]IVI Foundation - IIS La Fe Biomedical Research Institute Valencia, Spain; [2]IVIRMA Valencia, Valencia, Spain; [3]IVIRMA Sevilla, Sevilla, Spain; [4]IVIRMA Barcelona, Barcelona, Spain; [5]IVIRMA Bilbao, Bilbao, Spain; [6]IVIRMA Madrid, Madrid, Spain.

OBJECTIVE: Info about sperm DNA fragmentation (SDF) effect on clinical outcomes from ovum donation cycles is scarce, and classic measuring of reproductive success using outcomes per embryo transfer is a biased measure, since best embryos are the first transfer choice and does not compute the additional contribution of other embryos within the same cohort. We better addressed this problem studying raw live birth rates (LBR) at first embryo transfer (ET), in all ET (fresh+thawed), and CLBR, per ET, number of embryos replaced (EmbR) and oocytes consumed until reaching a first newborn.

DESIGN: Multicenter retrospective cohort study.

MATERIALS AND METHODS: Patients from IVF/ICSI with donated oocytes (n=819) between Jan 2000-Mar 2019, tested for SDF on ejaculated spermatozoa using TUNEL assay. Groups were established to compare all main outcomes: SDF >15% (H, high) and in 10% SDF ranges: <10%, 10%-20%, 20%-30%, >30%, by X^2 square tests, and CLBR estimated with Kaplan-Meier and Mantel-Cox test, considering the total number of embryo transfers, embryos transferred, and oocytes consumed to obtain the first livebirth.

RESULTS: Characteristics were comparable among groups, and the analysis was conducted from information from of 1903 ET, 2146 embryos and 5039 oocytes. LBR were unaltered by high DNA fragmentation: at 1st ET and in all ET, were 53.6% and 43.2% in men with H while 48.2% and 39.6% respectively, in <15% SDF (low, L). Distributing in groups according to their SDF level, LBR rates were similar ($p>0.05$) 48.7% (<10%), 45.5% (10%-20%), 58.0% (20%-30%) and 61.1% (>30%) at 1st ET, and 39.4% (<10%), 39.2% (10%-20%), 52.0% (20%-30%) and 38.3% (>30%) per all ET performed. CLBR per ET showed in L SDF or H SDF value, 66.7% *vs* 71.5% in the 2nd ET, 75.8% *vs* 80.1% in the 3rd ET, and 89.8% *vs* 82.3% in the 5th ET, without reaching significance, nor it was when compared by the SDF groups. CLBR according to the number of embryos transferred until reaching a newborn considering L or H SDF level was 55.0% *vs* 59.4% with two EmbR and 73.6% *vs* 79.0% with up to four EmbR, resulting in non-significant differences, as when calculated by SDF groups, 57.2% (<10%) and 61.5% (>30%) with two EmbR; 73.5% (<10%) and 83.5% (>30%) with four EmbR. Relative to the number of oocytes required per patient, CLBR were not statistically significant in both analyses. Similar results were found in groups H or L of fragmentation (42.8% *vs* 45.9%, 78.6% *vs* 82.0%, 91.8% *vs* 89.8%) when 5, 10 or 15 oocytes were used respectively. When comparing between SDF groups (<10% *vs* >30%) the rate of newborns was not reduced by high fragmentation at 5 (44.2% *vs* 38.1%), at 10 (79.4% *vs* 87.6%) and at 15 (90.8% *vs* 87.6%) oocytes consumed.

CONCLUSIONS: DNA fragmentation does not negatively affect the live birth rates of unselected patients undergoing an IVF/ICSI cycle with donated oocytes, neither per transfer, nor accumulated per transfer, embryo or oocyte, after the largest and most extensive data analysis done so far.

O-106 2:35 PM Sunday, October 18, 2020

PRESENCE OF ABNORMAL CELL CLEAVAGE, CELL FUSION OR BOTH SEEN DURING EMBRYO DEVELOPMENT ON TIME-LAPSE MICROSCOPY IS NOT PREDICTIVE OF CHROMOSOMAL ANEUPLOIDY. Alice J. Shapiro, M.D.,[1] Lindsay Kroener, MD,[1] Nicholas J. Jackson, PhD, MPH,[1] Zachary Haimowitz, B.S.,[2] Alin Lina Akopians, MD, PhD,[3] Wendy Y. Chang, MD,[3] Carolyn J. Alexander, MD,[3] Shahin Ghadir, MD,[3] Hal Danzer, MD,[3] Mark W. Surrey, MD,[3] Jason A. Barritt, PhD[2] [1]David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA; [2]ART Reproductive Center, Beverly Hills, CA; [3]Southern California Reproductive Center, Beverly Hills, CA.

OBJECTIVE: To determine whether the presence of abnormal cell cleavage, cell fusion or both seen on morphokinetic analysis of preimplantation embryos using time-lapse monitoring (TLM) is predictive of chromosomal aneuploidy when compared to embryos with normal development.

DESIGN: Retrospective cohort study at a large, private fertility center.

MATERIALS AND METHODS: All patients who utilized both the TLM device (Embryoscope®, Vitrolife, Sweden) and preimplantation genetic testing for aneuploidy (PGT-A) at a single IVF center from 1/2018 to 12/2019 were included in the study. Patients using donor oocytes were excluded. Evaluation of embryo development was performed on all embryos from the time of first cell division until 72 hours. Abnormal cell cleavage (AC) was defined as irregular first cleavage of the zygote resulting in more than two daughter cells and/or irregular second cleavage that formed five or more cells instead of four. Cell fusion (CF) was defined as a decrease in number of cells at any time point up until 72 hours. Normal development (ND) was defined as the absence of AC or CF. Trophoectoderm biopsy was performed on day 5, 6, or 7 in blastocysts of good or fair quality. PGT-A was performed using next generation sequencing. All embryos that were sufficient quality for blastocyst biopsy were included in the study. Statistical analyses were conducted using logistic regression with Huber-White standard errors to correct for multiple embryos within a patient.

RESULTS: A total 6,171 embryos were analyzed with TLM and of those, 1,083 embryos from 311 patients developed into blastocysts of sufficient quality to biopsy and were included in the analysis. Of the biopsied blastocysts, 8.1% (87/1,083) had AC, 1.2% (14/1,083) had CF and 0.4% (4/1,083) displayed both AC and CF. The vast majority of embryos, 90.2% (969/1,083), did not have AC or CF. The presence of AC, CF or both did not significantly increase with older age ($p=0.77$). Abnormal development (AC, CF or both) was significantly more likely to be seen in fair-quality compared to good-quality embryos (17.5% v. 5%, $p<0.001$). The aneuploidy rate was not increased in embryos displaying AC (49%), CF (48%) or both (48%) compared to embryos with ND (49%), after controlling for age ($p=0.99$).

CONCLUSIONS: While the presence of early abnormal cell cleavage or cell fusion on TLM is associated with lower quality morphological grade at the blastocyst stage, these markers of abnormal development are not associated with increased aneuploidy. Additional research is needed to assess ongoing pregnancy rates from these embryos to evaluate the clinical significance of AC and CF in early pre-implantation embryo development.

SUPPORT: The research described was supported by NIH/National Center for Advancing Translational Science (NCATS) UCLA CTSI Grant Number UL1TR001881.

DOES TOBACCO AFFECT FOLLICULAR AND EMBRYO HEALTH?. David Agudo, PhD,[1] Estefania Castro, Technician,[1] Alberto Pacheco, PhD,[1] Irene Martín Patón, Graduate,[1] María Cruz, PhD,[2] Fernando Bronet, PhD.[1] [1]IVI Madrid Madrid, Spain; [2]IVIRMA Global Headquarters, Madrid, Spain.

OBJECTIVE: The main objective of this study is to compare, between smokers and no smokers egg donors, embryo implantation, embryokinetics times, and apoptosis and necrosis in cumulus cells and follicular fluid cells.

DESIGN: We measured apoptosis and necrosis in the cumulus cells and the follicular fluid cells in these donors using flow cytometry (Anexina V kit, Miltenyi Biotech). We also compared the cumulative implantation rate (until pregnancy with positive fetal heartbeat or until there were no embryos to transfer in case of not getting pregnancy) among the three study groups. In addition, these cycles were incubated in embryoscope, in order to study their cells cleavages times.

MATERIALS AND METHODS: The target population of this study are 216 oocyte donors that meet the requirements established in our oocyte donation program. The oocyte donors, are classified in terms of their tobacco consumption habits. Group I: 79 no smokers, Group II: 82 smokers donors of 1-10 cigarettes per day, Group III: 54 smokers donors of more than 10 cigarettes per day. We perform an ANOVA statistical analysis to analyze the data.

RESULTS: The embryokinetics results showed us that the first cellular events, like second polar body appearance (tPB2) and pronucleus appearance (tPNa), appeared significantly before in the no smoker group ($p<0.05$ and $p=0.036$) as well as the duration of the first and second cell cycle, in this case the duration was significantly longer in no smokers donors ($p=0.012$ and $p=0.032$).

When comparing data of apoptosis and necrosis among the three groups, we found significant differences in necrosis data, being higher in group III (necrosis in cumulus 0.53% and granulosa cells 0.55%), than in group I and II (group I: necrosis in cumulus 0.35% and granulosa cells 0.36%), (group II: necrosis in cumulus 0.23% and granulosa cells 0.33%), with p value of 0.05 and 0.011 respectively.

When we compare the implantation rate among the three groups, we observed how this rate of cumulative implantation is lower in the groups of smokers donors (group II = 54.31% and group III = 55.69%) than in the group of donors who declared themselves no smokers (group I = 65.03%). However, the differences found were not statistically significant, ($p=0.07$), although with a clear tendency towards significance.

CONCLUSIONS: These results could indicate that the smoking habit could reduce the accumulated rates of implantation, although it would be necessary to increase the number of cases in the study in order to clarify the implantation trend or more studies would be necessary to reinforce this conclusion.

A possible biological explanation for the differences founded in implantation rates, could be the higher rate of necrosis found in the cumulus cells and follicular fluid cells, in the smokers donors, which could indicate a toxic follicular environment which could affect the embryonic viability. One of the possible effects of this toxicity, would be the shorter cell cycles founded in smokers donors than in no smokers donors, or the delay in some cellular events, like the meiosis restart.

O-108 3:05 PM Sunday, October 18, 2020

ULTRA LOW OXYGEN EXPOSURE DURING EXTENDED CULTURE OF HUMAN *IN VITRO* EMBRYO SIGNIFICANTLY IMPROVES USABLE BLASTULATION AND CUMULATIVE LIVE BIRTH RATES IN *IN VITRO* FERTILIZATION. Sophie Brouillet, PharmD, PhD,[1] Aneta Andreeva, RESIDENT,[1] Anna Gala, MD,[1] Alice Ferrieres-Hoa, MD,[1] Margaux Anav, MD,[1] Alice Fournier, MD,[1] Vanessa Loup, MD,[1] Noemie Ranisavljevic, M.D., Ph.D.,[2] Samir Hamamah, MD, PhD.[1] [1]Arnaud de Villeneuve Hospital CHU Montpellier, Montpellier, France; [2]CHU and University of Montpellier, Montpellier, France.

OBJECTIVE: Does ultra-low oxygen level during extended culture of human *in vitro* embryos improve IVF outcomes compared to low oxygen level?

DESIGN: A monocentric retrospective cohort study was performed from June 2014 to March 2019. A total of 120 couples were enrolled. The study was approved by local institutional review board (2019_IRB-MTP_09-01). All couples underwent one IVF cycle associated with low oxygen exposure (5%) througout *in vitro* culture (from day 0 to day 6) and then the subsequent IVF cycle associated with low oxygen culture (5%) during early embryo development (from day 0 to day 3) and ultra-low oxygen exposure (2%) during extended embryo culture (from day 3 to day 6). *In vitro* experiments have also been conducted to characterize the impact of oxygen modulation during *in vitro* culture on human embryo development and implantation potential (authorization: 10/04/2018, NOR SSAB1816140S).

MATERIALS AND METHODS: The first objective was to evaluate total and usable blastocyst formation rates in both "5% oxygen exposure" and "2% oxygen exposure" groups during extended culture of human *in vitro* embryos. The secondary objective was to evaluate cumulative implantation, clinical pregnancy and live birth rates obtained after fresh and frozen-thawed morula/blastocyst transfers in both "5% oxygen exposure" and "2% oxygen exposure" groups. The level of expression of numerous key factors in human embryo development and implantation have also been investigated in human embryos donated for the research and cultured under low (5%) or ultra-low (2%) oxygen level during extended embryo culture.

RESULTS: As expected, the maternal age and the total number of IVF cycles were significantly higher in the subsequent IVF attempt associated with "2% oxygen exposure". All other clinical and biological parameters were similar in both groups. The blastocyst formation rate (55% vs. 44%, $p<0.001$) and usable blastocyst formation rate (33% vs. 22%, $p<0.001$) were both significantly higher in the "2% oxygen exposure" group than in "5% oxygen exposure" group during extended embryo culture. There was a statistically insignificant trend in implantation, clinical pregnancy and live birth rates in the "2% oxygen exposure" group compared to the "5% oxygen exposure" group after fresh morula/blastocyst transfers. The cumulative implantation (33% versus 17%, $p<0.05$), clinical pregnancy (37% versus 15%, $p<0.01$), and live birth (23% versus 8%, $p<0.01$) rates were significantly higher in the "2% oxygen exposure" group than in "5% oxygen exposure" group, respectively. Key factors in trophoblast proliferation, survival and invasion were significantly increased in research embryos cultured under 2% of oxygen during extended culture compared to 5%.

CONCLUSIONS: Improved IVF outcomes were obtained in the same couples when ultra-low oxygen exposure (2%) was used compared to low oxygen exposure (5%) during extended embryo culture, in spite of the negative impact of increased maternal age. Ultra-low oxygen exposure may improve blastocyst formation and implantation potential by improving trophoblast implantation ability during IVF.

EARLY PREGNANCY

CHRONIC ENDOMETRITIS: WHAT IS THE PREVALENCE AMONG HEALTHY CONTROLS?. Dana B. McQueen, MD, MAS,[1] Kruti P. Maniar, M.D.,[2] Rafael Confino, BS,[2] Lia Bernardi, MD,[1] Mary Ellen Pavone, MD, MSCI.[1] [1]Northwestern Feinberg School of Medicine Chicago, IL; [2]Northwestern University, Chicago, IL.

OBJECTIVE: To evaluate the prevalence of chronic endometritis (CE) in women with unexplained recurrent pregnancy loss (RPL) and healthy controls.

DESIGN: Cohort Study.

MATERIALS AND METHODS: IRB approval was obtained. The RPL group included women with $\geq$ two pregnancy losses, endometrial biopsy (EMB) between 1/2016 and 12/2018, TSH values $<$ 4 mU/L, negative antiphospholipid antibodies and normal uterine anatomy. The control group included volunteers without a history of RPL, infertility, uterine fibroids, polyps, pelvic inflammatory disease or retained pregnancy tissue recruited between 5/2019 and 2/2020. Women 18-50 years of age were included. H&E and CD138 immunohistochemical staining were performed on all endometrial biopsies. A single pathologist blinded to patient history recorded the number of plasma cells per 10 high power fields (HPF) and the presence of endometrial stromal changes (spindling, edema, breakdown, pigment deposition, areas of hypercellularity, and presence of inflammatory cells). Assuming a 3% prevalence of CE in controls and 30% in RPL, 25 controls and 50 women with RPL were needed to detect a difference in the rate of CE with 80% power and alpha of 0.05.

RESULTS: 76 women were included, 50 with RPL and 26 controls. The cohort had a mean age of 34.6 (SD 4.1) years and mean BMI of 26.0 (SD 6.2) kg/m^2. Women with RPL had a mean of 3.1 (SD 0.9) prior pregnancy losses, while controls had no prior pregnancy losses. When the presence of

plasma cells alone was used to define CE, the prevalence among women with RPL was 56% (28/50) with ≥ 1 plasma cell, 44% (22/50) with ≥ 2 plasma cells and 26% (13/50) with ≥ 5 plasma cells by CD138 staining. Using these same criteria, the prevalence of CE among controls would be 31% (8/26) with ≥ 1 plasma cell, 27% (7/26) with ≥ 2 plasma cells and 8% (2/26) with ≥ 5 plasma cells. However, when both endometrial stromal changes and plasma cells were required for CE diagnosis, there were no cases of CE in the control group. Using this definition, the prevalence in the RPL group was 30% (15/50) with ≥1 plasma cells, 28% (14/50) with ≥2 plasma cells and 16% (8/50) with ≥5 plasma cells by CD138 staining, and was statistically significantly higher in women with RPL compared to controls (P=0.0015, 0.0016, and 0.04, respectively).

CONCLUSIONS: Establishing specific diagnostic criteria for CE is necessary for both research and evidence-based treatment guidelines. We demonstrate that while rare plasma cells were found in EMB samples from healthy controls, the presence of plasma cells and endometrial stromal changes was isolated to the RPL cohort. Given that no controls were found to have both plasma cells and endometrial stromal changes, we propose that the definition of CE include 1 or more plasma cells in addition to the presence of endometrial stromal changes. Cases in which endometrial stromal changes are visualized, but no plasma cells are identified by H&E, would benefit from CD138 staining to identify plasma cells. We demonstrate that when using strict criteria to define CE, women with RPL have a significantly higher rate of CE compared to controls. An EMB should be considered as part of the evaluation for RPL.

MEDICAL VERSUS EXPECTANT MANAGEMENT IN WOMEN WITH INCOMPLETE FIRST-TRIMESTER MISCARRIAGE INITIALLY TREATED WITH MISOPROSTOL: A RANDOMIZED CONTROLLED STUDY. Mahmoud A. Abdelaleem, MD, Mohammed Khairy Ali, MD, Samr Emam, MBBCh, Ahmed M. Abbas, MD. Department of Obstetrics and Gynecology Faculty of Medicine, Assiut University, Assiut, Egypt.

OBJECTIVE: To compare the effectiveness and safety of vaginal misoprostol versus expectant management in women with an incomplete first-trimester miscarriage who had been treated before with misoprostol.

DESIGN: Open labeled, parallel, randomized clinical trial (NCT03148561-clinicaltrial.gov).

MATERIALS AND METHODS: From July 2017 to July 2019, women with a first-trimester miscarriage who had been treated with misoprostol were invited to participate in our study. An incomplete miscarriage was diagnosed when there was a history of passage of tissue and there was heterogeneous material in the uterine cavity with an endometrial thickness of >10 mm by transvaginal ultrasound (TV/US). Eligible women who gave their informed consent were randomized to either group I: misoprostol group received misoprostol 800 μg once dose placed in the posterior vaginal fornix or group II: no intervention group (expectant management). The primary outcome was the number of patients with complete miscarriage at one week. Complete miscarriage is defined as endometrial thickness of <10 mm by TV/US. We calculated the sample size based on our primary outcome (the rate of complete miscarriage). Previous study reported that the success rate of expectant management of incomplete miscarriage after 1 week was 48.5%**.** Using two sided chi-square ($\chi 2$) test with α of 0.05, a total sample size of at least 84 patients in the 2 groups (42 in each arm) will have 80% power to detect a 30% difference between both groups [odds ratio of 3.8] (Epi-info™, CDC, USA).

RESULTS: Eighty-four women were divided equally into two groups; each group included 42 women. Both groups were homogeneous in baseline socio-demographic and obstetric data without statistically significant differences. As regard our primary outcome; we found that the rate of complete miscarriage at one week was significantly higher in misoprostol group than expectant group (29 (69.0%) vs. 7 (16.7%); p=0.000, respectively). There were two patients (4.8%) in group I and 5 patients (11.9%) in group II subjected to surgical evacuation after failed achievement of complete miscarriage at four weeks. The rate of complete miscarriage at two weeks was significantly higher in misoprostol group than expectant group (p=0.000). However; at four weeks; both groups were similar in the rate of complete miscarriage (p= 0.433).

CONCLUSIONS: Vaginal misoprostol seems to be effective in achieving complete uterine evacuation than expectant management in women with incomplete first-trimester miscarriage.

O-111 2:20 PM Sunday, October 18, 2020

GNRH ANTAGONISTS INHIBIT TROPHOBLAST INVASION, PROLIFERATION AND OUTGROWTH IN PLACENTA FROM WOMEN WITH ECTOPIC PREGNANCY. Bo Peng, Ph.D.,[1] Lobna Abdellatif, M.Sc.,[2] Paul J. Yong, M.D., Ph.D.,[2] Alexander G. Beristain, Ph.D.,[2] Andrew Horne, MB ChB, Ph.D.,[3] Mohamed Ali Bedaiwy, M.D., Ph.D.[2] [1]American University of the Caribbean, School of Medicine, Cupecoy, Sint Maarten (Dutch part); [2]University of British Columbia, Vancouver, BC, Canada; [3]The University of Edinburgh, Edinburgh, United Kingdom.

OBJECTIVE: Ectopic pregnancy (EP) is a leading cause of maternal morbidity and mortality. Besides surgical intervention, methotrexate (MTX) therapy is the only approved medical treatment for EP. In addition to its side effects, the rate of treatment failure could reach up to 30%. Gonadotropin-releasing hormone (GnRH) and its receptor are abundantly expressed in EP implantation sites. GnRH also has been shown to facilitate implantation by promoting trophoblast invasion. The objective of our study is to investigate the role of GnRH antagonists in inhibiting invasion, proliferation, and outgrowth in a *de novo* primary EP trophoblast cell model and a 3D placental explant model.

DESIGN: *In vitro* primary EP trophoblast cell cultures and *ex vivo* placental explants.

MATERIALS AND METHODS: Placental tissues (n=15) were collected post salpingectomy or salpingostomy, from women with tubal EP. Patients gave written consent to participate in our study. Placental tissues were carefully dissected to remove attached Fallopian tube tissues, then digested with Collagenase-I enzyme to establish *in vitro* primary culture. Villi from the first-trimester eutopic placenta (n=4) were obtained after elective termination of pregnancy and placed in Matrigel-coated culture inserts to establish *ex vivo* placental explants. Primary cultured ectopic cells and eutopic tissue villous explants were subjected to GnRH antagonists Ganirelix or Cetrorelix. The cell invasiveness was examined by a transwell cell invasion assay. Cell proliferation capabilities were evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay. Explant growth profiles were examined via imaging and measuring the area and length of outgrowth.

RESULTS: Ganirelix significantly inhibited the cell invasiveness of primary trophoblast cells isolated from ectopic placentas at 48h. The cell proliferation of these cells was significantly decreased after Cetrorelix treatment at 72h and 96h. Also, at 48h, Cetrorelix significantly attenuated both the growth area and the length of columns outgrowth from the eutopic placental explants.

CONCLUSIONS: GnRH antagonists attenuate cell invasiveness and proliferation of primary EP trophoblast cells, as well as the outgrowth of villous tissue explants from eutopic placentas. Thus, GnRH antagonists may have the therapeutic potential to treat EP medically.

O-112 2:35 PM Sunday, October 18, 2020

PARENTAL ORIGIN OF EMBRYONIC ANEUPLOIDY IN COUPLES WITH RECURRENT PREGNANCY LOSS. Dana B. McQueen, MD, MAS,[1] Marissa L. Luck, MD,[1] Lydia Hughes, MD,[1] Rachel Ruderman, MD, MPH,[1] Rafael Confino, BS,[1] Melissa K. Maisenbacher, M.S.,[2] Mary Ellen Pavone, MD, MSCI,[1] Lia Bernardi, MD.[1] [1]Northwestern Feinberg School of Medicine Chicago, IL; [2]Natera, San Carlos, CA.

OBJECTIVE: To evaluate the relationship between recurrent pregnancy loss (RPL) and parental origin of embryonic aneuploidy.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Institutional Review Board approval was obtained. All in vitro fertilization (IVF) cycles utilizing preimplantation genetic testing for aneuploidy between 1/2015 and 1/2020 were reviewed. Overall rates of embryonic aneuploidy, as well as rates of maternal and paternal aneuploidy were compared between groups. RPL was defined as three or more pregnancy losses less than 20 weeks gestational size. Continuous variables were compared with a student's t-test and categorical variables with a Chi-square. Assuming an aneuploidy rate of 50%, in order to detect a 10% difference between groups with 80% power and alpha of 0.05, 240 embryos from RPL group and 1200 embryos from non-RPL group were needed.

RESULTS: A total of 453 IVF cycles were included; 62 in women with RPL and 391 in women without RPL. There were no significant differences in maternal age, maternal body mass index (BMI), anti-mullerian hormone (AMH), paternal age, paternal BMI, abnormal semen analysis results, days of stimulation, number of oocytes, number fertilized oocytes or number of blastocysts biopsied between groups (Table). A total of 1720 embryos were analyzed, 275 in women with RPL and 1445 in women without RPL. There was no difference in the rate of embryonic aneuploidy (52.7% vs. 50.9%, P=0.63) or maternal aneuploidy (40.7% vs. 41.4%, P=0.96) between women with and without RPL. There was a significantly higher rate of paternal aneuploidy in women with RPL, 11.6% vs 7.8%, P=0.04. The paternal aneuploidy rate increased with number of prior pregnancy losses, with a rate of 20.5% (18/88) in cycles from women with a history of four or more pregnancy losses.

CONCLUSIONS: Paternal aneuploidy rates were significantly higher in IVF cycles of women with a history of three or more prior pregnancy losses. Further investigation is needed to determine if higher rates of paternal aneuploidy are associated with increased sperm DNA fragmentation. Ultimately, a comprehensive understanding of the male contribution to pregnancy loss is essential in order to effectively identify and treat paternal causes of RPL.

Mean (SD)	RPL (N=62 cycles, 275 embryos)	Not RPL (N=391 cycles, 1445 embryos)	P-value
Maternal Age, yr	36.6 (3.5)	37.5 (3.5)	0.06
BMI, kg/m^2	24.4 (4.1)	25.1 (5.0)	0.30

O-113 2:50 PM Sunday, October 18, 2020

SINGLE NUCLEOTIDE POLYMORPHISM (SNP) ARRAY ANALYSIS OF 63,277 PRODUCTS OF CONCEPTION (POC) SAMPLES: A 10-YEAR LABORATORY EXPERIENCE. Melissa K. Maisenbacher, M.S.,[1] Katrina Merrion, MS,[2] Brynn Levy, M.Sc.(Med)., Ph.D., FACMG,[3] William H. Kutteh, MD, PhD.[4] [1]Natera San Carlos, CA; [2]Natera, Inc., CA; [3]Columbia University, New York, NY; [4]Clinical Professor, Memphis, TN.

OBJECTIVE: To report on the spectrum of findings identified in a large cohort of POC samples using a SNP-based array platform.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: Review of 63,277 consecutive fresh POC samples sent over a 10-year period to a single reference lab. Fresh POC samples were shipped with maternal blood samples to rule out maternal cell contamination (MCC) and determine parental origin of abnormalities. Genotyping was performed using Illumina CytoSNP-12b microarrays with bioinformatics.

RESULTS: Fetal results were obtained on 54,466 of 63,277 samples (86.1%), 8559 (13.5%) had MCC and 252 (0.4%) had incomplete results. From the 54,466 cases with fetal results, 24,483 (44.9%) were euploid and 29,983 (55.1%) were aneuploid. The average maternal age at the time of pregnancy loss was 34.2 years (range 13.6-53.0 years). The average gestational age was 71.8 days (range 11-273 days). The male:female (M:F) ratio of normal results was 1.0:0.98. The M:F ratio of abnormal results was 0.82:1; excluding cases of monosomy X, the M:F ratio of abnormal results was 1:0.99. Abnormal results were categorized as single aneuploidy, multiple aneuploidy, triploidy, deletions/duplications, full paternal uniparental disomy (UPD) and other (Table 1). Monsomy of chromosome 21 and X were the most commonly seen, monosomy 18 was seen in 2 cases, and monosomy of chromosomes 2, 3, 4, 7, 11 and 21 were each seen in a single case. Trisomy of every chromosome was identified with chromosomes 15, 16, 12, 22, and X being the most common representing approximately 2/3 of all single aneuploidy cases.

TABLE 1. Rates of Abnormal Results

Type of Abnormality	Number of Cases	Percentage of Abnormal Cases (%)
Single aneuploidy	22,493	75.0
Multiple aneuploidy	1702	5.7
Triploidy	3981	13.3
Deletions/Duplications	1378	4.6
Full Paternal UPD	188	0.6
Other*	227	0.8
TOTAL	29,984	100

*Includes single UPD, tetraploidy, mosaicism and complex findings.

CONCLUSIONS: Testing of POC samples using traditional karyotyping presents challenges related to cell culture failure, long turnaround times and detection limitations. One study reported a 1:2 M:F ratio due to unidentified MCC and a cell culture failure rate of >20%.[1] SNP microarray analysis of POC samples allows for identification of MCC resulting in an almost 1:1 M:F ratio, a failure rate of <0.5%, and an average turnaround time of 5 business days. Rates of types of abnormalities seen in karyotype compared to SNP array are similar, but SNP array also identifies additional chromosomal causes of pregnancy loss including deletions and duplications down to 1 Mb.[1,2] Using SNP for miscarriage analysis is clinically effective and provides an accurate answer to explain a pregnancy loss and may help direct medical management.

A BIOCHEMICAL PREGNANCY LOSS AFTER THE FIRST FRESH EMBRYO TRANSFER: CURSE OR BLESSING? Liselotte Gezels, MD, Shari Mackens, MD, Annalisa Racca, MD, Anick De Vos, PhD, Herman Tournaye, MD, PhD, Christophe Blockeel, MD, PhD. Universitair Ziekenhuis Brussel Jette, Belgium.

OBJECTIVE: To evaluate whether subsequent reproductive outcomes differ in patients with a biochemical pregnancy loss (BPL) versus a negative pregnancy test following the first fresh embryo transfer (ET).

DESIGN: A single-center, 9-year (2010-2018), retrospective cohort study.

MATERIALS AND METHODS: Demographic and IVF/ICSI treatment characteristics were collected for both study groups. The outcome of the subsequent ET was retrieved with live birth rate (LBR) as primary endpoint. Secondary endpoints were subsequent ET's early pregnancy loss rate and cumulative LBR taking into account all ETs performed within one year after the first unsuccessful ET, as well as spontaneous conceptions during this time-period. The time to reach an ongoing pregnancy was calculated and compared between both study groups. Two multivariate logistic regression models were applied to correct for potential and relevant confounders a) LBR following the subsequent ET and b) LBR resulting from all ETs and spontaneous conceptions within one year.

RESULTS: Of the 2404 included first fresh single ETs, 2221 resulted in a negative hCG test and 183 in a BPL. Maternal age was the only demographic parameter found to be significantly different between both groups (32.8±4.7 years in the hCG- group vs 32.0±4.6 years in the BPL group, p=0.02). IVF/ICSI treatment cycle characteristics differed between groups in terms of the ET stage (48.8% blastocyst transfer in the hCG- group vs 65.9% in the BPL group, p<0.001) and the number of surplus vitrified embryos (respectively, 1.8±2.2 and 2.1±2.1, p=0.03). Unadjusted analysis of the LBR following the subsequent ET was in favor of the BPL group [35.2% compared to 27.6% in the hCG- group (p=0.05)]. No higher incidence was observed for another BPL or early miscarriage in that subsequent ET cycle (BPL rate of 9.2% in the hCG-group vs 12.8% in the BPL group, p=0.33 and early miscarriage rate of, respectively, 14.6% vs 15.1%, p=0.87). Unadjusted analysis of the LBR taking into account further ETs and spontaneous conceptions within the following year was significantly different and 54.8% in the hCG- group vs 63.3% in the BPL group (p=0.04). The time to reach an ongoing pregnancy was comparable between both groups (19.6±12.5 weeks for the hCG- group

vs 20.9±12.9 weeks for the BPL group, p=0.23). The multivariate logistic regression models correcting for relevant confounders refuted the unadjusted analyses and showed study groups to have similar success rates (respectively, OR 1.41, CI 0.97-2.05, p=0.07 for the LBR after the subsequent ET and OR 1.27, CI 0.90-1.80, p=0.18 for the LBR after one year).

CONCLUSIONS: Patients with a BPL versus a negative pregnancy test following the first fresh ET have comparable subsequent reproductive outcomes. When experiencing a BPL after a first fresh ET, patients can be reassured that they do not seem to have an increased risk of encountering another early pregnancy failure when compared to patients having a negative hCG test and that they have similar chances of reaching a successful pregnancy following the subsequent ET, but also at the timepoint of one year and this within a comparable time window.

LEGAL AND ETHICAL REPRODUCTIVE ISSUES

BRINGING INFORMED CONSENT TO THE 21ST CENTURY – THE IMPACT OF AN ONLINE RESOURCE AND CONSENT PROCESS ON FERTILITY PATIENT PERCEPTIONS. Abigail L. Bernard, MD,[1] Ashley K. Barbour, MPhys,[2] Jody L. Madeira, Ph.D., J.D.,[3] Steven R. Lindheim, M.D.,[4] Linnea R. Goodman, MD.[1] [1]University of North Carolina Raleigh, NC; [2]Brody School of Medicine at East Carolina University, Greenville, NC; [3]Professor of Law, Bloomington, IN; [4]Wright State University, Dayton, OH.

OBJECTIVE: To determine if the use of a multimedia electronic (e)-learning resource and e-consent process influences patients' perception of their treatment team and eases the administrative burden.

DESIGN: Prospective randomized controlled trial.

MATERIALS AND METHODS: Patients undergoing their first intrauterine insemination (IUI) or in-vitro fertilization (IVF) cycle were randomized to receive standard fertility counseling and sign paper consents with their physician and nurse team (conventional group) or to receive standard counseling plus access to an interactive multimedia e-learning and e-consent platform (EngagedMD group). Surveys were administered prior to treatment (T1) and at cycle completion (T2) to assess their treatment experience, perception of their treatment team, and the informed consent (IC) process. A therapeutic index (TI) score was generated based on the sum of patients' responses to six questions including how much they agreed or disagreed with statements regarding their physician/nursing team. Additionally, patients were surveyed about their perception of IC in general and their experience with the consent process. The six physicians and four nurses involved in patient care were surveyed regarding their experience during the study. Statistics were performed using the student's t-test and Chi-squared test where appropriate.

RESULTS: Demographics for the 77 patients (42=IVF and 35=IUI) including age, duration of infertility and education level were similar between the conventional and EngagedMD groups. Calculated TI scores revealed no difference at T1 ($p = 0.81$) or T2 ($p = 0.68$) between the conventional and EngagedMD groups. Regarding IC, there was no difference between patients' summed responses in the conventional and EngagedMD groups. Of those that used the online platform, most patients agreed that it was helpful (92.5%), user-friendly (81.4%), and would recommend it to a friend (85.2%). Of those that signed consents online, 25 of 27 (92.5%) patients preferred this over standard paper consents. When rating overall fertility treatment satisfaction on a 1-100 scale, there was no difference between those that used EngagedMD and those that did not (85.2 +/- 21/1 vs. 83.8 +/- 18.5; $p = 0.82$). While none of the physicians surveyed felt that the addition of e-consents aided in patient understanding, all physicians and nurses felt that having e-consents was a valuable addition to the practice and made the process easier.

CONCLUSIONS: The addition of an online learning and consent platform did not significantly impact patients' perception of their treatment team, nor their overall perception of the informed consent process. However, patients and providers using the online consent process agreed that it was a valuable addition to streamline the consent process.

DECISION REGRET AFTER AUTOLOGOUS IN VITRO FERTILIZATION IN WOMEN AGE 42 AND OVER. David Huang, MD, Eleni Greenwood Jaswa, MD, MSc, Marcelle I. Cedars, MD, Heather G. Huddleston, MD. University of California San Francisco Department of Obstetrics and Gynecology, San Francisco, CA.

OBJECTIVE: An increasing number of women greater than or equal to 42 years old choose to pursue autologous IVF (aIVF) despite persistently low success rates in this age group. Few data exist on these patients' reflections on their decision after undergoing aIVF. We aim to describe the level of decision regret in women age 42 and over who underwent aIVF and identify factors associated with moderate/severe regret.

DESIGN: Retrospective cohort survey study.

MATERIALS AND METHODS: Between 2012-2018, 463 women greater than or equal to 42 years old underwent aIVF at a single academic institution. Patients were invited to participate in an online survey that inquired their experience with IVF. The survey contained 38-items, including the validated Decision Regret Scale (DRS) as well as items examining demographics, perceived adequacy of counseling, reproductive outcomes, and impact of IVF on one's relationship, career, and philosophy of life. Our primary outcome was the DRS decision regret score: 0 (no regret), 1-25 (mild regret), and >25 (moderate/severe regret). Demographic and treatment-related variables were compared between patients who demonstrated moderate/severe regret and those with no/mild regret using the Student *t*-test or the chi-square test as appropriate.

RESULTS: Of the 463 eligible participants, 70 (15.1%) obtained at least one live birth from aIVF and 393 (84.9%) did not. The survey was completed by 62 (13.4%) patients; response rate was 37.1% (n=26) in those who obtained a live birth versus 9.2% (n=36) in those who did not. Mean age was 43.1y at time of IVF (range 42-47y), and the elapsed time between survey and last IVF averaged 4.7y (range 1.0-8.1y). Of the 62 respondents, 40.3% (n=25) had no regret, 33.9% (n=21) had mild regret, and 25.8% (n=16) had moderate/severe regret after aIVF. Median DRS score was 7.5 (interquartile range 0-28.75) and the mean was 15.3 (range 0-70). Age at initiating IVF, income, educational attainment, elapsed time from last IVF, and number of aIVF cycles were not associated with higher degree of regret. Having no insurance coverage for IVF was associated with increased regret, though the association did not reach statistical significance (p=0.06). Having no live births was associated with increased regret ($p<0.01$). Among those who were not successful from aIVF, 11.1% (n=4) endorsed no regret, 44.4% (n=16) had mild regret, and 44.4% (n=16) had moderate/severe regret. Of those who failed aIVF but was then successful with donor eggs (n=12), 50.0% (n=6) still reported moderate/severe regret.

CONCLUSIONS: There is a considerable risk of decision regret following aIVF in women age 42 and over. Degree of regret was influenced by insurance coverage for IVF and strongly associated with whether a live birth was achieved. Regret was not eliminated in those who then became successful through donor eggs. Providers should discuss this risk as part of the informed consent. Further data, particularly from those who were unsuccessful, is needed to substantiate these results and identify additional predictors for moderate/severe regret in order to improve patient counseling.

TOP TEN RESEARCH PRIORITIES FOR ETHICS, ACCESS, AND ORGANISATION OF FERTILITY CARE. James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Barbara Lynn Collura, MA,[2] Cindy Farquhar, FRANZCOG FRCOG MD MPH,[3] Priority Setting Partnership for Infertility[1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]RESOLVE: The National Infertility Association, McLean, VA; [3]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop the top 10 research priorities for ethics, access, and organization of fertility care.

DESIGN: International consensus development study. Healthcare professionals, people with fertility problems, and others were brought together in an open and transparent process using formal consensus methods advocated by the James Lind Alliance.

MATERIALS AND METHODS: Potential research questions were collated from an initial international survey, a systematic review of clinical practice guidelines, and Cochrane systematic reviews. A rationalized list of confirmed research uncertainties were prioritized in an international survey. Prioritized research uncertainties were discussed during a face-to-face consensus development meeting.

RESULTS: The initial survey was completed by 388 participants, from 40 countries, and 74 potential research questions were submitted. By reviewing 14 clinical practice guidelines and 162 Cochrane systematic reviews a further 19 potential research questions were identified. A rationalized list of 48 confirmed research uncertainties were entered into an interim prioritization survey completed by 317 respondents from 43 countries. The top 10 research priorities for ethics, access, and organization of fertility care were identified during a consensus development meeting involving 41 participants from 11 countries (Table 1).

1 Which public health interventions are effective in preventing infertility?
2 How can the cost of fertility treatment be reduced?
3 How can fertility treatment be made available in lower resource settings?
4 How should the information needs of people with fertility problems be met?
5 What age limit should be applied to women and men seeking fertility treatment?
6 What is the economic burden of infertility?
7 What is the minimum standard of care people with infertility should expect?
8 How should financial conflicts of interest be managed in clinical and research settings?
9 How should social egg freezing be regulated?
10 What are the optimal methods to report long term maternal and offspring outcomes across national and international settings?

Figure 1: Top 10 research priorities for ethics, access, and organization of fertility care

CONCLUSIONS: We anticipate the top 10 research priorities for ethics, access, and organization of fertility care will help research funding organizations and researchers to develop their future research agenda. Healthcare professionals, professional organisations, and patient advocacy groups should champion these research priorities.

ELECTIVE SINGLE EMBRYO TRANSFER RATES IN THE ERA OF PREIMPLANTATION GENETIC TESTING AND GESTATIONAL CARRIERS: A SART REVIEW.

Bryn Erin Willson, MD, Rebecca Lynne Surrey, MD, MS. UC Davis Health Sacramento, CA.

OBJECTIVE: In recent years, there has been increased utilization of elective single embryo transfer (eSET) as opposed to multiple embryo transfers. Randomized control trials have demonstrated similar pregnancy rates (PR) and live birth rates (LBR) between single and double embryo transfers, however there is a benefit of an overall reduction in multiple gestations, and subsequent neonatal morbidity, with eSET. Additionally, recent advancements in employment of preimplantation genetic testing (PGT) technology has contributed to the success of eSET.

DESIGN: Utilizing the Society for Assisted Reproductive Technology (SART) online database, the goal of this study was to evaluate how often SART-participating clinics utilize eSET with PGT tested embryos created from donor oocytes, specifically with the use of gestational carriers (GC).

MATERIALS AND METHODS: The SART database was queried using 2014, 2015, 2016, and 2017 data with filters "Gestational Carrier" and "PGTA." Donor oocytes cycle characteristics were then reviewed and data recorded including eSET percentage, singleton birth rate, twin birth rate, and higher order multiples birth rate.

RESULTS: In 2017, 1728 recipient cycle starts met criteria. Mean number of embryos transferred 1.3. eSET: 57.1%. Implantation rate 62.7%. Live birth rate 60.3%. Of live births: singleton birth rate 78.9% Twin birth rate 20.3%. Triplets or more 0.8%.Term live birth 78.5%. Preterm 18.1%. Very preterm 3.4%. eSET percentage and multiple birth rate from 2014, 2015, and 2016 are represented in the table below.

CONCLUSIONS: In the setting of improving success rates of assisted reproductive technology, the reproductive endocrinology community has made efforts to decrease the risk of multiples and subsequent neonatal morbidity. A major application of these efforts is to utilize eSET when appropriate. With employment of donor oocytes, PGT, and gestational carriers, eSET rates will likely continue to increase over time.

TABLE 1.

Year	eSET %	Rate of multiples (twin or higher order)	Number of recipient start cycles
2014	44.10%	27.8%	402
2015	47.40%	26.3%	669
2016	51.9%	24.8%	1101
2017	57.10%	21.1%	1728

O-119 2:50 PM Sunday, October 18, 2020

LIABILITY FOR EMBRYO MIX-UPS: LEGAL CASE REVIEW AND RECOMMENDATIONS.

Melody A. Rasouli, MD, MBA,[1] Christopher P. Moutos, MD,[2] John Y. Phelps, MD, JD, LLM, MHA.[3] [1]University of Nevada Las Vegas, Las Vegas, NV; [2]University of Texas Medical Branch, Galveston, TX; [3]University of Nevada Las Vegas, Las Vegas, NV.

OBJECTIVE: To discuss recent legal cases of embryo mix-ups to provide recommendations to fertility clinics and reproductive endocrinologists.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: Nexis Uni database and the Public Access to Court Electronic Records portal were used to access case law information and court documents with a focus on lawsuits against reproductive endocrinologists and fertility facilities offering embryo transfer. Emphasis was placed on court decisions, awarded damages, and legal and media coverage related to embryo mix-up events.

RESULTS: A 2018 case of embryo mix-up *Manukyan v CHA Health Systems* resulted in a custody case and a separate suit seeking damages for emotional distress and the $100,000 of legal expenses (1). Claims against the IVF facility included medical malpractice, negligence and intentional infliction of emotional distress (2). In *Andrews v. Keltz* another case of embryo mix-up, all complaints against the reproductive endocrinologist were dismissed, however, the judge ruled the embryologist exhibited negligence and violated the plaintiff's right to informed consent (3). In the case *Hebert v Ochsner*, discrepancies in embryo labeling resulted in the permanent closure of the fertility center (4). A systematic review done by the Center for Disease Control and Prevention found development and implementation of standardized labeling policies and strategies by physicians in the organization to be most effective at reducing patient misidentification due to specimen labeling errors (5).

CONCLUSIONS: When labeling errors and discrepancies in the records of embryo labeling are found, it may be prudent for a fertility clinic to review all patients potentially impacted and provide genetic testing to ensure current parentage prior to embryo implantation. Additionally, establishing a fertility practice as a separate independent business entity such as Limited Liability Company or a Professional Limited Liability Company can protect a physician's personal assets from claims made against the practice. It is advisable for fertility clinics to consider separately insuring embryologists through a stand-alone policy, or to add a rider to the physician's malpractice policy. When faced with a lawsuit with merit, the reproductive endocrinologist should consider an offer to settle for their malpractice insurance policy limit to when damage awards could exceed the policy limit.

HEALTH INSURANCE FOR INFERTILITY SERVICES: IT'S ABOUT WHERE YOU WORK, MORE THAN WHERE YOU LIVE. Nathanael B. Stanley, MA, Tara R. Foti, MPH. University of South Florida Tampa, FL.

OBJECTIVE: The objective of this research is to identify actual uses of existing infertility insurance mandates by people who access infertility services for reproduction, with the purpose of observing the role of employers in the applicability of state-mandated insurance for infertility services.

DESIGN: Accessibility of infertility services are disproportionately experienced by the global public based on sociodemographics such as income, education, race/ethnicity, sexual orientation, and geographic location. Currently, 17 of 50 states have infertility service insurance mandates (National Conference of State Legislatures, 2018), which are assumed to increase accessibility of those services, but no one has critically researched the effect these mandates have on increasing accessibility to those services. An important player in the applicability of this type of insurance is the employer, but current research has not observed the role of employers from both the perspective of patients and organizations that exist to provide financial support for using infertility services.

MATERIALS AND METHODS: Qualitative inquiry consists of 66 interviews with women and men who are U.S. residents age 18-45, as well as 8 expert interviews with organizations. Questions asked in the informal interviews are based on constructs of Social Cognitive Theory (SCT). The selection of these questions reflects the hypothesis that residence, employer, and presence and type of health insurance affect the decisions people make regarding when, how, and to what extent they access infertility services. In SCT, this type of influence on human behavior is referred to as reciprocal causation. Interviews were transcribed verbatim by the PI, and analyzed using MaxQDA using thematic coding. Inter-coder reliability reached at least 85% for all codes.

RESULTS: Results from 66 interviews with women and men in 33 states suggests it is the employer that influences access to any infertility health insurance more than the individual's residence in a state with mandated infertility health insurance. Responses from 8 experts confirm the role of employers in increasing access to infertility services, and express concern about restrictive language within different insurance mandates, knowing their organization's limitations in providing funding to everyone who needs these services to start a family. The majority of participants were currently using infertility services (51.52%), female (92.42%), mean age of 32.7 (*4.09*), mean household income of $155,107, primarily working in healthcare (21.21%), and do not identify with any religion (54.55%). Primary causes of infertility were unexplained (27.3%) and female factor (25.8%), and the majority of people had private health insurance individually or through their employer (87.9%).

CONCLUSIONS: State legislatures can affect reproductive autonomy for residents of other states because of how some employers choose to apply the infertility insurance mandate that exists in their state. It is important to address the effect of public policy qualitatively to truly observe their effectiveness.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: A total of 72,786 infertile women were identified in the Optum Clinformatics Datamart from 2003-2019 by infertility diagnosis, testing and treatment codes and compared with 3,845,790 non-infertile women seeking routine gynecologic care. Baseline comorbidities were assessed using the presence of ≥ 1 metabolic syndrome (MetS) diagnoses and the Charlson Comorbidity Index (CCI). The primary outcome of all-cause mortality was identified by linkage to Social Security Administration Death Master File outcomes and medical claims. The association of infertility with mortality was examined using Cox proportional hazard regression while adjusting for age, year of evaluation, smoking, number of visits per year, nulliparity, obesity, region of country and race.

RESULTS: Among 16,473,458 person-years of follow up, 13,942 women died. Overall, infertile women had a 24% higher risk of death (aHR 1.24, 95% CI 1.10-1.38) compared to non-infertile women. When stratified by age < 35 or ≥35 years or baseline medical comorbidity, the association between infertility and mortality remained (Table). Risk of death among infertile women did not differ significantly by follow up time. The association was similar for White, Black and Asian women. In contrast, there was no association between infertility and mortality among Hispanic women.

CONCLUSIONS: Infertile women are at increased risk of mortality, reinforcing the disease burden associated with infertility and its potential for longer-term health effects. Longer-term studies are needed to address the time course of this association.

NEIGHBORHOOD DISADVANTAGE AND ASSOCIATION WITH OVARIAN RESERVE.

Allison P. Schelble, MD,[1] Caitlin Elizabeth Martin, MD, MS,[2] Bronwyn S. Bedrick, MD, MSCI,[3] Joan Riley, PhD, HCLD,[1] Emily S. Jungheim, MD, MSCI.[4] [1]Washinton University School of Medicine St. Louis, MO; [2]Washington University School of Medicine, St. Louis, MO; [3]Johns Hopkins University, Baltimore, MD; [4]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: The purpose of this study was to evaluate the association between neighborhood disadvantage by Area Deprivation Index (ADI), which is a factor-based index measuring neighborhood disadvantage using US Census indicators of education, housing, poverty and employment, and markers of ovarian reserve including antral follicle count (AFC) and anti-Müllerian hormone (AMH).

DESIGN: Cross-sectional cohort study.

MATERIALS AND METHODS: 200 women aged 18-44 with regular menstrual cycles were included. Women who were currently pregnant or who had history of major chronic illness, infertility or ovarian surgery were excluded. Participants' zip codes were used to calculate national ADI percentile using the 2015 University of Wisconsin Neighborhood Atlas. Height and weight were obtained at enrollment to assess body mass index (BMI). AFC was obtained by transvaginal ultrasound. AMH was obtained at the time of participation. Overweight and obese participants (BMI>25) from the 25% most disadvantaged neighborhoods were compared to overweight and obese participants from the 75% least disadvantaged neighborhoods; normal weight participants were similarly compared. One-way ANOVA was used to compare the mean AFC and AMH between groups. Linear regression was used to control for confounding variables including age, race and smoking. Statistical analyses were performed using SPSS Version 25.

RESULTS: Participants had a mean age of 30.92 +/- 6.7 years at enrollment, BMI of 28.28 +/- 7.11, AFC of 27.86 +/- 15.36 and AMH of 2.94 +/- 1.96 ng/mL. There were 48 women who lived in the most disadvantaged neighborhood quartile, of which 75% (n=36) were overweight or obese. There were 145 women who lived in the 75% least disadvantaged neighborhoods, of which 54% (n=79) were overweight or obese. Overweight and obese women from the most disadvantaged neighborhoods had a significantly lower AFC and AMH compared to those from the least disadvantaged neighborhoods and this difference persisted when controlling for age, race and smoking (p=0.028 and p=0.007, respectively). Among normal weight women, there was no statistically significant difference in AFC or AMH when comparing women from the most disadvantaged neighborhoods to those from the least disadvantaged neighborhoods (p=0.227 and p=0.557, respectively).

CONCLUSIONS: Neighborhood disadvantage by ADI is associated with lower AFC and AMH in overweight and obese women, but is not significant in normal weight women. Living in a disadvantaged area may impact ovarian reserve, and this impact may be more pronounced in overweight women, suggesting a role for diet. ADI is a helpful measure of socioeconomic disadvantage and its use can be expanded to fertility medicine. Future studies are needed to explore the relationship between socioeconomic status and ovarian reserve, and to clarify the impact of obesity and diet.

BLACK RACE RESULTS IN LOWER LIVE BIRTH RATE (LBR) IN FROZEN-THAWED BLASTOCYST TRANSFER CYCLES (FET): AN ANALYSIS OF 7,002 SART FET CYCLES.

Reeva B. Makhijani, MD,[1] Alicia Y. Christy, MD,[2] Prachi N. Godiwala, MD,[1] Kim L. Thornton, MD,[3] Daniel R. Grow, MD,[1] Lawrence Engmann, MD.[1] [1]University of Connecticut Health Center Center for Advanced Reproductive Services, Farmington, CT; [2]Veterans Administration, Kensington, MD; [3]Boston IVF, Waltham, MA.

OBJECTIVE: Previous studies of fresh IVF cycles demonstrate lower pregnancy rates in black compared to white women, whereas a small FET study from a single site showed comparable pregnancy rates (1). We examined if racial disparities in IVF pregnancy outcomes persisted in FET cycles on a national level.

DESIGN: Retrospective cohort study with SART data comparing LBR in FET cycles with White, Black, Asian and Hispanic women.

MATERIALS AND METHODS: 12,835 SART FET cycles from 2014-16 were screened and 7,002 were included. Only blastocyst FET cycles with known pregnancy outcome were included. Exclusion criteria included missing race (n=4,668), age >43 years, FSH ≥15 IU/L or other race (n=1,165). Primary outcome was LBR. Secondary outcomes were implantation rate (IR), clinical pregnancy rate (CPR), multiple pregnancy rate (MPR) and clinical loss rate (CLR). Chi square test and one-way ANOVA with post-hoc Tukey were used for categorical and continuous variables, respectively. Multiple logistic regression adjusted for potential confounders including age, BMI, parity, smoking status, uterine or tubal factor diagnosis, prior fresh and frozen IVF cycles, use of PGT and number of embryos transferred. A p-value of 0.05 was considered statistically significant.

RESULTS: The groups differed in age, BMI, parity, smoking status, number of previous fresh or frozen cycles, infertility diagnosis, number of embryos transferred and use of PGT (p<0.01.) LBR was significantly lower in Black versus White and Asian, but not Hispanic groups. IR was significantly lower and CLR higher in Black women compared to all other groups. The adjusted odds of LBR was still lower in Black compared to White women (aOR 0.65 [95% CI 0.51-0.82]) and CLR higher (aOR 1.98 [95% CI 1.40 – 2.80]). There was no significant difference between groups in CPR or MPR (Table 1).

TABLE 1. SELECTED BASELINE AND CYCLE OUTCOMES FOR FET CYCLES

Outcomes	White (n=5055)	Black (n=489)	Asian (n=996)	Hispanic (n=462)	p-value
Age (y ± SD)	$34.4 \pm 3.9_a$	$35.6 \pm 3.8_b$	$35.6 \pm 3.7_b$	$35.2 \pm 4.0_b$	<0.01
No. Embryos transferred (n ± SD)	$1.4 \pm 0.6_a$	$1.6 \pm 0.6_b$	$1.4 \pm 0.6_a$	$1.6 \pm 0.6_b$	<0.01
PGT (%, n)	30.9_a (1561/5055)	18.4_b (90/489)	37.1_c (370/996)	24.9_d (115/462)	<0.01
IR (%, n)	42.3_a (3082/7283)	35.0_b (280/800)	41.8_a (581/1390)	37.8_a (277/733)	<0.01
CPR (%, n)	55.3 (2797/5055)	51.7 (253/489)	55. (549/996)	52.6 (243/462)	0.34
LBR (%, n)	45.9_a (2318/5055)	37.6_b (184/489)	44.7_a (445/996)	$43.3_{a,b}$ (200/462)	<0.01
MPR (%, n)	13.5 (377/2797)	15.0 (38/253)	11.5 (63/549)	17.3 (42/243)	0.15
CLR (%, n)	17.1_a (479/2797)	27.3_b (69/253)	18.9_a (104/549)	17.7_a (43/243)	<0.01

*Subscripts (a-d) indicate significant differences between groups.

CONCLUSIONS: Black race remains an independent predictor of reduced LBR in FET cycles, likely due to higher CLR and lower IR.

PSYCHOBIOLOGICAL, CLINICAL, AND SOCIOCULTURAL FACTORS THAT INFLUENCE AFRICAN AMERICAN WOMEN TO SEEK TREATMENT FOR INFERTILITY: A MIXED METHODS STUDY.

Morine Cebert, Ph.D., RN,[1] Eleanor Stevenson, PhD, RN,[2] Susan G. Silva, PhD,[3] Rosa Gonzalez-guarda, PhD, RN,[3] Peggy A. Shannon-Baker, PhD,[4] Renee E. Hart, MS,[5] Samad Jahandideh, PhD.[5] [1]NIH Bethesda, MD; [2]Duke University School of Nursing, Durham, NC; [3]Duke University School of Nursing, Durhan, NC; [4]Georgia Southern University, Statesboro, GA; [5]Shady Grove Fertility Center, Rockville, MD.

OBJECTIVE: Studies have shown that African American women in the U.S. have twice the prevalence of infertility (14%) than non-Hispanic White women (7%); yet are less likely to seek initial evaluation for infertility. This study sought to explore the facilitators and barriers affecting treatment seeking among African American women within reproductive endocrinology.

DESIGN: We conducted a convergent parallel mixed methods study that combined quantitative data from a retrospective chart review and semi-structured interviews of African American women seeking treatment at a large infertility clinic in the metropolitan Washington D.C Area between January 2015 and September 2019.

MATERIALS AND METHODS: Extracted variables and interview questions were derived from a systematic review examining treatment seeking for infertility. We analyzed retrospective chart review data using descriptive statistics for a random sample of electronic medical records of African American women. A one-time semi-structured interview was conducted with African American women seeking treatment for infertility. Interview transcripts were transcribed verbatim and underwent attributes, descriptive, and values coding prior to thematic analysis. Joint data displays were used for integration analyses.

RESULTS: The analysis sample included 391 records of African American women patients. The mean age of 35.5 years. Most reported minimal past medical history diagnoses and had experienced infertility symptoms, on average, for 24 months prior to evaluation. The majority (77.2%) experienced primary infertility, 45.6% were of female-factor-only origin, and 75.2% had qualifying insurance. Further, 13 African American women completed interviews. A total of 9 themes emerged: 4 barriers and 5 facilitators to treatment seeking. Barriers to treatment seeking for infertility were low risk perceptions, delayed referral despite clinical disclosure, limited or no knowledge of treatment options, and limited or no disclosure of fertility status to peers. Facilitators were symptoms of fertility distress, failing own lifestyle modifications, finding culturally competent providers, obtaining referral after complex gynecological surgeries, and social media influence. Many of the quantitative and qualitative findings converged, however, the psychological findings diverged showing that although many reported no mental health diagnoses on evaluation, fertility distress and stigma influenced seeking care.

CONCLUSIONS: African American women are often older and wait long periods of time prior to seeking treatment. Many of these delays can be related to knowledge of infertility risk factors and options of treatment. African American women may have many unmet psychological needs related to stigma of race and fertility status. Infertility facilities should consider the diversity and cultural competency of staff when attempting to help improve access to African American women. Additional awareness of infertility and treatment options should be encouraged at the primary care levels as well.

DOES ETHNICITY IMPACT OOCYTE CRYOPRESERVATION OUTCOMES? NATIONAL TRENDS AND OUTCOMES IN AUTOLOGOUS OOCYTE CRYOPRESERVATION IN THE UNITED STATES.

Quinton S. Katler, MD, MSc,[1] Lisa M. Shandley, MD, MSc,[2] Heather S. Hipp, MD,[2] Jennifer F. Kawwass, MD[1] [1]Emory University (Emory GYN / OB, Emory Reproductive Center), Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA.

OBJECTIVE: To characterize trends, characteristics and outcomes of oocyte cryopreservation (OC) cycles in the United States (U.S.) from 2012-2016, stratified by self-reported race/ethnicity.

DESIGN: Retrospective cohort analysis using the Society for Assisted Reproductive Technology Clinical Outcome Reporting System for cycles completed from 2012-2016.

MATERIALS AND METHODS: OC cycles were separated by race/ethnicity: Non-Hispanic White, Non-Hispanic Black, Asian/Pacific Islander, Hispanic, Other (American Indian, Alaskan Native, or mixed race). Trends in both absolute number of cycles as well as proportion of cycles within each group were calculated. Race/ethnicity was not reported for 47.2% of cycles; multiple imputation was used to account for missing values. Poisson regression models were used to estimate associations between race/ethnicity and oocyte yield and maturity.

RESULTS: Between 2012-2016, there were a total of 29,631 OC cycles. Of the cycles with reported race, the majority, 66.5%, were in White patients, 9.6% were in Asian/Pacific Islander patients, 7.1% were in Black patients, and 4.5% were in Hispanic patients. The total number of OC cycles increased yearly among all ethnic groups; this was most significant for Asian/Pacific Islander patients with an increase from 245 cycles in 2012 to 1,010 cycles in 2016 (p=0.001). Asian/Pacific Islanders also saw the largest increase in proportion of all OC cycles, from 8.4% to 11.4%. Among all cycles, the women were most likely to be under 35 years across ethnic backgrounds, with the exception of Asian/Pacific Islanders, who most commonly performed OC between 35 and 37 years. The majority of cycles were in women with a normal body mass index (BMI) (18.5-24.9 kg/m^2) across races, however Black and Hispanic patients had a disproportionate trend toward a higher BMI. Geographically, in the southern U.S., patients were

predominantly White, Black and Hispanic, while the western U.S. included mostly Asian/Pacific Islander patients. The majority of cycles (79.4%) were in patients who underwent one OC cycle, but Asian/Pacific Islander patients were more likely to do two or more cycles (2: 17.4%, 3 or more: 8.2%) in comparison to other ethnic groups. There was a trend towards higher gonadotropin dosing for Black patients (9.9% required >6,000 IU); however, this was not significant as compared to White patients in the adjusted analysis. After adjusting for age, BMI, stimulation protocol, and gonadotropin dose, predicted oocyte yield and percent maturation was similar across all racial/ethnic groups. Adverse cycle outcomes (e.g. infection, bleeding requiring transfusion, hospitalization) were rare overall.

CONCLUSIONS: Nationally, OC cycles are continuing to increase in number, most often in patients under 35 years, with consistent proportions of patients of different racial/ethnic backgrounds pursuing OC over time. Despite low absolute numbers, trends in cancellation and increased gonadotropin dosing are disproportionately seen for minority ethnic groups in comparison to White patients, particularly among Black and Asian/Pacific Islander patients.

ULTRASOUND CONFIRMED FIBROID PREVALENCE IN A COHORT OF REPRODUCTIVE AGED LATINX FEMALES: DATA FROM THE ENVIRONMENT, LEIOMYOMAS, LATINAS, AND ADIPOSITY STUDY (ELLAS). Torie C. Plowden, MD, MPH,[1] Anne Waldo, MS,[2] Nicole Contreras-Rodriguez, BS,[3] Felix Valbuena, MD,[4] Lisa M. Neff, MD,[5] Mercedes Carnethon, PhD,[6] Donna D. Baird, Ph.D.,[7] Erica E. Marsh, MD, MSCI, FACOG.[2] [1]Womack Army Medical Center Fort Bragg, NC; [2]University of Michigan, Ann Arbor, MI; [3]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI; [4]Community Health and Social Services (CHASS) Center, Detroit, MI; [5]Endocrinology, Metabolism, and Molecular Medicine, Northwestern University, Chicago, IL; [6]Northwestern University, Chicago, IL; [7]NIH, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

OBJECTIVE: Fibroids are thought to be highly prevalent in women by the age of 50 with prevalence being reported as 60-70%. Women of color, specifically African-American women, have consistently been found to have a higher prevalence of fibroids than Caucasian women with prevalence as high as 89% by the age of 50. Less is known about the prevalence of fibroids in other ethnic and racial groups, including the Latina/LatinX community. The purpose of this study was to characterize fibroid prevalence among a cohort of healthy, reproductive age LatinX females from the ELLAS study.

DESIGN: Cross-sectional analysis of data from a prospective longitudinal cohort study.

MATERIALS AND METHODS:Reproductive age women were recruited from southeast Michigan and were enrolled in this study from 2018 – 2020. Inclusion criteria included age 21-50 at the time of enrollment, self-identifying as Latino/Hispanic, female sex at birth, no history of malignancy or health condition requiring chemotherapy or radiation, and ability to understand and read either English or Spanish. All participants completed questionnaires on reproductive health and demographics, including age, country of birth, education history, annual household income, acculturation level, health literacy and insurance status. Presence of fibroids at least 0.5 cm in diameter was documented via transvaginal ultrasound conducted by a single ultrasonographer. Images were reviewed by a blinded ultrasonographer to determine presence and number of fibroids. SAS was used for statistical analysis.

RESULTS: 633 women have enrolled in ELLAS and 561 women have completed the first study visit. Mean age of the participants was 37.4 $\pm$ 6.94 years. Women with fibroids were significantly older than women without fibroids (41.1 $\pm$ 5.54 vs 37.0 $\pm$ 6.96; p <0.001) and fibroid prevalence increased significantly with age from 3% in 21-30 year olds to 17.1% in 46-50 year olds. There were no significant differences in demographics between women with and without fibroids including BMI, gravidity and parity. A total of 53 (9.4%) women had uterine fibroids identified on transvaginal ultrasound and of those, the vast majority (79.2%) had a single uterine fibroid with the remainder having between 2-5 fibroids.

CONCLUSIONS: This is the first prospective study of ultrasound confirmed fibroid prevalence in LatinX females. At the baseline ultrasound, we found that the prevalence of uterine fibroids among this cohort was much lower than reported in the literature for either Caucasian or African-American women – particularly amongst older women. Future research is needed to confirm these findings and understand the biological drivers of this difference in prevalence.

O-127 9:40 AM Monday, October 19, 2020

ENDOMETRIAL THICKNESS FOLLOWING OVARIAN STIMULATION WITH GONADOTROPIN, CLOMIPHENE, OR LETROZOLE FOR UNEXPLAINED INFERTILITY, AND ASSOCIATION WITH TREATMENT OUTCOMES. Alexander M. Quaas, MD, PhD,[1] Sarah Z. Gavrizi, MD,[2] Jennifer D. Peck, PhD,[2] Michael P. Diamond, MD,[3] Karl R. Hansen, MD PhD,.[2] Reproductive Medicine Network[1]University of California San Diego San Diego, CA; [2]University of Oklahoma College of Medicine, Oklahoma City, OK; [3]Augusta University, Augusta, GA.

OBJECTIVE: To determine the ability of endometrial thickness (EMT) to independently predict live birth rates (LBR) after ovarian stimulation with intrauterine insemination (OS-IUI) for unexplained infertility, overall and adjusted for OS regimen

DESIGN: Secondary analysis of the Assessment of Multiple Intrauterine Gestations from Ovarian Stimulation (AMIGOS) trial.

MATERIALS AND METHODS: LBRs were examined graphically by EMT. This distribution informed EMT category cut points (in mm): 3-5, 6-8, 9-12 and $\geq$ 13. Risk ratios (RR) and 95% confidence intervals (CI) were calculated using cluster-weighted generalized estimating equations to account for multiple IUI cycles in the same patient. Confounding by OS regimen, age, ethnicity, body mass index, duration of infertility treatment, and number of follicles $\geq$ 16mm was evaluated, and covariates changing RRs by $\geq$10% retained in adjusted analyses. Crude and adjusted associations between EMT and LBR were examined. Tests for trend were estimated by entering an ordinal variable for EMT into the model using approximate category midpoints as assigned values.

RESULTS: The overall mean EMT in patients with a LB (9.5 mm, 95% CI 8.9-10.0) was significantly higher than in those without LB (8.9, 8.8-9.1; p=0.004). Patients in the gonadotropin arm had a significantly higher mean EMT than those in the other two arms (p<0.0001). Compared to the referent EMT group of 9-12 mm, the unadjusted RR for LB for the EMT groups of $\leq$5 and 6-8 were 0.48 (95% CI 0.22-1.03) and 0.92 (0.69-1.23), respectively, demonstrating non-significant reductions in LBR. The test for trend demonstrated a statistically significant association of EMT and LBR (p=0.03, Table 1). Of all evaluated covariates, only OS regimen changed RRs by >10%, and was therefore included in the final adjusted model. After adjustment, the test for trend for an association between EMT and LBR was no longer significant (p=0.41). Stratified analyses revealed no differences in associations by treatment group.

CONCLUSIONS: LBRs in OS-IUI vary based on EMT measurements, with higher LBRs observed with increasing EMT. When adjusted for OS treatment type, there was no statistically significant association of EMT with LBR. Appreciable live birth rates are seen at all EMTs, even those of $\leq$5 mm, suggesting that OS-IUI cycles should not be canceled for thin endometrium.

TABLE 1. Association between LBR and EMT (n=2459 cycles)

EMT	LB [n (%)]	Cycles [n (%)]	Crude RR (95% CI)	Adjusted RR (95% CI)
$\leq$ 5	7 (3.6)	195 (7.9)	0.48 (0.22-1.03)	0.57 (0.26-1.26)
6-8	74 (7.8)	948 (38.6)	0.92 (0.69-1.23)	1.05 (0.78-1.41)
9-12	107 (9.8)	1088 (44.3)	1.00	1.00
$\geq$ 13	28 (12.3)	228 (9.3)	1.20 (0.81-1.76)	1.09 (0.74-1.59)
p (test for trend)			0.03*	0.41

INCIDENCE AND ULTRASONOGRAPHIC CHARACTERISTICS OF CESAREAN SCAR NICHES AFTER UTERINE CLOSURE BY DOUBLE-LAYER BARBED SUTURE: A PROSPECTIVE COMPARATIVE STUDY. Franco Alessandri, MD,[1] Simone Ferrero, MD PhD,[2] Michele Altieri, MD,[2] Giulio Evangelisti, MD,[2] Maria Grazia Centurioni, MD,[1] Fabio Barra, MD.[2] [1]IRCCS Ospedale Policlinico San Martino Genoa, Italy; [2]IRCCS Ospedale Policlinico San Martino, Genova, Italy.

OBJECTIVE: To assess the incidence and ultrasonographic characteristics of cesarean scar niches after uterine closure by double-layer barbed suture.

DESIGN: This was a prospective case-control study.

MATERIALS AND METHODS: Women who underwent elective cesarean section at ≥ 38 weeks of gestation were enrolled. Exclusion criteria were a previous cesarean section or uterine surgery. Low transverse hysterotomy was closed either by a double-layer unidirectional barbed suture or by a conventional double-layer smooth suture. The choice of the suture was based on the preference of the surgeon. The first uterine layer was done by continuous unlocked suture, including the endometrial layer and the second layer by continuous unlocked suture imbricating the first. Saline contrast hysterosonography was performed 6 weeks, 6 and 12 months after the surgical procedure. According to the modified Delphi procedure, a niche was defined as an indentation at the site of a Cesarean section with a depth of at least 2 mm. The niche depth was evaluated perpendicular to the uterine wall and was measured as the shortest visible distance between the apex of the niche and the delineation of the endometrium. Postoperative complications were recorded.

RESULTS: The study included 156 women; 94 patients underwent uterine closure by barbed suture and 145 patients by smooth suture. Six weeks after delivery, the residual myometrium thickness (± SD) was significantly higher in the barbed suture group (4.9 ± 1.6 mm) than in the smooth suture group (4.2 ± 1.5 mm; p<0.001). At 6-month follow-up, the incidence of overall niche was significantly lower in the barbed suture group (20.5%, n=17/83 vs 34.1%, n=45/132; p = 0.032). The incidence of complex niche was not different between the two groups (9.6%, n=8 vs. 7.8%, n=10; p=0.595). The mean (± SD) niche depths and largest diameters were 2.5 ± 1.4 mm and 1.9 ± 1.1 mm in the barbed suture group and 3.7 ± 0.7 mm and 2.9 ± 1.0 mm in the smooth suture group (p=0.001 and p=0.002), respectively. At 12-month follow-up, the incidence of niche remained significantly lower in the barbed suture group (21.1%, n=15/76 vs. 30.5%, n=39/118; p=0.042). There was no significant difference in the incidence of postoperative complications between the two groups.

CONCLUSIONS: The use of double-layer barbed suture during cesarean section seems to lead to a low incidence of scar niche formation and reduced size of the niches in patients who have developed them.

O-129 10:10 AM Monday, October 19, 2020

SLOWFLOWHD APPLICATION IN FET CYCLES. Seifeldin Sadek, MD,[1] Tamar Matitashvili, MD,[1] Hadi Ramadan, M.D.,[2] Laurel Stadtmauer, MD, PhD.[1] [1]Jones Institute Norfolk, VA; [2]Eastern Virginia Medical School, Norfolk, VA.

OBJECTIVE: To evaluate endometrial and subendometrial blood flow using SlowflowHD in women undergoing frozen embryo transfers (FET).

DESIGN: A prospective study of 46 women undergoing FET cycles with a normal endometrial cavity and a transfer of a good quality blastocyst.

MATERIALS AND METHODS: Blood flow to the endometrium was measured with the Voluson E10 system by a single examiner at 3 points in the cycle, day 15, Embryo Transfer day (ETD) day, and day of the pregnancy test (ET+11). The endometrial and subendometrial volume and varies indices VI, FI and VFI were measured using the virtual organ computer-aided analysis (VOCAL) imaging program. Using SlowflowHD a histogram analysis was done representing the ratio of the number of color voxels as a percentage. Finally, the S/D and RI were measured in 3 different radial arteries using Pulse Doppler (PD) in SlowflowHD. Continuous data were expressed as mean ±SEM, P values <0.05 was considered statistically significant, independent test for normal distribution and Mann-Whitney test for non-normal distribution.

RESULTS: There were no differences among groups in estradiol levels, progesterone levels, BMI, age, endometrial thickness (ET) and endometrial volume (EV), subendometrial volume. Endometrial and sub-endometrial blood flow increased from day 15 to ET day and trended higher in pregnant patients compared with non-pregnant patients with a significant difference on ET+11. VFI on ETD was 1.5 (pregnant), 1.1 (not pregnant), P=0.7, and ET+11 0.40 (pregnant), 0.057 (not pregnant) P=0.01. Using PD, flow increased in pregnant patients from day 15 to ETD. The percentage of blood flow in the endometrium was highest on day 15 and decreased on ETD and ET+11 in non-pregnant patients. However, there was no decrease in the percentage of blood flow relative to day 15 in pregnant women. Similar trends were seen with the subendometrial blood flow. Resistance to blood flow in small endometrial vessels showed no differences in pregnant and non-pregnant patients.

CONCLUSIONS: SlowflowHD is a new technology that can measure blood flow through the smaller vessels to the endometrium and the spiral arteries. This may represent a novel method to measure endometrial receptivity in a non-invasive way and there may be differences in patients who conceive.

OVIDUCTAL PATENCY OF WOMEN AFFECTS SIGNIFICANT INFLUENCES ON CLINICAL OUTCOME OF ART TREATMENT. Aisaku Fukuda, M.D., Ph.D.,[1] Hiroshi Matsumoto, B.S.,[1] Isao Tsuji, M.D., Ph.D.,[1] Yoshiharu Morimoto, M.D., Ph.D.[2] [1]IVF Osaka Clinic, Higashiosaka, Japan; [2]HORAC Grand Front Osaka clinic, Osaka, Japan.

OBJECTIVE: ART was originally invented for tubal factor infertility. It has been widely accepted that major cause of infertility is tubal disorder. Falloposcopic tuboplasty (FT), a novel technology for tubal patency disorders, has been applied as the first choice for tubal patency disorder before ART at our facility. It is obvious that oviduct plays an integral role in reproduction by providing the milieu for not only fertilization and embryo development, but also implantation. However, ART is applied on tubal factor without considering oviductal condition, patent or occluded. Therefore, the relation between ART outcome and oviductal patency was investigated on cleavage and blastocyst transfers on different age groups. Moreover, other conditions such as frozen or fresh ET, endometrial thickness, embryo developmental stages and patient ages as well as with or without FT, were analyzed by multivariate logistic regression analysis.

DESIGN: Retrospective cohort study at private fertility clinic.

MATERIALS AND METHODS: ART outcomes of 537 cycles which received ART after FT or without FT due to bilateral tubal occlusion from Jan. 2011 to Dec. 2019 were retrospectively analyzed. Tubal patency was diagnosed by HSG. The patients with bilateral tubal occlusion received FT to recover their patency for conventional infertility treatment or received ART directly by their choice. ART was performed on 155 cycles (Group A) directly without FT and 382 cycles after FT (Group B). Groups A and

B were subdivided by cleavage stage transfer (Group A-CL, n=212) or single blastocyst transfer (Group-A-BL, n=325). Clinical pregnancy rates (CPR) between ≤39 yo (Young) and ≥40 yo (Old) were compared. Moreover, logistic regression analysis was conducted to investigate which factors are relevant to CPR among cleavage stage or blastocyst transfers, with or without FT, embryo developmental stages, frozen or fresh transfer, endometrial thickness, and patient ages.

RESULTS: CPRs of without FT vs. after FT in Group A-CL and Group A-BL were 14.3% vs. 22.2% per ET (P=0.19) and 35.9% vs. 49.4% (P<0.05), respectively. CPRs of Young vs. Old in Group A-CL and Group A-BL were 16.1% vs. 31.2% (P=0.1), 12.5% vs. 7.1% (P=0.3) and 39.7% vs. 52.5% (P=0.06), 21.1% vs. 31.4% (P=0.42), respectively. Multivariate analysis revealed that receiving FT before ET (P<0.05), embryo stage (P<0.01) and patient age (P<0.01) were the factors associated with higher CPR. The odds of clinical pregnancy for patients who received FT before ET was 1.64 times higher than those without FT after controlling for embryo stage, fresh or frozen ET, endometrial thickness and patient age.

CONCLUSIONS: The present study suggests that tubal patency significantly influences clinical outcomes of ART. Reversal of tubal patency by FT or some other methods may improve implantation via modulation of endometrial condition with various enhancing factors such as cytokines and immunological substances brought by human tubal fluid. Not only ERA, chromic endometritis, endometrial flora and some other related factors, but also restoration of oviductal patency should be included to improve ART outcome.

PREVALENCE, INCIDENCE AND TRENDS IN ENDOMETRIOSIS DIAGNOSIS BY DIAGNOSTIC MODALITY, PROVIDER TYPE AND RACE. Jacob Christ, MD,[1] Onchee Yu, MS,[2] Renate Schulze-Rath, MD, MSc,[3] Susan D. Reed, MD, MPH, MS.[4] [1]University of Washington Seattle, WA; [2]Kaiser Permanente Washington, Seattle, WA; [3]Bayer AG, Berlin, Germany; [4]University of Washington Seattle, Seattle, WA.

OBJECTIVE: Population based estimates of endometriosis incidence and prevalence are few and vary widely. In a population-based US study we evaluated endometriosis incidence and prevalence and elucidated factors influencing these estimates including diagnostic method and provider type, by race and over time.

DESIGN: Ten-year population based retrospective cohort study.

MATERIALS AND METHODS: Study cohort included women enrollees at Kaiser Permanente Washington, aged 16-60 years, during January 2006-December 2015, who had a uterus, were continuously enrolled for at least 2 years prior to cohort entry and had at least 1 healthcare utilization. Incident endometriosis was identified via ICD-9/ICD-10 diagnosis codes. Incidence rates were age-adjusted by direct standardization to the 2015 study population. Secular trends in incidence overall, by race, by method of diagnosis and by practitioner type were assessed using Poisson regression analyses. Prevalent cases were defined as women with an endometriosis diagnosis prior to 2016. Chart review of women identified with an endometriosis ICD code provided development of a diagnostic algorithm to estimate surgical diagnosis. Imaging on day of diagnosis was used to infer diagnosis by imaging. All others were classified as a clinical diagnosis.

RESULTS: Among 332,056 eligible women who contributed 1,176,329 person-years, 2,863 incident endometriosis cases were identified. Incidence rates declined over the study interval from a high of 30.2 per 10,000 person-years in 2006 to 17.4 in 2015. Incidence rates were similar across races. Among 135,162 women contributed person-time in 2015, 2,521 (1.9%) had an endometriosis diagnosis. Diagnoses were assigned: 45.5% surgically, 5.7% by imaging and 48.8% clinically. Rates of surgically and clinically diagnosed endometriosis decreased over the study interval from 13.4 and 16.1 per 10,000 person-years in 2006 to 7.4 and 8.9 per 10,000 person years in 2015, respectively ($p < 0.001$). Diagnosing provider was: 73.6% obstetrician and gynecologist (OBGYN), 15.7% primary care provider (PCP) and 10.7% "other". Incidence of endometriosis diagnosed by an OBGYN and PCP decreased over the study interval from 22.9 and 5.1 per 10,000 person years in 2006 to 13.1 and 2.5 per 10,000 person years in 2015 ($p < 0.001$). Method of diagnosis and provider type did not differ across races.

CONCLUSIONS: Among a group of non-selected women in the US and without relying on patient self-report, we describe declining rates of endometriosis diagnoses over time and a disease prevalence lower than most previously published estimates (3.3-7.0%). Overall, race did not appear to have a major impact on any outcome. Among our cohort, rates declined uniformly across the main methods of diagnosis and diagnosing provider type. This may suggest that declining rates do not reflect a shift in how endometriosis was diagnosed, rather may be due to a change in management of dysmenorrhea (without assigned endometriosis diagnoses) or less likely, a true decrease in disease burden over time.

SUPPORT: Bayer AG provided financial support for the conduct of the study

O-132 10:55 AM Monday, October 19, 2020

SMALL UTERINE SEPTA: ARE THERE OTHER 3D ULTRASOUND MEASUERMENTS BEYOND SEPTAL LENGTH THAT BETTER CORRELATE TO REPRODUCTIVE OUTCOME? Caterina Exacoustos, MD, PhD,[1] Francesca Conway, MD,[2] Consuelo Russo, MD,[1] Francesco Giuseppe Martire, MD,[1] Terry Siciliano, MD,[3] Martina Cosentino, MD,[1] Carlo Ticconi, MD.[4] [1]University of Rome 'Tor Vergata' Italy; [2]University of Rome 'Tor Vergata', Rome, Italy; [3]Roma, Roma, Italy; [4]Via Edoardo Maragliano 26, Roma, Italy.

OBJECTIVE: Recently different classifications have recently been proposed to define a septate uterus mostly based on septal length, however great discrepancy has been observed between them especially for small septa. With regards to small indentations of the fundus the question is still open on the real reproductive impact of these small defects and the need for surgical treatment. The aim of this study was to propose other parameters based on 3D ultrasound (US) measurements to better classify small cavity indentation less 1cm.

DESIGN: Retrospective study on patients with 3D US diagnosis of a uterine internal fundal indentation, reproductive history of each patient was correlated to the type of uterine anomaly according to different classifications. Indentation length and other 3D US parameters were correlated to reproductive outcome.

MATERIALS AND METHODS: 664 patients with 3D US diagnosis of a uterine internal fundal indentation of ≥ 3mm were classify as septate or arcuate/normal according to the following classifications: Salim (2003), ESHRE/ESGE (2013), ASRM (2016), CUME (2018). We divided the study population in 3 group: patients with uteri with a fundal indentation ≤ 5mm, >5<10mm and ≥ 10mm. The reproductive history of each patient was correlated to the type of uterine anomaly according to the four different classifications in the total population and in the 3 sub groups. High discrepancy between classifications were observed for septal lengths >5<10mm whereas patients with uterine indentation ≤ 5mm and ≥ 10mm showed similarity in type and reproductive outcomes. Small uterine septa of >5<10mm were evaluated with other parameters of cavity indentation the like cavity width, fundal myometrial thickness and indentation angle. These other parameters were correlated to reproductive outcome thus in order to determine which one correlate to fertility problems.

RESULTS: We observed a large discrepancy between the 4 different classifications in diagnosing septate uterus especially in patients with indentation >5<10mm. Of the 664 patients 215 showed a fundal indentation length >5<10mm, of these 136 tried to conceive before our scan: 69(51%) were infertile, 65(48%) had at least one miscarriage, 38(28%) had recurrent abortion(≥2 miscarriages) and 5(4%) at least one delivery. The U Mann Whitney test showed among patients who try to conceive a significant correlation with recurrent abortion and an indentation angle > 128° Infertility was significantly correlated to a cavity width <32mm and a septal length/ fundal myometrial thickness ratio >75%.

CONCLUSIONS: Current classifications don't seem to correlate to each other and with reproductive outcomes. These wide discrepancies between different classifications is more evident in small cavity indentation >5<10mm. For these small uterine septa additional parameters like indentation angle > 128° showed more risk for recurrent miscarriage and cavity width < 32mm and septal length/fundal myometrial thickness ratio > 75% is more correlated to infertility. Further prospective study should verify if these parameters could guide the management of patients with small uterine septa.

THE ASSOCIATION BETWEEN PRIOR CESAREAN SECTION AND ASSISTED REPRODUCTIVE TECHNOLOGY (ART) OUTCOMES IN WOMEN UNDERGOING AUTOLOGOUS SINGLE THAWED EUPLOID EMBRYO TRANSFER.

Jenna Friedenthal, MD,[1] Dmitry Gounko, MA,[2] Tamar Alkon-Meadows, MD,[2] Carlos Hernandez-Nieto, MD,[2] Joseph A. Lee, BA,[2] Alan B. Copperman, MD,[1] Erkan Buyuk, MD.[1] [1]Icahn School of Medicine at Mount Sinai New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Rates of cesarean section (CS) continue to increase worldwide[1]. Although a CS is often a necessary intervention, it presents increased risk for short and long-term sequelae in mother and infant[2]. Previous work suggests an association between prior CS and reduced fertility in both natural and ART cycles [3-5]. To our knowledge, there is no published research exploring the relationship between a prior CS and subsequent single thawed euploid embryo transfer (euploid SET). The objective of this study was to determine whether prior mode of delivery correlates with subsequent ART outcomes in patients undergoing euploid SET.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All patients undergoing autologous euploid SETs at an academic center with a prior vaginal delivery (VD) or CS from 2012 to 2020 were identified. Cases included patients with 1 prior CS; controls included patients with 1 prior VD. Exclusion criteria included patients with >1 previous live birth and donor/recipient cycles. Our primary outcome was implantation rate (IR); secondary outcomes were ongoing pregnancy/live birth rate (OP/LBR), biochemical pregnancy rate (BPR), and clinical loss rate (CLR). Baseline demographics were obtained: age (at time of retrieval and transfer), body mass index (BMI), obstetric history, endometrial thickness at time of transfer (ETATT), presence of blood in catheter and catheter type as markers of transfer difficulty, embryo grade (Modified Gardner), and day of embryo biopsy for genetic testing. Statistical analysis was performed using Student's t-test, Mann-Whitney U test, and chi-square. Logistic multivariable regression models were used to calculate odds ratios and to adjust for confounders, with $P<0.05$ considered significant.

RESULTS: 551 euploid SETs met inclusion criteria and were included in analysis (VD: n=347; CD: n=204). Patients with a prior CS had a higher BMI (24.50 vs 23.47, p=0.009) than those in the VD cohort; demographic data were otherwise similar. In univariate analysis, IR and OP/LBR were significantly lower in patients with a prior CS compared with VD (58.33% vs 68.01%, P=0.02 and 50.00% vs 59.65%, P=0.03, respectively). After adjusting for age at time of retrieval and transfer, BMI, ETATT, difficulty of transfer, day of biopsy, and embryo grade, prior CS was associated with 41% lower odds of implantation (OR 0.59, CI 0.40-0.88). After adjusting for the same confounders, prior CS was also associated with 38% lower odds of ongoing pregnancy/live birth (OR 0.62, 0.42-0.92). We saw no differences in BPR or CLR.

CONCLUSIONS: This is the first study to demonstrate a significant reduction in IR and OP/LBR associated with a prior CS in patients undergoing euploid SET. Patients who deliver via CS may experience post-CS scarring and subsequent isthmocele formation which may alter the uterine milieu and lead to suboptimal implantation. Patients looking to build families with multiple offspring should be counseled that prior CS appears to be associated with significantly lower success following euploid SET. Our work further stresses the importance on a national level of reducing primary CS rates.

EFFECT OF FOLLICULAR PHASE LENGTH ON PREGNANCY OUTCOMES IN NATURAL FROZEN EMBRYO TRANSFER CYCLES.

Phillip A. Romanski, MD,[1] Pietro Bortoletto, MD,[1] Yung-Liang Liu, MD PHD,[2] Pak Chung, M.D.,[1] Zev Rosenwaks, M.D.[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine whether the length of the follicular phase affects pregnancy outcomes in natural frozen embryo transfer cycles.

DESIGN: Retrospective cohort study performed in an academic hospital setting.

MATERIALS AND METHODS: Patients who underwent their first natural frozen autologous day 5 embryo transfer cycle in our IVF clinic between 01/01/2013 and 12/31/2018 were included. Patients were stratified by length of their follicular phase in that cycle ($\leq$15 days and >15 days). A secondary analysis was performed to analyze only cycles in which a PGT euploid embryo was transferred. Demographic outcomes were collected. The primary outcomes were pregnancy and live birth rates. Logistic regression adjusted *a priori* for patient age and number of embryos transferred was used to estimate the odds ratio with a 95% confidence interval (CI) for pregnancy outcomes.

RESULTS: A total of 2,358 natural frozen embryo transfer cycles met inclusion criteria, including 1,287 cycles in the $\leq$15 day group and 1,071 cycles in the >15 day group. The mean cycle day of the LH surge was 13.1 $\pm$ 1.6 days (range 7-15) in the $\leq$15 day group and 18.8 $\pm$ 3.3 days (range 16-51) in the >15 day group. A diagnosis of oligo-ovulatory infertility was observed in 3.6% of women in the $\leq$15 day group and 9.1% of women in the >15 day group. The mean number of embryos transferred was 1.3 in both groups. The pregnancy rate was similar for patients with a follicular phase length $\leq$15 days (65.4%) and patients with a follicular phase length >15 days (69.0%, OR 1.12; 95% CI 0.94-1.33). In women who achieved pregnancy, there were no significant differences between the $\leq$15 day group and the >15 day group for biochemical pregnancies (15.7% versus 11.4%, OR 0.74; 95% CI 0.55-1.00), miscarriage rate (12.8% versus 11.8%, OR 1.04; 95% CI 0.77-1.42), or live birth rate (69.5% versus 74.6%, OR 1.14; 95% CI 0.91-1.43). In the secondary analysis of the PGT transferred embryos, there were similarly no differences observed between the two groups. The pregnancy rate was 70.0% for women with a follicular phase length $\leq$15 days and 73.8% for women with a follicular phase length >15 days (OR 1.21; 95% CI 0.88-1.66). After achieving a pregnancy, the live birth rate was 58.4% for women in the $\leq$15 day group and 61.2% for women in the >15 day group (OR 1.11; 95% CI 0.83-1.48).

CONCLUSIONS: The length of the follicular phase in patients who underwent a frozen natural embryo transfer did not affect the pregnancy rate. This finding was also observed in euploid embryo transfer cycles. In addition, biochemical, miscarriage, and live birth rates were comparable between both groups. Patients and providers can be reassured that a prolonged follicular phase length in a natural frozen embryo transfer cycle does not affect the pregnancy outcomes in that cycle. We conclude that follicular phase length should not be considered a factor when deciding between a natural or a programmed frozen embryo transfer cycle in ovulatory patients.

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY DOES NOT IMPROVE OUTCOME IN YOUNG PATIENTS UNDERGOING IVF TREATMENT: A SART CORS STUDY.

Papri Sarkar, MD,[1] Sangita K. Jindal, Ph.D.,[2] Erika P. New, MD, MPH,[1] Rachel Grimes Sprague, MD,[3] Jean Tanner, PhD,[1] Anthony N. Imudia, MD.[4] [1]University of South Florida Tampa, FL; [2]Albert Einstein College of Medicine / Montefiore Medical Center, Hartsdale, NY; [3]Shady Grove Fertility, Washington D.C., DC; [4]Department of Obstetrics and Gynecology, Morsani College of Medicine, University of South Florida, Tampa, FL.

OBJECTIVE: Preimplantation genetic testing for aneuploidy (PGT-A) is associated with significant improvement in ongoing pregnancy rates per transfer, reduction of multiple pregnancies using elective single embryo transfer (eSET), and reduced miscarriage rates in women > 35 years or older. As these improvements have not been observed in women < 35 years old, we sought to investigate whether offering PGT-A to favorable prognosis young women can be counterproductive and lead to suboptimal pregnancy outcomes.

DESIGN: Retrospective study.

MATERIALS AND METHODS: We analyzed data from 56,773 autologous ART cycles between 2014-2015 reported to the Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SART CORS) database. Patients that underwent "freeze-all" with subsequent eSET FET, were included. Comparison was made between FET cycles where the indication for stimulation/freeze-all was (1) to perform blastocyst PGT-A for selecting euploid embryos (study group) versus (2) cycles at risk of ovarian hyperstimulation syndrome (OHSS). OHSS cycles were selected as the control group so that we could compare the outcomes of PGT-A cycles to cycles from good prognosis patients. In the OHSS group, embryos were selected based on morphological criteria and no PGT-A was performed. We assumed that in the PGT-A group, euploid embryos were transferred and embryos with mosaicism or inconclusive results were discarded. Live birth (LBR), clinical pregnancy, and miscarriage rates were compared between PGT-A tested and untested cycles. Multivariable logistic regression was used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI) representing the association between PGT-A and selected outcomes (reference group: PGT-A untested). Analyses were stratified by age group (<35 and ≥ 35 years old).

RESULTS: A total of 6,816 FET cycles were selected for analysis. Of those cycles which met inclusion criteria, 2,931 were < 35 and 3,885 were ≥ 35 years old. In the < 35 age group, no difference in LBR was observed between patients who underwent eSET FET with PGT-A tested vs. untested (50.9 % vs. 51.7 %, P= 0.69, aOR 1.03, 95% CI: 0.87-1.21). Additionally, the clinical pregnancy rates (56.0% vs. 56.7%, P=0.71, aOR 1.00, 95% CI:0.85-1.18) and miscarriage rates (8.8% vs. 8.7%, p = 0.88, aOR 0.97, 95% CI:0.72-1.30) were not significantly different between PGT-A tested and untested groups. Among ≥ 35 years old group, no difference was observed between the PGT-A tested and untested groups in LBR (53.8% vs. 49.7%, p=0.15). However after adjusting for potential confounders, PGT-A tested cycles were 1.3 times more likely to have a live birth (95% CI:1.01-1.60)

CONCLUSIONS: Our results are consistent with prior evidence that patients who are ≥ 35 years old, PGT-A leads to a higher chance of LB. The benefits of PGT-A are not reflected in good prognosis patients < 35 years old. However, the observation that PGT-A is not associated with suboptimal pregnancy outcome as compared to good prognosis young patients, justifies its continued use in IVF population when indicated.

WHEN USING DONOR OOCYTES, DOES EMBRYO STAGE MATTER? AN ANALYSIS OF BLASTOCYST VERSUS CLEAVAGE STAGE EMBRYO TRANSFERS IN A DONOR OOCYTE IN VITRO FERTILIZATION (IVF) MODEL.

Sarah M. Capelouto, MD,[1] Audrey J. Gaskins, ScD,[2] Zsolt Peter Nagy, MD, PhD,[3] Daniel B. Shapiro, MD,[3] Jessica B. Spencer, MD, MSc,[4] Heather S. Hipp, MD.[5] [1]UT Southwestern Medical Center Dallas, TX; [2]Emory University, Rollins School of Public Health, Atlanta, GA; [3]Reproductive Biology Associates, Atlanta, GA; [4]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA; [5]Emory University School of Medicine, Atlanta, GA.

OBJECTIVE: Although studies in autologous oocyte IVF indicate that blastocyst embryo transfer is superior to cleavage stage, the latter are more often performed in poorer prognosis patients, introducing confounding. Oocyte donor IVF with high-quality oocytes offers an ideal model for further inquiry. We investigated if embryo transfer stage has an impact on outcomes in donor oocyte IVF, aiming to identify if any scenario exists in which cleavage transfer is non-inferior to blastocyst.

DESIGN: Retrospective cohort analyzing cycles from a frozen donor oocyte bank, 2008-2015.

MATERIALS AND METHODS: A total of 989 recipients underwent 1189 warming cycles using vitrified donor oocytes resulting in fresh embryo transfer. The association between embryo transfer stage and probability of live birth was investigated using cluster weighted generalized estimating equations, adjusted for recipient age, race, uterine factor infertility, transfer year, and number of day 3 quality cleavage embryos. We further stratified by number of embryos transferred, as double cleavage transfer is often weighed against single blastocyst transfer. Sensitivity analyses were performed restricting to cycles with ≤2 quality cleavage embryos, as in theory these were the cycles where choice between transfer stage was most clinically relevant.

RESULTS: Overall 138 cleavage and 1051 blastocyst embryo transfers were performed. There were no differences in recipient age (mean 40.9 years), race (69.3% White) or body mass index (mean 24.6 kg/m^2) by stage of embryo transfer. Cleavage stage transfers were associated with an adjusted relative risk (aRR) of live birth of 0.76 (95% CI 0.60, 0.89) compared to blastocyst. The association persisted when only including cycles with ≤2 quality cleavage embryos (aRR 0.69, 95% CI 0.55, 0.87) and excluding single cleavage transfers (aRR 0.77, 95% CI 0.63, 0.95), as the latter were the poorest prognosis cycles. After stratifying by number of embryos transferred, the trend toward lower success persisted when comparing the transfer of two cleavage embryos to one blastocyst embryo (Table 1).

TABLE 1. Association between stage/number of embryos transferred and risk of live birth

Transfer Stage	Number Embryos Transferred	N	Risk Ratio of Live Birth (95% CI)	
			Unadjusted	Adjusted
Cleavage	1	21	0.46 (0.20, 1.05)	0.50 (0.22, 1.16)
	2	111	0.86 (0.69, 1.07)	0.89 (0.71, 1.11)
Blastocyst	1	687	1.0 (REF)	1.0 (REF)
	2	359	1.20 (1.09, 1.34)	1.21 (1.07, 1.36)

CONCLUSIONS: Even in a donor oocyte model with presumably excellent oocyte quality, there is a benefit of extended culture and blastocyst stage transfer. The study is limited in its retrospective nature, however, and it is possible that embryos with small differences in quality were more likely subjected to extended culture.

SUPPORT: None

COMPARISON OF FRESH AND FROZEN EJACULATED SPERM IN DONOR OOCYTE RECIPIENT CYCLES: A PAIRED ANALYSIS UTILIZING SIBLING OOCYTES.

Kelly McCarter, MD,[1] Robert Setton, MD,[2] Alice Chung, BA,[2] Zev Rosenwaks, M.D.,[2] Steven Spandorfer, MD.[2] [1]Weill Cornell Medicine New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: Use of frozen ejaculated sperm is often necessary for fertilization in IVF-ICSI cycles in patients with non-male factor infertility. Studies assessing outcomes between fresh and frozen sperm have mostly been conducted in patients with male factor infertility or with surgically retrieved spermatozoa. While some studies have shown that frozen and fresh sperm result in similar outcomes, others have found fresh to be superior; however, often these studies have been unable to control for oocyte quality. ART using donor sibling-oocyte recipients (oocytes from the same donor stimulation transferred to two different recipients) offers a unique model that controls to the greatest degree possible for oocyte quality. We sought to determine if fresh and frozen ejaculated sperm are associated with similar pregnancy outcomes by analyzing paired donor egg recipient (DER) cycles using sibling oocytes.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Patients who underwent DER cycles where oocytes from a single controlled ovarian hyperstimulation cycle of a donor were split between two recipients were included. The two recipients of the single donor oocyte cycle were paired and categorized based on type of ejaculated sperm used for ICSI (fresh or frozen sperm) on fresh oocytes and the type of ejaculated sperm used for fresh embryo transfer. Patients with uterine and severe male factor infertility, including surgically retrieved sperm were excluded. Primary outcome was live birth rate. Secondary outcomes were positive pregnancy, implantation and miscarriage rates. Statistical analysis included paired t-tests, and $p<0.05$ was statistically significant.

RESULTS: 1,013 patients who underwent DER cycles between January 2010 and December 2016 were screened for inclusion, of which 408 patients received oocytes from a split donor oocyte cycle. 46 pairs of patients (92 recipients) used discrepant types of ejaculated sperm. The groups were similar for recipient age, gravity, parity, BMI, peak endometrial stripe thickness and number of embryos transferred. Of the frozen sperm samples used, 65.2% were from an anonymous donor and the rest were from the partner. Live birth rates for the fresh sperm group were found to be significantly higher compared to the frozen sperm group (67.3% ± 7.0% vs. 47.8% ± 7.4%, p=0.048). Positive pregnancy rates (76.1% vs. 67.4%, p=0.32), implantation rates (58.0% vs. 44.6% p=0.15) and miscarriage rates (12% vs. 32%, p=0.06) were statistically similar for fresh compared to frozen sperm. In a sub-group analysis, there were no differences in outcomes when fresh sperm was compared separately to partner or donor frozen sperm. There were also no differences in outcomes when comparing partner to donor frozen sperm.

CONCLUSIONS: In this idealized model that controls for oocyte quality to the greatest degree possible by using paired recipients from the same donor from the same stimulation cycle, we found that cycles using frozen sperm resulted in lower live birth rates than those using fresh sperm. These findings suggest that fresh sperm should be preferentially used in non-male factor infertility IVF-ICSI cycles.

WHAT PREDICTS DESIRE TO PROCEED WITH FERTILITY TREATMENT DURING A PANDEMIC? A RETROSPECTIVE COHORT STUDY FOLLOWING THE COVID-19 SHUTDOWN. Lauren Elizabeth Verrilli, MD, Kellie Woodfield, MD, Joseph M. Letourneau, MD, Erica Johnstone, MD. University of Utah, Salt Lake City, UT.

OBJECTIVE: We sought to identify factors that contributed to proceeding with ART following the COVID-19 shutdown.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients who had planned an IVF cycle or frozen embryo transfer between March 2019 and April 27th, 2020, but had not yet undergone their treatment prior to the COVID-19 shutdown were included in this study. Patient demographics were collected including age, parity, AMH, AFC, history of prior IVF cycles or transfer, and number of frozen blastocysts. Data on gamete source and use of a gestational carrier was included. When IVF was resumed, patient decision to move forward with treatment or delay was recorded. Chi-square tests and Wilcoxon rank sum tests were used to assess the association between proceeding with ART treatment for categorical variables or non-parametrically distributed continuous variables, as appropriate.

RESULTS: A total of 145 patients planning FET and 133 patients planning a fresh cycle were offered the option to restart treatment. In total, 62% of all patients desired to initiate treatment. Of the 133 fresh cycles, 69 (52%) patients proceeded immediately, compared to 104 of the 145 FET cycles (72%). Among the fresh cycles, there was a trend toward older age among those who moved forward (37 vs 35; p=0.05). FET cycles using a gestational carrier were more likely to continue to delay treatment (7% vs 1 % p=0.04).

CONCLUSIONS: The majority of patients whose IVF treatment was delayed with the COVID-19 pandemic shut down desired to resume treatment immediately when able. Those proceeding and delaying were similar with regards to most prognostic factors. Older age, however, showed a trend towards moving forward with a fresh IVF cycle and gestational carrier use was associated with continuing to pause on a transfer. While some patients voiced financial or health related concerns, the majority did not provide concrete reasons why they chose to delay or forgo treatment. Further research is needed to understand the reasons patients choose to proceed with fertility treatment in the setting of a pandemic, including more robust data on financial and personal or family health concerns.

MALE REPRODUCTION AND UROLOGY: CLINICAL

O-139 9:40 AM Monday, October 19, 2020

WHAT IS THE OPTIMAL THRESHOLD FOR TOTAL PROGRESSIVE MOTILE SPERM COUNT IN PREDICTING SPONTANEOUS CONCEPTION IN SUBFERTILE COUPLES? Lauren Elizabeth Verrilli, MD,[1] Sorena Keihani, MD,[2] Erica Johnstone, MD,[1] Heidi A. Hanson, PHD, MS,[3] Angela Presson, PhD, MS,[1] Alexander W. Pastuszak, MD, PhD,[2] James Hotaling, MD,[4] Joseph M. Letourneau, MD.[1] [1]University of Utah, Salt Lake City, UT; [2]University of Utah, Salt lake city, UT; [3]University of Utah Health, Salt Lake City, UT; [4]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT.

OBJECTIVE: Total progressive motile sperm count (TPMC) is commonly used in evaluating the male partner in subfertile couples. A TPMC value of >20 million is generally considered normal. We hypothesized that higher TPMC values are associated with more efficient conception rates in subfertile couples. We aimed to find a threshold that is best associated with time to spontaneous conception.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: We used longitudinal data from a cohort of subfertile men seen at a single institution from 2002-2017. Demographics and baseline semen parameters, as well as number of children before the first semen analysis (SA) were collected. Couples who used ART or IUI were excluded. Couples were categorized into two cohorts: 1) Male or unexplained infertility: this category included men with a known male factor diagnosis or absence of female factor infertility or 2) those with female factor infertility. Conception data within 5 years of the first SA were collected. We used a log-rank test to select TPMC thresholds associated with earlier time to conception in either cohorts. Cox proportional hazard models were used to compare time to conception across TPMC categories, adjusting for age, BMI, number of previous children and income.

RESULTS: A total of 5126 men with mean age of 32.5±6.5 years were included. Median TPMC was 113.1 M. Overall, 59% of couples were able to conceive spontaneously within 5 years of the male partner's first SA (median time: 27 months, 95% CI: 26–30). Overall, a TPMC threshold of 50 million provided the highest log-rank statistic in predicting earlier time to conception. Those with TPMC>=50 million had 60% increased chances of achieving natural conception within 5 years (HR: 1.60, 95% CI:1.45–1.76, P<0.001) In couples with male factor or unexplained infertility the best TPMC threshold was 70 million and in those with documented female factor infertility the best threshold was 60 million.

CONCLUSIONS: A TPMC threshold of 50 million provides a better prediction for time to spontaneous conception in a large cohort of subfertile men. The optimal threshold can be slightly different depending on the infertility cause at couples' level, however, the clinical significance of these small variations remains unknown.

Hazard ratio for 5-year conception per TPMC dichotomized at threshold for each cohort

	Hazard ratio (95% CI)[1]	p[1]	Hazard ratio (95% CI)[2]	p[2]
Overall cohort				
TPMC≥50 vs. TPMC<50	1.63 (1.50,1.77)	<0.001	1.60 (1.45,1.76)	<0.001
Male factor/unexplained (Cohort 1)				
TPMC≥70 vs. TPMC<70	1.58 (1.45,1.73)	<0.001	1.57 (1.42,1.73)	<0.001
Female factor (Cohort 2)				
TPMC≥6 vs. TPMC<60	1.69 (1.41,2.02)	<0.001	1.52 (1.24,1.85)	<0.001

O-140 9:55 AM Monday, October 19, 2020

INFLUENCE OF PATERNAL AGE ON ASSISTED REPRODUCTIVE TECHNOLOGY CYCLE AND PERINATAL OUTCOMES. Audrey M. Marsidi, MD,[1] Lauren M. Kipling, MPH,[2] Jennifer F. Kawwass, MD,[1] Akanksha Mehta, M.D., M.S.[3] [1]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA; [2]Emory University Rollins School of Public Health, Atlanta, GA; [3]1365 Clifton Road NE, Building B, Atlanta, GA.

OBJECTIVE: To characterize paternal age among assisted reproductive technology (ART) cycles performed in the United States, and to evaluate the impact of paternal age on ART cycle and perinatal outcomes.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: We collected data from all fresh, autologous in-*vitro* fertilization (IVF) cycles reported to Society of Assisted Reproductive Technology Clinic Outcome Reporting System (SART CORS) in 2017. SART CORS includes data on female demographics, medical and obstetric history, and infertility diagnosis, detailed treatment parameters, and pregnancy outcomes, when applicable. Male partner age became a mandatory field in 2017. Cycles utilizing donor gametes or those with missing and extreme age variables were excluded. Paternal age was categorized into two groups: ≤45 years and ≥46 years, with men aged ≤45 years serving as the reference group for comparison. Primary outcomes of interest were intrauterine pregnancy, live birth (≥20 weeks) and miscarriage (≤20 weeks). Secondary outcomes were full-term live birth (≥37 weeks) among singleton and twin gestations. Modified Poisson regression was performed to determine associations between paternal age and cycle and perinatal outcomes.

RESULTS: Among 77,209 fresh, non-donor IVF cycles, the average paternal age was 37.8 years (± 6.3); average maternal age was 35.5 years (± 4.6). Compared to men ≤45 years, paternal age ≥46 years old was associated with lower likelihood of pregnancy per cycle (aRR 0.81, 95% CI 0.76-0.87) and per transfer (aRR 0.85, 95% CI 0.81-0.90), as well as lower likelihood of live birth per cycle (aRR 0.76, 95% CI 0.72-0.84) and per transfer (aRR 0.82, 95% CI 0.77-0.88), after controlling for maternal age and other confounders. The likelihood of miscarriage was higher among men ≥46 years of age, compared to ≤45 years, including cycles where female partners were <35 years (15.3% vs. 13%), but did not maintain significance in the adjusted analysis.

CONCLUSIONS: Compared to paternal age ≤45 years, paternal age ≥46 is associated with lower likelihood of pregnancy and live birth among couples undergoing IVF. A trend toward increased miscarriage risk was noted as paternal age increased, even for couples where female age was <35. Overall, advanced paternal age negatively impacts reproductive IVF outcomes.

O-141 10:10 AM Monday, October 19, 2020

OPTIMAL TIMING FOR REPEAT SEMEN ANALYSIS DURING MALE INFERTILITY EVALUATION. Nahid Punjani, MD MPH,[1] Gal Wald, BA,[1] Omar Al Hussein Alawamlh, MD,[1] Vanessa L. Dudley, MSHS,[2] Miriam Feliciano, BSc,[2] Philip S. Li, M.D.,[2] Marc Goldstein, M.D.[2] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]Center for Male Reproductive Medicine and Microsurgery, Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY.

OBJECTIVE: To assess if the 4-week time period between semen analysis during the work-up of male infertility is optimal, or if an alternative time period may be more desirable.

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: Semen analyses were reviewed between 1997 and 2018 at Weill Cornell in New York City. Included men had two semen analyses completed at our institution, whom had no previous fertility interventions, and had semen analyses completed within 90 days of each other. Men with azoospermia or incomplete data were excluded. We examined Pearson correlation coefficients (*r*) between sperm concentration (million/ml) total sperm count (million), pH, volume (mL), motility (%) and progressive motility (grade 1-4), and morphology (%) for each pair of semen samples and assessed these over weekly time periods.

RESULTS: A total of 1080 semen samples were included for assessment from a total of 540 men. Optimal correlation for volume occurred at weeks 2 (r=0.807), 8 (r=0.802), and 12 (r=0.797). For concentration correlation was maximized at weeks 1 (r=0.950), 4 (r=0.840), and 5 (r=0.798). Total sperm count correlated at weeks 1 (r=0.929), and 2 (r=0.729), and 4 (r=0.806). Motility was maximally correlated at week 1 (r=0.711), 10 (r=0.760) and 13 (r=0.708). Morphology was optimally correlated at week 1 (0.935), 2 (r=0.818) and 10 (r=0.839).

CONCLUSIONS: Historically, repeat semen analysis has been suggested at least four weeks after the initial sample. Our data suggests that this may not be the optimal time. More optimal time periods are within the first two weeks or beyond two months depending on the parameter. These data suggests that the optimal time period for repeat semen analysis should be individualized depending on results of the initial analysis and factors such as recent changes in medications, lifestyle issues such as drug and alcohol abuse, weight change, stress, etc. Further, large studies are required for investigation of this trend.

O-142 10:25 AM Monday, October 19, 2020

ADVANCED MALE PARTNER AGE RESULTS IN LOWER FERTILIZATION AND BLASTULATION RATES IN PATIENTS WHO FAIL TO GENERATE A EUPLOID BLASTOCYST WHEN COMPARED TO PATIENTS WHO ACHIEVE A EUPLOID BLASTOCYST. Haley N. Glatthorn, MD,[1] Brent M. Hanson, MD,[2] Philip J. Cheng, MD,[2] James Hotaling, MD,[3] Richard Thomas Scott, Jr., MD,[2] Jason M. Franasiak, MD, HCLD/ALD.[2] [1]Rutgers Robert Wood Johnson Medical School New Brunswick, NJ; [2]IVI-RMA New Jersey, Basking Ridge, NJ; [3]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT.

OBJECTIVE: Advancing paternal age has been associated with worsened embryology outcomes, but it is unknown whether these effects are more pronounced in patients who ultimately fail to generate a euploid blastocyst. This study investigates the association between increasing paternal age and embryology outcomes in patients who did not generate a euploid embryo for transfer and compares the same outcome measures to couples who produced at least one euploid embryo through in vitro fertilization (IVF).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: This study was performed at a university-affiliated fertility practice from January 2012 to December 2018. Inclusion criteria were specified as couples undergoing a first cycle of IVF using an ejaculated semen sample followed by PGT-A, with fertilization achieved via intracytoplasmic sperm injection (ICSI). Linear regression models were utilized to assess the relationship between paternal age, fertilization rate, and blastulation rate. Fertilization and blastulation rates in patients who failed to achieve a euploid blastocyst were compared to those who met identical inclusion criteria but achieved at least one euploid blastocyst.

RESULTS: 4084 couples failed to generate a euploid blastocyst. Mean male partner age was 37.8 ± 6.4 years and mean female partner age was 35.8 ± 5.1 years. Overall fertilization rate was 79.3% and blastulation rate was 42.6%. After adjusting for female age, male partner age ≥40 within this group resulted in decreased blastulation rates (p=0.03) compared with younger male partner age, but there was no association between male partner age and fertilization rate (p=0.22).

These results were compared to 4368 patients who successfully generated a euploid embryo for transfer. In this group, the median number of euploid embryos produced was 3.0 (IQR 2.0-5.0). Mean male partner age was 37.1 ± 5.5 years and mean female partner age was 34.9 ± 4.0 years. Similar to

observations in couples with no euploid blastocysts, older male partner age (≥40 years) was associated with decreased blastulation (p<0.01), but did not affect fertilization rate (p=0.66). Both fertilization rate (85.0%) and blastulation rate (55.1%) were higher in patients who went on to develop a euploid blastocyst than in patients who did not.

Significantly lower fertilization rates (p<0.01) and blastulation rates (p<0.01) were noted among patients failing to generate a euploid embryo when compared with those who ultimately produced at least one euploid embryo. These findings held true for both younger (<40) and older (≥40) male partners.

CONCLUSIONS: In couples who fail to generate a euploid embryo, increasing paternal age negatively affects the rate of blastocyst formation but does not impact fertilization rate when male partner age of 40 is used as a cutoff. When compared to couples who generated at least one euploid blastocyst, couples who failed to develop a euploid embryo had lower fertilization rates and blastulation rates across all male partner age groups. These findings can be used to guide patient management and set expectations, particularly in the setting of an older male partner.

O-143 10:40 AM Monday, October 19, 2020

SPERM RETRIEVAL RATES AND OUTCOMES IN MEN WITH A HISTORY OF MALIGNANCY. Nahid Punjani, MD MPH,[1] Ryan Flannigan, MD,[2] Kathleen Hart, BSN RN MA,[1] Peter N. Schlegel, M.D.[1] [1]Weill Cornell Medicine, New York Presbyterian Hospital, New York, NY; [2]University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: To assess sperm retrieval rates and outcomes from a large series of cancer patients undergoing microsurgical testicular sperm extraction (mTESE).

DESIGN: Retrospective study of prospectively collected data.

MATERIALS AND METHODS: mTESE procedures performed by a high-volume surgeon at Weill Cornell between 1995 and 2020 were reviewed. Men with history of malignancy were included. Demographic data included male and partner age. Testicular size was recorded. Sperm retrieval and pregnancy were classified dichotomously, and fertilization rate was evaluated continuously. Treatment including chemotherapy and/or radiation was documented. Adjusted logistic regression models were completed to examine predictors of sperm retrieval.

RESULTS: A total of 177 men with malignancy at the time of mTESE procedure were included. The median male age was 35 (IQR 32-40). Median partner age was 32 (IQR 29-36). Mean FSH levels was 24.7 ± 13.8 IU/mL. A total of 121 men (68.4%) had history of only chemotherapy and 55 men (31.1%) had history of only radiation, 46 men (26.0%) had both and 47 (26.6%) had neither. Sperm retrieval occurred in 86 of 177 men (48.59%). Fertilization rate per injected oocyte was 2.87 ± 4.46. Pregnancy occurred in 62 of 175 men (Table 1), for a total of 35.0%. In the malignancy group, only testis size was marginally associated with sperm retrieval (OR 1.11, 95%CI 1.03-1.19). Testis size was marginally associated with pregnancy in those with malignancy history and with chemotherapy (OR 1.09, 95%CI 1.01-1.18 and OR 1.12, 95%CI 1.02-1.24, respectively).

CONCLUSIONS: Despite a history of malignancy, chemotherapy or radiation therapy, sperm retrieval rates with mTESE are near 50%, and clinical pregnancies occur among 34% of couples. Only testis size had limited associations with sperm retrieval and pregnancy, therefore, limited pre-operative factors exist to determine who will have successful retrievals.

O-144 10:55 AM Monday, October 19, 2020

TELEHEALTH FOR MALE-INFERTILITY IS FEASIBLE AND SAVES PATIENTS' TIME AND MONEY. Alex Zhu, DO,[1] Juan J. Andino, MD, MBA,[1] Zoey Chopra, BA,[2] Stephanie Daignault-Newton, MS,[1] Chad Ellimoottil, MD, MS,[1] James M. Dupree, IV, MD, MPH.[1] [1]Michigan Medicine, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.

OBJECTIVE: There has been a rapid expansion of video visits, a form of telehealth, with the COVID-19 pandemic; however, little is known about the feasibility or benefits of video visits for patients seeking male infertility care. Herein we summarize a single institution's experience using video visits to manage infertility prior to the COVID-19 pandemic. Specifically, we evaluate the number of patients engaging in video visits for the first time, and the patient resources saved by forgoing in-person appointments.

DESIGN: Retrospective case series of patients undergoing video visits for follow-up of male-infertility care.

MATERIALS AND METHODS: We identified all video visits performed at our institution between August 21, 2017 and March 17, 2020. We included men seen for male infertility by a single urologist. We used chart review to collect patient demographic information including age, primary language, race, and occupation. Patients were identified as blue collar versus white collar workers with respect to their engagement in manual labor. We determined whether patients had a prior video visit completed at our institution. We used Google Maps™ to calculate round-trip driving distance and time saved based on patients' city of residence. Driving costs saved were calculated by using American Automobile Association's cost estimate of $0.59/mile. Finally, Glassdoor.com salaries were used to estimate wages lost if taking a half or full day off to attend an in-person clinic visit.

RESULTS: 70 male infertility video visits were completed by 56 patients. Median age of patients was 36 years old (range 20-56), 96% identified preferred language as English, and 78% self-identified as white. There were a total of 49 unique occupations among the 56 men. 32% were blue collar workers and 68% were white collar workers. For 55 of 56 patients, this study period represented their first use of video visits in our health system.

Video visits allowed patients to save a median of 80 miles (interquartile range 46-244) and 97 minutes (IQR 64-250) of travel per visit. This resulted in a median of $47 (IQR 27–144) of driving costs saved per visit. By not having to miss a half or full day of work, patients potentially avoided a median of $102 (IQR $69 – 133) to $205 (IQR $137 – 266) in lost wages, respectively. Total median savings per patient ranged from $149 (half day off) to $252 (full day off). Median salary of our cohort was $51,331.

In total, 70 video visits saved 56 patients 11,646 miles and 12,070 minutes in travel. Total estimated savings to patients was $14,539 (half day off) to $22,206 (full day off).

TABLE 1. Clinical Outcomes by Cancer Treatment

	Cancer (n=177)	Chemotherapy (n=121)	Radiation (n=55)	Both (n=46)
Sperm Retrieved (%)	86 (48.6%)	52 (43.0%)	14 (25.5%)	9 (19.6%)
Pregnancy (%)	62 (35.0%)	38 (31.7%)	9 (16.4%)	6 (13.0%)
Sperm Retrieval (OR, 95%CI)				
Male Age	1.04 (0.99-1.10)	1.02 (0.95-1.09)	1.00 (0.88-1.14)	0.98 (0.85-1.14)
Male FSH	1.01 (0.98-1.03)	0.99 (0.96-1.03)	1.02 (0.97-1.07)	0.97 (0.90-1.05)
Testis Size	**1.11 (1.03-1.19)**	1.08 (0.99-1.18)	1.14 (0.99-1.31)	1.07 (0.90-1.26)
Pregnancy (OR, 95%CI)				
Male Age	**1.08 (1.00-1.16)**	1.05 (0.95-1.16)	0.99 (0.79-1.23)	1.03 (0.82-1.29)
Female Age	0.92 (0.83-1.02)	0.95 (0.84-1.07)	1.06 (0.80-1.39)	1.04 (0.78-1.37)
Male FSH	1.02 (0.99-1.06)	1.01 (0.97-1.05)	1.02 (0.96-1.08)	0.93 (0.82-1.05)
Testis Size	**1.09 (1.01-1.18)**	**1.12 (1.02-1.24)**	1.06 (0.89-1.26)	1.00 (0.81-1.23)

CONCLUSIONS: Video visits are a feasible option for follow-up infertility care and are a patient-centric modality that reduces travel and financial burdens. 98% of patients were first-time video visit users suggesting that men are amenable to using video visits for male infertility care. Calculated cost savings may have underestimated total expenses as we did not account for meals, parking fees and other expenses incurred by traveling for an in-person appointment.

MENTAL HEALTH

PARENT-CHILD RELATIONSHIP QUALITY AND CHILD PSYCHOLOGICAL ADJUSTMENT IN EGG DONATION FAMILIES: CHILDREN'S PERSPECTIVES AT AGE 5. Susan Imrie, PhD,[■] Joanna Lysons, MSc,[2] Vasanti Jadva, PhD,[2] Susan Golombok, PhD[2] [1]University of Cambridge, Cambridge, United Kingdom; [2]■ ■ ■.

OBJECTIVE: The first phase of this longitudinal study indicated that subtle differences may exist in mother-infant relationship quality between egg donation and IVF families, with egg donation mothers and infants showing less optimal relationship quality. The current study examined parent-child relationship quality and child psychological adjustment from the child's perspective in early childhood.

DESIGN: Forty-nine children born through egg donation (M = 66.96 months, SD = 3.64) and a comparison group of 43 IVF children conceived using the parents' own gametes (M = 66.79 months, SD = 3.80) were compared on a standardized assessment of children's perceptions of their families and themselves. Families were recruited through UK fertility clinics at the first phase of the study, and all were heterosexual two-parent families.

MATERIALS AND METHODS: Families were visited at home by trained researchers. Data collection with children was carried out in a separate room to parents. Children were administered the Berkeley Puppet Interview (BPI; Ablow & Measelle, 1993), an interviewing and coding method used to assess young children's perceptions of their family environment and themselves. The BPI was used to assess children's perceptions of their relationship with their mother and father separately on two scales: warmth/enjoyment, and anger/hostility. The measure was also used to assess children's self-perceptions of their levels of depression, anxiety, and strengths/competencies. Outcomes were examined between family types using independent samples t-tests.

RESULTS: Children conceived through egg donation rated their relationship with their mother as higher in warmth/enjoyment than did children conceived through IVF ($t(62.29) = -2.42$, $p = .02$). This difference was of a medium effect size $d = .55$. No differences were found between groups for children's ratings of their mother's anger/hostility. No differences were found between groups in children's perceptions of their relationship with their father on either the warmth/enjoyment or anger/hostility scale. Neither were there group differences in children's perceptions of their own levels of depression, anxiety or strengths/competencies.

CONCLUSIONS: The findings suggest that children in egg donation families view their family relationships and themselves in a largely similar way to children who are genetically related to both their parents. Where a difference was found, this indicated more positive mother-child relationships in egg donation families, as viewed by children themselves.

SUPPORT: The study was supported by the Wellcome Trust [208013/Z/17/Z]

O-146 9:55 AM Monday, October 19, 2020

SLEEP AND PSYCHOLOGICAL WELL-BEING: IS OBSTRUCTIVE SLEEP APNEA ASSOCIATED WITH DEPRESSION AND ANXIETY IN WOMEN WITH POLYCYSTIC OVARY SYNDROME? Xiaojie P. Zhou, MD,[1] Eleni Greenwood Jaswa, MD, MSc,[2] Nikolaus J. Lenhart, BS,[1] Jamie Corley, BA,[1] Marcelle I. Cedars, MD,[1] Heather G. Huddleston, MD.[2] [1]University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco School of Medicine, San Francisco, CA.

OBJECTIVE: Polycystic ovary syndrome (PCOS) is a common yet complex endocrine disorder in which affected women experience diverse comorbidities, including higher rates of depression and anxiety. Women with PCOS have also been shown to be at risk for obstructive sleep apnea (OSA). In the general population, OSA has been linked to depression and anxiety, with evidence to suggest that treatment of OSA has positive psychological effects. However, relationships between OSA and depression/anxiety have not been well-defined in PCOS. The purpose of this study was to determine whether being high-risk for OSA is associated with elevated depression and anxiety symptoms in women with PCOS.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: All patients seen at a university-based clinic between 2017-2020 with a confirmed PCOS diagnosis by the Rotterdam criteria were included. Participants completed validated questionnaires assessing for OSA (Berlin), depression (Patient Health Questionnaire-9, PHQ-9), and anxiety symptoms (Generalized Anxiety Disorder-7, GAD-7). The Berlin questionnaire consists of 3 categories related to OSA risk. A positive score in 2 or 3 categories is considered high-risk for OSA. Multivariate logistic regression analyses were used to determine the odds of moderate or severe symptoms of depression and anxiety defined by PHQ-9 score $\geq$10 and GAD-7 score $\geq$10 in the high-risk versus low-risk OSA groups. The models were adjusted for age, body mass index (BMI), free testosterone level and insulin resistance as measured by the homeostatic model assessment of insulin resistance (HOMA-IR) score.

RESULTS: A total of 196 women with PCOS were included, of which 37.8% screened high-risk for OSA. The mean age of all participants was 28.1 years (SD 6.1) and mean BMI was 31.0 kg/m^2 (SD 9.1). The high-risk OSA group had a higher mean PHQ-9 score as compared to the low-risk OSA group (12.0 vs. 8.3, p<0.0001), as well as a higher mean GAD-7 score (8.9 vs. 6.1, p=0.0003). Women in the high-risk OSA group had increased odds of moderate or severe depression (OR 3.01, 95% CI 1.66-5.49, p<0.0001) and anxiety (OR 2.81, 95% CI 1.49-5.29, p=0.001). These associations were only slightly attenuated in adjusted models: aOR for moderate or severe depression was 2.489 (95% CI 1.10-5.60, p=0.03) and aOR for moderate or severe anxiety was 2.49 (95% CI 1.05-5.92, p=0.04).

CONCLUSIONS: Among those with PCOS, women at high-risk of OSA experienced elevated levels of depression and anxiety symptoms compared to those at low risk for OSA, independent of the effects of age, BMI, hyperandrogenism and insulin resistance. The complex comorbidities of OSA and psychological conditions in women with PCOS allow for multiple targets of intervention. Routine OSA screening in women with PCOS should be undertaken, particularly in the setting of existing depression and anxiety. Referral for OSA diagnosis and treatment may have added psychological benefits in this population.

LONG-TERM PSYCHIATRIC ILLNESS IN WOMEN WITH PRIMARY INFERTILITY. Alessandra J. Ainsworth, MD,[1] Emily N. Sadecki, BA,[2] Lauren Kendall Rauchfuss, MD,[1] Amy Weaver, MS,[3] Yulian Zhao, Ph.D.,[4] Elizabeth A. Stewart, MD.[5] [1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic College of Medicine and Science, Rochester, MN; [3]Mayo Clinic Division of Biomedical Statistics and Information, Rochester, MN; [4]Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN; [5]Mayo Clinic Department of OB/GYN, Reproductive Endocrinology and Infertility, Rochester, MN.

OBJECTIVE: To evaluate the long-term risk of de novo psychiatric illness in women with a history of primary infertility compared to age-matched referent women.

DESIGN: Population-based retrospective cohort study.

MATERIALS AND METHODS: A random sample of 300 female residents of Olmsted County, MN, diagnosed with primary infertility from 1980-1999 were identified through the Rochester Epidemiology Project (REP) records-linkage system. Medical records were manually reviewed to confirm primary infertility diagnosis and date of diagnosis became the index date. Each woman was 1:1 age-matched (±1 y) to a referent woman residing in the county who had not been diagnosed with primary infertility or undergone hysterectomy prior to the index date. Diagnosis codes for depression, anxiety and bipolar disorder were electronically obtained for each pair using standard REP protocols. Diagnoses made prior to or up to 3 months after the index date were considered prevalent disorders. Each of the psychiatric disorders was evaluated separately; women with a prevalent disorder at index date were excluded from the estimation of risk for the other newly diagnosed disorders (de novo). Cox proportional hazards models were fit to estimate the hazard ratio (HR) and 95% confidence interval to compare the long-term risk between infertility cases and

referents. Live-birth was handled as a time-dependent covariate in Cox models for each outcome.

RESULTS: The mean ± SD age at index date was 29.9 ± 4.6 and 30.0 ± 4.6 for 300 infertility cases and 300 referents, respectively. There was no difference in prevalence of depression, anxiety, and bipolar disorder with 11.7%, 4.3% and 0.3% among infertility cases compared to 10.7%, 3.7%, and 0.7% among referents. The median duration of follow-up after index date was 21.5 years (interquartile range (IQR), 13.0-25.5) and 20.9 years (IQR, 4.9-24.9) for the infertility cases and referents, respectively. The risk of de novo bipolar disorder was 3.6 times higher for women with primary infertility (HR 3.63, 95% CI 0.77-17.09), however, this was not statistically significant as only 10 de novo diagnoses (8 infertility cases and 2 referents) were identified. We did not identify an increased risk of de novo depression (HR 1.07, 95% CI 0.79-1.45) or de novo anxiety (HR 1.25, 95% CI 0.88-1.76). Among women with primary infertility, we found no significant association between live birth and de novo bipolar disorder (HR 0.68, 95% CI 0.16-2.89), depression (HR 1.47, 95% CI 0.91-2.39), or anxiety (HR 1.48, 95% CI 0.88-2.47).

CONCLUSIONS: We found no increased rate of anxiety or depression in women with primary infertility compared to age matched referent women. However, a trend toward higher risk of de novo bipolar disorder was identified. Live birth after diagnosis of primary infertility showed a trend toward decreased incidence of bipolar disorder but increased rates of anxiety and depression. These findings suggest a need for additional studies to evaluate patient characteristics associated with development of de novo bipolar disorder or other psychiatric disorders that may benefit from additional psychiatric evaluation.

SUPPORT: Not applicable.

SHOULDA, COULDA, WOULDA: COUPLES' DECISIONAL REGRET AND EVALUATIONS REGARDING FERTILITY TREATMENTS SIX YEARS AFTER INITIATION. Colin Johnson, MD, Rachel Cusatis, PhD, Kathryn E. Flynn, PhD, Jay I. Sandlow, MD, Judith Myers, MS, Kate D. Schoyer, MD. Medical College of Wisconsin, Milwaukee, WI.

OBJECTIVE: To assess patients' evaluations about fertility treatments 6 years after their initial consultation with a reproductive specialist.

DESIGN: Longitudinal cohort study using prospectively collected patient-reported data and retrospectively collected clinical data.

MATERIALS AND METHODS: Patients and their partners seeking initial consultation with a reproductive specialist were invited to complete questionnaires prior to their first consultation, at 1 year, and at 6 years. At the 6-year assessment, participants were asked yes/no questions regarding the treatments that they received (Table 1). The Decisional Regret Scale was administered, 5 items assessing regret (0-100), referencing "the decision you made about how to add a child to your family." Medical records were used to ascertain whether each participant achieved a live birth using fertility treatments. Chi-squared tests and independent sample t-tests were used to explore whether gender, a live birth after fertility treatments, or decisional regret scores were associated with responses.

RESULTS: 45 couples and 34 individuals (77 women and 47 men, 80% retention) responded to the 6-year survey. Although 90% of patients were happy with the treatments they chose, 9% of patients wished they had tried more medical treatments, 10% of patients wished they had tried fewer medical treatments, and 5% of patients wished they had tried different medical treatments. There were no significant gender differences in responses. Participants who did not achieve a live birth through fertility treatments were more likely to wish they had tried more treatments (p=0.04) and be less happy with the treatments they chose (p<0.001) compared to those who achieved a live birth. Those who were happy with the treatments they chose had significantly lower decisional regret scores, and the highest regret scores were among those who wished they had tried different treatments (Table 1).

CONCLUSIONS: This longitudinal study provides novel insight into patients' evaluations regarding treatment several years after seeking a fertility consultation. Those who wished they had tried different treatments had the strongest regret. This data is helpful for providers to counsel patients about the impact of treatment decisions on future regret.

SUPPORT: Funding came from R21HD071332 from the National Institute of Child Health and Human Development as well as the Department of Obstetrics and Gynecology at the Medical College of Wisconsin.

O-149 10:40 AM Monday, October 19, 2020

DOES A WEB-BASED APP IMPACT QUALITY OF LIFE MEASURES DURING IN VITRO FERTILIZATION? Caitlin Elizabeth Martin, MD, MS,[1] Michael Lanham, MD,[2] Courtney A. Marsh, MD, MPH,[3] Kenan Omurtag, MD.[1] [1]Washington University School of Medicine, St. Louis, MO; [2]University of Michigan, Ann Arbor, MI; [3]University of Kansas, Overland Park, KS.

OBJECTIVE: To assess whether utilization of a web-based application as an adjunct to assist in medication management during In Vitro Fertilization (IVF) impacts quality of life and anxiety measures during IVF.

DESIGN: A multicentered, randomized controlled trial.

MATERIALS AND METHODS: There were 110 women recruited prior to starting IVF at the time of analysis. Subjects were recruited to assess quality of life during IVF, but were randomized to use a web-based application called "OnTrack" to assist with medication management versus no app with conventional medication management. Women in the application arm were also informed of daily medication changes per clinic protocol. Validated instruments were emailed to patients at three time points: prior to starting IVF (baseline), on day 6 of stimulation and just prior to retrieval. The validated measures included the CART (Concerns of Women Undergoing Assisted Reproductive Technologies) scale, FertiQoL (Fertility Patient Quality of Life) questionnaire and the STAI (Spielberger's State-Trait Anxiety Inventory). University of Michigan Redcap was used for data collection. Statistical analysis was performed in R with package LME4 v1.1-23. Linear mixed models with random intercept by subject were used to control for repeated measures. The data was assessed both together and by study arm to assess if the application use impacted the scores.

RESULTS: A total of 21 (19%) participants reported a history of anxiety. There was a decrease in the total CART score from the baseline to day 6 survey (p=0.004) and pre-retrieval (p=0.132). When comparing the app arm to the control arm, there were lower CART scores at day 6 (p=0.046) and a trend towards lower scores pre-retrieval (p=0.056). There was no significant effect of the application when assessing the FertiQoL scaled score and the STAI scores. When examining both groups together, there was a change in FertiQoL scaled scores from the baseline to pre-retrieval survey

TABLE 1. Independent Sample T-tests of Decisional Regret and Evaluation of Treatment Decisions (n=124)

Statement	Mean Decisional Regret Score if Answered "No"	Mean Decisional Regret Score if Answered "Yes"	p-value
I wish I had tried more medical treatments	9.2	30.5	0.009
I wish I had tried fewer medical treatments	8.4	30.8	0.03
I wish I had tried different medical treatments	9.1	50.0	0.01
I am happy with the medical treatments I chose	44.2	7.5	<0.001

(p=0.011). Lower STAI scores were noted at the pre-retrieval survey compared to baseline (p=0.039). The results were unchanged when controlling for a history of anxiety or history of prior IVF treatment.

CONCLUSIONS: The use of a web-based application to support medication management during IVF did not appear to have much impact on quality of life scores and anxiety measures during IVF. However, when examining the CART score in particular, there was a significant difference in CART scores in the application arm compared to the control arm, which suggests the application may have a positive impact in allaying patient concerns during the IVF process. Medication management during IVF is particularly anxiety-provoking for patients. Patient tools that can improve this component of the IVF experience warrant further study.

THE EMOTIONAL IMPACT OF THE ASRM GUIDELINES ON FERTILITY PATIENTS DURING THE COVID-19 PANDEMIC. Jenna M. Turocy, M.D.,[1] Alex Robles, M.D.,[1] Daniel Hercz, M.D.,[2] Mary D'Alton, M.D.,[3] Eric J. Forman, M.D.,[1] Zev Williams, M.D., PhD.[1] [1]Columbia University Fertility Center, New York, NY; [2]Jackson Memorial Hospital, Miami, FL; [3]Columbia University Medical Center, New York, NY.

OBJECTIVE: To survey fertility patients' agreement with ASRM recommendations during the COVID-19 pandemic and the emotional impact on them.

DESIGN: An online survey was sent to current fertility patients at a New York City academic fertility practice at the epicenter of the COVID-19 pandemic.

MATERIALS AND METHODS: Patient agreement with the ASRM recommendations during the COVID-19 pandemic and the emotional impact rated on a Likert scale. Ordinal data such as responses rated on a Likert scale were analyzed using Mann-Whitney Wilcoxon testing and responses were compared using Fisher exact or chi-square test as appropriate, with significance at $p<0.05$.

RESULTS: A total of 518 patients completed the survey for a response rate of 17%. Fifty percent of respondents had a cycle canceled due to the COVID-19 pandemic. Of those who had a cycle cancelled, 85% of respondents found it to be moderately to extremely upsetting with 22% rating it to be equivalent to the loss of a child. There was no difference on the emotional impact based on the type of cycle cancelled. Fifty-five percent of patients agreed that diagnostic procedures such as hysterosalpingograms should be cancelled while 36% of patients agreed all fertility cycles should be cancelled (22% unsure, 43% disagreed). Patients were slightly more likely to agree with the ASRM guidelines if they have an upcoming cycle cancelled ($p = 0.041$). Of all respondents 82% would have preferred to have the option to start a treatment cycle in consultation with their doctor.

CONCLUSIONS: Given the severity of the COVID-19 pandemic, the physical, financial and emotional impact of this unprecedented threat cannot be underestimated in our fertility patients.

NUTRITION AND LIFESTYLE

DOES BMI AFFECT EMBRYONIC MOSAICM? Baruch Abittan, M.D.,[1] Robyn A. Frankel, M.D.,[2] Amber Gamma, MS, CGC,[3] Randi H. Goldman, M.D.[1] [1]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Northwell Health Division of Medical Genetics, Great Neck, NY.

OBJECTIVE: To examine the association between body mass index (BMI) and embryonic aneuploidy and mosaicism by trophectoderm biopsy and preimplantation genetic testing for aneuploidy (PGT-A).

DESIGN: Retrospective cohort study in an academic fertility center.

MATERIALS AND METHODS: Patients' first fresh autologous stimulation cycles wherein all embryos were biopsied for PGT-A analysis between 2016-2019 were reviewed. BMI (kg/m^2) was recorded prior to cycle start and patients were stratified into World Health Organization BMI categories: underweight (BMI<18.5), normal weight (BMI 18.5-24.9), overweight (BMI 25-29.9), or obesity class I (BMI 30-34.9), II (BMI>35-39.9), or III (BMI>40). PGT-A was performed in a single external laboratory by array comparative genomic hybridization (aCGH) (2016-2017) or next generation sequencing (NGS) (2018-2019, during which mosaicism was additionally reported).

The associations between BMI and rates of euploidy and mosaicism, including low level (LL), high level (HL), whole chromosome, and segmental mosaicism, were determined using forward stepwise multivariable Poisson regressions, controlling *a priori* for age and AMH, and retaining other patient- and cycle-specific variables (e.g., diagnosis) that changed the effect estimates by >10%. For the regression analysis evaluating rate of euploidy, LL mosaic embryos were re-classified as euploid. Regression analyses evaluating rates of mosaicism used data from 2018-2019 only. Relative risks with 95% confidence intervals (RR [CI]) were determined using normal weight as the referent value.

RESULTS: Six-hundred one cycles resulted in 2,992 diagnosed embryos available for analysis. Most patients were of normal weight (N=321) or overweight (N=144), or had class I obesity (N=80). Overall, 21% of patients in the cohort had obesity (BMI >30). The average patient age was 36.0 years, and age and BMI were positively correlated (r=0.2). There was no difference in overall euploid or mosaicism rate stratified by BMI. Compared with normal weight, underweight (RR: 4.1 [1.5-11.3]), overweight (1.6 [1.1-2.5]), and obesity (1.6 [1.1-2.4]) were all associated with significantly higher rates of LL mosaicism (6.3% vs. 20.8%, 10.0%, and 9.1%, respectively). Compared with normal BMI, overweight was associated with lower rates of HL mosaicism (8.1% vs 3.7%, RR: 0.4 [0.2-0.8]) and whole chromosome mosaicism (7.1% vs. 3.7%, RR: 0.5 [0.3-0.9]).

CONCLUSIONS: This is the first study to examine the effect of BMI on embryo mosaicism. Our findings support previous research demonstrating that BMI is not associated with the rate of embryonic euploidy. While the overall rate of mosaicism did not differ among BMI categories, both low and high BMI were associated with increased rates of LL mosaicism compared with normal BMI, and overweight was associated with decreased rates of HL and whole chromosome mosaicism. Though a large proportion of our patient cohort had obesity, further research is needed to clarify the impact of BMI on embryo mosaicism.

MALE VITAMIN D STATUS AND MALE FACTOR INFERTILITY. Nicole Banks, MD,[1] Fangbai Sun, MPH,[2] Stephen A. Krawetz, PhD,[3] Robert M. Coward, MD,[4] Puneet Masson, MD,[5] JAMES F. SMIH, MD, MS,[6] J. C. Trussell, MD,[7] Nanette Santoro, MD,[8] Heping Zhang, PhD,[2] Anne Z. Steiner, MD, MPH.[9] [1]VCU Health, Richmond, VA; [2]Yale University School of Public Health, New Haven, CT; [3]Wayne State University School of Medicine, Detroit, MI; [4]University of North Carolina, Chapel Hill, NC; [5]Penn Medicine, Philadelphia, PA; [6]University of California, San Francisco, San Francisco, CA; [7]Upstate University Hospital, Syracuse, NY; [8]University of Colorado School of Medicine, Aurora, CO; [9]Duke University, Durham, NC.

OBJECTIVE: To determine the association between 25-hydroxyvitamin D (25OHD) levels in the male partner and fertility outcomes in couples with mild male factor infertility.

DESIGN: Secondary analysis of a randomized, controlled trial.

MATERIALS AND METHODS: Males (n=154) with sperm concentration ≤15 M/ml, motility ≤ 40%, or normal morphology ≤ 4% were eligible. Female partners were ovulatory, ≤ 40 years old, and had documented tubal patency. Men were randomized to a vitamin formulation including vitamin D 2000 IU daily or placebo. Couples attempted to conceive naturally for 3 months and with clomiphene citrate with intrauterine insemination of the female partner in months 4 through 6. Data were analyzed by baseline male 25OHD levels dichotomized at 20 ng/mL. The primary outcome was semen parameters at baseline (semen concentration, motility, morphology, and DNA fragmentation). Secondary outcomes were cumulative pregnancy, miscarriage, and live birth rates. Data were analyzed using Wilcoxon rank-sum test, Chi square, or Fisher's exact test, where appropriate. Multivariable logistic and linear regression models were created to adjust for potential confounders, including male age and race.

RESULTS: Semen parameters and sperm DNA fragmentation were not statistically significantly different in males with vitamin D deficiency compared to males with 25OHD levels ≥ 20 ng/mL (Table 1). Clinical pregnancy and live birth rates did not differ. Male 25OHD level ≥ 20 ng/mL was

associated with a lower pregnancy loss rate (adjusted OR, 0.11; 95% CI, 0.02 to 0.75; P = 0.024).

CONCLUSIONS: Vitamin D deficiency in the male partner is unrelated to semen parameters, pregnancy or live birth rates. Further study is warranted to better characterize the rate of miscarriage in couples with male vitamin D deficiency.

TABLE 1. Semen parameters at baseline by male vitamin D status

Parameters	Vitamin D < 20 ng/mL (n=26)	Vitamin D ≥ 20 ng/mL (n=128)	P value
Sperm concentration (million/ml)	19.0 (11.0-52.0)	19.0 (10.2-38.2)	0.504
Sperm concentration ≤ 15 million/ml	11/26 (42.3%)	52/128 (40.6%)	0.874
Normal morphology (%)	6.5 (4.0-10.0), n=22	5.0 (2.0-8.0), n=94	0.133
Normal morphology ≤ 4%	7/22 (31.8%)	41/94 (43.6%)	0.312
Total motility (%)	44.7 ± 20.2	43.8 ± 16.1	0.908
Total motility ≤ 40%	14/26 (53.8%)	58/128 (45.3%)	0.427
DNA fragmentation (SCSA, DNA fragmentation index) (%)	20.4 (13.6-35.1), n=23	19.7 (14.2-27.9), n=112	0.518
DNA fragmentation > 25%	9/23 (39.1%)	35/112 (31.3%)	0.463

O-153 2:20 PM Monday, October 19, 2020

OBESE WOMEN PRESENT AN INCREASED RISK OF MISCARRIAGE AFTER EUPLOID EMBRYO TRANSFER.

Mauro Cozzolino, MD,[1] Juan A. Garcia-Velasco, MD, PhD,[2] Marcos Meseguer, PhD,[3] Antonio Pellicer, MD,[1] Jose Bellver, MD PhD[4] [1]IVIRMA Foundation, Valencia, Spain; [2]IVI Madrid, Rey Juan Carlos University, Madrid, Spain; [3]IVIRMA Global,Valencia,Spain, Valencia, Spain; [4]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: To determine whether female body mass index (BMI) is associated with an increased risk of miscarriage after euploid embryo transfer.

DESIGN: Retrospective observational multicenter cohort study.

MATERIALS AND METHODS: We analyzed all the PGT-A cases performed in the seven largest IVI clinics in Spain (Barcelona, Bilbao, Madrid, Málaga, Sevilla, Valencia and Vigo) from January 2016 to April 2019. Patients in whom at least one euploid embryo was transferred after blastocyst stage biopsy were considered. Cases of no embryo survival after vitrification or ovum donation were excluded. We compared clinical and laboratory parameters among BMI groups considering miscarriage rate (total, clinical and biochemical) as the main outcome parameter. The study was approved by the Ethics Committee of the IVIRMA (identification code #1811-FIVI-089-MC). Statistical analysis was performed using chi-square or ANOVA test as required. Logistic regression analysis was also applied to the different BMI categories to control for possible confounders on live birth rates.

RESULTS: Cycles were divided into four BMI groups (kg/m^2): underweight (<18.5, n=155), normal weight (18.5–24.9, n=2,549), overweight (25–29.9, n=591), and obese (≥ 30, n=185). The number of PGT-A cycles per patient was similar among groups. The main PGT-A indication was advanced maternal age. Female age was slightly increased in the overweight group. There were no differences in ovarian stimulation parameters, except for an increased gonadotropin dosage in the overweight and obese groups. Fertilization rate, day of embryo biopsy, technique of chromosomal analysis, number of euploid embryos, number of transferred embryos, and method of endometrial preparation for embryo transfer (modified natural versus hormonally prepared cycles) were similar among BMI groups. Concerning IVF outcomes, implantation rate, pregnancy rate and clinical pregnancy rate showed a non-significant trend to poorer results in obese women. However, miscarriage rates were significantly higher in obese women compared to normal weight women (22.7 % (CI95% 16.7-28.7) vs 15.1% (CI95% 13.6-16.5), p=0.043), especially due to a significant increase in the clinical miscarriage rates. Live birth rates were also reduced in obese women (34.3 % (CI95 27.8-40.7) vs 44.5% (CI95 42.5-46.4), p = 0.034). Only female obesity and day 6 trophectoderm biopsy influenced independently on the reduced live birth rates.

CONCLUSIONS: Obese women present higher miscarriage rates and lower live birth rates than normal weight women after euploid embryo transfer, suggesting other etiologic mechanisms different to aneuploidy.

SUPPORT: No financial support

O-154 2:35 PM Monday, October 19, 2020

THE RELATIONSHIP BETWEEN FEMALE BODY MASS INDEX (BMI) AND EMBRYONIC EUPLOIDY AS DETECTED VIA NEXT GENERATION SEQUENCING BUT (NGS): A STUDY OF 5,703 CYCLES

. Jenna Friedenthal, MD,[1] Dmitry Gounko, MA,[2] Taraneh Gharib Nazem, MD,[2] Joseph A. Lee, BA,[2] Beth McAvey, MD,[1] Alan B. Copperman, MD[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Women with an elevated BMI (≥25 kg/m^2) have been shown to experience poor reproductive outcomes[1, 2]. Obese patients are at particularly high risk for adverse pregnancy outcomes[3]. Several studies have evaluated the impact of BMI on assisted reproductive technology (ART) outcomes [4, 5]. However, the association between BMI and rate of embryo euploidy as determined by NGS has yet to be fully explored. We sought to assess the impact of BMI on euploid rate (ER) as determined by NGS.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study included patients at an academic center who underwent in vitro fertilization with intracytoplasmic sperm injection from 2016 to 2020. BMI (kg/m^2) was categorized as follows: underweight (<18.5), normal weight (18.5-24.9), overweight (25-29.9), and obese (≥30). A secondary analysis that compared obese patients with all other BMI categories was also performed. Baseline demographics were obtained: age, AMH, cumulative gonadotropin dose (GND), total number of eggs retrieved, and number of metaphase II (MII) oocytes retrieved. Our primary outcome was ER as diagnosed by NGS. Secondary outcomes were maturation rate (MR), fertilization rate (FR), blastulation rate (BR), and biopsied blastocyst rate (BBR). Data were analyzed using ANOVA, Kruskall-Wallis test, chi-square, and logistic multivariate generalized estimating equation (GEE) regression models to adjust for confounders, with P<0.05 considered significant.

RESULTS: 4,067 patients underwent 5,703 cycles during the study time period and were included in analysis. Overweight (n=1,267 cycles) and obese (n=660 cycles) patients were older, had lower average AMH levels, required higher cumulative GND, and had significantly fewer total oocytes and MII oocytes retrieved than patients with a low (n=210 cycles) or normal (n=3,566 cycles) BMI (P< 0.05 for all).

After adjusting for age, AMH, cumulative GND, and number of oocytes retrieved, overweight patients demonstrated a slightly higher BR (OR 1.02, CI 1.01-1.03) compared to patients with normal weight; however, we found no association between BMI and ER, MR, FR, or BBR (P>0.05 for all). Additionally, when comparing obese patients with all other BMI groups, after adjusting for confounders, we found no association between obesity and ER (OR 1.01, CI 0.98-1.04). There was also no association between obesity and MR (OR 0.99, CI 0.98-1.01), FR (OR 0.99, CI 0.98-1.01), BR (OR 1.01, CI 0.99-1.03), or BBR (OR 1.00, CI 0.98-1.01).

CONCLUSIONS: In the largest study to date evaluating the association between BMI and rate of embryonic euploidy as diagnosed by NGS, our results demonstrated that BMI is not predictive of euploid rate. In particular, obesity does not appear to result in increased risk of embryonic aneuploidy. Although mouse models have suggested potentially deleterious effects of abnormal metabolites from obesity on oocyte quality, spindle formation, and chromosome alignment, our findings suggest that the detrimental effect of elevated BMI on pregnancy and ART outcomes may be the result of non-genomic, endocrine, uterine, or an unspecified alternative etiology.

TIME-RESTRICTED FEEDING OF NORMAL DIET INCREASES BODY WEIGHT AND IMPAIRS THE DEVELOPMENTAL COMPETENCE OF OOCYTES AFTER IVF IN FEMALE MICE.

Hiroshi Matsumoto, B.S.,[1] Shu Hashimoto, Ph.D.,[2] Nafuko Konishi, M.D.,[3] Satoshi Mizuno, Ph.D.,[1] Masayasu Koyama, M.D., Ph.D.,[3] Aisaku Fukuda, M.D., Ph.D.,[1] Yoshiharu Morimoto, M.D., Ph.D.[4] [1]IVF Osaka Clinic, Higashiosaka, Japan; [2]Osaka City University Graduate School of Medicine, Osaka, Japan; [3]Obstetrics and Gynecology, Osaka City University Graduate School of Medicine, Osaka, Japan; [4]HORAC Grand Front Osaka clinic, Osaka, Japan.

OBJECTIVE: Previous studies have revealed that time-restricted feeding (tRF) reprograms clock gene transcription in peripheral tissues, especially in the liver and influences metabolic pathways in numerous organs, resulting in the changes in the phenotypes associated with metabolic diseases that are characterized in obese male mice. However, the impact of temporally restricted food access on females especially reproductive capabilities has not been fully evaluated so far. Here, we investigated reproductive function of mice fed normal diet either ad libitum or under tRF.

DESIGN: Experimental animal study.

MATERIALS AND METHODS: Mice were fed normal diet (29.9% protein, 11.6% fat, 58.5% carbohydrates) either ad libitum or under tRF for 11 weeks. They were allowed food access between ZT15.5 (3.5 hr after lights off) and ZT24 (just before lights on) under tRF. Comparisons of total calorie intake, body weight and average feeding speed during the period over which food access was allowed were made between the mice fed ad libitum and under tRF (n=140). Diurnal pattern of mRNA levels of *Per2* and *Cry1*, core circadian suppressor genes in the liver were compared between ad libitum and tRF. The numbers and cytoplasmic reactive oxygen species (ROS) levels of oocytes retrieved after ovarian hyperstimulation and blastulation rates after IVF were compared between ad libitum and tRF (n=53).

RESULTS: Total calorie intake of tRF mice was significantly lower than ad libitum (817.6 $\pm$ 43.9kcal vs 866.0 $\pm$ 31.8kcal, $p<0.01$). However, mice fed under tRF was significantly heavier than ad libitum (22.9 $\pm$ 1.5g vs 21.7 $\pm$ 1.3g, $p<0.01$). Feeding speed of mice fed under tRF and ad libitum was 1.25 $\pm$ 0.72 kcal/h and 0.48 $\pm$ 0.36 kcal/h, respectively ($p<0.01$). The oscillation of *Per2* and *Cry1* mRNA levels was jumped in tRF mice as compared to ad libitum. The number of oocytes retrieved from the mice fed under tRF was similar to ad libitum (21.0 $\pm$ 3.3 vs 23.3 $\pm$ 2.6, $p=0.58$). However, the ROS level of oocytes retrieved from the mice fed tRF was significantly higher than ad libitum ($p<0.01$). The blastulation rate of fertilized ova from mice fed under tRF was significantly lower than ad libitum (73.4% vs 89.0%, $p<0.01$).

CONCLUSIONS: As previously reported in the studies of male obese mice, time-restricted feeding increased the peak to trough ratio of mRNA levels of hepatic clock genes. However, body weight was significantly increased by tRF as compared to ad libitum though total calorie intake was small. Oocyte developmental competence was also impaired by tRF. According to several reports, eating fast is associated with postprandial high blood glucose levels that could engender cytoplasmic ROS. It is suggested that eating fast forced by time-restricted feeding is harmful to reproductive function and ROS production in the ooplasm is underlying this impairment.

PRE-CONCEPTION RISK PREDICTION INDEX FOR SEVERE MATERNAL MORBIDITY AMONG INFERTILE WOMEN.

Gayathree Murugappan, MD,[1] Ruben J. Alvero, MD,[2] Deirdre J. Lyell, MD,[3] Abha Khandelwal, MD, MS,[3] Stephanie A. Leonard, PhD[3] [1]Stanford University Medical Center, Sunnyvale, CA; [2]Stanford University, Sunnyvale, CA; [3]Stanford University Medical Center, Stanford, CA.

OBJECTIVE: Infertile women who become pregnant are at increased risk of severe maternal morbidity (SMM), defined by the CDC as indicators of a life-threatening complication. The degree to which age and medical comorbidities compound the risk of SMM among infertile women is unknown. Our goal was to create a pre-conception risk prediction index for SMM among infertile women.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: We identified births among infertile women $\leq$ 45 years of age using the Optum® insurance claims database from 2012-2017. Infertile women were identified using infertility diagnosis, testing, or treatment codes and fertility drug dispensing codes. The primary outcome was SMM, identified as any indicator from the CDC Index except blood transfusion alone, which can overestimate true cases. Comorbidities were selected from prior literature. Multivariable logistic regression was performed on all comorbidities significant in bivariate analyses while adjusting for education, race/ethnicity and delivery year. A risk score was then created for each comorbidity in the index. Discrimination of the index was assessed with an ROC curve.

RESULTS: Among 46,161 births, the overall rate of SMM was 2.4% (n=1,120). The highest risk comorbidities were bleeding disorders and pulmonary hypertension, followed by chronic renal and cardiac disease (Table). HIV, substance abuse, and PCOS were not significant. The AUC for the comorbidity index was 0.72.

CONCLUSIONS: We created an index to predict the likelihood that individual comorbidities in an infertile woman would lead to SMM. The discrimination of the index was good based on ROC curves. Our goal after further validation is to develop an open-access online calculator to individualize SMM risk prediction for infertile patients during pre-conception counseling.

Risk Factor	Incidence of SMM, n (%)	aRR (95% CI)	Risk Score
Bleeding Disorder	309 (10.25)	5.15 (4.33-6.13)	7
Pulmonary Hypertension	10 (20.83)	5.04 (2.01-12.59)	7
Chronic Renal Disease	68 (6.22)	1.96 (1.43-2.68)	3
Cardiac Disease	242 (6.11)	2.04 (1.67-2.50)	3
Anemia	401 (4.43)	1.56 (1.33-1.83)	2
Asthma	148 (4.11)	1.60 (1.29-1.99)	2
Hypertension	184 (5.76)	1.55 (1.24-1.94)	2
Age $\geq$ 40 Years	197 (3.28)	1.37 (1.13-1.67)	1
Neuromuscular Disease	234 (3.79)	1.31 (1.08-1.59)	1
Uterine Fibroids	180 (3.84)	1.39 (1.13-1.71)	1
Gastrointestinal Disease	180 (3.93)	1.26 (1.02-1.56)	1
Prior Cesarean Delivery	116 (3.87)	1.13 (0.87-1.47)	NS
Prior Uterine Surgery (Non-Cesarean)	101 (4.50)	1.20 (0.92-1.58)	NS
Connective Tissue Disease	33 (4.11)	0.69 (0.44-1.08)	NS
Endometriosis	82 (3.02)	1.02 (0.77-1.35)	NS
Thyroid Disease	126 (3.21)	1.11 (0.86-1.43)	NS
Mental Health Disorder	309 (3.18)	1.14 (0.96-1.35)	NS
Diabetes Mellitus	94 (4.14)	1.13 (0.86-1.48)	NS

PEDIATRIC AND ADOLESCENT GYNECOLOGY

O-157 1:50 PM Monday, October 19, 2020

UNDERSTANDING THE INFLUENCE OF GENDER IDENTITY AND SEXUAL ORIENTATION ON THE FUTURE PARENTING DESIRES OF TRANSGENDER AND NON-BINARY ADOLESCENTS IN COMPARISON TO THEIR CISGENDER SIBLINGS.

Brett Stark, MD,[1] Shea Allison Nagle, MPH,[2] Adam Hunter, MPH,[2] Evelyn Mok-Lin, MD,[3] Sabra L. Katz-Wise, PhD[4] [1]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [2]Harvard T.H. Chan School of Public Health, Boston, MA; [3]REI UCSF, Center for Reproductive Health, San Francisco, CA; [4]Boston Children's Hospital, Boston, MA.

OBJECTIVE: To assess the influence of gender identity and sexual orientation on the attitudes of transgender and non-binary (TNB) adolescents and their cisgender siblings toward future parenting options and intentions.

DESIGN: This study used a multiphase mixed methods design through integration of cross-sectional quantitative data with qualitative data sequentially collected in 2017-2018.

MATERIALS AND METHODS: TNB adolescents and their cisgender siblings participated in a one-time, one-on-one semi-structured interview and survey. Interview data was coded to develop themes that then guided analysis of the survey data. To assess the fertility attitudes of TNB and their cisgender siblings, a modified version of the Transgender Youth Fertility Attitudes Questionnaire (TYFAQ) was utilized. Possible answers to the TYFAQ survey included "agree," "maybe," or "disagree." Outcomes were treated as ordinal and associations were analyzed using the Mann-Whitney U test.

RESULTS: A total of 40 participants were included in the analysis (29 TNB adolescents, 11 cisgender siblings). Four major themes were noted when comparing the two groups: 1) the role of gender identity and gender dysphoria 2) desire for future economic and social stability 3) perceived personal reproductive potential 4) future partner's gamete compatibility. TNB adolescents were more likely to say they would consider adoption someday (93% vs 54%, p = .0068). Cisgender adolescents were more likely than TNB adolescents to say it is important to have biological children (65.5% vs 27%, p = 0.05). Cisgender boys were more likely to feel pressured by their family to have biological children than their transmasculine TNB peers (20% vs 0%, = 0.04). In comparing heterosexual adolescents to those who identify as lesbian, gay, bisexual, or queer (LGBQ), heterosexual adolescents were more likely to say it is important to have biological children in the future (77% vs 18%, p=0.0023). Among TNB adolescents, those currently using gender-affirming hormones were less likely to think their feelings about children might change in the future (p = 0.029). TNB adolescents with a prior diagnosis of gender dysphoria were more likely to say they wanted to have kids someday (71% vs 37%, p = 0.003) and less likely to say their family would be sad if they did not have biological children (0% vs 25%, p = 0.03). TNB adolescents who endorsed parental support were more likely to say it is not important to have biological children in the future (72% vs 25%, p = 0.05), and those that that do not participate in a support group were more likely to say their parents would be disappointed if they did not have biological children (25% vs 0%, p = 0.003).

CONCLUSIONS: Sexual orientation and gender identity are important factors to consider when assessing an adolescent's desire for future family building. TGN youth, on average, express lower desires for biological children when compared to their cisgender siblings, which is influenced by their experience with dysphoria and perception of community support. These factors should be considered when counseling adolescents on their future fertility and family building options.

O-158 2:05 PM Monday, October 19, 2020

CIRCULATING INFLAMMATORY MARKERS AND ENDOMETRIOSIS PAIN SYMPTOMS AMONG ADOLESCENTS AND YOUNG ADULT WOMEN. Amy L. Shafrir, Sc.D.,[1] Britani Wallace, MPH,[2] Allison F. Vitonis, M.S.,[2] Kathryn L. Terry, Sc.D.,[2] Stacey A. Missmer, ScD[3] [1]Boston Children's Hospital and Boston Center for Endometriosis, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]College of Human Medicine, Michigan State University, Grand Rapids, MI.

OBJECTIVE: Endometriosis is characterized by immune dysregulation. Limited research, particularly among adolescents and young adults (AYA), has investigated the association between circulating inflammatory markers and endometriosis-related pain symptoms.

DESIGN: Cross-sectional analysis of circulating inflammatory markers from 264 laparoscopically-confirmed endometriosis participants and 275 population-based controls from the Women's Health Study: from Adolescence to Adulthood, a cohort of primarily AYA women.

MATERIALS AND METHODS: Participants completed the World Endometriosis Research Foundation (WERF) Endometriosis Phenome and Biobanking Harmonization Project (EPHect) clinical questionnaire including items on presence and severity of dysmenorrhea and acyclic pelvic pain. Using multiplex microarrays, we measured interleukin (IL)-1β, -6, -8, -10, -16, tumor necrosis factor (TNF) α, monocyte chemotactic protein (MCP)-1, -4, chemokine ligand (CCL) 17, and Interferon gamma-induced protein (IP) 10 in plasma samples collected and processed using the WERF EPHect standards. We used linear regression to compute age-adjusted geometric mean (GM) marker levels with 95% confidence intervals (95%CI) for presence and severity of dysmenorrhea or acyclic pain among endometriosis cases and controls. We assessed effect modification by case status using the Wald test statistic.

RESULTS: More severe dysmenorrhea was associated with lower IL-8 levels among both endometriosis cases and controls [cases: IL-8 GM_{severe}=4.02 (95%CI=3.78-4.27) pg/ml vs. GM_{mild}=5.24 (95% CI=3.96-6.93) pg/ml, P_{trend}=0.01; controls: GM_{severe}=2.93 (2.63-3.27) pg/ml vs. GM_{mild}=3.64 (3.26-4.06) pg/ml, P_{trend}=0.007; $P_{interaction}$ (P_{int})= 0.15]. MCP-4 levels were lower among cases with severe [GM_{severe}=75.9 (68.9-83.6) pg/ml] compared to mild dysmenorrhea [GM_{mild}=108 (69.3-168] pg/ml, P_{trend}=0.03], but no trend was observed among controls (P_{int}=0.06). TNFα and IL-8 levels were lower among controls who ever experienced acyclic pain compared to never [TNFα GM_{ever}=5.98 (5.53-6.47) pg/ml vs. GM_{never}=6.62 (6.37-6.88) pg/ml, P=0.03; IL-8 GM_{ever}=2.87 (2.57-3.22) pg/ml vs. GM_{never}=3.61 (3.41-3.81) pg/ml, P<0.001], with no association observed for cases (TNFα P_{int}=0.13; IL-8 P_{int}<0.001). MCP-1 levels were higher among endometriosis cases with acyclic pain [MCP-1 GM_{ever}=139 (131-148) pg/ml vs. GM_{never}=123 (113-134) pg/ml; P=0.03] but not among controls (P_{int}=0.03) and decreased with increasing acyclic pelvic pain severity for cases but not controls (cases: P_{trend}=0.02, P_{int}=0.07). Among cases, MCP-4 levels decreased with increasing acyclic pain severity (P_{trend}=0.04), whereas IL-1β levels increased with increasing acyclic pain severity (P_{trend}=0.05) with no effect modification by case status (P_{int}>0.12).

CONCLUSIONS: Among AYA participants, IL-1β, -8, MCP-1, -4, and TNFα were associated with the presence and severity of dysmenorrhea and acyclic pelvic pain, with differential associations by case status for IL-8, MCP-1, and MCP-4. No associations were observed for IL-6, -10, -16, CCL-17, or IP-10.

O-159 2:20 PM Monday, October 19, 2020

IDENTIFYING BEST FIT IMPLEMENTATION STRATEGIES FOR IMPROVING FERTILITY CARE FOR ADOLESCENT AND YOUNG ADULT (AYA) CANCER SURVIVORS. Anna Dornisch, BS, Emily Yang, BS, Jamie Gruspe, MPH, Bonnie N. Kaiser, PhD MPH, Teresa Helsten, MD, Paula Aristizabal, MD MAS, Hui-Chun I. Su, MD MSCE. University of California San Diego La Jolla, CA.

OBJECTIVE: Oncofertility care remains under-implemented with limited tools to scale up effective implementation strategies. Guided by the Consolidated Framework for Implementation Research (CFIR), the objective was to systematically assess factors that influence implementation of oncofertility care and map strategies, particularly electronic health record (EHR) enabled ones, that fit adult and pediatric oncology care contexts.

DESIGN: Sequential mixed methods study.

MATERIALS AND METHODS: Using purposeful sampling, we recruited healthcare providers (HCPs) and female AYA cancer survivors from a comprehensive cancer center and a freestanding children's hospital. Participants underwent semi-structured interviews and focus groups based on CFIR. Thematic analysis was used to develop inductive codes and CFIR provided deductive codes to characterize barriers and facilitators to oncofertility care and implementation strategies. Two coders independently coded each transcript with a third coder resolving discrepancies by consensus. Developed strategies were evaluated quantitatively by HCPs for acceptability, appropriateness and feasibility. Score range for each measure was 1-5; higher scores indicate more acceptability, appropriateness and feasibility.

RESULTS: We recruited 19 oncology and fertility HCPs and 9 AYA survivors. We identified barriers and facilitators to fertility care in the CFIR domains of individual, inner setting, outer setting and process, allowing us to conceptualize oncofertility care in three necessary stages: oncofertility needs screen, referral and fertility preservation counseling. To fit an adult and pediatric contexts, five implementation strategies were mapped: fertility needs screen using a Best Practice Advisory (BPA), fertility referral order, televideo fertility counseling, provider audit & feedback (A&F) and a provider educational session. Mean acceptability, appropriateness and feasibility scores across strategies were high (Table). Six additional strategies were designed but did not fit our contexts.

	BPA	A&F	Educational Session
Appropriateness Score Mean (95% CI)	4.4 (4.1, 4.7)	4.0 (3.5, 4.6)	4.7 (4.5, 4.9)
Acceptability Score Mean (95% CI)	4.4 (4.0, 4.7)	4.0 (3.4, 4.6)	4.7 (4.5, 5.0)
Feasibility Score Mean (95% CI)	4.4 (4.2, 4.7)	4.2 (3.7, 4.6)	4.7 (4.5, 4.9)

CONCLUSIONS: Access to oncofertility care remains a challenge for young cancer patients, in part due to unaddressed barriers and facilitators across clinical settings. An implementation science approach systematically assessed oncofertility care, mapped strategies and explored their acceptability, appropriateness and feasibility, providing a theory-based approach and scalable EHR tools to support wider dissemination.

O-160 2:35 PM Monday, October 19, 2020

SERUM MICRORNA'S AS DIAGNOSTIC BIOMARKERS OF ENDOMETRIOSIS IN ADOLESCENT FEMALES. Alla Vash-Margita, MD, Ramanaiah Mamillapalli, PhD, Tran C. Dang, BS, Luisa M. Coraluzzi, BSN, Hugh S. Taylor, MD. Yale University School of Medicine New Haven, CT.

OBJECTIVE: The prevalence of endometriosis in adolescent girls with chronic pelvic pain reaches 75%. Despite this high prevalence, diagnosis of endometriosis in adolescent females remains delayed. Laparoscopy has diagnostic and therapeutic benefits, but major surgery may not be acceptable to young patients. The search for noninvasive biomarkers is ongoing. Recently serum microRNA's have been shown to have diagnostic value in adult women. This study assessed levels of several microRNA's in young women as potential marker of endometriosis.

DESIGN: This was a prospective study evaluating adolescent subjects with a clinical suspicion for endometriosis.

MATERIALS AND METHODS: Female subjects ages 14-25 were seen at the Pediatric/Adolescent Gynecology or Reproductive Endocrinology Clinics for evaluation of chronic pelvic pain and screened for endometriosis under an approved IRB protocol. Subjects with surgically proven endometriosis or imaging suggestive of the disease were assigned to the endometriosis group. Subjects who underwent laparoscopy with no endometriosis were assigned to the control group. Serum was collected from blood samples, and miRNAs were extracted. Expression levels of six microRNAs, miR-125b-5p, miR-150-5p, miR-342-3p, miR-451a, Let-7b, and miR-3613-5p were determined using quantitative real-time polymerase chain reaction (qRT-PCR), and normalized to U6 levels. A student t test was used to compare the clinical characteristics of subjects in the endometriosis and control groups. The fold-change of miRNAs of endometriosis and control groups were compared using Mann-Whitney U test. Logistic regression and receiver operating characteristic (ROC) analysis were performed to determine the diagnostic power of the combination of these six miRNAs.

RESULTS: Subjects (N=27) who were diagnosed by laparoscopy as well as imaging were divided into the endometriosis (N=19) or control (N=8) groups. Of those with endometriosis, fourteen subjects had biopsy proven pelvic endometriosis and in five subjects endometriosis was diagnosed based on imaging (endometrioma). Demographics (age, BMI, ethnicity) between endometriosis and control groups were not statistically significant. The mean age of subjects was 16.6 and 17.3 years, and BMI 24.1 and 28.2 kg/m^2 for the endometriosis and control groups, respectively. The vast majority of subjects with endometriosis were Caucasian (68.4%) and had stage I-II disease (78.6%). qRT-PCR results showed increased levels of miR-125b-5p, miR-150-5p, miR-Let-7b, miR-342-3p and miR-451a, while miR-3613-5p was decreased. Logistic regression analysis of this training set showed that a combination of all six microRNAs resulted in the highest AUC (1.00, p=0.004).

CONCLUSIONS: Endometriosis in girls and young women is highly prevalent yet under-diagnosed. A highly sensitive and specific diagnostic test will have great clinical significance in adolescent females with pelvic pain and suspicion of endometriosis. This study demonstrated that a combination of microRNAs, if validated, can be used as an effective diagnostic tool for endometriosis in adolescent females.

O-161 3:05 PM Monday, October 19, 2020

TURNER SYNDROME: UNDERSTANDING INDIVIDUALIZED MEDICAL RISKS DETERMINED BY KARYOTYPE SUBGROUP. Vaishnavi Purusothaman, MD, MA,[1] Victoria W. Fitz, MD, MSCR,[1] Jennifer R. Law, MD, MSCR,[1] Emma M. Rosen, MSPH,[2] Mary Peavey, MD[1] [1]University of North Carolina, Chapel Hill, NC; [2]UNC Gillings School of Public Health, Chapel Hill, NC.

OBJECTIVE: Turner Syndrome (TS) is the most common sex chromosome abnormality in females and is associated with several phenotypic conditions with a high risk of subsequent comorbidity. Numerous karyotypes are associated with TS, including 45X and 45X/46XX, but there is limited data regarding the relationship between karyotype and phenotype in TS. In this retrospective cohort, we aim to characterize the prevalence of congenital malformations and acquired diseases by karyotype. This information will allow clinicians to provide individualized counseling to women with TS based on their specific risks.

DESIGN: Retrospective cohort of patients presenting to the University of North Carolina Turner Syndrome Clinic from April 2014 to January 2020.

MATERIALS AND METHODS: Patients were categorized into four exposure groups by karyotype: 45X, 45X/46 XX, miscellaneous karyotypes with no Y chromosome material, and miscellaneous karyotypes with Y chromosome material. Clinical information and laboratory results, including prevalence of structural cardiac anomalies, structural renal anomalies, autoimmune thyroid disease, hypertension, dyslipidemia, celiac disease, renal dysfunction, growth failure, hearing loss, and being overweight or obese were collected from chart abstraction. Descriptive statistics were performed using SAS and prevalence of each outcome was reported. Fisher's exact test was used to compare the prevalence of each outcome between the groups.

RESULTS: A total of 105 patients were identified and categorized into four groups: group 1 (45X, n=38), group 2 (45X/46 XX, n=13), group 3 (miscellaneous with no Y chromosome material, n=43), and group 4 (miscellaneous with Y chromosome material, n=11). The median age at last visit was 13 (range 1-24). Structural renal and cardiac anomalies were most prevalent in the 45X group, with a prevalence 51.4% (P<0.01) and 66.7% (P=0.02), respectively. Growth failure was least common in patients with 45X/46XX (46.2%), compared to those with 45X (79%), miscellaneous karyotype with Y chromosome material (100%), and miscellaneous karyotype without Y chromosome material (79.1%; P<0.05). The prevalence of dyslipidemia, being overweight or obese, hypertension, liver dysfunction, and hearing loss was similar in all groups. No patients in our cohort developed glucose intolerance (median age 15), and only two patients developed renal dysfunction (median age 14). Similarly, very few patients in the group developed autoimmune thyroid disease (17/102) and celiac disease (6/96).

CONCLUSIONS: Medical comorbidities vary depending on karyotype and mosaicism. The 45X karyotype was associated with a more severe structural phenotype, with a higher prevalence of congenital anomalies and growth failure. Notably, there was no difference in the metabolic phenotype between the karyotype groups in our cohort. Providers should be aware of these individual differences when caring for women with TS.

O-162 2:50 PM Monday, October 19, 2020

PREDICTIVE FACTORS FOR FERTILITY PRESERVATION IN PEDIATRIC PATIENTS WITH PLANNED GONADOTOXIC TREATMENT. Glory E. Mgboji, BS,[1] Christina N. Mitchell, MD,[2] Mindy S. Christianson, MD[2] [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins Medical Institutions, Lutherville, MD.

OBJECTIVE: To characterize a female pediatric patient population seen for fertility preservation consultation at an academic center and to identify demographic and clinical factors associated with receiving fertility preservation treatment (FPT).

DESIGN: Retrospective chart analysis.

MATERIALS AND METHODS: We performed an analysis of female pediatric patients seen for fertility preservation consultation at an academic fertility center between 2005-2019. Fisher exact tests were used to compare fertility preservation status based on demographic and clinical factors. Logistic regression models were constructed to calculate odds ratios with 95% confidence intervals describing factors associated with fertility preservation.

RESULTS: In the study period, 106 females ages 3-21 were seen for consultation with a mean age of 16.6 years. Diagnoses included: hematologic malignancies (41.5%), gynecologic malignancies (9.4%), non-malignant hematologic disease (14.2%), other malignancies (31.1%), and non-malignant conditions (3.8%). Of all patients, 64.2% pursued fertility preservation with treatments including oocyte cryopreservation (35.8%) and ovarian tissue cryopreservation (23.6%). Patients who underwent gonadotoxic therapy prior to consultation had a lower odds of receiving FPT (OR= 0.24, 95% CI 0.10-0.55). Age, race, diagnosis, time elapsed from diagnosis, and median household income were not significantly associated with odds of FPT.

CONCLUSIONS: Pediatric patients who received prior chemotherapy had a lower odds of pursuing FPT. This finding emphasizes the need for early intervention in patients facing gonadotoxic therapies. Additional studies

are needed to further investigate the implications of these data and to explore the barriers to early interventions for FPT in these patients.

PRACTICE MANAGEMENT

COST-EFFECTIVENESS ANALYSIS OF THE ORIGINATOR RECOMBINANT HUMAN FOLLICLE-STIMULATING HORMONE (R-HFSH) AND URINARY HIGHLY PURIFIED MENOPAUSAL GONADOTROPIN (HMG) BASED ON DATA FROM A LARGE GERMAN REGISTRY. Klaus F. Bühler, MD,[1] Robert Fischer, MD,[2] Edel Falla, MSc,[3] Jeroen Luyten, PhD,[4] Claudia Roeder, PhD,[5] Boyang Bian, PhD,[6] Wilma Bilger, PhD,[7] Monica Lispi, MSc,[8] Thomas M. D'Hooghe, MD, PhD[9] [1]Department of Gynaecology, Jena-University Hospital-Friedrich Schiller University, Jena, Germany; [2]MVZ Fertility Center Hamburg GmbH, Hamburg, Germany; [3]IQVIA, London, United Kingdom; [4]KU Leuven (University of Leuven), Leuven, Belgium; [5]Pharma Value Consulting, Oberwil, Switzerland; [6]EMD Serono, Inc, Billerica, MA; [7]Merck Serono GmbH, Darmstadt, Germany; [8]Merck KGaA, Darmstadt, Germany; [9]Merck Healthcare KGaA, Darmstadt, Germany.

OBJECTIVE: Recombinant human follicle-stimulating hormone (r-hFSH) and urinary highly purified menopausal gonadotropin (hMG) are two treatment options in assisted reproductive technology (ART). We used outcomes from the real-world setting in Germany (RecDate) to compare the costs per live birth for r-hFSH and hMG.

DESIGN: Cost-effectiveness analysis.

MATERIALS AND METHODS: All women in the RecDate registry undergoing ART for the first time, receiving either r-hFSH or hMG between 2007 and 2012, were included. Total dose of FSH used, pregnancy and live birth rates (adjusted for age, body mass index, infertility type, gonadotropin-releasing hormone [GnRH] protocol, year and in-vitro fertilisation centre using propensity score weighting) were extracted. Costs for oocyte retrieval, embryo transfer, pregnancy and live birth were obtained from publicly available German sources. These clinical outcomes and costs were integrated in a decision-tree model developed to consider up to three treatment cycles (each comprising one fresh and related freeze-thaw transfers). The model was used to compare cumulative live birth rates and the cost per live birth for the two treatments.

RESULTS: Effectiveness data were identified from 48,437 cycles in 28,641 women across 71 centres. r-hFSH was associated with higher cumulative live birth rates per patient compared with hMG after the first treatment cycle and after up to three consecutive treatment cycles (Table). The lower total costs for the first cycle and for up to two or three consecutive cycles in the r-hFSH group were driven by lower medication costs and better reproductive outcomes, translating into a lower cost per live birth compared with hMG for all cycles (Table).

CONCLUSIONS: In a large German registry (RecDate), r-hFSH was associated with higher cumulative live birth rates and lower total costs per patient compared with hMG. The lower cost per live birth for r-hFSH indicated that r-hFSH may offer better economic efficiency than hMG.

SUPPORT: **Funding**: Merck KGaA, Darmstadt, Germany

SOCIAL MEDIA IN THE TIME OF COVID-19: AN EVALUATION OF SOCIETY FOR ASSISTED REPRODUCTIVE TECHNOLOGY (SART) MEMBER CLINICS. Miriam A. Andrusier, M.P.H.,[1] Seth J. Barishansky, M.D., M.S.,[2] Elizabeth A. Dilday, M.D.,[3] Angela K. Lawson, Ph.D.,[4] Luis R. Hoyos, M.D.[5] [1]SUNY Downstate Health Sciences University, Brooklyn, NY; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC; [3]Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, University of California, Los Angeles, Los Angeles, CA; [4]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [5]UCLA, Los Angeles, CA.

OBJECTIVE: To evaluate the available COVID-19 content in regard to fertility care on the social media (SM) platforms from Society for Assisted Reproductive Technology (SART) member clinics.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: From March 17-30/2020, following the release of the first American Society for Reproductive Medicine (ASRM) COVID-19 recommendations, SART member clinics' SM platforms including Facebook and Twitter were examined. The presence of information on COVID-19, its pregnancy implications, acknowledgement of and compliance with ASRM recommendations, mention of Centers for Disease Control and Prevention (CDC) risk mitigation strategies and local health department guidelines, as well as advertisement for telehealth and availability of mental health resources were queried. Websites were categorized by practice size ($<$500 vs. $\geq$500 cycles/year), type (academic vs. private) and degree of statewide COVID-19 burden based on CDC surveillance data (low: 0-1000; high: $\geq$1000 diagnosed cases). Group differences were evaluated using χ^2.

RESULTS: SM accounts were available from 84% (315/375) of SART member clinics and were more common among private compared to academic clinics [96% (274/286) vs. 46% (41/89), respectively, P$<$0.05]. No difference was found in the presence of COVID-19 posts when comparing private and academic clinics [80% (220/274) vs. 78% (32/41), respectively, P=0.68]. Private clinics were more likely to post individualized recommendations rather than ASRM recommendations, and to advertise the use of telehealth [34% (93/274) vs. 7% (3/41) and 64% (174/274) vs. 46% (19/41), respectively, P$<$0.05, all values]. There was no difference in the advertisement of mental health resources on SM [31% (86/274) vs. 44% (18/41), respectively, P=0.15]. Larger compared to smaller clinics were more likely to provide information on COVID-19, its pregnancy implications, and to acknowledge ASRM recommendations, CDC risk mitigation strategies and local health department guidelines on SM [86% (112/130) vs. 76% (140/185); 49% (64/130) vs. 34% (62/185); 49% (64/130) vs. 34% (62/185); 59% (77/130) vs. 42% (77/185) and 33% (43/130) vs. 22% (40/185), respectively, P$<$0.05, all values]. Larger clinics were also more likely to advertise telehealth and mental health resources on SM [71% (92/130) vs. 55% (101/

TABLE. Cumulative live birth rates and costs per complete treatment cycles 1–3 (fresh and frozen embryo transfers) with r-hFSH and hMG (2007–2012)

	Treatment cycle 1 (n=28,641)			Treatment cycle 1 and 2 (n=7,296)			Treatment cycle 1, 2 and 3 (n=1,783)		
	r-hFSH	hMG	Difference	r-hFSH	hMG	Difference	r-hFSH	hMG	Difference
Live birth (%)	24.9	22.4	2.5	41.7	37.7	4.0	51.5	47.0	4.5
Medication costs (€)*	972	1,072	-99	1,703	1,904	-201	2,270	2,571	-302
Total costs (€)†	9,547	9,579	−32	14,790	15,017	−226	17,324	17,757	−433
Cost per live birth (€)	38,341	42,763		35,449	39,845		33,630	37,753	

* Gonal-f and Menogon HP/Menopur, based on the total dose (IU) and duration of controlled ovarian stimulation. † r-hFSH/hMG acquisition, IVF preparation, oocyte retrieval, embryo transfer, pregnancy and live birth costs.

185) and 42% (54/130) vs. 27% (50/185), respectively, P<0.05, all values]. Clinics in high COVID-19 burden states were less likely to follow ASRM recommendations compared to clinics in low burden states [36% (56/154) vs. 50% (80/161), respectively, P<0.05].

CONCLUSIONS: Use of SM accounts for dissemination of COVID-19 related information was common among SART member clinics with SM presence. However, academic clinics were less likely to have any, and when they did, less likely to offer telehealth, possibly hindering care for their patients. Conversely, larger clinics were more likely to provide pertinent information and advertise telehealth and mental health resources. Private, smaller and high COVID-19 burden clinics were less likely to report compliance with ASRM recommendations.

TRAITS OF PATIENTS SEEN VIA TELEMEDICINE VERSUS IN-PERSON FOR NEW PATIENT VISITS IN A FERTILITY PRACTICE. Vinita M. Alexander, MD,[1] Allison Schelble, MD,[1] Kenan Omurtag, MD[2] [1]Washington University in St. Louis, St. Louis, MO; [2]Washington University School of Medicine, St. Louis, MO.

OBJECTIVE: Integration of telemedicine (TM) into reproductive endocrinology and infertility (REI) is quickly occurring due to changes in the practice environment and recently, COVID19. However, no US studies have investigated telemedicine's impact on REI practices. This study aimed to evaluate differences in demographics, time to treatment initiation, clinical outcomes, and dropout rates between patients using telemedicine relative to in-person (IP) visits.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All new patients seen via TM (between June 2017 to February 2020) at an academic practice were compared with control new IP visits (seen in 2019). The following were evaluated for each new patient encounter by visit type (TM or IP): demographics, cancellation, distance to clinic, infertility diagnosis, duration of infertility, time to treatment initiation, number of clinic-contacts (i.e. number of e-messages or phone calls from patient) prior to treatment start, and dropout rate. We performed t-test analysis by group for continuous independent variables and Chi-square analyses by group for categorical independent variables. Binary logistic regression analysis was performed to estimate the odds of initiating treatment in the TM group.

RESULTS: Seventy-one patients were identified in the TM group, and 71 followed in the IP group. The average age of the IP and TM groups was similar, at 33.5 ± 5.0 and 33.2 ± 5.2, respectively (p=0.723). There were no differences between groups in the following: BMI (p=0.723), area deprivation index (p=0.235), and treatment recommended (e.g. ovulation induction, IVF, surgery, etc.) (p=0.475). There were no differences between the TM and IP groups in: treatment dropout rates (p=0.075), cancellation rates (p=0.379), time to treatment initiation (mean 74.82 days in TM group; 77.5 days in IP group; p = 0.315), or number of times the patient contacted the clinic prior to treatment start (p=0.153). Of those who became pregnant, time to positive pregnancy test was not significantly different between the TM (n=11, mean 176.4 days) and IP groups (n=19, mean 226.45 days) (p=0.368). Compared to IP patients, TM patients were significantly more likely to live further away (mean 223.6 miles vs 69.28 miles, p = 0.006) and have a longer duration of infertility (mean 41.9 months vs 19.49 months, p = 0.006). The lengths of TM appointments were significantly shorter than IP visits (mean 56.3 ± 9.1 minutes vs 59.3 ± 4.6 minutes, p < 0.001) and much less likely to contain documentation of height or weight (p=0.001). In the TM group, age and distance from clinic were not significantly associated with likelihood of dropping out of treatment (p=0.467).

CONCLUSIONS: Telemedicine appears to be of particular interest to patients who live further from clinics and have longer durations of infertility, and it could help reduce visit times. Patients seen in person and via telemedicine are equally likely to pursue treatment. Telemedicine consultation for new-patient visits is feasible in REI practice and is especially useful in areas with limited access to fertility specialists and beyond in a post-COVID landscape.

O-166 2:35 PM Monday, October 19, 2020

MAKING IT (NET)WORK: A SOCIAL NETWORK ANALYSIS OF "FERTILITY" ON TWITTER BEFORE AND DURING THE COVID-19 PANDEMIC. Meghan Brooke Smith, MD,[1] Jennifer K. Blakemore, MD,[2] Jacqueline Ho, MD MS,[1] James A. Grifo, MD, PhD[2] [1]University of Southern California, Los Angeles, CA; [2]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: To characterize activity, text sentiment, and online community characteristics regarding "fertility" on Twitter (TW) before and during the COVID-19 pandemic using social network analysis (SNA).

DESIGN: Cross sectional study.

MATERIALS AND METHODS: SNA uses graph theory to understand structure, flow, content, and relationships of networks among individuals. SNA was performed using NodeXL, a software platform that performs social network and content analysis. The search term "fertility" on TW was investigated during the weeks of February 20-27th, 2020 (Pre-COVID) and April 29th-May 6th, 2020 (during-COVID). User demographics, tweet content, and characteristics of the network were collected and analyzed during these time periods. These included: # users (vertices); edges (connections, defined as unique and total); self-loops (tweet without connection to another user); connected components (groups of users communicating back and forth frequently); maximum vertices in a connected component (largest group size); maximum and average geodesic distance (number of tweets to connect two users in the network); graph density; positive and negative sentiment tweets; top 5 hashtags; and top 5 word pairs. Statistical analyses included a z-ratio for comparison of proportions, with p<0.05 considered significant.

RESULTS: There were 1426 unique users and 401 groups in the pre-COVID data compared to 1492 unique users and 453 groups in the during –COVID data. There was no difference in the number of total connections [96.8% (1381/1426) vs 96.0% (1433/1492), p=0.25] or self-loops [20.0% (286/1426) vs 22.1% (329/1492), p=0.19]before and during the COVID-19 pandemic. The percentage of unique connections per user decreased during COVID-19 [91.6% (1381/1508) pre-COVID vs 83.3% (1433/1720) during COVID, p<0.0002]. The average and maximum distance between users in the community increased during COVID (maximum: 5 pre-COVID, 8 during-COVID; average 1.95 pre-COVID, 2.43 during-COVID). The percentage of positive sentiments per total number of tweets increased during COVID [58.1% pre-COVID (773/1331) vs 64.3% (1198/1863) during-COVID, p<0.0004]. The overall character of the TW fertility social network remained constant at both time points with a broadcast "spoke and out wheel" shape. The top 5 hashtags changed during COVID to include COVID19. The top word pairs changed from "family, hereditary; parents, children" to "fertility, treatment; healthcare, decisions."

CONCLUSIONS: Despite the challenge to the fertility community amidst COVID19, overall TW sentiment regarding fertility was more positive during than before the pandemic. Top hashtags/word pairs changed to reflect the emergence of COVID and the unique healthcare decision making challenges faced. While the character, # of users, and total connections remained constant, unique connections and distance between users changed to reflect more self-broadcasting and less tight connections. Given no change in network structure where time at home could have led to increased social media (SM) use, further study is needed to leverage SM in these situations.

PATIENT PREFERENCES FOR FOLLOW-UP OF GENDER AFFIRMING HORMONE THERAPY. Erin Inman, MD,[1] Daria Stelmak, BS,[1] Emily K. Kobernik, MPH, MS,[1] Juan J. Andino, MD, MBA,[2] Daphna Stroumsa, MD, MPH, MSc,[1] Molly B. Moravek, MD, MPH,[1] John F. Randolph, Jr., MD[1] [1]University of Michigan, Ann Arbor, MI; [2]Michigan Medicine, Ann Arbor, MI.

OBJECTIVE: Approximately 1.4 million people in USA identify as transgender and a large portion (78%) of these will seek out gender-affirming hormonal therapy (HT). Given ongoing discussions about who should provide

HT, our objective was to characterize patient preferences about which providers they seek for HT care and how follow-up can be provided.

DESIGN: Prospective cross-sectional survey.

MATERIALS AND METHODS: Between May to October 2019 a survey was administered at a Midwest tertiary medical center's outpatient clinics prior to implementation of telemedicine. Adult patients 18 years or older initiating or continuing gender affirming hormone therapy were included. The 38-item survey included questions on demographics, barriers to care, and preference for HT follow-up care. All physicians were reproductive endocrinology and infertility physicians or general obstetrician-gynecologists specialized in gender-affirming care. Interest for telemedicine was measured using a likert scale (1, strongly not interested to 5, strongly interested). Bivariate analysis was performed to compare demographic characteristics and survey responses across patient interest in telemedicine. Multivariable logistic regression was used to identify patient factors independently associated with interest in telemedicine.

RESULTS: Among 111 patients, 70.3% (n = 78) self-identified as transgender, 5.4% (n = 6) as gender queer, non-binary, or gender-nonconforming, 17.1% (n =19) as female, and 7.2% (n = 8) as male. Regarding follow-up for HT care, 63.1% (n=70) preferred an in-person visit with a specialist followed by 21.6% (n = 24) video visit with their specialist. Only 15.3% (n = 17) of patients preferred follow-up with a primary care provider (PCP). 29% (n=31) reported that they would never feel comfortable transitioning care, and the most common concern patients had in transitioning care to their PCP was the expertise of the provider (64.0%, n = 71).

Notably, 52.3% (n = 58) of patients were interested in a video visit (4 or 5 on a Likert scale). Factors associated with interest in telemedicine included identifying as a transgender man (OR 3.94, 95% CI [1.24-12.53]), minority race/ethnicity (OR 6.71 [1.79- 25.17]), no need to travel (OR 3.34, [1.14-9.85]), no concerns about video visits (OR 14.66, [4.34-49.56]), and concern about their PCP offering a broad range of gender services (OR 8.63, [2.41-29.67]). Age, income, education, and insurance providers were not significantly different among patients interested in telemedicine and those who were not interested.

41% of patients (n=46) had no concerns regarding the use of video visits for follow-up. The most common concern chosen by patients was a preference for in-person communication (50.5%, n=56).

CONCLUSIONS: Patients presenting for HT follow-up prefer continued care with a specialist as opposed to a PCP. Prior to implementation, a majority of patients were interested in telemedicine. As such, video visits are a feasible way for specialists to offer continued management of gender affirming HT to their patients.

O-168 3:05 PM Monday, October 19, 2020

SURVEY OF CURRENT PRACTICE AND SATISFACTION OF SREI MEMBERS: AN SREI COMMITTEE REPORT. Laurel Stadtmauer, MD, PhD,[1] Paula Amato, MD,[2] Seifeldin Sadek, MD,[1] Elizabeth A. McGee, MD,[3] Brooke Rossi, MD,[4] Bradley S. Hurst, M.D.[5] [1]Jones Institute, Norfolk, VA; [2]Oregon Health & Science University, Portland, OR; [3]University of Vermont Larner College of Medicine, Burlington, VT; [4]Ohio State University Medical College, Columbus, OH; [5]Carolinas Medical Center Atrium Health, Charlotte, NC.

OBJECTIVE: To identify the current practice and satisfaction of reproductive endocrinologists in the U.S.

DESIGN: Cross-sectional survey.

MATERIALS AND METHODS: Cross-sectional survey including 37 questions assessing practice patterns/metrics, compensation, and physician satisfaction. Survey invitations were emailed 3 times in the 4th quarter of 2019 to 982 full members of Society for Reproductive Endocrinology and infertility (SREI). This survey was exempt from IRB approval as it was voluntary and anonymous. Results were compared to a similar SREI survey sent to SREI members in 2014 published by Barnhart et al. in 2016. Continuous data were expressed as mean ±SD.

RESULTS: 314 individuals responded (32%): 48% women and 51% men, a 10% increase in women compared to 2014. 78% were Caucasian, median age range was 51-60 years, and the median years of practice 18 years.

Respondents worked a mean of 51 hours per week. 43% work in academia, 40% in private groups, 12% corporate or hospital owned practice, and 5% solo practice, which represents a 6% increase in the proportion of corporate practices from the prior survey; 29% have left academics a to join a private practice, while only 8% have left private practice for an academic position.

The mean practice size was 7.6 ±5.2, increased from 5.5 in 2014. 66% expect to add more physicians within five years. A mean of 617 ±914 fresh IVF cycles were performed annually, compared to 470 previously. Surgery volume varies widely, with the mean number of major and minor cases at 19.9±41.7, and 21.1 ±47.9, respectively, per practice.

The mean reported compensation was $493,118.18 ±93813.60 up from $400,512 in 2014 with a median salary of $400,000. 39% are salaried, for 41% compensation is revenue-based and the remainder receive compensation based on a combination of factors. 66% feel that their compensation is fair, and 13% are considering leaving their position due to compensation. 31% were equity partners (down from 44%), and 27% report that their practice offers partnership in a mean of 3.1 years.

35% felt very positive about the current state of the specialty of REI, and 42% felt somewhat positive. 78% had a positive professional morale, decreased from 85% in 2014. 68% report that patient interaction is the most satisfying part of their job, and the least satisfactory is work schedule for 48%. 91% would again choose REI as a career.

CONCLUSIONS: Based on the 2019 SREI membership survey, the morale in our sub-specialty remains high. It is a predominately middle-aged Caucasian specialty, but the number of female physicians has increased. Average compensation has increased compared to 2014, and the number of IVF cycles performed per group has increased. The number of REI's in academic practice remained stable compared to 2014.

Acknowledgment: The authors would like to thank the SREI Board of Directors and Members for supporting this report.

O-169 1:50 PM Monday, October 19, 2020

SAFETY EVALUATION OF A NOVEL PROGESTERONE VAGINAL RING (PVR) IN LUTEAL PHASE SUPPORT: SARA TRIAL RESULTS. Laurel Stadtmauer, MD, PhD,[1] Vicki L. Schnell, MD,[2] John K. Park, MD,[3] Cristin C. Slater, MD,[4] Eric D. Foster, PhD,[5] Sarah A. Grover, MBBS,[5] Patrick W. Heiser, PhD[5] [1]Jones Institute, Norfolk, VA; [2]Center of Reproductive Medicine, Houston, TX; [3]Carolina Conceptions, Raleigh, NC; [4]Idaho Center for Reproductive Medicine, Boise, ID; [5]Ferring Pharmaceuticals, Inc, Parsippany, NJ.

OBJECTIVE: To assess the safety and tolerability of the PVR after implementation of manufacturing enhancements via comparison to the similarly designed pivotal phase 3 trial which established the safety and efficacy of once-weekly PVR relative to daily 8% progesterone vaginal gel (Stadtmauer 2013).

DESIGN: Prospective, open-label, single-arm, multi-center trial.

MATERIALS AND METHODS: Women aged 18-34 years old with body mass index $\leq$38 kg/m^2 and diagnosed with tubal, idiopathic, male factor, ovulatory dysfunction, or endometriosis-linked infertility underwent ovarian stimulation with highly purified human menotropin (HP-hMG) at a fixed dose of 225 IU/day, followed by adjustments according to individual response in a standardized long agonist protocol. Weekly administration of the PVR started the day after oocyte retrieval (OR) followed by fresh blastocyst transfer according to ASRM guidelines (2017) and continued for up to 10 weeks. The primary endpoint was the cumulative rate of any spontaneous abortion, defined as two positive β-hCG tests but followed by observation of any empty intrauterine gestational sac or one without a fetal heartbeat or absence of viable fetuses up to 12 weeks after OR.

RESULTS: Across 14 U.S. trial sites, 254 evaluable subjects were treated with PVR. Mean subject age was 30.8 years, BMI 26.5 kg/m^2, AMH 2.8 ng/mL, and FSH 7.0 mIU/mL. Adverse events (AEs) occurring in $\geq$5% of the population included nausea (8.7%) and headache (5.1%). Incidence of predefined vaginal/cervical AEs of special interest was low (2.0%), comprised of 6 events of vaginal bleeding, 3 events of vulvovaginal pain, and 1 event of cervix disorder. Fresh embryo transfer after IVF/ICSI was performed in 243 (95.7%) of the 254 exposed subjects. The mean number of oocytes retrieved/subject was 11.3, resulting in 4.3 day 5 blastocysts and 3.0 good quality day 5 blastocysts. Biochemical abortion rates were 10.3%. The

primary objective was met, with a cumulative spontaneous abortion rate of 7.4% with upper bound of the 95% confidence interval (CI; 4.4%, 11.5%) below the predefined threshold of 15.0% set based upon the observed 10.0% rate (CI 7.6%, 12.8%) in the pivotal trial (Stadtmauer 2013). Clinical pregnancy rates were 43.2% at 10 weeks post OR.

CONCLUSIONS: This trial established a safety bridge between PVR produced via enhanced manufacturing processes and the legacy PVR based upon a rate of spontaneous abortion comparable to that observed in the pivotal phase 3 trial. Weekly administration of the PVR was well-tolerated with good pregnancy outcomes associated with its use in conjunction with HP-hMG stimulation. Based upon demonstrated safety and efficacy coupled with more convenient dosing than existing therapeutics, PVR offers an important option for luteal phase supplementation.

SECOND GENERATION ARTIFICIAL INTELLIGENCE TECHNOLOGY FOR PREIMPLANTATION GENETIC TESTING (PGT) IMPROVES PREGNANCY OUTCOMES IN SINGLE THAWED EUPLOID EMBRYO TRANSFER CYCLES (STEET).

Julia Buldo-Licciardi, M.D.,[1] Mike Large, Ph.D.,[2] David H. McCulloh, Ph.D.,[3] Caroline McCaffrey, PhD,[4] James A. Grifo, MD, PhD[5] [1]Hackensack University Medical Center, Hackensack, NJ; [2]CooperSurgical, Houston, TX; [3]NYU Langone Fertility Center, New York, NY; [4]NYU Langone School of Medicine, New York, NY; [5]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: To evaluate whether the use of artificial intelligence technology in PGT (PGTai) improves STEET pregnancy outcomes.

DESIGN: Retrospective cohort study in single university-based fertility center.

MATERIALS AND METHODS: Three next generation sequencing (NGS) platforms were compared in analyzing trophectoderm biopsies: standard NGS, NGS with first generation artificial intelligence (PGTai 1.0^{SM} Technology Platform) and NGS with second generation artificial intelligence (PGTai 2.0^{SM} Technology Platform). PGTai 2.0 utilizes proprietary low-pass SNP calling mechanisms to confirm or reject non-diploid copy number regions of interest. Outcomes included rates of implantation, clinical pregnancy, biochemical pregnancy, spontaneous abortion and ongoing pregnancy and/or live birth (OP/LBR). OP/LBR was defined as pregnancies greater than 20 weeks over total number of STEETs. Significant differences were calculated using chi-squared test.

RESULTS: The OP/LBR was significantly higher in the PGTai 2.0 group compared to standard NGS (128/182 (70.3%) vs. 328/529 (62.0%)). PGTai 2.0 vs. NGS showed increased implantation rates (151/182 (82.9%) vs. 415/529 (78.4%)) and clinical pregnancy rates (141/182 (77.4%) vs. 379/529 (71.6%)), but the differences did not reach significance. PGTai 2.0 vs. NGS decreased biochemical pregnancy rates (7/151 (4.63%) vs. 36/416 (8.6%)) and spontaneous abortion rates (16/141 (11.3%) vs. 47/329 (12.4%)), but these differences did not reach significance. Outcomes in the PGTai 1.0 group were similar to standard NGS.

CONCLUSIONS: The goal of PGT is to increase live birth rates per retrieval and PGT using second-generation artificial intelligence technology with NGS significantly improves pregnancy outcomes over standard NGS and PGTai 1.0. Larger scale analysis will determine if this next generation of PGTai provides improved diagnostic precision by decreasing the percentage of false positive results, which may narrow the number of embryos diagnosed as mosaic.

USE OF FROZEN DONOR OOCYTES ARE ASSOCIATED WITH A DECREASED LIVEBIRTH RATE COMPARED TO FRESH DONOR OOCYTES: A SART DATABASE ANALYSIS.

Channing Burks, MD,[1] Kristin Van Heertum, MD,[2] Alexandra C. Purdue-Smithe, PhD,[3] Sunni L. Mumford, PhD,[3] Rachel S. Weinerman, MD[1] [1]University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH; [2]Nashville Fertility Center, Nashville, TN; [3]NICHD, Bethesda, MD.

OBJECTIVE: To evaluate the pregnancy and perinatal outcomes of embryos derived from fresh and frozen donor oocytes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The SART database was used to identify all donor oocyte cycles that resulted in a fresh embryo transfer during 2014 and 2015. Gestational carrier cycles were excluded. Generalized linear regression models were used to compare pregnancy and perinatal outcomes of pregnancies after fresh embryo transfer of embryos that were derived from fresh compared to frozen donor oocytes. Models were adjusted for the following factors: maternal age, BMI, current smoking status, parity, infertility diagnosis, prior IVF attempt, ICSI, assisted hatching, number of embryos transferred, multiple gestation and fetal heart reduction. Live birth rate was the primary outcome. Secondary outcomes include miscarriage rate and birthweight.

RESULTS: There were 14,972 embryo transfer cycles analyzed; 11,482 cycles (76.7%) utilized embryos derived from fresh and 3,490 cycles (23.3%) utilized embryos derived from frozen donor oocytes. The mean ages of oocyte donors and intended parent recipients were 26.3 years (±SD 3.6) and 41.4 years (±SD 5.4) respectively. On initial comparison of embryos derived from fresh and frozen donor oocytes, the live birth rate was 41% and 42% respectively. However, once the data was adjusted for the above factors, a significant decrease in live birth was observed with embryos derived from frozen donor oocytes (aRR 0.85, 95% CI 0.8-0.89). A significant increase in biochemical pregnancy loss was noted with embryos derived from frozen donor oocytes (5.6 [fresh] vs 8.6% [frozen], aRR 1.29, 95%CI 1.08-1.53). There was no difference in the proportion of clinical miscarriage between the two groups (12.6 vs 17.4%, aRR 1.06, 95%CI 0.95-1.19). Additionally, there was no difference in low birthweight (32.9 [fresh] vs 29.5% [frozen], aRR 0.98, 95%CI 0.89-1.07) or large for gestational age infants (4.6 vs 6.2%, aRR 1.27, 95%CI 0.96-1.69) between the two groups. This remained true when singletons were analyzed separately for both low birthweight (11.8 vs 12.6%, aRR 1.17, 95%CI 0.93-1.46) and large for gestational age (7.8 vs 9.4%, aRR 1.25, 95%CI 0.94-1.65).

CONCLUSIONS: The use of frozen donor oocytes has become an increasingly popular option in recent years for patients electing to use donor egg. This study, reassuringly, does not suggest a difference in birthweight between fresh and frozen donor oocytes. However, these results do indicate an increased risk for biochemical pregnancy loss and a decrease in live birth rate with frozen donor oocytes. This finding deserves further research in order to optimize the use of frozen donor oocytes in clinical practice.

O-172 2:35 PM Monday, October 19, 2020

FIRST REGISTERED PILOT TRIAL TO VALIDATE THE SAFETY AND EFFECTIVENESS OF MATERNAL SPINDLE TRANSFER TO OVERCOME INFERTILITY ASSOCIATED WITH POOR OOCYTE QUALITY.

Nuno Costa-Borges, PhD,[1] Eros Nikitos, MSc,[2] Katharina Spath, PhD,[3] Klaus Rink, PhD,[1] Konstantinos Kostaras, MD, PhD,[2] Ioannis Zervomanolakis, MD,[2] George Kontopoulos, MD,[2] Panagiotis Polyzos, MD,[2] Stylianos Grigorakis, MD,[2] Thomas Prokopakis, MD,[2] Yannis Vasilopoulos, MD,[2] Nikos Vlahos, MD, PhD,[2] Dominique de Ziegler, MD,[2] Dagan Wells, Ph.D.,[4] Panagiotis Psathas, MD PhD,[2] Gloria Calderón, PhD[1] [1]Embryotools, Barcelona, Spain; [2]Institute of Life, Athens, Greece; [3]Juno Genetics, Oxford, United Kingdom; [4]University of Oxford, Oxford, United Kingdom.

OBJECTIVE: Poor quality oocytes frequently fail to fertilise or produce embryos that arrest during their first days of culture *in vitro*. Oocyte cytoplasmic dysfunctions (including, but not limited to mitochondria) have

been indicated as a major cause of this problem. Since maternal spindle transfer (MST) allows replacement of the entire cytoplasm of an affected oocyte, it holds promise for the enhancement of embryonic development. Recent studies in the mouse and in human oocytes donated for research have confirmed the technical feasibility of MST and provided reassurance concerning safety. Here we present results from the first registered pilot trial aiming to reveal whether MST has potential to overcome infertility caused by poor oocyte quality.

DESIGN: This pilot trial (ISRCTN 11455145) was restricted to 25 patients, selected based on their multiple previous failed IVF attempts, in each case associated with massive embryo development arrest. Female age over 40y/o and severe male factor were exclusion criteria. Procedures were authorized by the National Authority of Assisted Reproduction (437/23.9.2016) and approved by the Hospital's IRB. Informed consent was obtained from patients and donors to conduct all procedures and follow-up the children born.

MATERIALS AND METHODS: The meiotic spindle from patient's oocytes was isolated in a minimal cytoplasmic volume and transferred to a previously enucleated donor oocyte. MST oocytes were inseminated by ICSI and cultured up to 6 days in a time-lapse incubator. Good morphology blastocysts underwent biopsy, aneuploidy testing and analysis of mitochondrial DNA (*mtDNA*) carryover levels. SNPs analysis and DNA fingerprints were used to confirm the origin of the nuclear genome and mtDNA in biopsied samples, amniotic fluid and somatic tissues of resulting children.

RESULTS: A total of 25 MST cycles were performed in patients with an average age of 37.1 y/o and a mean number of previous failed IVF attempts of 5.7 (min 3 and max 11). The mean number of MII oocytes used for MST per patient was 4.4. MST was applied successfully in 113 of 123 oocytes (91.9%) used. Normal fertilization was confirmed in 76.1% (86/113) of injected oocytes and 52 of these developed into good quality blastocysts (60.5%). Genetic screening revealed 50% (26/52) of embryo biopsy specimens to be euploid and mtDNA carryover levels <1%. In 16/25 cases, at least one euploid blastocyst of good morphology was obtained. Thus far, single blastocyst transfers were performed in 9 patients, resulting in 6 clinical pregnancies (66.7%). Two patients have delivered a healthy child and 3 more pregnancies are ongoing. Genetic analyses of the biopsied cells, amniotic fluid and samples collected after birth (blood, urine, saliva, cord blood, placenta) confirmed the parentage of the children and the origin of the donated mtDNA. Follow-up studies are being performed on the children born.

CONCLUSIONS: Given the difficult reproductive history of the patients, results are encouraging. However, more carefully controlled pilot trials and follow-up studies are needed to provide more insights into the efficacy of MST to overcome infertility.

O-173 2:50 PM Monday, October 19, 2020

ONLY SEGMENTAL OR MOSAIC ANEUPLOID EMBRYOS AVAILABLE FOR TRANSFER: A RARE PHENOMENON IN PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY (PGT-A) CYCLES USING TARGETED NEXT GENERATION SEQUENCING (NGS).

Tarek K. Khader, MD,[1] Julia G. Kim, MD, MPH,[2] Jason M. Franasiak, MD, HCLD/ALD,[3] Yiping Zhan, Ph.D,[4] Emre Seli, MD,[2] Richard Thomas Scott, Jr., MD[2] [1]Yale School of Medicine, New Haven, CT; [2]IVI RMA New Jersey, Basking Ridge, NJ; [3]IVI-RMA New Jersey, Basking Ridge, NJ; [4]The Foundation for Embryonic Competence, Basking Ridge, NJ.

OBJECTIVE: Use of next generation sequencing (NGS) for preimplantation genetic testing for aneuploidy (PGT-A) improves resolution for detecting segmental aneuploidy (SEG) and mosaicism (MOS). However, these additional categories create difficult management decisions when the only available embryo for transfer falls into one of these categories. With this in mind, this study sought to investigate: 1) how often the only available embryo carries a SEG or MOS diagnosis, and 2) whether this risk is modified by age and the number of embryos tested in a cohort.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: All cycles at a single center utilizing targeted NGS-based PGT-A between July 2016 and December 2019 were included in the analysis. Each embryo's PGT-A result was placed into 1 of 4 categories: 1) aneuploid (at least 1 whole chromosome aneuploidy present), 2) SEG (no whole chromosome aneuploidy, but deletion or duplication present), 3) MOS (no whole chromosome aneuploidy or segmental present, but mosaic range diagnosis present), and 4) euploid (no abnormalities). Only euploid, SEG, and MOS embryos were considered eligible for transfer. The percentage (%) of cycles in which the only eligible embryo for transfer carried a SEG or MOS diagnosis was then calculated for the entire study population, according to female age, and according to the number of embryos in a given cohort. The relationship between female age and each diagnostic category was also evaluated using logistic regression.

RESULTS: A total of 7,220 retrieval cohorts resulting in 34,717 embryos were evaluated. The overall prevalence of aneuploidy, SEG, and MOS per embryo were 29.4%, 7.3%, and 3.3% respectively. Female age was strongly associated with the presence of whole chromosome aneuploidy ($p<0.0001$). The older the female subjects' age the lower were the SEG or MOS results rate ($p<0.001$). The number of cycles in which the only available embryo contained a SEG or MOS was 2.5 and 1.2 percent respectively across the entire cohort. The risk was similar across all ages and never exceeded 7.2 and 2.5 percent respectively in any age year. The percent of SEG only or MOS only cycles decreased as number of embryos in the cohort increased and was <1% when at least 5 embryos were available for testing.

CONCLUSIONS: Few PGT-A cycles analyzed by NGS result in a scenario where the only available embryo for transfer carries a SEG or MOS diagnosis. This low risk is consistent across all age groups and in our cohort female age was inversely associated with risk of SEG or MOS diagnosis. These findings are relevant in guiding pre-cycle PGT-A counseling and expectations.

ENHANCING CELL INJECTION SYSTEMS BY REAL TIME CONFIRMATION OF CYTOPLASMIC PENETRATION.

Amir Mor, MD PhD,[1] Lauren Gatenby, B.S.,[2] Emily Dzekunskas, BS,[2] Linkai Zhu, PhD,[2] Kenneth Bondioli, PhD,[2] Zongliang Jiang, Ph.D,[2] Emre Seli, M.D.[1] [1]Yale School of Medicine, New Haven, CT; [2]Louisiana State University, Baton Rouge, LA.

OBJECTIVE: Visual assessment of true cell penetration with a microinjection pipette is not always feasible due to cloudy solutions, adjacent cells, and light microscopy wavelength limitations. This is especially true for microinjection in bovine oocytes and zygotes due to their cytoplasmic opacity. We hypothesized that an increase in electrical resistance upon bovine zygote plasmatic membrane piercing can serve as a real-time tool to confirm cell penetration and embryo viability.

DESIGN: Experimental study.

MATERIALS AND METHODS: In the first part of the study, the minimal electrical resistance increase (minΔR [MΩ]) that occurs when penetrating visually viable zygotes (compared to non-viable ones) was determined. Bovine zygotes were produced by in vitro fertilization. Electrical resistance of the microinjection pipette tip was measured continuously throughout the procedure. ROC analysis was performed. In the second part of the study, the ability of the minΔR [MΩ] (identified in the first part of the study) to predict cell penetration and viability was tested by the microinjection of in vitro transcribed (IVT) mRNA coding for the fluorescent 'mCherry' nuclear protein into zygotes. Cleavage embryos showing nuclear fluorescence 20 hours post injection were considered viable.

RESULTS: ROC analysis showed minΔR $>$ 4 MΩ to identify visually viable embryos (n=67) versus non-viable ones (n=15) (97% sensitivity, 100% specificity, AUC 0.99 (CI 0.95 – 1.00)). In the second part of the study, 11 zygotes had minΔR $>$ 4 MΩ at the time of IVT mRNA injection. Seven of them (64%) cleaved and showed positive nuclear fluorescence 20 hours post injection. Eight zygotes had minΔR $\leq$ 4 MΩ and none of them (0%) showed nuclear fluorescence 20 hours post injection.

CONCLUSIONS: When attempting cytoplasmic zygote microinjection, electrical resistance increase can serve as a reliable tool to confirm successful cell penetration and embryo viability, independent of optical visualization. This technology can potentially be integrated into a manual or robotic cell injection system.

O-175 1:50 PM Monday, October 19, 2020

MANUFACTURING OOCYTES THROUGH SOMATIC CELL NUCLEAR TRANSFER. Aysha Trout, B.A., Philip Xie, B.S., Robert Setton, M.D., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: Somatic cell haploidization in a project of neogametogenesis is normally monitored by the sole extrusion of a pseudo-polar body. Here we determined whether an earlier identification of a meiotic-like spindle after somatic cell nuclear transfer (SCNT) enhances the likelihood of successful haploidization.

DESIGN: Constructs were observed for meiotic-like spindle identification at least 2 hours after SCNT. Oocytes with either negative (NS) or positive (PS) spindle were inseminated, together with an unmanipulated control. Embryo development and molecular karyotype were assessed between the two cohorts.

MATERIALS AND METHODS: Metaphase II oocytes from B6D2F1 mice were exposed to cytochalasin B, and under Oosight™ visualization, meiotic spindles and polar bodies were removed. A single *cumulus* cell was fused with the resulting ooplast using Sendai virus. Reconstituted oocytes were assessed for the presence of a newly formed meiotic-like spindle and inseminated by piezo-ICSI. Piezo-ICSI of unmanipulated oocytes served as control. Successful haploidization was confirmed by the extrusion of a pseudo-polar body at the time fertilization, and time-lapse imaging was used to monitor preimplantation development. Whole genome sequencing of resulting blastocysts determined ploidy.

RESULTS: Out of 320 oocytes that underwent SCNT, 186 (58%) displayed a meiotic-like spindle at least 2 hours later, while the remaining did not (42%). Control oocytes (n=49), 92 NS oocytes, and all 186 PS oocytes underwent piezo-ICSI insemination. NS and PS groups, although at a lower rate than the control (86%, $P<0.0001$), survived at a comparable rate of 63% and 52%, respectively. Of the surviving NS oocytes, only 10% showed successful haploidization by extrusion of a pseudo-polar body, while 55% of PS oocytes haploidized ($P<0.00001$). The control oocytes fertilized at a superior rate of 74% compared to the experimental groups ($P<0.00001$); however, between the two experimental cohorts, NS oocytes fertilized at a rate of 7%, while PS oocytes fertilized at a significantly higher rate of 53% ($P<0.00001$). Lastly, although at lower rates than the control (81%, $P<0.0001$), NS and PS oocytes developed to blastocysts at comparable rates of 50% and 27%, respectively. DNA sequencing of trophectoderm biopsies (4-8 cells) from 2 NS blastocysts and 6 PS blastocysts showed that both NS blastocysts (100%) and 4 PS (67%) blastocysts were euploid.

CONCLUSIONS: The assessment of a meiotic-like spindle after SCNT demonstrated a higher proportion of haploidized and fertilized oocytes. In both cohorts, we were able to observe a full preimplantation development morphokinetically comparable to the control and proved to be euploid. Once the reproducibility and safety of this technique are demonstrated, it may be applied in humans to generate oocytes for women of advanced maternal age or with exhausted ovarian reserve.

DEVELOPMENT OF A NOVEL TECHNIQUE TO EDIT THE GENOME OF THE MALE GAMETE. June Wang, B.A., Philip Xie, B.S., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: Editing the genome at the gamete level may prevent the creation of mosaic embryos. For spermatozoa, this is a challenge due to the unique compaction of their DNA. Our aim is to identify whether an ooplasm-mediated technique can promote editing of the mouse spermatozoa genome.

DESIGN: To facilitate decondensation of the male genome, enucleated oocytes were injected with individual spermatozoa (haploid ICSI, or h-ICSI), creating pseudo-blastocysts containing only the male genome. Gene editing was performed via injection of a CRISPR solution designed to knock out the *Tyr* gene to create an albino phenotype. A control group was produced through standard ICSI with the same CRISPR solution (diploid ICSI, or d-ICSI), following the established approach for heritable genome editing. Gene editing success was analyzed in the resulting embryos and compared between groups. An initial assessment of mosaicism was conducted on h-ICSI embryos.

MATERIALS AND METHODS: Metaphase II oocytes were retrieved from superovulated B6D2F1 mice and divided into two groups: h-ICSI and d-ICSI. Oocytes for h-ICSI were enucleated and given 2 hours to rest. Both groups then underwent piezo-actuated ICSI with a solution of pre-complexed Cas9 and *Tyr* knockout gRNA. Embryos were incubated for 24 hours, and then cryopreserved. DNA was extracted, and a 423-bp region around the CRISPR target site was amplified. CRISPR activity was analyzed by the T7E1 assay. To assess mosaicism, additional h-ICSI embryos were cultured and disaggregated into blastomeres before freezing. DNA was analyzed by Illumina sequencing.

RESULTS: Of 96 oocytes, 57 underwent d-ICSI as the control group and 31 underwent h-ICSI. Overall, 75% (43/57) of d-ICSI embryos survived after ICSI, 70% (30/43) developed to the 2-cell stage, and 36% (10/28) contained gene modification at the target site. Of the h-ICSI group, 74% (23/31) survived after sperm injection, 43% (10/23) progressed to the 2-cell stage, and 29% (2/7) had confirmed gene editing. A significant difference ($P < 0.05$) was seen only for the rate of development. Of the 8 h-ICSI embryos evaluated for mosaicism, 6 demonstrated gene modification. Of these, half were mosaic, while the remaining 3/6 uniformly had the albino gene knocked out.

CONCLUSIONS: We propose a haploid ICSI technique that allows successful editing of the spermatozoa genome at a comparable rate to the standard diploid ICSI approach. Once our editing technique is optimized, individual pseudo-blastomeres of h-ICSI embryos can be used as the male gamete to inseminate oocytes. If reproduced successfully in humans, our model may address the inheritance of paternal monogenic disorders.

A NON-HUMAN PRIMATE MODEL OF OVARIAN ISCHEMIA AND REPERFUSION REVEALS PHYSIOLOGICAL HYPOXIA IN THE PRIMORDIAL FOLLICLES. Adam J. Krieg, Ph.D., Melinda J. Murphy, B.S., Alison Ting, Ph.D. Oregon National Primate Research Center, Beaverton, OR.

OBJECTIVE: During ovarian transplantation, the tissue undergoes both ischemia and reoxygenation, which can result in oxidative damage to the remaining follicle pool. In order to optimize fertility preservation techniques, it is essential to determine the native levels of oxygen (O2) in the ovary, particularly the primordial follicle. Using an ischemia and reperfusion model in nonhuman primates, our studies would have direct applicability to human fertility studies.

DESIGN: Basic science study using non-human primates (rhesus macaques) to measure O2 dynamics in the primate ovary exposed to ischemia and reperfusion.

MATERIALS AND METHODS: The ovaries of ten juvenile female rhesus macaque (1-1.5 years of age) were exposed by laparotomy and the O2 level of the tissue ovarian cortex (1.0-2mm from surface) was measured using an O2 sensor equipped with a microprobe. One random ovary in each animal was exposed to ischemic (ovarian vessel clamping; 20 min) and reperfusion (unclamping; 5-20 min) conditions. Tissue O2 in the ovary underwent ischemia-reperfusion (I/R) was measured throughout the procedure. The vessel of the contralateral ovary was unclamped and serveds as control (CTRL). Bromodeoxyuridine (BrdU) was injected in each animal to label growing follicles. Five animals were also injected with pimonidazole in order to label hypoxic tissues in the ischemic and control ovaries, and underwent bilateral oophorectomy 24 hours later. The remaining five animals underwent oophorectomy 18 days after surgery to measure longer term follicle damage. Formalin-fixed and paraffin-embedded ovaries were processed for immunohistochemical detection of BrdU, pimonidazole, and the hypoxia marker gene CA-IX. Mean O2 concentrations at discrete timepoints were compared by One-Way ANOVA using Tukey's test for multiple comparisons.

RESULTS: The baseline O2 concentration of juvenile rhesus ovarian cortex was equivalent to $5.6 \pm 2.3\%$ (atmospheric O2 is $\sim$20.9%). After 5 minutes of ischemia, oxygen dropped to $1.7 \pm 1.5\%$ ($P = 0.014$); and remained low ($1.4 \pm 1.7\%$, $P = 0.027$). After 5 minutes of reoxygenation, O2 returned to baseline ($6.6 \pm 3.9\%$, $P = 0.96$). IHC detection of pimonidazole and CA-IX revealed robust pimonidazole uptake and CA-IX expression in the

primordial follicles of both control and ischemic ovaries, with expansion of staining to the medullar and stromal cells in ischemia. BrdU was detected in growing follicles in all ovaries, with little change due to ischemia and reoxygenation.

CONCLUSIONS: The oxygen concentration of the juvenile rhesus ovary is approximately 5% O2, equivalent to many other tissues. However, the robust pimonidazole and CA-IX staining of the oocyte and granulosa cells suggest that the local environment of the primordial follicle experiences physiological hypoxia (<1.5% O2). Similar levels of BrdU uptake in CTRL and I/R ovaries suggest short-term follicle growth (in secondary and antral follicles) was not affected by O2 fluctuation. The maintenance of physiological hypoxia could be an important consideration for maintaining follicle quiescence and oocyte quality during fertility preservation procedures.

SURVIVIN-SODIUM IODIDE SYMPORTER REPORTER AS A NON-INVASIVE DIAGNOSTIC MARKER TO DIFFERENTIATE BETWEEN UTERINE LEIOMYOSARCOMA VERSUS LEIOMYOMA.

Natalia Garcia, PhD,[1] Mohamed Ali, B.Pharm, MSc,[1] Mara Ulin, MD,[1] Maaten Bosland, PhD,[2] Weiqiao Zeng, PhD,[1] Liaohai Chen, PhD,[1] Ayman Al-Hendy, MD, PhD[1] [1]The University of Illinois College of Medicine, Chicago, IL; [2]University of Illinois at Chicago, Chicago, IL.

OBJECTIVE: The aim of this study is to evaluate the use of Survivin-Sodium iodide symporter (Ad-SUR-NIS) as a reporter gene to differentiate between uterine leiomyoma (LM) and uterine leiomyosarcoma (LMS) by positron emission tomography (PET) imaging.

DESIGN: Laboratory research studies using LMS and LM animal models.

MATERIALS AND METHODS: 28 Adult female nu/nu Nude mice, 6-8 weeks of age, weighing between 20-25 g, were used. A total of $2x10^7$ cells of LMS or LM cells were inoculated subcutaneously into the right flank. One week after inoculation with visible and palpable tumors, the mice were transfected via retro-orbital with Ad-SUR-NIS ($1x10^9$ PFU/mouse) or PBS (control). 24 hours after Ad-SUR-NIS injection, 14 animals were submitted to PET/CT scanning using $NaBF_4^{18}$ as a radiotracer to assess the expression of NIS reporter gene. For safety evaluation, 14 animals were euthanized after 24 hours of the Ad-SUR-NIS transfection. Tumors and organs (brain, liver, kidney, spleen, lung, ovary, uterus and heart) were collected and histopathologic analysis was performed by a pathologist.

RESULTS: 5 minutes after the $NaBF_4^{18}$ administration, the PET/CT scan images showed an increased radiotracer uptake attributable to Ad-SUR-NIS on the LMS tumors when compared to LM. Presumably, due to the overexpression of NIS in LMS in contrast to LM. The nature of the tumor masses (LMS vs LM) were confirmed histologically. 24 hours after the Ad-SUR-NIS or PBS transfection LM and LMS tumors along with the organs, were collected. H&E-stained sections were examined histologically and compared to the PBS group. No pathological changes were found in any of these tissues after Ad-SUR-NIS transfection.

CONCLUSIONS: Ad-SUR-NIS PET reporter is a promising imaging biomarker which differentiates uterine LMS from LM using $NaBF_4^{18}$ as a radiotracer. This new diagnostic method can provide a much-needed tool in clinical practices to effectively triage women with suspicious uterine masses.

OVARIAN AGING AND REPRODUCTIVE SENESCENCE IN MOUSE MODEL OF MITOCHONDRIAL DYSFUNCTION.

Jasmine L. Chiang, MD,[1] Noha Ahmed, MD, PhD,[1] Jeremy B. Foote, DVM, PhD,[1] Nripesh Prasad, PhD,[2] Srinivasu Karri, PhD,[1] Kelly Pagidas, MD,[3] Ashley M. Wiltshire, MD,[1] Deidre Gunn, MD,[1] Keshav K. Singh, PhD[1] [1]University of Alabama at Birmingham, Birmingham, AL; [2]HudsonAlpha Discovery, Huntsville, AL; [3]TCM University, Lincoln, RI.

OBJECTIVE: To evaluate the mechanisms of female reproductive aging and senescence induced by mitochondrial dysfunction in mice.

DESIGN: Prospective cohort design study. 13 female mice with mitochondrial dysfunction (mtDNA-depleter) and 13 wild-type (WT) female mice were studied at three time points in their reproductive life cycle: 4-6, 8-10, and 11-12 months of age.

MATERIALS AND METHODS: A transgenic mouse model with an inducible gene for mitochondrial dysfunction (mtDNA-depleter) was previously created by our lab. All protocols were approved by our institutional IACUC. At each of the three time points, reproductive markers were assessed, including estrous cyclicity, plasma anti-Mullerian hormone (AMH), ovarian follicles, estrogen receptor staining, and uterine and vaginal atrophy. Breeding experiments were performed to assess fertility. Differences between the mtDNA-depleter and WT groups were evaluated by independent two-sample t-test.

RESULTS: Twenty-six female mice were studied from 4 to 12 months of age. The estrous cycles in 4-6-month mtDNA-depleter mice were prolonged, 9.4 days (n = 7), versus 5.3 days in WT (n = 9), p-value of 0.021. By 11-12 months, both groups had prolonged estrous cycles consistent with physiologic aging. AMH levels in 4-6-month mtDNA-depleter mice were decreased, 84 (n = 4), versus 114 ng/mL in WT (n = 5), p-value of 0.013. AMH was reduced in older mice at 8-10 and 11-12 months, but there were no significant differences between groups. Looking at the data collectively for all three time points, there were fewer tertiary (early antral, antral, or pre-ovulatory) follicles in mtDNA-depleter mice than in WT, 3.5 versus 4.9 per cut section, respectively (p-value of 0.039). There were fewer corpora lutea in mtDNA-depleter mice than in WT, 0.90 versus 1.7 per cut section, respectively (p-value of 0.027). Collectively, average uterine weight in mtDNA-depleter mice was lower, 62.2, versus 92.3 mg in WT mice, p-value of 0.0028. Vaginal epithelium in 4-6-month mtDNA-depleter mice was thinner, 98 μm (n = 4), versus 200 μm in WT mice (n = 4), p-value of 0.035. In breeding experiments, mtDNA-depleter mice at age 3 and 5 months did not produce litters. Estrogen receptor levels were reduced in mtDNA-depleter mouse ovary relative to WT, evident from both immunofluorescence and semi-quantitative PCR analysis.

CONCLUSIONS: Mitochondrial dysfunction in mice is associated with premature reproductive aging and senescence, as evidenced by early onset of prolonged estrous cycles, diminished ovarian reserve, uterine and vaginal atrophy, and sterility. Mitochondrial dysfunction is also associated with premature estrogen receptor down-regulation in the mouse ovary.

INVESTIGATION OF APOPTOSIS AND FOLLICLE ACTIVATION BY PROTEOMICS IN AN EXPERIMENTAL MODEL OF CYCLOPHOSPHAMIDE-INDUCED FOLLICLE DEPLETION IN OVARIAN CULTURE.

Xia Hao, PhD student,[1] Amandine Anastácio, PhD, Post-Doc,[1] Kenny A. Rodriguez-Wallberg, MD, PhD, Associate Professor[2] [1]Laboratory of Translational Fertility Preservation, Karolinska Institutet, Stockholm, Sweden; [2]Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden.

OBJECTIVE: The mechanisms of primordial follicle depletion (PrFD) and infertility following cyclophosphamide (CPA) treatment remain unclear. This study investigated mechanisms of CPA-induced PrFD focusing on apoptosis and follicle over-activation and associated protein profile changes.

DESIGN: Experimental controlled study using a mouse ovarian culture model.

MATERIALS AND METHODS: Ovaries (n=24) from B6CBA/F1 postnatal day-4 mouse were cultured according to O'Brien *et al* [1]. The ovaries were randomly assigned to CPA-treated group (5 μM 4-hydroperoxyCPA) or control. Ovaries were analyzed 24, 48 or 72 h after treatment. Follicle density on histology (counted number of follicles/area) was estimated for primordial follicle density (PFD) and growing follicle density (GFD). Apoptosis was assessed by a qualitative analysis of TUNEL assay at 24 h. Mass spectrometry-based proteomics analysis was performed at 24 h (4 ovaries/group), followed by gene ontology analysis on PANTHER for protein class, molecular function, biological process and pathways.

RESULTS: In CPA-treated ovaries, PFD showed a marked progressive reduction and a lower PFD was found at all timepoints compared to controls. At 72 h, PFD decreased by 82.4% from 401.4±266.7 follicles/mm^2 at 24 h in the CPA-treated group, whereas it decreased by 25.2% from 673.2±231.9 follicles/mm^2 at 24 h in control. On the contrary, GFD was higher in CPA-treated ovaries than in controls at all timepoints. At 24 h, 109.8±63.8 follicles/mm^2 were counted in CPA-treated group vs 61.8±1.6 follicles/mm^2 in

control. These numbers increased around 50% in both groups at 48 h. However, from 48 h to 72 h, a GFD reduction of 15.1% was observed in CPA-treated ovaries vs a further GFD increment of 34.5% in controls.

The TUNEL assay revealed positive stained oocytes in primordial follicles and granulosa cells of growing follicles in CPA-treated ovaries but this was not observed in controls.

The proteomics analysis identified 9531 proteins. Of those, 9018 were common to both groups, 245 were found only in CPA-treated group and 268 only in control. Comparing to control, CPA-treatment increased proteins related to defense/immunity, nuclei acid binding, translation regulation, intercellular signal and cell proliferation, such as transmembrane proteins, immunoglobulins, DNA helicase. Additionally, proteins related to transporter and transfer/carrier decreased in CPA-treated group. In pathways, apoptosis, B and T cell activation were only involved in CPA-treated group, while PI3K was only in control.

CONCLUSIONS: The preliminary findings indicated a reduced PFD and an increased GFD in CPA-treated ovaries, suggesting that both apoptosis and follicle over-activation may be involved in the PrFD. The GFD decrease at 72 h suggested that activated follicles were damaged by CPA in longer culture. The TUNEL assay revealed direct damage to oocytes in CPA-treated ovaries. The proteomics analysis supported these findings, as apoptosis related proteins were increased in CPA-treated ovaries whereas proteins related to maintenance of primordial follicle dormancy were only identified in control.

OPENING THE BLACK BOX: RELATION BETWEEN AI PREDICTED EMBRYO IMPLANTATION AND TRADITIONAL MORPHOKINETIC AND MORPHOLOGICAL ANNOTATIONS. Jørgen Berntsen, M.Sc., Jens Rimestad, M.Sc., Jacob Theilgaard Lassen, M.Sc., Mikkel Fly Kragh, PhD. Vitrolife A/S Viby, Denmark.

OBJECTIVE: Is there a correlation between predictions from an artificial intelligence (AI) model trained solely on fetal heart beat outcome and time-lapse parameters annotated by embryologists?

DESIGN: A deep neural network was trained on clinical outcome from 98,583 embryos with either known fetal heart beat (n=12,432) or that were discarded (n=86,151). The data were obtained from 18 different clinics from 2011 to 2019. All embryos were incubated for at least 4 days. In addition, a data set with 17,249 embryos were used for test. Correlation of score predictions with manually labelled morphokinetic and morphological parameters on the test data were assessed.

MATERIALS AND METHODS: Videos in the test data with annotations by embryologist were analysed for parameters including direct cleavage (DC), tB, ICM and TE. DC annotations include DC from 1 to 3 (DC1-3), DC from 2 to 5 (DC2-5) and absence of DC (no-DC). Annotations of tB was grouped into 5 intervals ranging from <100, 100-105, 105-110, 110-115, >115 hours post insemination. Wilcoxon sum rank test was used to test significant differences between scores and manual annotations. The trained AI outputs a score between 1 and 9.9, increasing with the likelihood of implantation.

RESULTS: The trained AI was tested on a data set (n=17,249) that had not been used during training. For embryos showing DC1-3, DC2-5 or no-DC (n=6,049), the average scores were 3.48, 4.04, 5.50, respectively. The scores were significantly different between all groups ($p<0.0001$). Embryos from these 3 groups that reached the blastocyst stage (n=2,434) showed average scores of 6.41, 6.31, 7.39, for DC1-3, DC2-5 and no-DC, respectively. The scores in the no-DC group were significantly different from both DC1-3 and DC2-5 ($p<0.0001$). However, there was no significant difference between DC1-3 and DC2-5 ($p=0.71$). This maybe due to that DC1-3 and DC2-5 only included 161 and 159 embryos, respectively.

For the tB groups (n=2,447) the average scores were 8.64, 8.05, 7.27, 6.56 and 5.59 for the intervals <100, 100-105, 105-110, 110-115, >115, respectively. For the different groups of ICM grades (n=1,636) the average scores were A=8.51, B=7.55 and C=5.56, respectively. For the different groups of TE grades (n=1,636) the average scores were A=8.75, B=7.71 and C=5.70, respectively. For tB, TE and ICM there were significant differences for the scores between all groups ($p<0.0001$).

CONCLUSIONS: AI output correlated with standard morphokinetic and morphological parameters such as direct cleavages (DC), time to blastocyst (tB), inner cell mass (ICM) and trophectoderm (TE).

Our results suggest that the AI score reflects parameters known to correlate with implantation. However, this does not imply that the AI directly estimates these parameters. As the AI is trained directly on the entire video sequence it likely identifies features of embryo development that human analysis may not recognize.

SUPPORT: The work was partly funded by the Innovation Fund Denmark (IFD) under File No. 7039-00068B.

COMPARISON OF PRONUCLEAR (PN) NUMBER OBSERVATIONS BASED ON EMBRYOLOGIST'S EXPERIENCE AND DETECTION BY ARTIFICAL INTELLIGENCE (AI) TRAINED WITH DEEP LEARNING TECHNOLOGY. Hiroyuki Watanabe, M.S.,[1] Noritaka Fukunaga, Ph.D.,[1] Sho Sanami, Ph.D.,[2] Hiroya Kitasaka, Ph.D.,[1] Yuji Tsuzuki, M.S.,[2] Yuta Kida, M.S.,[1] Seiji Takeda, M.S.,[2] Fumiya Kondo, M.S.,[1] Sho Takeda, B.S.,[1] Yoshimasa Asada, M.D., Ph.D.[1] [1]Asada Ladies Clinic, Nagoya, Japan; [2]Dai Nippon Printing Co., Ltd., Tokyo, Japan.

OBJECTIVE: Gamete and embryo evaluation in human IVF programs are critical skills that are developed through formal followed by actual experience over many years in a laboratory. Whilst the aim is to ensure consistency in evaluation between embryologists in any one laboratory, it is a major challenge to ensure and maintain high accuracy across operators.

Therefore, we have developed an automatic PN number detection system utilizing deep learning technology to provide an effective system for clinical use. In this study, the accuracy of PN number detection assessed by AI was compared with that assessed by junior, intermediate, and senior embryologists in order to indicate the effectiveness of the AI generated system vs. human assessment.

DESIGN: Training data, for constructing the AI for automatic PN number detection, consisted of 70-80 images before and after pronucleus formation of one fertilized embryo were captured by a time-lapse incubator. Using these 70-80 images as one set, 300 sets of each 0PN, 1PN, 2PN, 3PN embryos were inputted into the AI algorithm. For comparison of data from embryologists, we selected three junior embryologists on the first day of work, three intermediate embryologists with three years of experience, and three senior embryologists with more than six years of experience.

MATERIALS AND METHODS: For testing data to evaluate accuracy of the AI algorithm, we used a total of 40 time-lapse videos including 0,1,2,3 PN embryos in which the PN numbers were decided by different embryologists.

For the test data set, the PN number of each embryo was judged by each junior, intermediate, senior embryologist, and the AI. The correct answer rates were then compared.

RESULTS: The correct answer rates for 0PN were 70.0% (junior), 96.7% (intermediate), 100% (senior) and 100% by AI. The correct answer rates for 1PN were 66.7% (junior), 85.2% (intermediate), 88.9% (senior) and 66.7% by AI. The correct answer rates for 2PN were 81.8% (junior), 97.0% (intermediate), 100% (senior) and 81.8% by AI. The correct answer rates for 3PN were 63.3% (junior), 96.7% (intermediate), 90.0% (senior) and 70.0% by AI.

CONCLUSIONS: Whilst the accuracy of the AI was higher in some of the assessments (e.g. junior on 1 and 3 PNs and that of intermediate on 0 PN), it was not consistent with assessments by seniors. For the AI to be clinically useful it should have not only higher accuracy across all users but also be stable across different PN states. We are therefore continuing to improve the AI to have a higher accuracy for PN number detection by introducing into the algorithm, Z-axis multi-sliced images.

NONINVASIVE DETECTION OF BLASTOCYST PLOIDY (EUPLOID VS. ANEUPLOID) USING ARTIFICIAL INTELLIGENCE (AI) WITH DEEP LEARNING METHODS. Josue Barnes, B.S.,[1] Jonas Malmsten, D.P.S.,[1] Qiansheng Zhan, Ph.D.,[1] Iman Hajirasouliha, Ph.D.,[1] Olivier Elemento, Ph.D.,[1] Jose Sierra, Ph.D.,[2] Nikica Zaninovic, Ph.D.,[1] Zev Rosenwaks, M.D.[3] [1]Weill Cornell Medicine, New York, NY; [2]QED Analytics LLC, Princeton, NJ; [3]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: The current method of preimplantation genetic testing for aneuploidy (PGT-A) involves invasive trophectoderm (TE) biopsy. Although PGT-A has improved the success rate per embryo transfer, it has notable limitations. These include the cost of sequencing, mosaicism, the skill required to biopsy TE cells, and the fact that only a select number of blastocysts (BLs) can be tested. Embryologists rely on morphological assessment and clinical information to select BLs for PGT-A. The development of noninvasive methods of embryo screening, as an alternative to PGT-A, is essential. We propose an embryo selection method that leverages the power of deep learning classification methods trained on spatial and temporal information stored in time-lapse images (TLM) that capture embryo development along with clinical parameters; this method can be used to select embryos for PGT-A and to predict embryo ploidy (euploid vs. aneuploid) without a biopsy.

DESIGN: In our study, we used a retrospective dataset consisting of 10,872 embryos of known ploidy status (euploid or aneuploid) to train and validate several deep learning models.

MATERIALS AND METHODS: We developed deep learning models for embryo image analysis based on pre-trained ResNet18. The models utilized images of human embryos captured using time-lapse microscopy (EmbryoScope™) at 110 hours post-ICSI and known PGT-A results (aneuploid n = 6,443; euploid n = 4,429) as ground truth labels. The developed models use several clinical features, including maternal age, morphokinetics, BL grade, and BL score. Using an 80/20 training-validation split of the data, performances were measured by validation accuracy and the AUC. Class activation mapping (CAM) was employed to identify which areas within embryo images were used to predict ploidy.

RESULTS: Several models were trained and validated, each with varying features.

Model	Features	AUC	Accuracy
A	Image	0.6214	62.87%
B	Image, Age	0.7293	68.06%
C	Image, Morphokinetics	0.6094	62.55%
D	Image, BL Score	0.6901	64.07%
E	Image, BL Grade	0.6876	65.51%
F	Image Age, Morphokinetics	0.7341	68.29%
G	**Image, Age, BL Score**	**0.7558**	**70.23%**
H	Image, Age, BL Grade	0.7595	69.54%
I	**Image, Age, Morphokinetics, BL Score**	**0.7614**	**69.68%**
J	Image, Age, Morphokinetics, BL Grade	0.756	69.03%

CONCLUSIONS: The implementation of deep learning image analysis permits a more objective assessment of BLs and, with the addition of oocyte age, morphokinetics, and BL grade or score, improves the model's ability to predict embryo ploidy in a noninvasive manner. CAM results from BL images suggest that the model focuses on the presence and absence of cavitation to predict embryo ploidy at 110 hours.

EMBRYOLOGY LAB-ON-A-CHIP: AUTOMATED OOCYTE DENUDATION MICROFLUIDIC DEVICE. Amir Mokhtare, M.S.,[1] Philip Xie, B.S.,[2] Alireza Abbaspourrad, Ph.D.,[1] Zev Rosenwaks, M.D.,[2] Gianpiero D. Palermo, M.D., Ph.D.[2] [1]Cornell University, Ithaca, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To develop an automated microfluidic device to perform cumulus cell (CC) removal prior to intracytoplasmic sperm injection (ICSI) in a controlled microenvironment aimed at minimizing mechanical stress to the oocytes.

DESIGN: We developed a semi-automated oocyte denudation microfluidic chip (ODMC) modulated by microcontrollers and operated by a graphical user interface (GUI). The device consists of a 2-layer microchannel with a channel width of 200 μm. The bottom layer is etched with bas-relief structures to create chaotic mixing within microchannels. To assess mechanical stress on the oocytes, microfluidic profiles and shear stress present in manual pipetting (MP) and ODMC were quantified by computational fluid dynamics (CFD) simulations. Denudation efficiency was defined as the percentage of complete removal of CCs. ICSI was performed on oocytes processed by ODMC and compared to those obtained from MP to assess the oocyte developmental potential.

MATERIALS AND METHODS: The COCs were retrieved from superovulated B6D2F1 mice and individually dissected. ODMCs were fabricated from polydimethylsiloxane by planar photolithography and installed with inlet and outlet reservoirs that moderated the flow of denudation medium within the system. Individual COCs were loaded in the ODMC and denuded by chaotic mixing created by the bas-relief structures. The GUI visualized the denudation process in real-time and released denuded oocytes at the operator's discretion. Denuded oocytes by MP or ODMC were inseminated by piezo-actuated ICSI. Embryo developmental parameters were assessed in a time-lapse incubator.

RESULTS: Murine COCs were processed by our novel ODMC with optimized geometry and operating parameters including oscillating frequency, flow rate, and density of bas-relief structures. Orchestrated oscillating frequency and flow rate were able to tumble the COCs to allow interaction with bas-relief structures to strip off CC evenly. CFD simulation indicated that the maximum shear stress imposed on COCs was 40% less in ODMC with comparable denudation efficiency being at 95% for ODMC and 91% of MP without oocyte damage. Piezo-actuated ICSI was performed on 50 oocytes processed by MP or ODMC, and yielded comparable post-ICSI survival (82% vs. 84%), fertilization (90% vs. 90%), and blastulation rates (80% vs. 81%), with comparable morphokinetic development.

CONCLUSIONS: This device validated the potential of a fully automated embryology laboratory on a chip for ICSI without compromising oocyte developmental competence. Once the operation parameters are optimized for human gamete manipulation, this device can significantly reduce time and labor while providing optimal quality control and minimizing inter- and intra-operator variability. In conjunction with artificial intelligence, additional modules for different tasks can be fully automated such as maturity recognition, robotic ICSI, and embryo evaluation.

FLUORESCENCE LIFETIME IMAGING MICROSCOPY (FLIM) DETECTS DIFFERENCES IN METABOLIC SIGNATURES BETWEEN EUPLOID AND ANEUPLOID HUMAN BLASTOCYSTS. Jaimin S. Shah, M.D.,[1] Marta Venturas, M.Sc.,[2] Tim H. Sanchez, Ph.D.,[3] Alan S. Penzias, M.D.,[1] Dan Needleman, Ph.D.,[2] Denny Sakkas, PhD[4] [1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [2]Harvard University, Cambridge, MA; [3]None; [4]Boston IVF, Waltham, MA.

OBJECTIVE: To determine whether non-invasive imaging via FLIM can detect metabolic differences in discarded human blastocysts with known ploidy status.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: We studied 150 discarded human blastocysts that had been biopsied and vitrified on day 5 or 6 with Gardner morphology Grade A or B in a University affiliated private IVF laboratory. PGT-A deemed 17 blastocysts as euploid and 133 as aneuploid. A comparison was made between euploid embryos and all aneuploid embryos as a group then by specific chromosomal abnormality (any monosomy/trisomy [n=85], chaotic [n=30], triploidy [n=12], or autosomal monosomy [n=6]). Embryos were warmed, cultured for 2 hours and imaged via FLIM to analyze their metabolic signatures. Embryo metabolic state was assessed using FLIM to measure autofluorescence of NADH and FAD. Eight metabolic parameters were obtained from each blastocyst (4 for NADH and 4 for FAD): short (T_1) and long (T_2) fluorescence lifetime, fluorescence intensity (I), and fraction of the molecule engaged with enzyme (F). The redox ratio (Intensity of NADH)/(Intensity of FAD) was also calculated for each

embryo. Multilevel models were used for analysis with $p < .05$ showing significance.

RESULTS: The mean (± SD) patient ages in years for the euploid and aneuploid groups were 36.4 ± 4.7 and 36.8 ± 3.9, respectively. Our data showed a number of statistically significant metabolic differences when comparing euploid versus aneuploid embryos. Comparing euploid versus all combined aneuploid embryos demonstrated significant metabolic differences in NADH-*F* ($p < .03$) and FAD-*I* ($p < .01$). Furthermore, comparing euploid versus the grouped chromosomal aneuploidies, NADH-*F* ($p < .05$), FAD-*I* ($p < .01$), and redox ratio ($p < .04$) showed significant metabolic differences.

CONCLUSIONS: FLIM has identified significant metabolic differences between euploid and aneuploid embryos. These findings provide preliminary evidence that FLIM may be a useful non-invasive clinical tool. Additional data is required to elucidate the true directional relationship between ploidy status and metabolism. Further studies are planned to determine if metabolic signatures via FLIM can assist in clinical embryo selection.

SUPPORT: Supported by the Blavatnik Biomedical Accelerator Grant at Harvard University. Becker and Hickl GmbH and Boston Electronics sponsored research with the loaning of equipment for FLIM.

O-186 10:55 AM Tuesday, October 20, 2020

IT TAKES TWO TO DOUBLE WITNESS: EVALUATING THE REAL TIME REQUIRED FOR MANUAL VERSUS ELECTRONIC DOUBLE WITNESSING IN THE *IN VITRO* FERTILIZATION (IVF) LABORATORY.

Rebecca Holmes, PhD, HCLD,[1] Kelly A. Wirka, MS, TS (AAB),[2] Brooke Hayward, SM, MBA,[2] Allison B. Catherino, PhD,[2] Jason E. Swain, PhD, HCLD[3] [1]CCRM Boston, Newton, MA; [2]EMD Serono, Inc. (a business of Merck KGaA, Darmstadt, Germany), Rockland, MA; [3]CCRM IVF Network, Lone Tree, CO.

OBJECTIVE: To examine, via head-to-head comparison with manual double witnessing, the impact of an electronic witnessing system (EWS) on double-witnessing procedures in an IVF laboratory, and to assess the time required to double witness procedures, including the interruption time required for the second witness.

DESIGN: Noninterventional, longitudinal study over 3 months.

MATERIALS AND METHODS: Three procedures of varying complexity levels – intracytoplasmic sperm injection (ICSI), Day 3 embryo assessment, and embryo transfer (fresh or frozen) – were double witnessed both manually and electronically during 2 weeks each month. This study was determined exempt from Institutional Review Board review by Western IRB, USA. Five embryologists in a single IVF laboratory double witnessed procedures manually (performer), second witnessed by a second person (witness), and using an EWS (Gidget®, Genea Biomedx, Sydney, AUS). Time was tracked for all sessions, including the interruption time when the second witness was kept away from an initial task. Study procedures occurred over 6 independent weeks, selected *a priori* to capture different workloads and staff availability. To address potential bias, the sequence of witnessing sessions was alternated.

RESULTS: Overall, 76.6% (49/64) of ICSIs, 44.4% (32/72) of embryo assessments, 100% (2/2) of fresh embryo transfers, and 93.9% (31/33) of frozen embryo transfers (FETs) underwent double witnessing manually and using the EWS. Witnessing of 114 procedures, including 342 witnessing times (114 EWS, 114 manual, and 114 interruptions to witnessers), were analyzed. For the performer, EWS reduced the mean (standard deviation) time to witness by 29.7 (38.8) seconds per ICSI, 16.8 (26.5) seconds for Day 3 embryo assessment, 27.0 (19.8) seconds per fresh embryo transfer, and 18.5 (15.0) seconds per FET. Overall, EWS saved the performer 25.3 seconds per procedure compared with manual witnessing ($p<0.0001$; 95% confidence interval –36.70, –13.84). When accounting for the second witness interruption time required for manual double witnessing, EWS reduced the total times (performer's waiting and witnesser's interruption) by 91.5 (23.58) seconds per ICSI, 62.0 (18.86) seconds for Day 3 embryo assessment, 58.3 (18.86) seconds per fresh embryo transfer, and 59.4 (13.31) seconds per FET. The time saved did not differ by embryologist, sequence of double witnessing, or period of data collection, indicating that time savings were independent of workload and staff availability.

CONCLUSIONS: Electronic witnessing can significantly reduce the overall time required for double witnessing by 3.1- to 5.2-fold. For the first time, these data represent a fair comparison between manual double witnessing and an EWS, as they account for the second witness interruption time. An EWS may help to improve laboratory efficiency and workflow by minimizing interruptions, which have long been underestimated in today's complex IVF laboratory practice.

SUPPORT: Study sponsored by EMD Serono, Inc., Rockland, MA, USA (a business of Merck KGaA, Darmstadt, Germany).

ENDOMETRIOSIS

O-187 9:40 AM Tuesday, October 20, 2020

EFFICACY AND SAFETY OF RELUGOLIX COMBINATION THERAPY IN WOMEN WITH ENDOMETRIOSIS-ASSOCIATED PAIN: PHASE 3 RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY (SPIRIT 2).

Sawsan As-Sanie, MD, MPH,[1] Christian M. Becker, MD,[2] Neil Johnson, MD,[3] Bruce Arthur Lessey, MD, PhD,[4] Mauricio S. Abrao, MD,[5] Eric L. Brown, MD,[6] Krzysztof Wilk, MD,[7] Juan Camilo Arjona Ferreira, MD,[8] Vandana Mathur, MD, FASN,[9] Yulan Li, PhD,[8] Qurratul Ann Warsi, MD, MAS,[8] Rachel B. Wagman, MD,[8] Linda C. Giudice, MD, PhD[10] [1]University of Michigan Medical Center, Ann Arbor, MI; [2]University of Oxford, Oxford, United Kingdom; [3]Robinson Research Institute, University of Adelaide, Australia; [4]Wake Forest Baptist Health, NC; [5]Gynecologic Division, BP - A Beneficencia Portuguesa de Sao Paulo, Sao Paulo, Brazil; [6]Medi-Sense, Inc., Atlanta, GA; [7]Boni Fratres Hospital Obstetrics and Gynecology Department Katowice, Katowice, Poland; [8]Myovant Sciences, Inc., Brisbane, CA; [9]MathurConsulting, Woodside, Woodside, CA; [10]University of California, San Francisco, San Francisco, CA.

OBJECTIVE: To evaluate the efficacy and safety of treatment with Relugolix combination therapy (Rel-CT; relugolix 40 mg [an oral gonadotropin-releasing hormone receptor antagonist], estradiol 1 mg, norethindrone acetate 0.5 mg) compared with placebo in women with endometriosis-associated pain. SPIRIT 2 is the first of two identical pivotal phase 3 studies assessing Rel-CT that have been completed.

DESIGN: Multinational, phase 3, randomized, double-blind, placebo-controlled study.

MATERIALS AND METHODS: Premenopausal women (age 18-50 years) with surgically diagnosed endometriosis (EM) and a history of moderate to severe dysmenorrhea (DYS) and non-menstrual pelvic pain (NMPP) were randomized 1:1:1 to 24 weeks of treatment with daily Rel-CT, delayed Rel-CT (relugolix 40 mg monotherapy for 12 weeks followed by Rel-CT for 12 weeks), or placebo. Co-primary endpoints were the comparison between Rel-CT and placebo on the proportion of DYS and NMPP responders at Week 24, based on daily Numerical Rating Scale (NRS) scores (0=no pain, 10=worst pain imaginable). A responder was a woman who achieved a predefined, clinically meaningful reduction from baseline in NRS score (2.8 for DYS and 2.1 for NMPP) with no increase in analgesic use. Secondary endpoints included change from baseline in EHP-30 pain domain scores and opioid use. Safety assessments included adverse events and bone mineral density (BMD) changes by dual-energy X-ray absorptiometry.

RESULTS: A total of 623 patients were randomized and 507 (81%) completed the study. Both co-primary endpoints were met: the proportion of DYS responders was 75.2% with Rel-CT vs 30.4% with placebo, and for NMPP was 66.0% vs 42.6%, respectively (both $p<0.0001$). In the delayed Rel-CT group, the DYS and NMPP responder rates were 72.8% and 52.9%, respectively. At baseline, mean NRS for DYS and NMPP for Rel-CT were 7.2 (severe) and 5.9 (moderate), decreasing to 1.7 (mild) and 2.9 (mild) at Week 24, and equating to 75.1% and 49.2% reduction from baseline in DYS and NMPP, respectively. Patients receiving Rel-CT vs placebo had significant improvements in daily functioning as measured by the EHP-30 pain domain score (–32.2 vs –19.9, $p<0.0001$) and more were opioid-free (82% vs 66.2%, $p<0.0001$) at Week 24. Adverse event incidence was overall comparable between Rel-CT and placebo. Mean percent change from baseline to Week 24 in lumbar spine BMD was –0.78% vs 0.02%, respectively, in the Rel-CT and placebo groups and –1.92% in the delayed Rel-CT group.

CONCLUSIONS: Once-daily oral Rel-CT significantly reduced DYS and NMPP in women with surgically confirmed EM and reduced pain-related functional limitations, while reducing the need for opioids. Rel-CT was associated with minimal BMD loss and was generally well tolerated.

QUINAGOLIDE VAGINAL RING FOR ENDOMETRIOSIS: RESULTS FROM THE CLINICAL PHASE 1 PROGRAM. Yu Bagger, MD, Joan-Carles Arce, MD, PhD. Ferring Pharmaceuticals Copenhagen, Denmark.

OBJECTIVE: To describe the pharmacokinetics (PK) and safety as well as changes in reproductive hormone levels, menstrual cyclicity and endometrial histology of several intravaginal doses of quinagolide, a non-ergot, selective dopamine receptor 2 agonist, being developed for the management of endometriosis.

DESIGN: Analysis of the three clinical phase 1 trials including 134 female healthy volunteers. Trial 1 was randomized, placebo-controlled and single-blind. Trial 2 was randomized, placebo-controlled and double-blind. Trial 3 was randomized and double-blind.

MATERIALS AND METHODS: Trial 1 investigated the PK of quinagolide at a single dose of 25, 50 and 75 μg intravaginal tablets and after repeated dosing (5 days) of 75 μg intravaginal and oral tablets. Trial 2 investigated the PK of quinagolide vaginal rings designed for extended release for up to 35 days with target release rates of 4.5, 9 and 13.5 μg/day. Trial 3 investigated the PK, reproductive hormone levels, menstrual cyclicity and endometrial histology with the use of quinagolide vaginal rings with target release rates of 4.5 and 13.5 μg/day, administered for two consecutive menstrual cycles. Safety was evaluated in all trials.

RESULTS: In Trial 1, intravaginal administration of 75 μg quinagolide tablets for 5 days led to maximum concentration (C_{max}) and area under the curve (AUC) values that were approximately 1.6-fold and 5-fold higher, respectively, than oral administration. Intravaginal administration circumvented first-pass metabolism. Median time to reach maximum concentration (t_{max}) was 8.5 hours with intravaginal versus 0.8 hours for oral administration. In Trial 2, quinagolide vaginal ring administration resulted in a median t_{max} of 36-48 hours across release rates. The plasma concentration of quinagolide initially increased in a dose-proportional manner to peak and then declined; trough levels remained 1-10 pg/mL for all release rates for up to 35 days. In Trial 3, repeated administration of quinagolide vaginal rings for two consecutive menstrual cycles showed consistent C_{max} and AUC between cycles for each release rate and no apparent accumulation. Furthermore, quinagolide vaginal ring had no impact on serum FSH, LH, estradiol and progesterone levels in the early follicular or mid-luteal phases. Ovulation was not affected, with confirmed presence of corpus luteum in 93% of the women after two cycles. There were no changes in menstrual cycle duration (median 25.5-28.0 days), bleeding duration (median 4.0-5.0 days), or mid-luteal phase endometrial histology (all secretory) with quinagolide vaginal ring at any of the release rates. Quinagolide vaginal rings were well tolerated. There was no apparent effect of dose or release rate on the adverse event frequency.

CONCLUSIONS: Intravaginal administration of quinagolide has a higher bioavailability than oral administration. The vaginal rings provide adequate plasma concentrations of quinagolide throughout an entire menstrual cycle lasting up to 35 days. Quinagolide vaginal rings are well tolerated and do not alter reproductive hormone levels, menstrual cyclicity or endometrial histology.

ENDOMETRIOSIS STROMAL CELLS INDUCE BONE MARROW MESENCHYMAL STEM CELLS DIFFERENTIATION AND PD-1 EXPRESSION THROUGH PARACRINE SIGNALING. Ramanaiah Mamillapalli, PhD, Chen Peng, MD, PhD, Shutaro Habata, MD, PhD, Hugh S. Taylor, M.D. Yale University School of Medicine, New Haven, CT.

OBJECTIVE: Endometriosis is an estrogen-dependent, inflammatory disorder characterized by the growth of endometrial cells as lesions outside the uterus. Bone marrow-derived cells (BMDCs) engraft into these lesions and promote their growth. The interactions between BMDCs and resident cells in lesions are still poorly characterized. Specifically, the ability of endometrial stromal cells to induce specific cell-type differentiation of BMDCs has not been investigated. Here we investigate the role of paracrine communication in BMDC differentiation.

DESIGN: Endometrial biopsies were collected from 20 women with and 15 without endometriosis identified by laparoscopy and histologically verified; stromal cells were isolated and cultured. BMDCs were co-culturing with stromal cells to determine if endometrial cells from endometriosis affected BMDC differentiation. A murine model of endometriosis was created and the lesions were collected after 12 weeks. Western blot, qRT-PCR and immunochemical techniques were performed to measure the gene and protein expression.

MATERIALS AND METHODS: Primary endometrial stromal cells were cultured from endometrial biopsies and used for co-culture experiments with BMDCs. Total RNA and protein were extracted from cell cultures using Trizol reagent and used for qRT-PCR and western blot to analyze the gene and protein expression, respectively. Endometriosis was induced in 9-week-old female C57BL/6 mice by suturing donor uterine sections to the walls of the peritoneal cavity. A Sham control group was also created using no uterine tissue. After 12 weeks, all mice were euthanized and lesions were collected. Tissue sections from lesions were subjected to immunochemical studies for localization of T-cells as well as BMDCs that express PD-1.

RESULTS: *In-vitro* studies demonstrated that both mRNA and protein levels of vimentin (stromal cell marker), cytokeratin (epithelial cell marker) and *PD-1* (T-cell marker) were significantly increased in BMDCs co-cultured with primary stromal cells from endometriosis (ENDO) patients compared to stromal cells from normal endometrium (CNTL). Significant increases in mRNA expression for all three markers (3, 7 and 2.5 fold, respectively; $p<0.05$) were observed after 1, 3 and 6 days of co-cultures. In our *in vivo* endometriosis model we confirmed the localization of T-cells in endometriotic lesions using IHC. A 15 fold increase of PD-1 protein levels in lesions was confirmed in GFP BMDCs engrafted into endometriotic lesions. The number of GFP labeled cells that are engrafted into lesions as well as the number of BMDCs that express PD-1 were significantly higher ($p<0.05$) in endometriosis compared to controls.

CONCLUSIONS: In endometriosis local paracrine factors promote BMDCs cell differentiation into stromal, epithelial cells and immune cells. Further, stromal cells from endometriosis specifically lead to upregulation of PD-1 in bone marrow derived T-cells engrafted into endometriotic lesions, potentially suppressing immune mediated endometriosis rejection. Therapeutics to target and inhibit PD-1 may be helpful in treating endometriosis.

ESTRADIOL IS ASSOCIATED WITH DECREASED CARDIOVASCULAR RISK COMPARED TO ETHINYLESTRADIOL WHEN CONTAINED IN COMBINED HORMONAL PREPARATIONS: IMPLICATIONS FOR THE DEVELOPMENT OF NEW ENDOMETRIOSIS THERAPIES. Sophia von Stockum, PhD, Clare Barnett, MBBS (Hons), MPH, Anja Bauerfeind, PhD, Klaas Heinemann, MD, PhD, MBA. ZEG Berlin GmbH Berlin, Germany.

OBJECTIVE: Combined estrogen-progestin preparations have a long history in women's health and are currently used for multiple indications, including the treatment of endometriosis-related symptoms. Empirically, estradiol (E2) and its ester, estradiol valerate (E2Val) carry a reduced cardiovascular risk due to their reduced impact on the hepatic system compared to the most-widely used estrogen ethinylestradiol (EE). However, robust comparative studies in pre-menopausal women are limited. A new hormonal product containing E2 in combination with the progestin norethindrone acetate (NETA) and the gonadotropin-releasing hormone receptor antagonist, relugolix, has been developed for the treatment of uterine fibroids and endometriosis. This analysis tries to quantify the cardiovascular risk of E2/E2Val-NETA in pre-menopausal women.

DESIGN: A pooled analysis of four large cohort studies assessing the risk of cardiovascular events in users of combined oral contraceptives (COCs).

MATERIALS AND METHODS: Data regarding users of COCs containing either E2/E2Val or EE$\leq$30μg were retrieved from four large prospective, controlled, observational, cohort studies in 14 European countries, US and Canada. Baseline characteristics, including reproductive, contraceptive and medical history, were summarized using descriptive statistics. Propensity score sub-classification was applied to balance baseline parameters between cohorts and time-to-event analysis of venous and arterial thromboembolic events was carried out based on the extended Cox model to calculate crude and adjusted hazard ratios (HR) including 95%-confidence intervals (CI).

RESULTS: The analysis was based on 210,000 women, who contributed 470,000 women years of exposure. The observed prevalence of prognostic factors at baseline showed typical features of US and European COC users. However, the mean age in the E2/E2Val cohort was higher compared to the EE $\leq 30\mu g$ cohort (31.7 years $\pm$9.76 and 26.1 years $\pm$7.89, respectively). A time-to-event analysis of the VTE data was carried out based on the extended Cox model. Validity of the model was demonstrated by the standardized differences summarized over strata as weighted average yielded upon PS subclassification, which were consistently <0.25 and mostly <0.1. A comparison between cohorts showed a decreased risk of venous thromboembolism in users of COCs containing E2/E2Val vs users of COCs containing EE $\leq 30\mu g$; adjusted hazard ratio: 0.49 (95% CI, 0.28-0.84). A risk reduction in the E2/E2Val cohort was also observed with regards to arterial thromboembolic events; adjusted hazard ratio: 0.26 (95% CI, 0.08-0.83).

CONCLUSIONS: Data presents a solid safety assessment of combined hormonal preparations in over 200,000 pre-menopausal women and shows a decreased cardiovascular risk of E2/E2Val when compared to low-dose EE. This provides reassurance for current users of E2/E2Val-containing COCs and opens new perspectives for the development of safe and effective endometriosis treatments, such as the recently developed product containing E2/NETA, in combination with relugolix.

SUPPORT: This analysis was supported by a grant from Myovant Sciences. Dataset is owned by ZEG Berlin GmbH.

HOW SHOULD WE MANAGE WOMEN WITH MILD, MODERATE, AND SEVERE ENDOMETRIOSIS IN LIGHT OF UNCERTAINTY ABOUT THE EFFECTIVENESS AND SAFETY OF LAPAROSCOPIC SURGERY? A COCHRANE REVIEW UPDATE TO INFORM FUTURE DEBATE AND CLINICAL PRACTICE.

Celine Bafort, MD,[1] Yusuf Beebeejaun, MRCOG MHDL MBBS BSc(Hons),[2] Carla Tomassetti, MD, PhD,[1] Jan Bosteels, MD, PhD,[3] James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons)[4] [1]University Hospitals Leuven, Leuven, Belgium; [2]King's College London, London, United Kingdom; [3]Imeldalaan, Bonheiden, Belgium; [4]Institute for Women's Health, University College London, Greater London, United Kingdom.

OBJECTIVE: Limited evidence regarding the surgical management of mild, moderate, and severe endometriosis is driving the substantial variation in clinical practice and differences in patient outcomes. We prepared a Cochrane review evaluating the effectiveness and safety of laparoscopic surgery for endometriosis.

DESIGN: Cochrane systematic review informing the development of clinical practice and research recommendations.

MATERIALS AND METHODS: Randomised trials evaluating laparoscopic surgery for endometriosis were included. Selection of studies, assessment of trial quality, and extraction of relevant data were performed independently by two researchers. We calculated the summary estimates and 95% confidence intervals using a random effects model.

RESULTS: Fourteen randomised trials, reporting data from 1381 women with endometriosis, were included. Laparoscopic surgery improved pregnancy rates when compared with diagnostic laparoscopy (OR 1.91; 95% CI 1.24, 2.95). Laparoscopic surgery improved overall pain, measured 12 months following surgery, when compared with diagnostic laparoscopy (MD 1.65; 95% CI 1.11, 2.19). There was no difference in reported adverse events (OR 0.95; 95% CI 0.06, 16.31). When comparing laparoscopic ablation with laparoscopic excision there was poor reporting of outcome data. When comparing conservative laparoscopic surgery with radical laparoscopic surgery in women with deep endometriosis infiltrating the rectum there was no difference in reported quality of life. Radical laparoscopic surgery was associated with more adverse events, including rectal lumen stenosis (OR 0.09; 95% CI 0.00, 1.79).

CONCLUSIONS: Laparoscopic surgery should be routinely offered to women with mild to moderate endometriosis. There is uncertainty regarding the most appropriate laparoscopic method to excise or destroy endometriotic deposits. Further research is required to evaluate the role of laparoscopic surgery in the management of severe endometriosis. Clinicians, professional societies, and patient advocacy groups should champion the routine access to laparoscopic surgery for women with mild to moderate endometriosis.

O-192 10:55 AM Tuesday, October 20, 2020

INCREASED CELLULAR SENESCENCE IN DEEP INFILTRATING ENDOMETRIOSIS.

Helena Malvezzi, MSc,[1] Camila Hernandes, PhD,[1] Bruna C. de Azevedo, PhD,[1] Carla A. Piccinato, PhD,[1] Juliana Meola, PhD,[2] Sérgio Podgaec, M.D. PhD.[1] [1]Albert Einstein Hospital, São Paulo, Brazil; [2]Universidade de São Paulo, Ribeirão Preto, Brazil.

OBJECTIVE: Endometriosis is characterized by increased inflammatory process and to be apoptosis resistant. Senescence cells are apoptosis resistant and present the senescence associated secretory phenotype (SASP). Cellular senescence is an irreversible suspension of cell proliferation process, responsible for controlling tissue growth. In endometriosis, senescence cells would be regulating cell cycle block which would favor disease maintenance and progression.

DESIGN: A cross-sectional study with biopsies of deep infiltrating endometriotic lesions and ectopic endometrium from women with (n=27) and control endometrium from women without endometriosis (n=19) in both cycle phase (secretory and proliferative).

MATERIALS AND METHODS: Biopsy tissues were prepared for senescence markers (p16 and Lamin b1) detection using immunohistochemistry technique followed by histometry to calculate antibody positive areas in the tissue. For tissue IL-17A detection, multiplex assay was used. Wilcoxon test was used for pared samples and gamma generalized linear models to evaluate groups relationship. Alfa lower than 0.05 was considered significant.

RESULTS: Deep infiltrating lesion from secretory and proliferative phase had 4.4 ($p<0.001$) and 2.82 ($p<0.001$) times more p16 expression than secretory eutopic endometrium. Also, proliferative eutopic endometrium had 3.05 ($p<0.002$) times more p16 expression than secretory eutopic endometrium. Although no difference between cycle phases was detected, lesions had less lamin b1 expression compared to eutopic endometrium ($p=0.016$). Higher concentration of IL-17A was found in the proliferative phase of the lesions ($p=0.014$) compared to proliferative eutopic endometrium and in the secretory phase of the eutopic endometrium ($p=0.014$) compared to control endometrium. IL-17A increases p16 expression in 1.04 times ($p=0.029$).

CONCLUSIONS: Deep infiltrating lesions presents more senescence markers than eutopic endometrium, as the increase in p16 expression and the depletion in lamin b1 expression. The p16 protein plays a critical role in regulating cell senescence, being a potent inhibitor of cell proliferation and lamin b1 is associated with maintaining the structure of the nuclear membrane during cell cycle processes. Our results suggest that IL-17A increases p16 expression and as there were more IL-17A and p16 in lesions compared to eutopic endometrium, we believe that IL-17A could be favoring p16 expression in deep infiltrating lesions and thus maintaining an inflammatory and senescent environment. This environment, in addition to providing a basal state of inflammation, may be causing more cells to enter senescence, favoring disease maintenance.

COPY NUMBER LOSSES IN SPECIFIC REGIONS OF COMMON VARIATION ARE SIGNIFICANTLY MORE PREVALENT IN INFERTILITY PATIENTS COMPARED WITH A POPULATION OF DEMONSTRATED FERTILITY AND LOW FETAL WASTAGE.

Edward Robert Wassman, Jr., MD,[1] Rakesh Chettier, MS,[2] Lesa M. Nelson, BS,[1] Moises A. Serrano, PhD, DABMGG,[1] Dane Zdunich, BS,[1] Kenneth Ward, MD[2] [1]Predictive Laboratories, Salt Lake City, UT; [2]Juneau Biosciences, LLC, Salt Lake City, UT.

OBJECTIVE: Chromosomal microarray analysis (CMA) is a valuable standard of care for assessment of individuals with developmental disabilities and other pathological states. However, interpretation of incident copy number variants (CNV) is highly dependent upon use of prevalence data from "normal" populations. Infertility which is present in up to 15% of any population is known to be genetically heterogeneous, however such patients would typically appear in CNV databases in the "normal" population and relevant findings may go unsuspected.

DESIGN: We performed bioinformatic analysis of the variation observed in 539 consecutive women receiving services at a major US Infertility practice for the presence of potentially relevant CNV relating to their underlying condition or unsuspected genetic risks. We compared these to a population of 79 women with exceptional fertility (grand multiparas) as demonstrated by 5 or more uncomplicated term deliveries with no clinically apparent reproductive losses.

MATERIALS AND METHODS: CNV were assessed with an FDA approved CMA (Affymetrix, CytoscanDX). CNV association analysis of the entire databases of CNV segments in the "infertile" and "grand multipara" cohorts was undertaken with ParseCNV program (http://parsecnv.sourceforge.net/).

RESULTS: A typically wide range of CNV and runs of homozygosity (ROH) was observed, with many overlapping known common regions of variation and the majority predicted to be likely benign. Potential impactful rare gene findings have been reported elsewhere, including two well described recurrent pathogenic CNV observed in 3 patients each, and an appreciable number of deletions encompassing all or part of genes for known over 40 autosomal recessive conditions suggesting CNV analysis would add positively to expanded carrier screening programs.

A striking presence of genomic deletions in three regions in the "infertile" cohort (6-18%), none of which were observed in any of the "grand multiparas" (p value range: 0.02-$\leq$0.000005) We used one-sided Fisher's exact test to test for enrichment of either deletion or duplication CNVs between the "infertile" case subjects and the comparison individuals. These differential CNVs all occurred in regions of common well-known CNV of gene families on chromosomes (chr) 7, 14, and 11 (typically 12-40% prevalence range for regions; Database of Genomic Variants [DGV]; http://dgv.tcag.ca/). There was no difference in the relative occurrence of any duplications or ROH.

CONCLUSIONS: Deletions significantly differential in prevalence between these groups were observed in several regions of very common known CNV, which may have plausible link to key theories on reproductive success and evolution. The variants observed on the first two regions (chr7 & 14) involved variant transcripts of the T-cell receptor-g and -a respectively. On chromosome 11 the deletions involved the 52N1 and 52N5 families of olfactory receptor genes. Both the immune response and olfactory perceptions have been suggested to be involved with the evolution of eutherian mammalian reproduction and fertility in humans.

INFERTILITY AND RISK OF PREMATURE MORTALITY: A PROSPECTIVE COHORT STUDY.

Yixin Wang, MD,[1] Leslie V. Farland, Sc.D.,[2] Stacey A. Missmer, ScD,[3] Janet Rich-Edwards, PhD,[4] Audrey J. Gaskins, ScD,[5] Jorge E. Chavarro, MD, Sc.D.[1] [1]Harvard T.H. Chan School of Public Health, Boston, MA; [2]University of Arizona, Tucson, AZ; [3]College of Human Medicine, Michigan State University, Grand Rapids, MI; [4]Brigham and Women's Hospital, Boston, MA; [5]Emory University, Rollins School of Public Health, Atlanta, GA.

OBJECTIVE: To prospectively investigate the association between infertility and risk of premature mortality (before age 70 years).

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: We followed 103,748 women participating in the Nurses' Health Study II who attempted conception and who were free of cardiovascular disease (CVD), type 2 diabetes, and cancer at enrollment in 1989. Biennial questionnaires updated information on infertility status (defined as attempting conception for at least 12 months), pregnancies, lifestyle characteristics, and several health-related outcomes. Hazard ratios (HR) and 95% confidence intervals (CI) for the associations of infertility and underlying reasons for infertility with the risk of premature mortality were estimated using Cox proportional hazards models, adjusting for race/ethnicity, and time-varying age, body mass index, oral contraceptive use, hormone replacement use, aspirin use, family history of CVD, cigarette smoking status, physical activity, and diet quality.

RESULTS: During 28 years of follow-up, 32,464 women (31%) reported infertility and 2,327 women died before age 70, including 1,065 deaths caused by cancer and 211 by CVD. Women who experienced infertility were 20% (95% CI: 10%, 31%) more likely to die prematurely from any cause during follow-up than women who never reported infertility. This relation was largely driven by deaths from cancer (HR, 1.19; 95% CI: 1.05, 1.35). The association between infertility and all-cause mortality was stronger among women who first experienced infertility early in their reproductive life. The HR (95% CI) for all-cause mortality for women first experiencing infertility before age 26y, between ages 26 and 30y, and after age 30y were, respectively, 1.21 (1.07, 1.37), 1.19 (1.07, 1.32), and 1.08 (0.91, 1.28).

CONCLUSIONS: Our findings suggest that a history of infertility may be associated with a greater risk of premature mortality, particularly among women first experiencing infertility before age 30y. Future research is needed to confirm these novel finding.

O-195 10:10 AM Tuesday, October 20, 2020

EVALUATING THE RISK OF UNEXPLAINED INFERTILITY IN WOMEN WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS.

Yael Klionsky, MD,[1] Alexander Kotlyar, MD,[2] Hugh S. Taylor, M.D.[3] [1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Yale School of Medicine, Oange, CT; [3]Yale University School of Medicine, New Haven, CT.

OBJECTIVE: The presence of infertility among women with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) remains unclear. To date, there have been no large-scale studies assessing this risk. Using a large population database, our primary objective was to examine if the risk of unexplained infertility in women of reproductive age with RA and SLE is different compared to women without these diseases. A subgroup analysis sought to assess the effects of age, ethnicity, and insurance status on this risk.

DESIGN: Cross-sectional analysis of a large healthcare database

MATERIALS AND METHODS: This study used Explorys, Inc (IBM Watson Health) a large population health database which aggregates de-identified patient data from a variety of electronic health records in multiple health systems across the United States. As such, this work is IRB exempt. This is a cross-sectional analysis that utilized data in excess of 72 million patients from the Explorys, Inc database as of February 12, 2020. We used this platform to collect data points such demographic information, diagnostic codes, laboratory studies, and drug prescriptions. Only women with unexplained infertility were included in this analysis. We identified women between 18 and 45 years of age with a diagnosis of infertility and a diagnosis of RA or SLE. A control group of women with infertility and without RA or SLE were included for comparison. Chi-squared test was used for categorical variables with $p<0.05$ being considered significant.

RESULTS: The distribution of patients for both diseases is outlined in table 1. Women with a diagnosis of RA were noted to have a higher risk of unexplained infertility ($p<0.0001$, OR 2.7, 95% CI of 2.5-3.0). Women with a diagnosis of SLE were also noted to have a higher risk of unexplained infertility ($p<0.0001$, OR 2.1, 95% CI of 1.8-2.3). Subgroup analysis indicated Asian women with RA did not have an increased risk of infertility. The presence of RA was associated with a higher risk of unexplained infertility for all other age, insurance, and ethnicity groups. SLE was associated with a higher risk for unexplained infertility for all subgroups.

TABLE 1.

	Infertility Present (n)	Infertility Absent (n)
RA	440	47750
No RA	41350	12311690
	Infertility Present (n)	Infertility Absent (n)
SLE	347	48700
No SLE	42330	12489710

CONCLUSIONS: Women with a diagnosis of RA or SLE have a higher risk of unexplained infertility compared to women who did not have RA or SLE. Future studies will elucidate the mitigating effects of ethnicity among RA patients and insurance status among SLE patients.

SUPPORT: None

O-196 10:25 AM Tuesday, October 20, 2020

CHARACTERIZATION OF PITUITARY AND OVARIAN HORMONE CONCENTRATIONS DURING TREATMENT WITH RELUGOLIX COMBINATION THERAPY.

Ingrid Duijkers, MD, PhD,[1] Elizabeth M. Migoya, Pharm D,[2] Juan Camilo Arjona Ferreira, MD,[3] Christine Klipping, MD, PhD[4] [1]dinox consultancy bv, Groningen, Netherlands; [2]Myovant Sciences Inc., Brisbane, CA; [3]Chief Medical Officer, Brisbane, CA; [4]Dinox BV, Berlin, Germany.

OBJECTIVE: To characterize the effects of Relugolix combination therapy (Rel-CT; relugolix 40 mg, estradiol [E2] 1 mg, norethindrone acetate 0.5 mg) on pituitary (luteinizing hormone [LH] and follicle-stimulating hormone [FSH]) and ovarian (E2 and progesterone [P]) hormone concentrations, follicular growth, and endometrial thickness.

DESIGN: An open-label, single-cohort study. Healthy, premenopausal, ovulatory women (n=70) received oral administration of Rel-CT once daily for 84 days.

MATERIALS AND METHODS: Blood samples for determination of LH, FSH, E2 and P serum concentrations were collected every 3 (±1) days during the treatment and post-treatment periods. LH, FSH and P were quantified using a validated, enzyme-linked immunosorbent assay. E2 serum concentrations were quantified using a validated liquid chromatography-tandem mass spectrometry method. The size of the dominant follicle and endometrial thickness were measured by transvaginal ultrasound performed every 3 (±1) days during the treatment and post-treatment periods.

RESULTS: Relugolix, an orally active, potent, non-peptide gonadotropin-releasing hormone (GnRH) receptor antagonist, blocks endogenous GnRH from binding to GnRH receptors, preventing the release of LH and FSH from the anterior pituitary gland. Reduction in FSH minimizes follicular growth and development, with consequently lower production of E2. In the absence of an LH surge, and ovulation, the corpus luteum does not develop, resulting in decreased production of P. In the current study, during treatment with Rel-CT, mean LH concentrations were below 1.0 U/L, and FSH concentrations were suppressed, being maintained between 2 and 3 U/L, with an absence of pre-ovulatory peaks. Follicular growth was diminished, with a mean dominant follicle size consistently at approximately 6 mm. Mean (median) E2 concentrations were maintained between 32.6 and 44.5 pg/mL (30.6 and 40.1 pg/mL), comparable to concentrations in the early follicular phase of the menstrual cycle, as a result of profound suppression of ovarian E2 production and exogenous administration of E2 as part of Rel-CT. Endometrial proliferation was markedly suppressed, with mean endometrial thickness between 4 and 5 mm. Mean P concentrations remained between 1 and 1.3 nmol/L, with individual concentrations below 5 nmol/L (corresponding to 1.57 ng/mL), reflecting an absence of luteal activity. Over 84 days, Rel-CT inhibited ovulation in 100% of women.

CONCLUSIONS: Rel-CT consistently suppressed pituitary and ovarian hormone concentrations, follicular growth and endometrial thickness. The reduction in systemic E2 and progesterone concentrations is expected to minimize hormone-induced growth and proliferation of uterine fibroids and endometriosis lesions, resulting in an improvement of disease-related symptoms without adverse consequences related to a hypoestrogenic state.

CELL-LEVEL EXPRESSION OF SARS-COV-2 CELL ENTRY FACTORS IN HUMAN ENDOMETRIUM DURING THE PRECONCEPTION PERIOD.

Felipe Vilella, PhD,[1] Wanxin Wang, PhD,[2] Inmaculada Moreno, PhD,[3] Stephen R. Quake, DPhil,[4] Carlos Simon, MD, PhD[5] [1]Igenomix Foundation/INCLIVA, Valencia, Spain, Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Paterna, Spain; [2]Stanford University, Stanford, CA; [3]Igenomix Foundation / INCLIVA, Valencia, Paterna, Spain; [4]Chan Zuckerberg Biohub, San Francisco, CA; [5]Igenomix Foundation, INCLIVA, Valencia, Spain, Department of Obstetrics and Gynecology, Valencia University, valencia, Spain, Department of Obstetrics and Gynecology, BIDMC, Harvard University, Boston, MA- USA Boston, U.S.A., Valencia, Spain.

OBJECTIVE: ACE2 enzyme serves as SARS-CoV-2 human receptor through binding of the viral S protein and subsequent trimming of S protein between S1 and S2 units by host serine proteases as TMPRSS2, CTSB or CTSL. Here, we aim to investigate the expression of the different cell entry proteins involved in SARS-CoV-2 infection in the different cell types of the human endometrium throughout the menstrual cycle using single-cell RNA-seq (scRNAseq).

DESIGN: Gene expression patterns for SARS-CoV-2 entry molecules were analyzed by scRNAseq in a total of 73,181 endometrial single cells obtained from endometrial biopsies from 19 reproductive-age women across the full menstrual cycle (Fluidigm C1: 2,149 cells) and 10 women from the same cohort (10x: 71,032 cells). For two women, both C1 and 10x data were collected as anchors for comparison.

MATERIALS AND METHODS: After tissue dissociation, single cell capture was performed on Fluidigm C1 system (n= 2,149 cells) or Chromium 10x system (Chromium Next GEM Chip G, 10x Genomics) (n= 71,032 cells) followed by reverse-transcription, cDNA generation and library construction. Barcoded libraries were sequenced in pair-end reads on Nextseq (Illumina) for the C1 dataset or Novaseq (Illumina) for the 10x dataset . Data pre-processing, quality filtering, and statistical analyses were performed using custom Python, R, and Java scripts.

RESULTS: Expression analysis across the menstrual cycle showed no significant expression of *ACE2* in stromal or unciliated epithelial cells in any cycle phase. *TMPRSS2* was expressed more highly in glandular epithelial cells during the early proliferative phase and towards the end of the cycle. Interestingly, expression of *CTSB* and *CTSL* was observed in both stromal and epithelial cells across all phases of the menstrual cycle, with *CTSB* the more abundant of the two. All four genes were simultaneously expressed in less than 0.7% of glandular epithelial cells.

Expression analysis during the secretory phase did not detect significant expression of *ACE2* (less than 2% of epithelial or stromal cells). *TMPRSS2* showed mild expression in about 12% of unciliated epithelial cells. In contrast, *CTSB* and *CTSL*were highly expressed in ∼80% and ∼40% of cells during the mid-late secretory phase, aligning with what we detected via Fluidigm. In addition, while *CTSB* was highly expressed in both epithelial and stromal cells, *CTSL* was more highly expressed in stromal cells across the menstrual cycle.

CONCLUSIONS: Percentages of endometrial cells expressing *ACE2, TMPRSS2, CTSB,* or *CTSL* were <2%, ∼12%, ∼80%, and ∼40%, respectively, with <0.7% of cells expressing all four. This finding implies low efficiency of SARS-CoV-2 infection in the endometrium before embryo implantation, providing information to assess preconception endometrial infection risk in COVID-19 asymptomatic carriers.

O-198 10:55 AM Tuesday, October 20, 2020

HIGH PREVALENCE OF MEASLES NON-IMMUNITY IN REPRODUCTIVE AGE WOMEN.

Claire M. Smith, MSN, RN,[1] Sedona Speedy, MD,[2] Christina E. Boots, MD, MSCI[3] [1]Northwestern Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: To determine if the percentage of reproductive age women who are immune to measles is at or above the level required for herd immunity (95%) and to evaluate the patient characteristics and demographics that correlate with measles non-immunity.

DESIGN: Retrospective case control.

MATERIALS AND METHODS: A retrospective chart review of women seeking preconception and fertility care who underwent serum testing for measles, rubella, and/or varicella immunity between March 1, 2018 and May 1, 2020 were included in the analysis. Serum tests resulted as either immune, non-immune, or equivocal, as determined by serum IgG titer levels for the respective diseases. Women with equivocal results underwent further testing to quantitate titers and determine immunity. Equivocal results that did not have follow up testing were excluded from the final analysis. Clinical characteristics were collected on the women including age, BMI, parity, race, and ethnicity. Students t test and chi square tests were used for continuous and categorical outcomes. Multivariable logistic regression was performed to control for confounding. A post hoc power analysis was performed.

RESULTS: 3,255 women were included in the study. Of the 1,396 women tested for measles antibodies (n=1396), 20.1% were considered non-immune

and 79.9% were immune. Of the 2,654 women tested for rubella antibodies, only 3.5% were non-immune, while 93.7% were immune and 2.8% were equivocal. Of those tested for varicella (n=3023), 7.5% were non-immune, 89.2% were immune and 3.2% were equivocal. Women who were considered non-immune to measles were younger and had a higher body mass index (BMI) after adjusting for confounders. More specifically, women born after 1984 and obese women were more likely to be measles non-immune.

	Immune	Non-Immune	P-Value
Age (mean years +- SD)	35.5 ± 4.31	34.9 ± 4.49	0.035
Birth Year <1985	82.4% (n=612)	17.6% (n=131)	0.016
Birth Year >/=1985	77.2% (n=504)	22.8% (n=149)	
BMI (mean kg/m^2 +- SD)	26.4 ± 6.59	27.7 ± 7.28	0.009
Non-obese (BMI <30)	81.1% (n=215)	18.9% (n=71)	0.028
Obese (BMI >/=30)	75.2% (n=976)	24.8% (n=248)	

CONCLUSIONS: Among women seeking preconception and fertility care, the seroprevalence of measles immunity is only 79.9%, which is significantly lower than that required for herd immunity (95%). Interestingly, low IgG titers for measles are associated with a younger age and higher BMI. Additional testing to correlate IgG titers with clinical immunity needs to be performed. In the meantime, and given this high prevalence, measles immunity should be included in the preconception evaluation.

FERTILITY PRESERVATION

O-199 9:40 AM Tuesday, October 20, 2020

MAJORITY OF WOMEN UNDERGOING ELECTIVE OOCYTE CRYOPRESERVATION DO NOT ATTAIN OPTIMAL NUMBER OF OOCYTES CRYOPRESERVED FOR REASONABLE LIKELIHOOD OF FUTURE LIVE BIRTH. Amy Wijekoon, MD, Heather G. Huddleston, MD, Marcelle I. Cedars, MD, Eleni Greenwood Jaswa, MD, MSc. University of California San Francisco San Francisco, CA.

OBJECTIVE: This study aimed to evaluate the frequency with which women undergoing planned oocyte cryopreservation (OC) ultimately banked an optimal quantity of eggs.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Subjects included 999 women undergoing planned OC between January 2012 and February 2020. The primary outcome of optimal number of oocytes cryopreserved (OOC) was defined as ≥80% probability of at least one live birth (LB) using a published model accounting for age (Goldman et al., 2017). Baseline factors were compared between those with and without OOC using Student's t-test, Mann-Whitney U-test, and Chi squared test as appropriate. Logistic regression modeling identified predictors for achieving OOC, controlling for age, race, antral follicle count (AFC), anti-mullerian hormone (AMH), insurance status, and total cycles.

RESULTS: 415 women undergoing planned OC (42%) achieved OOC after an average of 1.5 cycles. The majority of women ≤35 years achieved OOC (63%); however, few women ages 39-40 years, and no women ≥41 years, achieved OOC (Table 1). Based on median oocytes frozen, the majority of women ≤38 years achieved >50% probability of at least one LB; however, at >38 years, women achieved much lower chances of LB (Table 1). Average age (34 v 37 years, p<0.001), AFC (12 v 7, p<0.01), AMH (3.1 v 1.5 ng/mL, p<0.01), and total number of cycles (1.5 v 1.4, p=0.01) differed between the cohorts that did and did not achieve OOC, respectively. In the multivariate logistic regression, age (aOR 0.69, p<0.001), AFC (aOR 1.05, p<0.01), AMH (aOR 1.50, p<0.01), total number of cycles (aOR 2.15, p<0.01), and Asian (aOR 0.54, p=0.01) or other non-White (aOR 0.60, p=0.02) race were independent predictors of the primary outcome. Insurance coverage was not associated with odds of achieving OOC.

CONCLUSIONS: The majority of women (58%) who undergo planned OC do not bank sufficient eggs to yield an 80% chance of LB. Ovarian reserve markers and age predicted failure to achieve OOC and should be weighed when counseling. Asian/other non-white races had lower adjusted odds of achieving OOC compared to white race patients. Future studies should investigate the cause of these racial differences in planned OC outcomes.

TABLE 1. Cycle outcomes by age group

	Age (years) at first planned OC								
	≤35	36	37	38	39	40	41	42	≥43

PLANNED OOCYTE CYROPRESERVATION – 10-15 YEAR FOLLOW-UP: RETURN RATES AND CYCLE OUTCOMES. Jennifer K. Blakemore, MD,[1] James A. Grifo, MD, PhD,[2] Shannon Devore, MD,[1] Brooke Hodes-Wertz, MD, MPH,[3] Alan S. Berkeley, MD[4] [1]NYU Langone School of Medicine, New York, NY; [2]NYU Langone Prelude Fertility Center, New York, NY; [3]NYU Langone Prelude Fertility Center, New York, NJ; [4]New York University School of Medicine, New York, NY.

OBJECTIVE: Planned oocyte cryopreservation (POC) has increased exponentially since the experimental label on egg freezing was lifted in 2012[1]. Given the relatively recent change, many questions remain concerning long term oocyte utilization. Our objective was to evaluate the outcomes of POC patients most likely to have a final disposition.

DESIGN: Retrospective cohort study of all patients who underwent at least one cycle of POC between 1/2005 and 12/2009.

MATERIALS AND METHODS: All patients who underwent POC in the study time-period were reviewed. Patients who 1) only had a POC consult, 2) started a cycle but did not get retrieved or 3) underwent OC for medical indications were excluded. Primary outcome was disposition of oocytes at 10-15 years. Secondary outcomes included thaw types, lab outcomes and live-birth (LB) rates. **Outcomes/variables treated per patient.**

RESULTS: 231 pts with 280 cycles were included. The mean age at 1st retrieval was 38.2 years (range 23-45), with 90% of patients between of 35-42 years. Utilization of POC consistently increased over the 5 years. A total of 3250 oocytes were retrieved, with an average of 10 M2/retrieval. To date, 88 patients (38.1%) have thawed their oocytes, 109 (47.2%) remain in storage, 27 (11.7%) discarded and 7 (3.0%) transported elsewhere. The return rate (patients who thawed oocytes) was similar by SART age group: 40.0% in <35, 44.1% in 35-37, 36.3% in 38-40, 33.3% in 41-42, and 25.0% in >42 year olds. The mean age of discarding oocytes was 47.4 years (range 40-57) with rates by SART age group: 6.7% in <35, 8.8% in 35-37, 12.4% in 38-40, 14.8% in 41-42, and 25.0% in >42 years old. Rates of continued storage were also similar by SART age group: 46.7% in >35, 44.1% in 35-37, 48.7% in 38-40, 48.2% in 41-42, and 50.0% in >42 year olds. Of the 88 patients who thawed oocytes, the mean age at time of thaw was 43.9 years (range 38-50) with mean of 5.9 years frozen (range 1-12). 9 patients (10.2%) thawed for secondary infertility. 62.5% of patients created embryos with a partner, 37.5% with donor sperm. On average, 14.3 oocytes were thawed/patient, with 74.2% survival (range 0-100%) and an mean fertilization rate of 68.8% of surviving oocytes. 39/88 patients (44.3%)

planned a fresh transfer (ET). 36/39 had at least 1 embryo for fresh ET and 11 patients had a total of 14 babies. 49/88 patients (55.7%) planned for PGT-A with a mean of 4.2 embryos biopsied (range 0-14) and euploidy rate of 28.9%. 17 patients (34.7%) had all aneuploidy or no embryos biopsied. 24 patients underwent a total of 36 single euploid ET with 18 LBs from 16 patients. Notably, 8 PGT-A patients have a euploid embryo but no ET yet which will affect the future cumulative pregnancy rate. Overall, 80 thaw patients had a final outcome: 20 had nothing for ET (arrested/aneuploid); of the 60 who had at least one ET, 27 had a total of 32 babies - for a LB rate of 33.8%.

CONCLUSIONS: This is the first study to report actual final outcomes useful for patient counseling: a utilization rate of 38.1% and a "no use" rate of 58.9% similar across age groups. Further studies with larger cohorts are needed. Whether newer patients are epidemiologically the same as this cohort remains to be seen.

PREDICTING THE PROBABILITY OF HAVING ONE EUPLOID BLASTOCYST IN ELECTIVE OOCYTE CRYOPRESERVATION CYCLES: A COUNSELING RESOURSE.

Patrizia Rubino, MS,[1] Luca Pagliardini, Bs,[2] Eric Urcia, MS,[3] Charlotte Khoury, MS,[4] John Wilcox, MD, FACOG,[1] Bradford Kolb, MD, FACOG,[1] Jeffrey R. Nelson, DO FACOOG,[1] John M. Norian, MD FACOG,[1] Robert Boostanfar, MD FACOG,[3] Daniel A. Potter, MD FACOG,[4] Tih Tan, MS[1] [1]HRC Pasadena, Pasadena, CA; [2]IRCCS San Raffaele Scientific Institute, Milano, Italy; [3]HRC Encino, Encino, CA; [4]HRC Newport Beach, Newport Beach, CA.

OBJECTIVE: Women selecting elective fertility preservation (EFP) often ask about the 'ideal' number of oocytes to store for future use. As preimplatation genetic testing (PGT) becomes more popular, many couples may request PGT for their egg thaw cycles. However, current predictive models do not take PGT into consideration, when considering the number of oocytes needed to freeze for a succesful outcome. The purpose of the present study was to provide an evidence-based tool to counsel patients on the ideal number of oocytes to freeze in order to have at least one euploid blastocyst. Additional analyses on frozen egg donor cycles is also provided.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The data from 186 cycles (Jan 2017 to Dec 2018) with vitrified/warmed oocytes were retrospectively analyzed. Only cycles with PGT performed on all available blastocysts were included. A sensitivity analysis on the probability to obtain at least one euploid blastocyst (positive result) in relation to the number of thawed oocytes was conducted. Patients were categorized into four groups according to their age at freezing: egg donors (n=52), < 36 (n=54), between 36 and 39 (n=50), >39 (n=30). All donors were from an in-house program. The sliding window method was used to calculate the probability of a positive result for different numbers of thawed oocytes. The dimension of the window was 5 oocytes and was centered on the number of thawed oocytes to test.

RESULTS: The mean age of the women was 33.0 ± 6.6 (min: 23; max: 47). The minimum number of thawed oocytes was 1 while the maximum was 65 (median [IQR]: 11 [7-17]). A total of 2832 oocytes were thawed, 2464 survived (87.0%) 1783 fertilized (72.3%) and 777 (43.6%) reached the blastocyst stage (blastulation rate for fresh cycles in the same study period: 62.5% p<0.01). The number of thawed oocytes needed to obtain 90% probability of a positive result for donors and women with age <36 was 9 and 12, respectively. For the other age groups no number of thawed oocytes guaranteed a 90% probability of a positive result. The threshold to reach the positive result with a probability of 80% was also evaluated: 5, 11 and 14 oocytes were needed, respectively, for the donor, <36 and 36-39 age groups. The group with age >39 did not reach a 80% probability of a positive result with any number of thawed oocytes. Finally, the best result achievable for each age groups was analyzed: for donors a probability of 100% required 11 oocytes, for the <36 group a probability of 100% required 12 oocytes, for the 36-39 group a probability of 89% required 15 oocytes and for the >39 group a probability of 60% required 15 oocytes.

CONCLUSIONS: The number of oocytes needed to obtain at least 1 euploid blastocyst in PGT cycles with frozen oocytes was higher than the number that the models predicts for fresh oocytes (1). In agreement with previous studies (2), our cryopreserved oocytes showed a significantly lower blastulation rate compared with our fresh oocytes possibly explaining our findings. Data on PGT in egg frozen cycles are minimal in the literature and our results may be used to provide counseling for women desiring EFP.

SOCIO-DEMOGRAPHIC DISPARITIES IN UTILIZATION OF FERTILITY SERVICES AMONG REPRODUCTIVE AGE WOMEN DIAGNOSED WITH CANCER IN THE US: A SECONDARY ANALYSIS OF THE 2011-2017 NATIONAL SURVEY FOR FAMILY GROWTH (NSFG).

Paxton E. Voigt, BA,[1] Jesse Benjamin Persily, BA,[2] Sameer Thakker, BA,[1] Jennifer K. Blakemore, MD,[3] Frederick L. Licciardi, M.D.,[4] Bobby B. Najari, MD MSc[2] [1]NYU Langone School of Medicine, New York, NY; [2]New York University School of Medicine, New York, NY; [3]NYU Langone Prelude Fertility Center, New York, NY; [4]NYU Langone Health, New York, NY.

OBJECTIVE: Previous studies have shown disparities in access to fertility services (FS) in women diagnosed with cancer on local and regional levels[1]. We sought to investigate the relationship between socio-demographic factors and use of FS on a national level among reproductive age women diagnosed with cancer in the US.

DESIGN: Secondary analysis of the 2011-2017 waves of the NSFG.

MATERIALS AND METHODS: We used the provided sample weights and the complex sample analysis required by the NSFG survey design. All women who indicated a cancer diagnosis were included. Women who sought FS before their cancer diagnosis were excluded. Women who sought FS any time after their cancer diagnosis were compared to women who never sought FS after their diagnosis. Comparisons included demographic and healthcare utilization characteristics. Statistical analyses included multivariate logistic regression, with $p < 0.05$ considered statistically significant.

RESULTS: 580 respondents reported a history of cancer. 35 (6.03%) accessed FS before their cancer diagnosis and were excluded from analysis, leaving 545 women included for analysis. The average age of the sample population was 35.1 years old. 76% identified as Non-Hispanic White, 11.3% as Hispanic, 8.1% as Black and 4.6% as Non-Hispanic Other. The average income was 256.8% of the poverty level. The majority of respondents self-identified as Protestants (53.8%), followed by non-religious (23.5%). Additionally, the majority were married (43.9%) and had at least attended some college (61.5%). 43 women (7.41%) accessed FS after their cancer diagnosis and 502 (86.6%) never accessed FS. Using the NSFG sample weights, this equates to a population of 161,500.7 and 1,811,955.3, respectively. In multivariate analysis, socioeconomic status, marital status, and race were found to be statistically significant predictors for utilizing FS following a cancer diagnosis. Women of higher socioeconomic status were more likely to pursue FS (OR 1.00, CI 0.91-1.09, p< 0.001). Women who were married were more likely than those who were divorced, separated (OR 0.18, CI 0.07-0.049, p < 0.001) or never married (OR 0.16, CI 1.03-1.10, p<0.001) to pursue FS. Hispanic (OR 0.185, CI 0.013-2.547 p=0.015) and Non-Hispanic Other (OR 0.323, CI 0.056-1.868, p<0.015) were less likely to utilize FS. Age (p=0.943), religion (p=0.137) and education (p=0.814) were not found to be statistically significant predictors of accessing FS. Interestingly, having insurance (p=0.380), having a usual place to access healthcare (p=0.700) and good self-perceived health status (p=0.907) were not statistically significant predictors of FS use.

CONCLUSIONS: In this nationally representative cohort of reproductive age women diagnosed with cancer, there were socioeconomic and racial differences between those who did and did not utilize FS. This difference did not

appear to be due to insurance coverage or access to healthcare. While expanding insurance coverage is necessary to ensure equal FS opportunity to all, further studies are needed to ensure socioeconomic and racial disparities are addressed.

THE USE OF OOCYTE CRYOPRESERVATION (OC) FOR FERTILITY PRESERVATION (FP) IN GIRLS WITH SEX CHROMOSOME DISORDERS (SCD): A CASE SERIES DESCRIBING OUTCOMES.

Rachel A. Martel, BA,[1] Jennifer K. Blakemore, MD,[2] Mary Elizabeth Fino, MD[2] [1]NYU Grossman School of Medicine, Manhattan, NY; [2]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: Women with SCD, such as Turner Syndrome, will likely experience an accelerated decline of ovarian reserve[1], and may therefore pursue FP with OC in adolescence or young adulthood (AYA). We sought to characterize the outcomes of AYA patients with SCD after consultation.

DESIGN: Retrospective case series of all AYA (<25 years) patients (pts) with SCD seen for OC consultation at a university based fertility center from 2011-2019.

MATERIALS AND METHODS: All AYA pts seen for consult in the study time period were reviewed. Only those with a SCD were included. Primary outcomes were pt age, SCD, number who attempted OC, number of FP cycles attempted, and cycle outcomes. Statistics included multiple logistic regression with $p<0.05$ considered significant.

RESULTS: 22 pts were included for analysis: 16 with Turner Syndrome (TS), 5 with Turner Syndrome Mosaicism (TSM) and 1 with 47XXX. Median age at consult was 14 (range 8-21). 14 (64%) pts elected for OC: 8 TS, 5 TSM, and 1 47XXX who pursued a total of 31 OC cycles. Reasons for not undergoing OC after consult included lack of menarche or elevated FSH. Table 1 shows cycle outcomes. Of the 14 pts who attempted OC, 10 underwent retrieval and 9 had oocytes successfully frozen. 7 pts (50%) underwent >1 cycle and 6 (43%) had ≥1 cancellation. 3/3 pts who pursued cycles after 1st cancellation never got to retrieval. Looking at potential clinical predictors: age, SCD type, and FSH at cycle start did not predict ability to freeze M2s or cycle cancellation. Notably, there was a wide range of FSH, with only 1 pt with a high level and 4 with an FSH <1mIU/mL. Of the AMH data available, all pts >1ng/mL froze M2s. Only pt #10 returned after OC: at age 21 with a partner, and attempted 4 cycles of ovulation induction and 2 cycles of IVF. All 6 cycles were cancelled for low response, and her oocytes remain frozen.

CONCLUSIONS: AYA pts with SCD have a high risk of poor response and cycle cancelation but the majority froze M2s. OC offers an important option to have genetic offspring but setting expectations is important. A larger sample size is needed to evaluate possible clinical predictors of success.

O-204 10:55 AM Tuesday, October 20, 2020

OOCYTE CRYOPRESERVATION VERSUS OVARIAN TISSUE CRYOPRESERVATION AS FERTILITY PRESERVATION FOR ADULT WOMEN UNDERGOING GONADOTOXIC THERAPY: A COST-EFFECTIVENESS ANALYSIS.

Esther H. Chung, MD,[1] Stephanie L. Lim, MD,[1] Haley A. Moss, MD, MBA,[2] Kelly S. Acharya, MD[3] [1]Duke University Medical Center, Durham, NC; [2]Division of Gynecologic Oncology, Duke University Medical Center, Durham, NC; [3]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC.

OBJECTIVE: Until recently, fertility preservation for adult women facing cancer diagnoses and gonadotoxic therapy was limited to mature oocyte cryopreservation (OC) or embryo cryopreservation. In December 2019, the American Society for Reproductive Medicine designated ovarian tissue cryopreservation (OTC) as no longer experimental. While indications for and the populations opting for each of these treatments often differ, the choice between OC or OTC (or both) will arise as OTC becomes more commonplace. This study's objective was to compare the cost-effectiveness of OC versus OTC for fertility preservation in adult oncofertility patients. No such cost analysis has been performed in this population to date.

DESIGN: Cost-effectiveness study.

MATERIALS AND METHODS: A decision analytic cost-effectiveness model was designed from the payer perspective to compare two strategies: (1) mature oocyte cryopreservation (OC); (2) ovarian tissue cryopreservation (OTC). All clinical costs and probabilities were abstracted from the literature. The cost of each strategy was calculated as average payer costs and included costs of oocyte cryopreservation prior to chemotherapy, thaw and fertilization cycles, frozen embryo transfers, laparoscopic oophorectomy, tissue processing, and robotic transplantation, among others. Effectiveness was quantified as the percentage of patients who achieved a live birth, with secondary effectiveness as the percentage of patients who achieved a clinical pregnancy. Incremental cost-effectiveness ratios (ICERs) were determined to establish cost-effectiveness, and sensitivity analyses were run to assess for variations in costs and clinical probabilities.

RESULTS: The base case cost of each strategy was: OC $16,588 and OTC $10,032. OC had an effectiveness of 1.6% and OTC an effectiveness of 1.0% at achieving a live birth. OC was more costly but more effective than OTC, with an ICER of $1,163,954 per additional live birth when compared to OTC. In the secondary analysis, OC had an ICER of $1,434,989 per additional clinical pregnancy compared to OTC. In a sensitivity analysis of utilization of cryopreserved oocytes or ovarian tissue, OC is less expensive and more effective when the utilization rate is 63% or higher. In another sensitivity analysis of the cost of oocyte cryopreservation prior to chemotherapy, OC is less expensive and more effective when the cost is less than $8,100.

CONCLUSIONS: Given current pricing and utilization rates, OC is more effective but markedly more costly than OTC, with an ICER of $1,163,954 per additional live birth. However, OC becomes cost-saving with increased utilization or when the cost of oocyte cryopreservation prior to chemotherapy is much lower than the current average cost. These findings indicate that lowering the high entry cost of OC and increasing its utilization can significantly impact its overall cost-effectiveness.

QUALITY-OF-LIFE IMPROVEMENT WITH RELUGOLIX COMBINATION THERAPY IN PATIENTS WITH HEAVY MENSTRUAL BLEEDING ASSOCIATED WITH UTERINE FIBROIDS: RESULTS FROM THE LIBERTY PHASE 3 PROGRAM. Ayman Al-Hendy, MD, PhD,[1] Elizabeth A. Stewart, MD,[2] Roberta Venturella, MD, PhD,[3] Alfred Poindexter III, MD,[4] Claudio Villarroel, MD,[5] Jennifer Kang, MS, MPH,[6] Rachel B. Wagman, MD,[7] Elke Hunsche, PhD,[8] Andrea S. Lukes, MD, MHSc[9] [1]Department of Surgery, University of Illinois at Chicago, Chicago, IL; [2]Mayo Clinic Department of OB/GYN, Reproductive Endocrinology and Infertility, Rochester, MN; [3]Magna Graecia University of Catanzaro, Catanzaro, Italy; [4]Advances In Health, Houston, TX; [5]Institute for Mother and Child Research (IDIMI), Faculty of Medicine, University of Chile, Santiago, Chile; [6]Myovant Sciences, Inc., Brisbane, CA; [7]Myovant Sciences Inc., Brisbane, CA; [8]Myovant Sciences GmbH, Basel, Switzerland; [9]Carolina Women's Research and Wellness Center, Durham, NC.

OBJECTIVE: To evaluate the effect of Relugolix combination therapy (Rel-CT) on Quality of Life (QoL) using the Uterine Fibroid Symptom Health-Related QoL (UFS-QoL) questionnaire, an instrument developed to assess symptom severity (SS) and health-related QoL (HRQoL) in women with uterine fibroids (UF).

DESIGN: LIBERTY 1 and LIBERTY 2 were Phase 3, multinational, randomized, double-blind, placebo-controlled studies that evaluated the effect of Rel-CT (once-daily relugolix 40 mg, estradiol 1 mg, norethindrone acetate 0.5 mg) on heavy menstrual bleeding (HMB). Since UF-associated symptoms frequently impact women's daily activities and emotional wellbeing, assessments of SS, overall HRQoL as well as HrQoL subscales were secondary endpoints in the studies.

MATERIALS AND METHODS: Patients completed the UFS-QoL at baseline, Week 12, and Week 24. Changes from baseline to Week 24 in the UFS-QoL SS and HRQoL scale scores and HRQoL subscale scores (activities, concern, energy/mood, control, self-consciousness, sexual function) were assessed in pooled data from LIBERTY 1 and 2. Least-squares mean changes in UFS-QoL SS scale and HRQoL (sub)scale scores were compared between the Rel-CT and placebo groups, using a repeated measures mixed-effects model, with treatment, visit, region, baseline menstrual blood loss (MBL) volume, and treatment by visit interaction as fixed effects. Higher UFS-QoL SS scores reflect more severe symptoms; higher HRQoL (sub) scores indicate better QoL. Contribution of changes in subscale scores to the HRQoL total score change was also assessed.

RESULTS: In total, 253 patients were randomized to Rel-CT and 256 patients to placebo (modified intent-to-treat population). At baseline, mean (SD) MBL volume was 243 (183) and 215 (127) mL, respectively, and mean (SD) UF volume 73 (127) and 73 (123) cm^3, respectively; 48% vs 54% of patients on Rel-CT vs placebo were African American. UFS-QoL SS was reduced with Rel-CT from a mean (SE) of 57.0 (1.4) at baseline to 22.4 (1.6) at Week 24, compared with placebo from 59.6 (1.4) at baseline to 46.9 (1.6) at Week 24; the between-treatment difference (Rel-CT vs placebo) in change scores (–21.4) was statistically significant ($p<0.0001$). Total HRQoL improved significantly ($p<0.0001$) with Rel-CT vs placebo (difference: 24.5): from 38.3 (1.4) at baseline to 76.6 (1.7) at Week 24 with Rel-CT compared with placebo from 35.7 (1.4) at baseline to 48.2 (1.7) at Week 24. All HRQoL subscales improved significantly ($p<0.0001$) with Rel-CT vs placebo, with between-treatment differences: concern 34.9; control 17.9; activities 28.2; energy/mood 21.0; self-consciousness 22.5; sexual function 17.2. Changes in all subscales contributed to improvement in total HRQoL score, with the activities and concern subscales having the largest impact.

CONCLUSIONS: Improvements in MBL, pain, and anemia observed with Rel-CT are associated with significant reductions in symptom severity and improvements in QoL for women with HMB associated with UF. Rel-CT improved many different aspects of QoL, including daily activities, emotional wellbeing, and sexual life.

RELUGOLIX COMBINATION THERAPY SIGNIFICANTLY REDUCED MENSTRUAL BLOOD LOSS WITH FIRST TREATMENT CYCLE IN WOMEN WITH HEAVY MENSTRUAL BLEEDING ASSOCIATED WITH UTERINE FIBROIDS: RESULTS FROM THE LIBERTY PHASE 3 PROGRAM. Roberta Venturella, MD, PhD,[1] Ayman Al-Hendy, MD, PhD,[2] Andrea S. Lukes, MD, MHSc,[3] Jennifer Kang, MS, MPH,[4] Laura McKain, MD,[4] Elizabeth A. Stewart, MD[5] [1]Magna Graecia University of Catanzaro, Catanzaro, Italy; [2]Department of Surgery, University of Illinois at Chicago, Chicago, IL; [3]Carolina Women's Research and Wellness Center, Durham, NC; [4]Myovant Sciences, Inc., Brisbane, CA; [5]Mayo Clinic Department of OB/GYN, Reproductive Endocrinology and Infertility, Rochester, MN.

OBJECTIVE: To evaluate the time to treatment response with once-daily Relugolix combination therapy (Rel-CT), assessed by decrease in menstrual blood loss (MBL) volume observed in the Phase 3 LIBERTY studies.

DESIGN: LIBERTY 1 and LIBERTY 2 were multinational, randomized, double-blind, placebo-controlled studies that evaluated effect of Rel-CT (relugolix 40 mg [an oral gonadotropin-releasing hormone receptor antagonist], estradiol 1 mg, norethindrone acetate 0.5 mg) on heavy menstrual bleeding associated with uterine fibroids (UF). Reduction in MBL volume was a predefined secondary endpoint.

MATERIALS AND METHODS: Premenopausal women (age 18–50 years) with ultrasound-confirmed UF and MBL $\geq$80 mL per cycle (assessed by the alkaline hematin method) were randomized 1:1:1 to Rel-CT (n=254), Delayed Rel-CT (relugolix 40 mg monotherapy for 12 weeks followed by Rel-CT for 12 weeks, n=259), or placebo (n=257) for 24 weeks. Treatment response was assessed by measurement of MBL volume using monthly collections of feminine products and subsequent alkaline hematin extraction. The primary endpoint was defined as an MBL volume <80 mL and a reduction in MBL volume $\geq$50% from baseline. Pooled results from the LIBERTY 1 and 2 studies in the modified intent-to-treat population for Rel-CT (n=253) and placebo (n=256) groups are presented. No notable differences were observed between Rel-CT and Delayed Rel-CT groups. The mean percent changes in MBL volumes from baseline were compared using the mixed-effects model, and responder rates were compared using the stratified Cochran–Mantel–Haenszel test.

RESULTS: The enrolled women had a mean age of 42.1 years, mean body mass index of 31.5 kg/m^2, mean uterine volume of 408 cm^3, and mean largest fibroid volume of 78 cm^3. Mean (standard deviation) baseline MBL volume was 228.8 (154.3) mL. Approximately half of patients were Black or African American; 76% were from North America. In the Rel-CT group, a significantly greater mean percent reduction of 52.4% in MBL volume was observed in the first menstrual cycle compared with 14.7% for placebo ($p<0.0001$). By the second menstrual cycle, the reduction in MBL volume was 80.2% with Rel-CT compared with 11.6% for placebo ($p<0.0001$). The improvement was sustained through end of the study (24 weeks), at which point the observed mean reduction in MBL volume in the Rel-CT group was 84.7%, with a treatment difference from placebo of 65.2% ($p<0.0001$). Moreover, 72.3% of women met the primary endpoint by reaching both an MBL volume <80 mL and a reduction in MBL of at least 50% from baseline. The differences in the proportion of patients meeting the primary endpoint were statistically significant and clinically meaningful between the pooled Rel-CT and placebo groups from the Week 4 visit through to the end of the treatment period at Week 24 ($p<0.0001$).

CONCLUSIONS: A rapid clinical response, evidenced by significant reduction in MBL volume, was observed in patients treated with once-daily Rel-CT. This improvement in MBL was significant and clinically meaningful compared with placebo and was maintained throughout the treatment period.

RECTAL VERSUS SUBLINGUAL MISOPROSTOL IN DECREASING BLOOD LOSS DURING ABDOMINAL MYOMECTOMY: A RANDOMIZED CLINICAL TRIAL. Ahmed M. Abbas, MD, Sara M. Tolba, MBBCh, Ahmed M. Abdelmagied, MD, Tarek Farghaly, MD, Ahmed Nasr, MD. Department of Obstetrics and Gynecology Faculty of Medicine, Assiut University, Assiut, Egypt.

OBJECTIVE: The current study aims to compare the effectiveness of rectally administered PGE1 synthetic analogue (misoprostol) 400 mcg versus sublingual administered misoprostol before abdominal myomectomy to decrease blood loss during the operation.

DESIGN: Randomized, single-blind, clinical study(Clinicaltrials.Gov:NCT02716142).

MATERIALS AND METHODS: The current study was conducted between March 2017 and December 2019. The study included women with

documented uterine fibroids on pelvic imaging, age between 18 and 50 years, pre-operative hemoglobin >8 g/dl, with five or less symptomatic subserous or intramural fibroids and the uterine size less than 24 weeks pregnancy. Sample size was calculated based on a study stated that the mean blood loss with rectal misoprostol was 574±194.8 ml. Using two sided chi-square (x2) test with alpha error of 0.05, a total sample size of at least 58 patients (29 in each arm) will have 80% power to detect 25% difference in mean blood loss with sublingual misoprostol intake. Women were randomized to (group A) received 400 mcg misoprostol (2 tablets) rectally one hour before the operation, and group (B) received 400 mcg misoprostol sublingual at the same time. The primary outcome was the mean amount of intraoperative blood loss. Chi^2-test was used to compare the nominal data of the study groups while student t-test was used to compare the quantitative data of the groups.

RESULTS: The study included 60 patients (30 in each arm). Both groups had no statistical significant differences as regarding the baseline or clinical data. The mean amount of blood loss in rectal group was 247.44 ± 106.04 ml vs. 256.17 ± 116.27 ml in the sublingual group (p=0.06). No difference between both groups regarding the change of hemoglobin level and hematocrit value pre- and post-operatively (p>0.05). similarly, no difference between both groups regarding the duration of surgery (p=0.9) and the need for post-operative blood transfusion (p=0.08). Both groups were similar regarding the rate of adverse effects (p=0.97). Fever and chills were the most common observed adverse effects.

CONCLUSIONS: Both rectal and sublingual misoprostol 400 mcg are equally effective in decrease the blood loss during abdominal myomectomy with quiet similar adverse effects.

SUPPORT: None

A NOMOGRAM PREDICTING THE LIKELIHOOD OF INCOMPLETE REMOVAL OF SUBMUCOUS MYOMAS IN PATIENTS UNDERGOING HYSTEROSCOPIC MYOMECTOMY.

Fabio Barra, MD,[1] Franco Alessandri, MD,[2] Maria Grazia Centurioni, MD,[2] Michele Altieri, MD,[1] Umberto Leone Roberti Maggiore, MD, PhD,[3] Carolina Scala, MD,[4] Salvatore Giovanni Vitale, MD PhD,[5] Simone Ferrero, MD PhD[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]IRCCS Ospedale Policlinico San Martino, Genoa, Italy; [3]Department of Gynecologic Oncology, IRCCS National Cancer Institute, Milan, Italy; [4]Istituto G. Gaslini, Genova, Italy; [5]University of Catania, Catania, Italy.

OBJECTIVE: To develop a nomogram predicting the likelihood of incomplete removal of submucous myomas in patients undergoing hysteroscopic myomectomy.

DESIGN: Data on 571 consecutive patients who underwent hysteroscopic myomectomy for submucous myomas were prospectively collected. Patients who underwent hysteroscopic procedures in an earlier period formed the training cohort (n=424) for nomogram development, and those who underwent procedure thereafter formed the validation cohort (n=147) to confirm the model's performance. This study was registered in clinicaltrials.gov (NCT04400942).

MATERIALS AND METHODS: Before hysteroscopy, patients underwent a transvaginal ultrasound to evaluate the presence and characteristics of myomas. Pre and intraoperative variables associated with incomplete myoma resection in the training cohort were evaluated by univariate logistic regression analysis. Beta-coefficients of significant variables in derivation set were used to generate the nomogram, which was based on proportionally converting each regression coefficient in logistic regression to a 0-100-point scale. The predictive performance of the nomogram was measured by concordance index (C index) and calibration with 1000 bootstrap samples to decrease the overfit bias. The receiver operating characteristic curve was analyzed to calculate the optimal cutoff value by maximizing the Youden index for identifying procedures at a high risk of incomplete myoma resection.

RESULTS: Out of 424 hysteroscopic procedures in the training cohort, there were 49 (11.6%) incomplete myoma resection. 17.7% of the procedures were performed by surgical fellows, 58.0% by consultants, and 24.3% by consultants expert in hysteroscopic surgery. The following variables (odds ratio; 95% CI) were independently associated to incomplete myoma resection: procedure performed by fellows (5.228; 2.395-11.414), largest diameter of myoma ≥4 cm (4.410; 1.464-13.287), intramural myoma extension ≥75% (3.982; 1.725-9.194), uterine volume ≥50 cm^3 (3.562; 1.473-8.616), number of myomas >2 (3.514; 1.294-10.252), concomitant presence of adenomyosis (2.951; 1.179-7.389), previous laparotomic or laparoscopic myomectomy (2.624; 1.006-6.844). No significant association was found for: uterine myoma topography, extension of myoma base, previous 3-month hormonal therapy, menstrual cycle phase, previous vaginal delivery or cesarean section, concomitant presence of ≥1 endometrial polyp. The nomogram deriving from significant variables was characterized by a C index (95% CI) of 0.81 (0.78-0.85) and 0.80 (0.75-0.86) in predicting the incomplete myoma resection in the training and validation cohorts, respectively, and had well-fitted calibration curves. By identifying a cutoff value of 77, the positive and negative predictive values of the nomogram were 81.2% (76.2%-83.4%) and 88.9% (83.6%-95.2%) for the training cohort, and 84.6% (79.7%-88.4%) and 90.2% (86.0%-95.7%) for the validation cohort.

CONCLUSIONS: This nomogram may support clinicians by identifying patients at high risk of incomplete hysteroscopic myoma resection.

COLLAGENASE *CLOSTRIDIUM HISTOLYTICUM*-TREATED UTERINE FIBROIDS SHOW REDUCTION OF TISSUE STIFFNESS AND CELL PROLIFERATION, AND INDUCTION OF CELL DEATH THROUGH AUTOPHAGY AND NECROPTOSIS, AND ALTERATION OF HIPPO SIGNALING.

Md Soriful Islam, PhD,[1] Friederike L. Jayes, DVM, PhD,[2] Bhuchitra Singh, MD, MPH, MS,[1] Joshua T. Brennan, MPH,[1] Phyllis C. Leppert, MD, PhD,[2] James H. Segars, MD[1] [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Duke University, Durham, NC.

OBJECTIVE: Uterine fibroids are prevalent collagen-rich fibrotic tumors, with limited therapeutic options. Collagens in fibroids contribute to an increased mechanical stiffness of extracellular matrix (ECM) with activation of mechanotransduction, thus promoting the fibrotic process. YAP is a transcriptional effector of Hippo signaling that acts as a sensor to regulate a wide range of physical and mechanical stresses, including stiffness of ECM. In a soft matrix, YAP becomes phosphorylated and degraded in the cytoplasm, preventing the YAP-mediated transcription of genes involved in cell growth and fibrosis. Collagenase *Clostridium histolyticum* (CCH) is used to treat fibrotic conditions, such as Dupuytren's contracture and Peyronie's disease. Here, we tested the hypothesis that degradation of collagens by CCH would alter stiffness of ECM leading to changes in markers of cell growth, cell death and Hippo signaling.

DESIGN: Analysis of fibroid tissues from a Phase 1 clinical trial (NCT02889848) after injection of CCH. A fixed dose (1.16 mg) of CCH was injected in 3 fibroids and tissues were harvested at 24-48 h. Nine additional fibroids (n=3 per dose) were injected with increasing doses of CCH at 0.05 mg/cm^3 (dose 1), 0.1 mg/cm^3 (dose 2), and 0.2 mg/cm^3 (dose 3), and harvested at 60-90 days. Non-injected control fibroids were harvested at the same timepoints.

MATERIALS AND METHODS: Mechanical stiffness was quantified with unconfined rheometry. Markers for cell proliferation (PCNA), autophagy (LC3B), necroptosis (RIPK3), and Hippo signaling (phosphorylated YAP or p-YAP) were quantified with immunofluorescence staining and ImageJ software. Two-tailed t-test was used for data analysis. Statistical significance was defined as $p<0.05$.

RESULTS: Fibroid tissues varied in stiffness but overall stiffness of CCH-injected tissues was reduced by 26% and 32% compared to controls at the early and late time points, respectively, and 47% at the two highest doses. The cell proliferation marker PCNA was increased at 24-48 h ($p<0.05$), after CCH injection, but was decreased in fibroids (5 of 6) after 60 days at high doses (0.1 and 0.2 mg/cm^3) ($p<0.05$). There was an increase in the autophagy marker, LC3B ($p<0.05$), and the necroptosis marker, RIPK3 ($p<0.05$), among 55% (6 of 11) and 36% (4 of 11) CCH-treated fibroids, respectively, suggesting the activation of autophagic and necroptotic cell death. Changes in Hippo signaling factors were assessed, specifically phosphorylated YAP (p-YAP), the transcriptionally inactive form of YAP. Notably, p-YAP was increased, particularly at the highest dose of CCH (2 of 3) ($p<0.05$).

CONCLUSIONS: The injection of collagenase led to a reduction of tissue stiffness and markers of cell growth at the highest doses. These changes were accompanied by increased staining for markers of cell death via autophagy and necroptosis and alteration of Hippo signaling. The reduction in PCNA staining accompanied by an increase in p-YAP suggests that CCH-treatment could lead to a reduction in fibroid growth. Though preliminary, these data suggest that CCH might represent a new approach to reduce fibroid growth.

PRO-INFLAMMATORY AND IMMUNOSUPPRESSIVE ENVIRONMENT CONTRIBUTES TO THE DEVELOPMENT AND PROGRESSION OF UTERINE FIBROIDS. Hoda Elkafas, B. Pharm, MSc,[1] Maria Victoria Bariani, Ph.D.,[1] Mohamed Ali, BPharm, MSc,[1] Lauren Prusinski Fernung, M.D., Ph.D.,[2] Balasubashini Muralimanohara, Ph.Dm,[3] Hailian Shen, MD/PhD,[3] Tom Boyer, Ph.D.,[3] Qiwei Yang, PhD,[1] Ayman Al-Hendy, MD, PhD,[1] Nahed Ismail, MD, Ph.D.[4] [1]University of Illinois at Chicago, Chicago, IL; [2]Medical College of Georgia at Augusta University, Augusta, GA; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]University of Illinois at Chicago, CHICAGO, IL.

OBJECTIVE: Uterine fibroids (UFs) are the most common benign tumors in reproductive-age women. Previous studies suggested that UFs originate from a single deregulated myometrial stem cell (MMSC) that converts to a UF-initiating cell (UFSC). However, the mechanism underlying UF development after this conversion remains unknown. It is well known that chronic inflammation predisposes to tumor development and progression, but the contribution of an inflammatory microenvironment to the natural history of UFs remains elusive. This work aimed to analyze the immune/inflammatory signaling and the immune checkpoint axis in UFSCs and UF tissues.

DESIGN: Laboratory research studies using human myometrium and UF tissues, primary cells, and stem cells (SCs).

MATERIALS AND METHODS: Tissue microarrays (TMA) comprising 7 patient-matched samples of UF and adjacent myometrium (MM) tissues, derived from consented women undergoing surgical intervention at UT Health San Antonio, were used for immunohistochemical analysis. Fresh UF and adjacent myometrium (MM) tissues were collected via the University of Illinois Medical Center at Chicago from consented women and subjected to primary and SCs isolation (n=3), using dual Stro-1 and CD44 surface markers. MM and UF primary and SCs were cultured under their specific conditions. Conditioned media from these cells were collected, concentrated, and subjected to secreted cytokine profiling using a 65-plexHuman Cytokine/Chemokine Discovery assay. Ingenuity Pathway Analysis (IPA) was used to establish perturbed gene networks, including those linked to the inflammatory pathway. Two-tailed unpaired Student's t-test was used to assess any statistically significant differences ($P < 0.05$).

RESULTS: IHC-TMA staining showed a significant upregulation of transcription factor NFkB and downstream pro-inflammatory cytokines; IL-1β, TNFα, INFg, and Thymic stromal lymphoprotein (TSLP) in UFs compared to adjacent MM tissues ($P<0.05$). These cytokines play a crucial role in the activation of T cells and antigen-presenting cells in the tumor microenvironment. Notably, the expression of immune check-point PDL-1 protein was increased in UFs compared to MM tissues ($p<0.05$). Further, the levels of neutrophils and dendritic cells growth factors (GM-CSF and G-CSF), CX3CL1 (a pro-inflammatory chemokine that promotes NK cells cytotoxicity and their secretion of IFNg), IL-1α/ IL-9 (T cell growth factor), and FGF-2 (fibroblast growth factor) were significantly higher in conditioned media from UFSCs compared to the ones from MMSCs ($p<0.05$). Also, primary UF cells secreted higher levels of G-CSF, INF-g, IL-12P70, CCL11, and stem cell factor (SCF) than MM primary cells ($p<0.05$).

CONCLUSIONS: Our results suggest, for the first time, that UFs and UFSCs exhibited a pro-inflammatory and pro-tumorigenic phenotype that promotes stem cell proliferation as well as the generation of an immunosuppressive tumor microenvironment; two key events that contribute to the development and progression of UF. Targeting these immunomodulatory molecules could provide a novel non-hormonal therapy for uterine fibroids

MENOPAUSE AND PRIMARY OVARIAN INSUFFICIENCY

O-211 1:50 PM Tuesday, October 20, 2020

FORECASTING EARLY ONSET DIMINSHED OVARIAN RESERVE FOR YOUNG REPRODUCTIVE AGE WOMEN. Blair R. McCallie, BS, Mary E. Haywood, PhD, Michelle M. Denomme Tignanelli, PhD, Rachel Makloski, RN, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD. Colorado Center for Reproductive Medicine Lone Tree, CO.

OBJECTIVE: Diminished ovarian reserve (DOR) is a condition where the number or quality of oocytes is compromised, significantly impacting a woman's reproductive potential. While this is expected as women reach their fifth decade, about 10% of younger women (<35 years) will be diagnosed with premature DOR. With the causes of early-onset DOR being largely unknown, the objective of this study was to investigate the biological networks associated with DOR in young women and the subsequent molecular impact on preimplantation embryos.

DESIGN: Research study.

MATERIALS AND METHODS: Whole peripheral blood was collected from patients with consent and IRB approval: young women presenting with diminished ovarian reserve (DOR; n=40) and age-matched young women with normal ovarian reserve (CONT; n=40). A diagnosis of young DOR was defined as maternal age $\leq$34 years (range 27-34), antral follicle count <10 and AMH <1.0 (ng/ml). Maternal exome sequencing (Illumina NovaSEQ 6000; GATK4 analysis aligned to the hg38 reference genome with BWA-MEM) identified exclusive DOR variants using Ingenuity Pathway Analysis (Qiagen). Sequencing validation was performed with Taqman SNP Genotyping Assays (Applied Biosystems). Global methylome sequencing (n=6 individual blastocysts) was performed using the Methyl-Maxi-Seq platform (Zymo Research) with Bismark software for bisulfite sequencing alignment and statistical analysis utilizing the Student T-test ($P<0.05$). Transcriptome sequencing (n=12 individual blastocysts) was performed on the HiSeq 4000 (Illumina) and reads were mapped to the human genome using gSNAP with ANOVA in R used to quantify statistical significance ($P<0.05$).

RESULTS: Exome sequencing revealed 730 significant DNA variants across the genome that were observed exclusively in the young DOR patients ($P<0.01$). Bioinformatic analysis revealed a significant impact to the Glucocorticoid receptor (GR) signaling pathway ($P<0.01$). Each young DOR female had an average of 6.2 deleterious DNA variants within the GR signaling pathway. Successful validation included gene members of the GR signaling pathway (*AGT*, *KRT6A*, *KRT19*, *NCOA2*, *TAF1*) and key ovarian genes (*AHRR*, *CCDC8*, *IGFBP5*, *LRRC17*, *PCDH11X*, *PDGFD*). Additional stratification based on patient age resulted in a cut-off at 31 years for young DOR discrimination. Embryonic global methylome sequencing resulted in only a very small number of total CpG sites with methylation alterations (1,775; 0.015% of total) in the DOR group ($P\leq0.05$). Additionally, there was no co-localization between these limited number of altered CpG sites and significant variants, genes or pathways. RNA sequencing also resulted in no biologically significant transcription changes between DOR blastocysts and controls ($P\leq0.05$).

CONCLUSIONS: GR signaling DNA variants were observed in women with early-onset DOR potentially compromising oocyte production and quality. Utilization of a targeted SNP assay in forecasting premature DOR for young reproductive-age women may allow for earlier identification and clinical intervention, giving them greater chances of creating a family with their own oocytes.

DOES A DIAGNOSIS OF UNEXPLAINED INFERTILITY IMPACT AGE AT MENOPAUSE? LONG TERM FOLLOW-UP FROM FASTT. Denis A. Vaughan, MD,[1] Marlene B. Goldman, ScD,[2] June L. Fung, PhD,[2] Katherine G. Koniares, MD,[3] Carleigh B. Nesbit, DO,[4] Thomas L. Toth, MD,[5] Richard H. Reindollar, MD[2] [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Tufts Medical Center, Boston, MA; [4]Dartmouth Hitchcock Medical Center, Lebanon, NH; [5]Boston IVF, Waltham, MA.

OBJECTIVE: To investigate age at menopause in women who were enrolled in a large randomized controlled trial (RCT, FASTT[1]).

DESIGN: Long term follow up of RCT participants.

MATERIALS AND METHODS: Between March 2019 and February 2020, a telephone survey was administered to women who had been enrolled in FASTT, an RCT that investigated time to conception and cost effectiveness of treatment for unexplained infertility in women aged 21-39 years. The survey included a smoking history with a heavy smoking history defined as at least 5 pack years. Statistical analyses were performed using SAS v 9.2. Categorical variables were compared between groups using chi-square and Fisher's exact tests and continuous variables with two-sample t-tests and analysis of variance where appropriate, with $P<0.05$ as significant. The National Health and Nutrition Examination Survey (NHANES, 2017-2018 cycle) data for women age 40-56 years was used to compare data from the current study to the general population.

RESULTS: Of the 503 women originally enrolled in FASTT, 311 (61.8%) were contacted of whom 286 (56.9%) consented to participate in the survey. Mean age and day 3 FSH at enrollment in FASTT was 33.1 ± 3.2 years and 6.8 ± 2.2 mIU/ml for those who participated in the follow up survey. Mean age at follow-up was 49.5 ± 3.4 years with 253 (89.4%) Caucasian. 82 women (29.3%) reported no longer having menses at follow up with 54 (19.3%) confirming that they have not had a spontaneous menstrual period in ≥12 months with a mean age at spontaneous menopause of 48.8 years ± 3.6 years. In NHANES, 179/785 (22.8%) women reported not having regular menses for the prior 12 months secondary to menopause. Mean ± SD of age of menopause was 47.6 ± 4.4 years which was not significantly different from the present study (P=0.07). 17 women (6.1%) had undergone a hysterectomy and 3 (1.1%) had undergone a bilateral salpingo-oopherectomy. 35 women (18.5%) who had delivered a live birth during FASTT had gone through menopause at follow up compared to 19 (20.9%) of those who did not (P=0.64). 48 women (18.3%) who had at least one live birth were post-menopausal at follow up compared to 6 (35.3%) of those who had never had a live birth (P=0.11). Of those women who were post-menopausal, there was no significant difference in age at menopause between those who had never had a live birth (49.5 ± 3.6) compared those who had at least one live birth (48.7 ± 3.6 years). Neither a history of ever smoking nor a history of heavy smoking impacted the mean age at spontaneous menopause compared to those who never smoked (48.1 ± 4.8 and 47.9 ± 5.5 vs 49.0 ± 3.2 years, P=0.56, P=0.59 respectively). Controlling for age at enrollment of FASTT, day 3 FSH at enrollment was not significantly different between those who had undergone spontaneous menopause compared to those who had not at the time of follow-up. (7.3 ± 2.2 vs 6.6 ± 2.1 mIU/mL, P=0.53).

CONCLUSIONS: Being diagnosed with unexplained infertility did not increase the risk for earlier menopause in this follow up study compared to U.S. women. A higher day 3 FSH at enrollment in FASTT or being a current or former smoker were not independent risk factors for earlier menopause.

GRAVIDITY, PARITY, BREASTFEEDING AND AMH: FINDINGS FROM THE OVARIAN AGING AND RESERVE STUDY (SOAR). Emma Giuliani, MD,[1] Anne Waldo, MS,[1] Lia Bernardi, MD,[2] Mercedes Carnethon, PhD,[2] Lisa M. Neff, MD,[2] Erica E. Marsh, MD, MSCI, FACOG[1] [1]University of Michigan, Ann Arbor, MI; [2]Northwestern University, Chicago, IL.

OBJECTIVE: Very few studies on anti-mullerian hormone (AMH), the most commonly used serum biomarker of ovarian reserve in women, have been conducted in young, healthy women of non-European race, and factors affecting its levels are still largely unknown. The objective of this analysis was to investigate whether gravidity, parity and breastfeeding are associated with AMH levels in reproductive aged African American women (AAW).

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: The Study of Ovarian Aging and Reserve (SOAR) leveraged an existing NIEHS study cohort of AAW aged 23-34 years. Anthropometric measurements, health information and serum AMH levels (picoAMH assay - Ansh Labs, Webster, TX) were analyzed. Multivariable linear regression models adjusted for age, age^2, BMI, current hormonal contraception use, and history of irregular menstrual cycles were used to estimate the effect of gravidity, parity and breastfeeding on AMH levels (SAS 9.4 - Cary, NC).

RESULTS: A total of 1,646 women with a mean age of 29.2±3.4yo, mean BMI of 33.7±9.6 Kg/m^2, and median AMH value of 4.1 ng/mL (IRQ 2.3-6.7) were included, of which 449 (26.6%) were nulligravidae, 206 (12.2%) had been pregnant but never given birth, and 1,034 (61.2%) had at least one live birth. Mean gravidity was 3.1±2.0 and parity was 2.1±1.3. Mean age at first pregnancy was 19.9±3.6yo, while mean years since last pregnancy and last birth were 4.4±3.7 and 5.1±3.8, respectively. A history of breastfeeding was reported in 38.7% of women with an average cumulative breastfeeding time for all children per woman of 5.4±8.7 months. In adjusted models, history of pregnancy was inversely associated with lnAMH (-0.13, 95% CI -0.24 to -0.03, p=0.01). No significant association was seen between AMH levels and number of pregnancies among women who were ever pregnant, number of livebirths among parous women, history of breastfeeding, or cumulative breastfeeding time in parous women.

CONCLUSIONS: In this large cohort of AAW, a population that is largely underrepresented in the ovarian reserve literature, history of pregnancy was inversely associated with AMH. The finding of lower AMH levels in women with at least one proven pregnancy is consistent with previous studies that have demonstrated that higher AMH levels are associated with certain conditions that may lead to infertility, such as polycystic ovarian syndrome. A better understanding of how factors related to previous pregnancies influence AMH levels in women of different backgrounds will improve physician interpretation of ovarian reserve testing and patients' counseling.

O-214 2:35 PM Tuesday, October 20, 2020

ASSOCIATION BETWEEN OVARIAN RESERVE AND MENSTRUAL CYCLE LENGTH. Benjamin S. Harris, MD, MPH,[1] Anne Z. Steiner, MD, MPH,[2] Anne Marie Jukic, PhD[3] [1]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC; [2]Duke University, Durham, NC; [3]National Institute of Environmental Health Sciences, Durham, NC.

OBJECTIVE: To determine the association between anti-Müllerian hormone (AMH) levels and menstrual cycle length.

DESIGN: Secondary analysis of a prospective time-to-conceive cohort study.

MATERIALS AND METHODS: We used data from Time to Conceive (TTC), a prospective time-to-pregnancy study of women, aged 30 to 44. Participants completed up to 4 months of daily diaries while attempting to conceive. Conception cycles were excluded. Ovulation was determined by ovulation predictor kit, cervical mucus, or basal body temperature records. Serum was analyzed for AMH (Ultrasensitive AMH ELISA, Ansh Labs). AMH levels were examined in two ways: continuous linear variable, and four categories. We examined continuous menstrual cycle length with linear mixed models, and short cycles (<25 days), long cycles (35+ days), short follicular phase (≤10 days), and long follicular phase (18+ days) with marginal models and GEE, adjusting for, age, race, body mass index, education, and cycle of blood draw.

RESULTS: There were 3,179 menstrual cycles from 689 women included in the analysis. Results presented in Table. Compared with an AMH level of 1.6-3.4 ng/mL, AMH level <1.6 ng/mL was associated both with cycles that were about one day shorter and with 1.5 times the odds of short cycles . An AMH level >8 ng/mL was associated both with cycles that were 2.5 days

TABLE. Association of Categorical AMH with Change in Menstrual Cycle Length, Long and Short Cycles, and Follicular Phase

	Menstrual Cycle Length	Long Cycles (>35 days)	Short Cycles (<25 days)	Follicular Phase Length	Long Follicular Phase (≥18 days)	Short Follicular Phase(≤ 10 days)
AMH (ng/mL)	Adjusted Cycle Length (in days) (95% CI)	Adjusted OR (95% CI)	Adjusted OR (95% CI)	Adjusted Cycle Length(in days) (95% CI)	Adjusted OR (95% CI)	Adjusted OR (95% CI)
<1.6	**-0.994 (-1.47, 0.519)**	**0.587 (0.289,1.193)**	**1.46 (1.04, 2.06)**	**-1.69 (-3.39, 0.013)**	**0.405 (0.239,0.687)**	**1.29 (0.753, 2.24)**
1.6 – 3.4	**REFERENCE**					
>3.4-8	**1.29 (0.841, 1.76)**	**2.42 (1.38, 4.24)**	**0.463 (0.298, 0.718)**	**0.469 (-1.13,2.07)**	**1.24 (0.806,1.88)**	**0.669 (0.342, 1.31)**
>8	**2.46 (1.79, 3.12)**	**5.69 (2.91, 11.1)**	**0.296 (0.142, 0.617)**	**4.75 (2.59, 6.91)**	**2.33 (1.42,3.83)**	**0.328 (0.098, 1.10)**

longer and with over 5 times the odds of long cycles. When evaluating follicular phase length, an AMH of >8 ng/mL was associated both with follicular phases that were 4.8 days longer and with over 2.3 times the odds of being long. However, there was no statistically significant association between AMH and short follicular phase.

CONCLUSIONS: Among women age 30-44 attempting to conceive naturally, increasing levels of AMH are associated with longer menstrual cycles and follicular phase lengths, respectively. Findings support the biological impact of ovarian reserve on cycle length and ovulation timing.

O-215 2:50 PM Tuesday, October 20, 2020

INFLUENCE OF ARTHRITIS AND TREATMENTS ON OVARIAN RESERVE: A PROSPECTIVE STUDY. Vinita M. Alexander, MD,[1] Jillian Ashley-Martin, PhD,[1] Joan Riley, PhD, HCLD,[1] Amber R. Cooper, MD,[2] Valerie Ratts, MD,[1] Emily S. Jungheim, MD, MSCI[3] [1]Washington University in St. Louis, St. Louis, MO; [2]Vios Fertility Institute St Louis, St. Louis, MO; [3]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: Women with autoimmune disease may experience an accelerated loss of ovarian function due to the disease itself and the disease treatments. We examined serum levels of Anti-Mullerian hormone (AMH) in patients with arthritis and the influence of five arthritic drug regimens (no medications, methotrexate, TNFα-antagonist, a combination of the two, or other regimens containing steroids, hydroxychloroquine, etc.) on AMH level.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Serum AMH levels were measured using Elecsys® AMH immunoassay at two time points (T_0 and T_1) in 129 premenopausal women (age 18 to 45) with a diagnosis of Rheumatoid Arthritis, Spondyloarthritis, or Juvenile Idiopathic Arthritis. AMH levels at T_0 in arthritis patients were compared to an existing control population of healthy females age 18 to 44 without infertility (n=200). Participating women provided information on sociodemographic characteristics (age, race, body mass index, smoking history) and medical history (current and past treatment regimens for arthritis, disease severity measures, obstetric history, and inability to conceive after 12 months of trying) at baseline and follow-up.

Association between sociodemographic characteristics and diminished ovarian reserve (DOR, AMH < 1.1 ng/mL) was quantified using univariate logistic regression. To identify women with highest rates of ovarian reserve loss over time, percent change in AMH per year was dichotomized at the 75th percentile. Univariate and multivariable logistic regression was carried out to identify sociodemographic and clinical variables associated with the highest annual percent decrease in AMH (>75th percentile, or > 28% change in AMH per year).

RESULTS: Median time between T_0 and T_1 was 1.7 years. At time T_0, mean (standard deviation) AMH in the arthritis population (2.00 ± 2.18) was significantly lower than in the control population (2.52 ± 5.98) ($p < 0.001$)). At T_0, 59 women met criteria for DOR. At highest risk for DOR were women with history of sterilization (OR 2.30, 95% CI: 1.00-5.25), or over age 35 (OR 8.24, 95% CI: 1.40-41.47). Women over age 35 (OR 4.75, 95%CI: 1.50-15.09) or who sought care for infertility (OR 3.02, 95% CI: 1.12-8.12) were at increased odds of having the highest annual percentage loss in ovarian reserve. After controlling for age, compared to those on no medications, patients on these regimens were less likely to be in the highest quartile of ovarian loss: methotrexate alone (OR 0.07, 95%CI: 0.01-0.61) and methotrexate plus TNFα-antagonists (OR 0.09, 95%CI: 0.11-0.79).

CONCLUSIONS: This is the first study to prospectively describe AMH in a large cohort of premenopausal women with arthritis with mean follow-up of over one year. We found AMH levels in women with arthritis are lower than in healthy controls, and those with accelerated loss in AMH are more likely to be over 35 or report a history of difficulty conceiving. Odds of a high rate of ovarian reserve loss are lower with long-term methotrexate compared to other drug regimens or no medications. Our findings suggest long-term methotrexate use is not harmful to ovarian reserve as measured by AMH.

O-216 3:05 PM Tuesday, October 20, 2020

ENDOCRINE EFFECTS OF INTRAOVARIAN INJECTION OF PLATELET-RICH PLASMA (PRP) IN WOMEN WITH PREMATURE OVARIAN AGING. David H. Barad, MD, MS,[1] David F. Albertini, PhD, MS,[1] Norbert Gleicher, MD[2] [1]Center for Human Reproduction, New York, NY; [2]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY.

OBJECTIVE: Since PRP treatments have been without prior validation quickly entering IVF practice, to investigate short-term effects of PRP treatments in a formal study format.

DESIGN: Prospective registered studies: NCT04275700 and NCT3542708.

MATERIALS AND METHODS: Premature ovarian failure (POF), also called primary ovarian insufficiency (POI) is characterized by amenorrhea and FSH >40.0mIU/mL. Affected women may, however, still have sporadic menses and may even occasionally achieve spontaneous pregnancy. In contrast, premature ovarian aging (POA), also called occult primary ovarian insufficiency (oPOI), represents a milder form of ovarian insufficiency, characterized by abnormally high FSH (though below 40.0mIU/mL) and abnormally low age-specific AMH. During 2018-2020, 51 women with a diagnosis of POF/POI or POA/oPOI presented to our center for PRP treatments, 20 with POF/POI (PPR#1; age, 34.1 ±5.0 years) and 31 with POA/oPOI (PRP#2, 39.7 ± 6.3 years). To qualify for PRP treatment, patients must have failed a maximal ovarian stimulation with gonadotropins (600IU/day) after at least 6 weeks of pre-supplementation with DHEA (75mg/day) and CoQ10. (800-1,000mg/day. PRP was prepared from patients' bloods using the RegenLab™ USA PRP preparation system (New York, N.Y). The supernatant was withdrawn, and 2.5 ccs of patient plasma was used to re-suspend platelets. Under intravenous sedation and ultrasound control 0.70 cc of PRP was injected subcapsular into ovaries at 7 different sites. In PRP#1, injections were given into only 1 by computer randomly selected ovary, with the 2ndovary serving as control; in PRP#2, both ovaries were injected. Patients were followed with vaginal ultrasounds and estradiol (E) and FSH determinations in blood every 3 days for 12 days, and then weekly, for up to 12 weeks. Since study recruitment is still incomplete, we here only report endocrine changes over the first 60 days following PRP injection without regard to randomization.

RESULTS: FSH was 184.9 ± 58.4 mIU/mL (PRP#1) and 60.5 ± 47.8 mIU/mL (PRP#2). PRP#I over first 60 days revealed no changes in E or FSH levels although 4/20 (20%) demonstrated follicle growth on ultrasound. PRP#2 patients actually revealed a significant fall in E and rise in FSH over the first 30 days, though then followed up with a rise in E (P= 0.007) and drop in FSH (P= 0.038).

CONCLUSIONS: These observations are to our knowledge the first time-controlled hormonal observations in women with POF/POI and POA/oPOI following intraovarian PRP treatments. Not unexpectedly, they demonstrate different hormonal response patterns between the 2 study groups, though both patient populations appear to develop a hormonal response to PRP. Three ongoing PRP trials in different populations should reveal further clinical outcome data.

SUPPORT: Intramural funds from The Center for Human Reproduction and grants from The Foundation for Reproductive Medicine.

HOW DOES QUALITY OF LIFE IMPACT TRANSGENDER PATIENTS' INTEREST IN FERTILITY COUNSELING AND PRESERVATION? Hillary Pearson, M.D.,[1] Alixandra Domney, M.D., M.P.H.,[1] Aren Skolnick, DO,[2] Randi H. Goldman, M.D.,[3] Christine Mullin, M.D.[3] [1]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Department of Endocrinology/Diabetes and Metabolism, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhassett, NY; [3]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Transgender patients face unique challenges in the medical setting, which may lead to poorer quality of life (QOL). Fertility counseling is a critical component of care for transgender individuals. This study aims to investigate if an association exists between QOL and transgender patients' interest regarding their fertility and fertility counseling.

DESIGN: Lifestyle survey.

MATERIALS AND METHODS: Adult transgender patients at a single academic medical center from 2019-2020 were surveyed using the validated Functional Assessment of Chronic Illness Therapy (FACIT) Measurement System. This questionnaire is traditionally used for patients with chronic conditions to quantitatively assess subcategories of QOL,

including social (SWB), functional, emotional, sexual, and financial well-being (FiWB). The questionnaire was specifically adapted to assess QOL parameters of transgender patients and approved for use. Composite scores may range from 37-106, with higher scores indicating better QOL. T-tests were used to compare composite scores between patients who felt that their QOL influenced their interest in fertility versus those who did not.

RESULTS: Of 47 patients surveyed, 43 completed FACIT in its entirety. Most patients (30/47, 63.8%) reported that they were never offered fertility counseling. Of the 17 patients who were offered counseling, 6 discussed fertility with their doctor once, 8 twice, and 3 discussed options $\geq$3 times.

Fifty-eight percent (25/43) of patients felt that at least one QOL subcategory either positively or negatively influenced their feelings towards fertility. The average QOL score for these patients was not different than the average score for those who felt that their interest in fertility was unaffected by any subcategory (76.2 vs. 77.3, NS). The mean composite QOL score for patients whose interest in fertility was positively affected by at least one subcategory was significantly higher than that of patients who did not feel that any QOL subcategory positively affected their interest (84.3 vs. 67.5 respectively, p=0.009). FiWB was reported to most negatively impact level of interest in fertility (60%), while SWB was reported to most positively impact their level of interest (66.7%). Most patients did not feel that any QOL subcategory influenced their fertility interest.

CONCLUSIONS: Despite increased access to care, the majority of transgender patients surveyed were not offered fertility counseling, and the most commonly selected QOL subcategory that participants felt negatively impacted their interest in fertility was FiWB. We as a field have the unique opportunity to support transgender individuals by providing education regarding fertility planning and building biologically linked families.

SUPPORT: None.

IS THE MID-LUTEAL PROGESTERONE CHECK AN EXAMPLE OF MEDICALIZATION IN THE TREATMENT OF SAME-SEX FEMALE COUPLES UNDERGOING DONOR SPERM INTRAUTERINE INSEMINATION?

Jenna Friedenthal, MD,[1] Joseph A. Lee, BA,[2] Noah Copperman, BS,[2] Daniel E. Stein, MD,[1] Tanmoy Mukherjee, MD,[1] Alan B. Copperman, MD[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Evaluation of mid-luteal progesterone (MLP) is frequently performed in order to assess evidence of ovulation. While some researchers have demonstrated a positive association between MLP and live birth [1], others have demonstrated no difference in MLP between fertile and non-fertile cycles [2, 3]. Several studies have evaluated MLP in ovulation induction (OI) cycles within heterosexual couples [4, 5], yet, data regarding the clinical value of MLP in same-sex female couples is limited. It has been suggested that medicalization, the process by which human conditions and problems come to be defined and treated as medical conditions, adds to healthcare costs while not impacting treatment. Our study aimed to evaluate whether MLP in same-sex female couples is associated with changes in outcomes in natural cycles using donor sperm intrauterine insemination (DIUI).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: This was a retrospective study of all same-sex female couples undergoing DIUI from 2004 to 2020. Cases included all patients who had evaluation of MLP. Controls included all patients without MLP testing. MLP was obtained approximately 7 days after ovulation. Medicated cycles for OI were excluded. Our primary outcome was implantation rate (IR); secondary outcomes were ongoing pregnancy/live birth rate (OP/LBR), biochemical pregnancy rate (BCPR), and clinical loss rate (CLR). Baseline demographics were obtained: patient age, body mass index (BMI), day 3 follicle stimulating hormone (D3FSH), gravidity, parity, and endometrial thickness (EnT) at time of ovulation. Statistical analysis was performed using student t-test, Mann-Whitney U test for skewed data, and chi-square. Logistic multivariable generalized estimating equation (GEE) regression models age were used to calculate odds ratios and to adjust for potential confounders, with P<0.05 considered significant.

RESULTS: 660 patients met inclusion criteria and were included in the study; 47 underwent assessment of MLP and 613 did not undergo MLP assessment. There were no differences in demographics between the groups. The mean MLP in those assessed was 10.78ng/mL. Of those in the MLP group, 17/47 (36.17%) subsequently received supplemental progesterone; 14 received vaginal progesterone, while 3 utilized oral progesterone. In an unadjusted analysis, there were no significant differences in clinical outcomes between the groups. After adjusting for age, BMI, D3FSH, and EnT at time of ovulation, having mid-luteal progesterone evaluated did not predict IR (OR 3.65, 0.49-27.34, p=0.21) or OP/LBR (OR 3.83, CI 0.46-31.71, p = 0.21). No differences in BCPR or CLR were observed.

CONCLUSIONS: Our results demonstrate that MLP assessment does not appear to be associated with clinical outcomes in same-sex female couples undergoing natural cycles with DIUI. Our findings suggest that clinicians may reconsider the evaluation of the MLP within same-sex female couples who use DIUI, as it does not appear to enhance treatment outcome. Larger, prospective studies may further delineate the cost-benefit analysis of MLP assessment in this patient cohort.

O-219 2:20 PM Tuesday, October 20, 2020

DECISION REGRET FOLLOWING FERTILITY PRESERVATION FOR THE TRANSGENDER INDIVIDUAL COMPARED TO THE CISGENDER WOMAN.

Viji Sundaram, MD,[1] Brett Stark, MD,[1] Eleni Greenwood Jaswa, MD, MSc,[2] Evelyn Mok-Lin, MD[3] [1]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]REI UCSF, Center for Reproductive Health, San Francisco, CA.

OBJECTIVE: 1) To determine differences in depression, anxiety, body image, quality-of-life (QOL), and decision regret scale (DRS) score in trans individuals who undergo fertility preservation (FP) compared to those who do not; 2) to determine if DRS score following FP varies between transgender individuals and cis-gender women.

DESIGN: Cross Sectional Cohort.

MATERIALS AND METHODS: All transgender individuals, both birth-assigned males and females, presenting for initial consultation for FP at the University of California, San Francisco between January 2016 to November 2019 were retrospectively contacted for study participation. Those desiring participation completed a web-based survey including questions on demographics, partner information, decision satisfaction, and the following standardized scales: Beck Depression Inventory II (BDI-II), Hospital Anxiety & Depression Scale (HADS), Body Image Scale for Transsexuals (BIS), Satisfaction with Life Scale (SLS), Short Form Health Survey (SF-36), and DRS. Cis-gender women, who underwent elective oocyte cryopreservation at the same institution, were recruited from 2012 to 2016 and completed an online survey with demographics and DRS scores. Data analysis was performed with descriptive statistics; chi-square test for comparison of categorical variables; Wilcoxon rank-sum (Mann-Whitney) test for comparison of continuous variables.

RESULTS: 32 birth-assigned (BA) females and 28 BA-males were identified for inclusion and contacted for survey completion. 16 (50%) BA-females and 13 (46%) BA-males completed the survey. 10 BA-females and 12 BA-males underwent FP. Of the 7 trans people (6 BA-females & 1 BA-male) that elected not to undergo FP, common reasons for declining were: need to be off gender-affirming therapy (5/7, 71%), not desiring biological children (3/7, 43%), and fear of ultrasound (2/7, 29%). 503 surveys were distributed to cis-gender women with 201 women (41%) responding. Transgender patients undergoing FP were significantly younger (27.8 years) than cis-gender patients (36.1 years, p<0.01); more likely to have a partner [trans n=11 (50%), cis n=55 (26%), p<0.01]; and more likely married [trans 5 (23%), cis n=4 (2%), p=0.001]. BDI-II, HADS Anxiety, BIS, SLS, SF-36, and DRS scores were not significantly different between trans individuals who underwent FP and those who did not. Median DRS score for all trans people undergoing FP was 7.5 (mean 12.3, SD 14.5), consistent with mild regret from a score of 1-25, while median for cis-gender women was 0 (mean 10.1, SD 15.0, p=0.31). BA-females and BA-males undergoing FP reported DRS median scores 5 (mean 9, p=0.89) and 7.5 (mean 15, p=0.20), respectively, both of which were not significantly different from cis-gender women nor from each other (p=0.43).

CONCLUSIONS: Transgender individuals seek FP earlier in life and are more likely partnered or married at time of FP compared to cis-gender women. Depression, anxiety, body image, and QOL are not significantly different between trans people who undergo FP and those who do not. Gender does not appear to have an effect in decision regret following FP.

O-220 2:35 PM Tuesday, October 20, 2020

THE EFFECT OF ESTROGEN THERAPY ON SPERMATOGENESIS IN TRANSGENDER WOMEN. Annika Sinha, MD, Cecile A. Ferrando, MD, MPH. Cleveland Clinic Foundation Cleveland, OH.

OBJECTIVE: To describe the histopathology parameters of orchiectomy specimens obtained from transgender women following gender-affirming surgery who have used gender-affirming hormone therapy (GAHT).

DESIGN: This is a retrospective cohort study of all transgender women (individuals assigned male at birth who identify as female) who underwent orchiectomy with or without vaginoplasty at a tertiary referral center between December 2015 and March 2020.

MATERIALS AND METHODS: Patients were identified by their Current Procedural Terminology codes for orchiectomy. Once identified, the electronic medical record was queried for demographic and peri-operative data and pathology records were reviewed. The following pathology parameters were recorded: testicular volume, testicular weight, presence of spermatogenesis (active vs reduced), maturation arrest, testicular atrophy, hyalinization, scarring/fibrosis, Sertoli cell and Lydig cell phenotypes. Patients were grouped into one of 3 categories describing duration of GAHT use: 0-3 years, 3-5 years, >5 years. Descriptive statistics were performed and comparisons between outcomes (demographic data and pathology parameters) were made between the GAHT groups.

RESULTS: Eighty-five (N=85) patients underwent orchiectomy during the study period with 85.9% (73) undergoing concurrent vaginoplasty. Mean age and BMI of the cohort were 39 (16) years and 28.4 (5.4) kg/m2. There were no differences between the GAHT groups with the following exception: patients using GAHT 3-5 and >5 years were more likely to be using GAHT compared to those on it 0-3 years (100% vs 100% vs 83.3% GAHT use, p=0.007). Also, while this was not statistically significant, patients in the 3-5 and >5 year groups were also more likely to smoke marijuana (26.3% vs 21.2% vs 4.2%, p=0.09). Mean testicular weight and volume across the cohort were 60.1 (24.9) gms and 65.5 (41.1) cm3. Spermatogenesis was present in 28.2% (24) of specimens with active spermatogenesis noted in 8.2% (7). Hyalinization, scarring/fibrosis and atrophy were present in 28.2% (24), 20% (17), 25.9% (22) of specimens, respectively. There were no differences in pathology parameters across the GAHT groups. Testicular weight and volume were not associated with any differences in pathology parameters. Additionally, age was not associated with testicular weight or volume or pathology parameters with the exception of the following: when patients where categorized as either $<$ 40 years of age (n=48) versus $>$ 40 years of age (n=37), patients who were older were more likely to have hyalinization (43.2% vs 16.7%, p = 0.01) as well as atrophy (40.5% vs 14.6%, p = 0.007).

CONCLUSIONS: Duration of GAHT is not associated with any differences in orchiectomy pathology parameters in patients undergoing gender-affirming surgery. The use of GAHT appears to be associated with a reduction in fertility potential in many patients; however, some patients may still have some potential based on the parameters observed in this study.

O-221 2:50 PM Tuesday, October 20, 2020

INITIAL EVALUATION OF SAFETY AND EFFICACY OF ADMINISTRATION OF ESTRADIOL (E2) BY SUBCUTANEOUS (SC) INJECTIONS TO MALE-TO-FEMALE (MTF) TRANSGENDER PATIENTS. Jennifer A. LaBudde, MD, Wendy Y. Craig, PhD, Daniel I. Spratt, MD. Maine Medical Center Portland, ME.

OBJECTIVE: The primary aim of this study was to determine if SC injection of E2 valerate could produce serum E2 levels within our clinic's target therapeutic range for MTF patients (75-200 pg/mL) without causing significant adverse effects. Secondary aims were to assess: 1) if SC E2 can suppress serum total testosterone (T) levels (<50 ng/dL) as effectively as oral (PO) E2 , 2) if SC administration has less of a hepatic effect than PO, 3) if serum E2 levels remain within the target range between weekly injections and 4) if SC E2 is acceptable to patients.

DESIGN: Retrospective chart review of MTF patients treated in Maine Medical Center Reproductive Endocrinology clinic.

MATERIALS AND METHODS: All charts of MTF patients seen from 2011-2020 were reviewed. Patients were allowed to choose PO, SC or transdermal (TD) administration. Inclusion criteria were age 18-79 years, PO or SC E2 therapy, and serum E2 and T levels measured by LabCorp (Calabasas CA). E2 valerate was injected SC using a 5/8' 25g needle. 17β-E2 was administered orally. Serum E2, T, estrone (E1), and sex hormone binding globulin (SHBG) levels and fasting lipid panels were measured in SC and PO patients and values compared by Mann Whitney U test. Peak and nadir serum E2 concentrations were measured in a subgroup of SC patients. Serum sex steroid concentrations were measured by liquid chromatography/mass spectrometry. Local and systemic adverse effects were assessed by history and physical exam. The study was approved by the Maine Medical Center IRB.

RESULTS: 102 charts were reviewed. Of 65 patients who were offered PO, TD or SC therapy (the SC option became available in May 2017), 23 choose SC. 61 patients were included in the final analysis, 23 in the SC group and 38 in the PO group. Median dose of E2 for the PO group was 4 mg/day [full range=1-12]; for SC E2 it was 4 mg/week [full range=2-6]. For the SC and PO groups the median E2 were 155.5 [75-291] (n=18) and 122 [76-208] pg/mL (n=38) respectively. Median and range of serum T levels in the SC and PO groups were 16 [4.5-82] (n=14) and 13 [4.8-515] (n=38) ng/dL respectively. E1 serum levels in the SC and PO groups were 49.0 [31.0-104.0] (n=10) and 495 [198-926] (n=12) pg/mL (p=0.003). SHBG and lipid levels did not vary significantly between the two groups (not shown). In a subgroup of SC patients, the median serum E2 decreased from 212 [158-245] to 112 [87-150] pg/mL from the day after to the day before an injection (n=12). 22/23 patients in the SC group chose to continue this method, 0/23 patients experienced a systemic reaction and 1/23 experienced a local site reaction.

CONCLUSIONS: These preliminary data suggest that SC E2 injection is a safe and effective option for administration of E2 that appears to be well accepted by patients. It is well absorbed with minimal adverse effects and suppresses serum T levels as effectively as PO E2. SC E2 has less hepatic effect as reflected by serum E1 levels (but not SHBG or lipids in this small sample size). Serum E2 levels decrease between weekly injections and additional studies are required to refine dosing to maintain E2 values within the target range. Additional pharmacodynamic studies are also indicated.

O-222 3:05 PM Tuesday, October 20, 2020

A SURVEY STUDY OF THE LARGEST SERIES OF GAY AND BISEXUAL MEN PURSUING PARENTHOOD. Philip J. Cheng, MD,[1] Mark Leondires, M.D.,[2] Brent M. Hanson, MD,[1] Daniel J. Kaser, MD,[1] James Hotaling, MD[3] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]Reproductive Medicine Associates of Connecticut, Norwalk, CT; [3]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT.

OBJECTIVE: An increasing number of gay and bisexual men (GBM) are becoming parents. There is a lack of data to help GBM navigate this complex process. The aim of this study is to assess the needs and unique challenges of GBM who are interested in paternity with a focus on those who want to have biologically-linked children.

DESIGN: IRB-approved web-based questionnaire.

MATERIALS AND METHODS: Between April 2019 and May 2020, GBM were invited to participate in an online, anonymous survey through a high-volume fertility center and Facebook groups focused on GBM interested in parenthood. We used a standardized questionnaire with 26 multiple choice and Likert scale questions that focused on family building preferences, sperm source, egg donor and surrogate characteristics, access to care, legal issues, and financial burden.

RESULTS: 110 men who identified as gay (107, 97.3%) or bisexual (3, 2.7%) completed the questionnaire. The median age was 35 years (IQR 33-40) and the majority of respondents were in a relationship (103, 93.6%) and highly educated, with 69 men (62.7%) earning a post-graduate degree.

A subset of 85 men (77.3%) with an interest in biological parenthood were analyzed separately. The majority of respondents (67, 78.8%) desired more than one child and 54 (63.5%) used or plan to use sperm from both partners. While 83.6% of the 55 men who had pursued fertility services felt that the staff addressed their needs as a GBM, many of them had to travel to another state or country for services (40, 47.2%) and 23 (27.0%) men reported that these services were illegal for GBM where they lived. Only 8 (9.4%) men reported having insurance coverage for any costs associated with assisted reproductive technology and/or surrogacy. Accordingly, the majority of men (62, 72.9%) reported that financial issues were significant considerations in their family building decisions.

CONCLUSIONS: We have created a standardized survey tool to assess the needs of GBM, which can facilitate an individualized approach to treatment and measure access and barriers to care. The majority of gay and bisexual men surveyed want to pursue biological parenthood. These men face unique reproductive challenges, including impaired access to fertility care due to

legal and financial obstacles. Based on this survey, providers should be aware of educational levels, financial costs, and a common desire for two genetically-related intended fathers.

OVARIAN STIMULATION

O-223 1:50 PM Tuesday, October 20, 2020

DIFFERENTIAL OVARIAN RESPONSE TO GONADOTROPIN PREPARATIONS DESPITE SIMILAR OVARIAN RESERVE: MENOPUR IN GNRH (GONADOTROPIN RELEASING HORMONE) ANTAGONIST SINGLE EMBRYO TRANSFER - HIGH RESPONDER (MEGASET-HR) TRIAL ANALYSIS. Andrew F. Khair, PhD, MBA, Eric D. Foster, PhD, Anshul Sinha, B.Tech, Okan Umit Elci, PhD, Gaurang S. Daftary, MD, MBA, Patrick W. Heiser, PhD. Ferring Pharmaceuticals Inc, Parsippany, NJ.

OBJECTIVE: Assess possible interactions between treatment group [highly-purified human menopausal gonadotropin (HP-hMG) or recombinant follicle stimulation hormone (r-FSH)] and ovarian reserve as indicated by baseline levels of anti-Müllerian Hormone (AMH) on the number of oocytes retrieved.

DESIGN: Post-hoc analysis of a randomized, open-label, assessor-blind, non-inferiority trial conducted at 31 U.S. trials sites.

MATERIALS AND METHODS: 620 ovulatory women aged 21-35y with BMI 18-30 kg/m2 and serum anti-Müllerian hormone (AMH) $\geq$5 ng/mL were randomized 1:1 to a 150 IU start dose of HP-hMG (N=311) or rFSH (N=309) in a GnRH antagonist cycle with dose adjustments based upon response from day 6 onward. Human chorionic gonadotropin (hCG) was used to trigger oocyte maturation (GnRH agonist if at high risk of ovarian hyperstimulation syndrome [OHSS]). Central laboratory serum hormone measurements were measured at baseline and stimulation days: 6, day of/after trigger. Fresh transfer of a single blastocyst was performed in hCG-triggered cycles; all embryos were frozen if the risk of OHSS was high. Live births resulting from all fresh and any frozen transfers occurring within 6 months of randomization were collected. A normal regression model was used to explore interactions between treatment group and baseline AMH on the number of oocytes retrieved.

RESULTS: Demographics across treatment arms were similar (mean patient age: 30 years for both; HP-hMG, rFSH mean [SD] BMI: 24.4 [3.3], 24.3 [3.4] kg/m2; AMH: 7.8 [3.6], 7.5 [2.4] ng/mL; antral follicle count: 30.5 [15.5], 31.0 [12.2]). The average number of oocytes per patient in the rFSH arm (22.2 [11.54]) was significantly higher than in the HP-hMG arm (15.1 [10.12]) as were serum estradiol levels at stimulation days 6 and trigger and OHSS rates, described previously.[1] Cumulative live birth rates were similar between treatment groups at 51.5% and 50.6% in rFSH and HP-hMG arms respectively. A positive effect of baseline AMH levels on the number of oocytes retrieved was identified and differed statistically by treatment group (p value=0.032); subjects with higher baseline level of AMH had a larger ovarian response to rFSH versus HP-hMG. For every 1.6 ng/ml (11.1 pmol/L) increase in baseline AMH, rFSH stimulation results in one extra oocyte versus HP-hMG in predicted high-responders.

CONCLUSIONS: Increasing baseline AMH was associated with higher oocyte yields but no difference in cumulative live birth rates in rFSH vs HP-hMG treated patients, with an accompanying increase in OHSS rates also observed in the rFSH arm. This unexpectedly exaggerated ovarian response, which is positively correlated with increasing ovarian reserve based upon the well-established biomarker AMH, highlights a key distinction between the gonadotropin preparations evaluated, creating opportunities for further optimization of stimulation.

SERUM GONADOTROPIN ASSOCIATION WITH LIVE BIRTH IN HIGH-RESPONDERS UNDERGOING OVARIAN STIMULATION: MENOPUR IN GONADOTROPIN RELEASING HORMONE (GNRH) ANTAGONIST SINGLE EMBRYO TRANSFER - HIGH RESPONDER (MEGASET-HR) TRIAL ANALYSIS. Sarah A. Grover, MBBS, Eric D. Foster, PhD, Anshul Sinha, B.Tech, Okan Umit Elci, PhD, Gaurang S. Daftary, MD, MBA, Patrick W. Heiser, PhD. Ferring Pharmaceuticals Inc, Parsippany, NJ.

OBJECTIVE: To explore possible relationships between live birth rate (LBR) and age, endocrine variables [baseline anti-Müllerian hormone (AMH); Stimulation days 1, 6, day of/after trigger estradiol, progesterone, human chorionic gonadotropin (hCG), luteinizing hormone, and follicle stimulating hormone (FSH)] after controlled ovarian stimulation of predicted high-responders with either highly-purified menopausal gonadotropin (HP-hMG) or recombinant FSH (rFSH).

DESIGN: Post-hoc analyses of a randomized, open-label, assessor-blind, non-inferiority trial conducted at 31 U.S. trial sites.

MATERIALS AND METHODS: Ovulatory women aged 21-35 years with BMI 18-30 kg/m^2 and serum AMH $\geq$5 ng/mL (N=620) were randomized 1:1 to a 150 IU start dose of HP-hMG or rFSH in a GnRH antagonist cycle; dose revision was allowed from Day 6 onward based upon response. Serum hormone parameters at baseline and during stimulation were assessed by central laboratory. HCG was used to trigger oocyte maturation (GnRH agonist if at high risk of ovarian hyperstimulation syndrome) followed by mandatory single blastocyst transfer. Live birth outcomes resulting from all fresh and any frozen transfers occurring within 6 months of randomization were collected. Full efficacy and safety outcomes were presented previously.[1] Logistic regression was performed to separately identify relationships between each factor (per visit, as appropriate) and the cumulative live birth rate. Interaction effects of the factors with the treatment group (HP-hMG, rFSH) were investigated. Results were reported as odds ratio (OR) and 95% confidence intervals (CI) with corresponding p-values: **OR (CI; p-value)**.

RESULTS: Serum hCG on the last day of stimulation in HP-hMG treated subjects had a significant effect on the probability of live birth: **1.38 (1.00, 1.89; 0.048)**. For every 1 mIU/mL increase in hCG, the odds of live birth increased by 38%. hCG could not be detected in the serum of rFSH treated subjects. A significant serum FSH interaction by treatment group was identified on Day 6. For every 1 IU/mL increase in serum FSH the odds ratio of live birth was reduced by 13% in rFSH treated compared to HP-hMG treated subjects: **0.87 (0.77,0.98; 0.020)**. No other significant treatment interactions on live birth were found in the time points/factors evaluated.

CONCLUSIONS: The present analyses suggest that hCG derived from HP-hMG contributes positively to the likelihood of live birth when used in ovarian stimulation of predicted-high responders, creating an opportunity to target a serum hCG threshold through HP-hMG dosing. Moreover, the negative association of serum FSH levels in rFSH treated relative to HP-hMG treated subjects on stimulation day 6 following a fixed dose of 150 IU, could be explained by FSH isoform differences or hCG modulation early in the cycle. Further studies are required to confirm these findings and to provide mechanistic insight.

FRESH VERSUS FROZEN EUPLOID BLASTOCYST TRANSFER OUTCOMES IN PREDICTED HIGH-RESPONDERS: MENOPUR IN GNRH (GONADOTROPIN RELEASING HORMONE) ANTAGONIST SINGLE EMBRYO TRANSFER - HIGH RESPONDER (MEGASET-HR) TRIAL ANALYSIS. Patrick W. Heiser, PhD,[1] Jack L. Crain, MD,[2] Lauren Johnson, MD, MSCE,[2] Jennifer L. Patrick, MS, PhD,[2] Eric D. Foster, PhD,[1] Anshul Sinha, B.Tech,[1] Okan Umit Elci, PhD,[1] Gaurang S. Daftary, MD, MBA[1] [1]Ferring Pharmaceuticals, Inc, Parsippany, NJ; [2]Reproductive Endocrinology Associates of Charlotte, Charlotte, NC.

OBJECTIVE: To evaluate the impact of blastocyst ploidy on fresh and frozen transfer outcomes in predicted high-responders.

DESIGN: Post-hoc assessment of a randomized, open-label, assessor-blind, non-inferiority trial conducted at 31 U.S. centers.

MATERIALS AND METHODS: 620 ovulatory women aged 21-35y with BMI 18-30 kg/m^2 and serum anti-Müllerian hormone (AMH) $\geq$5 ng/mL (N=620) were randomized 1:1 to a 150 IU start dose of HP-hMG or rFSH in a GnRH antagonist cycle, with dose adjustments based upon response from day 6 onward. Human chorionic gonadotropin (hCG) was used to trigger oocyte maturation (GnRH agonist if at high risk of ovarian hyperstimulation syndrome [OHSS]). Day 5 trophectoderm biopsies were performed

for preimplantation genetic testing (PGT) by real-time polymerase chain reaction analysis. Fresh transfer of a single, best quality blastocyst selected by morphology was performed in hCG-triggered cycles; all embryos were frozen if the risk of OHSS was high. PGT results were only available to guide blastocyst selection for frozen transfers. Live births resulting from all fresh and any frozen transfers occurring within 6 months of randomization were collected, allowing for comparisons of single euploid blastocyst transfer outcomes in different transfer settings via logistic regression. To eliminate the confounding variable of a prior failed transfer in the trial, only outcomes from subjects' first transfer were considered. Full efficacy and safety outcomes were presented previously.[1]

RESULTS: There was no evidence of a difference between fresh and frozen transfer live birth rates for first trial transfer, even after normalization based on karyotype.

CONCLUSIONS: The novel MEGASET-HR trial design provides an opportunity to compare outcomes in morphologically-selected fresh vs euploid frozen transfer cycles. Use of PGT for embryo selection in frozen transfer cycles did not improve live birth rates in predicted high-responders $\leq$35 years of age. Importantly, euploid blastocyst outcomes were higher in fresh versus frozen transfer, questioning an emerging U.S. practice trend favoring freeze-all cycles in high-responders.

Live Birth n/N (%)			Live Birth n/N (%)	p-value*
First transfer, fresh	198/389 (50.9%)	First transfer, frozen, euploid	52/106 (49.06%)	0.899
First transfer, fresh, euploid	157/261 (60.15%)	First transfer, frozen, euploid	52/106 (49.06%)	0.104

* p-values based on treatment-adjusted logistic regression model.

EFFECT OF HOSPITAL VOLUME ON THE INCIDENCE OF MAJOR COMPLICATIONS IN PATIENTS HOSPITALIZED WITH OVARIAN HYPERSTIMULATION SYNDROME.

Rachel S. Mandelbaum, MD,[1] Liat Bainvoll, BS,[2] Meghan Brooke Smith, MD,[1] Shinya Matsuzaki, MD, PhD,[1] Jacqueline Ho, MD MS,[1] Kristen Bendikson, MD,[1] Richard J. Paulson, MD, MS,[1] Jason D. Wright, MD,[3] Koji Matsuo, MD, PhD[1] [1]University of Southern California, Los Angeles, CA; [2]Keck School of Medicine at USC, Los Angeles, CA; [3]Columbia University Medical Center, New York, NY.

OBJECTIVE: A relationship between higher hospital volume and improved outcomes has been established for many medical conditions and surgical procedures. However, it has not been previously studied with regards to ovarian hyperstimulation syndrome (OHSS). This study aimed to elucidate the association between hospital volume and OHSS-related complications in hospitalized patients.

DESIGN: A retrospective analysis of the National inpatient Sample from January 2001 to December 2011.

MATERIALS AND METHODS: Patients hospitalized with OHSS were included. International Classification of Disease 9th edition codes were used to examine incidence of major complications. Major complications were defined by the presence of ICD-9 codes for hypotension, shock or systemic inflammatory response syndrome, hemorrhage, coagulopathy, venous or arterial thromboembolism, pulmonary embolism, stroke, cerebral edema, myocardial infarction, pericardial effusion, pneumonia, respiratory failure, pulmonary edema, ovarian torsion, or ileus/small bowel obstruction. Annualized hospital volume was defined as the average number of patients with OHSS treated by a given hospital per year: low-volume (average 1 case/year), mid-volume (average $>$1 but $<$3.5 cases/year), and high-volume (average $\geq$3.5 cases/year, *i.e.* the top-decile). Characteristics and major complication rates related to hospital treatment volume were assessed with multivariable analysis.

RESULTS: There were 11,968 cases of OHSS treated at 735 hospitals; 2,441 (20.4%) patients were treated at low-volume centers, 5,078 (42.4%) at mid-volume centers, and 4,449 (37.2%) at high-volume centers. Of the entire cohort, 1,625 (13.7%) patients experienced a major complication during hospitalization. Patients treated at high-volume centers had lower rates of major OHSS-related complications (low-volume 15.6%, mid-volume 15.2%, and high-volume 11.0%; $P<0.001$). On multivariable analysis, treatment at a high-volume center was independently associated with a nearly 20% lower rate of major OHSS-related complications (adjusted-odds ratio 0.82, 95% confidence interval 0.70-0.97, $P=0.021$).

CONCLUSIONS: Major complications were common among patients admitted to the hospital with OHSS. Our study suggests that higher hospital volume may be associated with improved outcomes in OHSS.

PROLONGING FOLLICULAR STIMULATION TO OPTIMIZE OOCYTE YIELD DOES NOT COMPROMISE IMPLANTATION POTENTIAL OF SCREENED EMBRYOS.

Jenna Friedenthal, MD,[1] Sydney Chang, MD,[1] Dmitry Gounko, MA,[2] Joseph A. Lee, BA,[2] Alan B. Copperman, MD,[1] Tanmoy Mukherjee, MD[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: The number of oocytes retrieved following stimulation is an independent predictor of in vitro fertilization (IVF) cycle outcome. During fresh IVF cycles, oocyte maturation trigger (OMT) must be carefully timed in order to simultaneously optimize oocyte development and endometrial receptivity, which is based on the timing of luteinization. However, with the increased utilization of freeze-all cycles, reproductive endocrinologists have shifted the focus of stimulation to maximizing oocyte yield. The potential benefits of this strategy must be weighed against potential negative impacts, including hyperstimulation syndrome and impaired oocyte quality. Prior work has shown that delayed administration of OMT does not negatively impact the oocyte maturation rate, fertilization rate, and euploid rate[1]. Studies to date have not yet evaluated associated clinical pregnancy outcomes. Our goal was to determine whether delayed OMT is associated with IVF outcomes following single thawed euploid embryo transfer (euploid SET).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: The study included patients who underwent euploid SET in GnRH-antagonist IVF cycles from 2016 to 2019. IVF cycles were divided into two groups: (1) administration of OMT in the presence of at least 2 follicles 18mm in diameter, and (2)delayed OMT despite the presence of at least 2 18mm follicles . Preimplantation genetic testing for aneuploidy (PGT-A) was performed using next generation sequencing (NGS). Primary outcome was implantation rate (IR). Secondary outcomes included ongoing pregnancy/live birth rate (OP/LBR) and clinical loss rate (CLR). Cycles involving transfer of $>$1 screened embryo or unscreened embryos were excluded. Statistical analysis was performed using T-tests, Wilcoxon two-sample T-test (non-parametric), and a logistic regression analysis with a generalized estimation equation to control for confounders with $p<0.05$ considered significant.

RESULTS: 2,701 euploid SETs were performed during the study period. Among these, 2,132 were from cycles in which OMT was administered in the presence of $\geq$2 mature follicles, and 569 were from cycles in which OMT was delayed despite the presence $\geq$2 mature follicles. Univariate analysis demonstrated differences in patient age and peak estradiol. In an unadjusted analysis, there was a significant difference in IR between patients who were triggered when 2 mature follicles were visualized vs delayed OMT (61.12% vs 66.26%, P=0.02). However, after adjusting for confounders, there were no significant differences in IR (OR 0.72, 95% CI 0.48-1.08), OP/LBR (OR 0.75, 95% CI 0.51-1.10), or CLR (OR 0.80, 95% CI 0.38-1.71).

CONCLUSIONS: In the largest study to date evaluating the impact of delayed OMT during controlled ovarian stimulation cycles, our results demonstrated no association between delay in OMT and IR, OP/LBR, or CLR. Patients can be reassured that prolonging stimulation to optimize oocyte yield does not negatively impact cycle outcome. Prospective studies are needed to more definitively understand the optimal timing of trigger administration.

DOES THE TIMING OF CABERGOLINE ADMINISTRATION IMPACT RATES OF OHSS?

Eryn Sarah Rubenfeld, M.D., Daniel Dahan, NA, Yehuda Dahan, NA, Michael H. Dahan, M.D. McGill University, Montreal, QC, Canada.

OBJECTIVE: To investigate whether the timing of dopamine agonist (either at the time of trigger or on the day of oocyte collection) impacts the rates, symptomatology or severity of ovarian hyperstimulation syndrome (OHSS) in a group with GnRH-agonist triggering.

DESIGN: A retrospective cohort study of 285 patients undergoing IVF treatment at the McGill University Health Center (MUHC) between June 1st, 2011 and December 31st, 2019.

MATERIALS AND METHODS: 285 patients who were at high risk of OHSS based on peak serum estradiol (E2) levels > 3,500 pg/mL (the equivalent of approximately 13,000 pmol/L) or stimulation of at least 17 follicles were divided into two groups. Both groups were on the GnRH-antagonist protocol, had final oocyte maturation triggered using a GnRH-agonist and received cabergoline 0.5mg orally daily for 7 days. 101 subjects initiated Cabergoline at the time of trigger (Trig), while 184 patients started on the day of oocyte retrieval (Retriev). Statistical analysis was performed with Analysis of Variance (ANOVA) or chi-squared (X^2) testing where appropriate. Data is presented as mean±SD or %. The Navot criteria for OHSS were used. A power analysis suggested an 82% power to detect the observed differences with an alpha error of 5%.

RESULTS: Both groups were of similar ages (p=0.72), basal serum FSH levels (p=0.11) and rates of PCOS (p=0.57). Trig appeared to be at slightly higher risk of OHSS based on a statistically higher antral follicle count (20.2±4.2 vs. 19.0±4.3; p=0.02), higher number of stimulated follicles >10mm at trigger (25.7±7.0 vs. 22.8±8.3, p=0.003) and higher peak serum E2 (17325±2542 vs. 14822±3098; p=0.0001). Other stimulation parameters including FSH dose were similar. The Trig group had lower rates of mild and moderate OHSS (24% vs. 36%; p=0.045). Neither group had any patients develop severe OHSS. Fewer patients in Trig presented with pelvic free fluid (13% vs. 23%; p=0.03). In the subgroup of patients who had blood drawn (N=181), the Trig subjects showed less hemoconcentration (hemoglobin 12.6 vs. 13.5; p=0.0001, albumin 30.4 vs. 29.5; p=0.0001 and potassium 3.9 vs. 4.2; p=0.0002). There were no differences in the number of subjects presenting with discomfort or bloating (p=0.7). No patients in Trig reported weight gain, compared to 2 patients in Retriev.

CONCLUSIONS: Our findings suggest a potential benefit to prescribing Cabergoline to start on the day of GnRH agonist trigger for patients who are at risk of OHSS, as opposed to waiting until the day of oocyte collection. Our study is the first one to look specifically at whether the timing of cabergoline administration affects the rates and severity of OHSS. Larger, prospective studies in women receiving hCG should confirm these findings.

MALE REPRODUCTION AND UROLOGY: RESEARCH

O-229 1:50 PM Tuesday, October 20, 2020

FUNCTIONAL AND TAXONOMIC DYSBIOSIS OF THE GUT, URINE, AND SEMEN MICROBIOME IN MALE INFERTILITY.

Scott Lundy, MD PhD,[1] Naseer Sangwan, PhD,[1] Neel Parekh, MD,[1] Manesh Panner Selvam, PhD,[1] Sajal Gupta, MD,[1] Peter McCaffrey, MD,[2] Kovi Bessoff, MD, PhD,[2] Ayin Vala, MS,[2] Ashok Agarwal, PhD,[1] Edmund Sabanegh, MD,[1] Sarah C. Vij, MD,[1] Charis Eng, MD, PhD[1] [1]Cleveland Clinic, Cleveland, OH; [2]Vastbiome, Millbrae, CA.

OBJECTIVE: The microbiome refers to the unique community of microbes present in nearly every niche in the human body, but the role of the genitourinary and gastrointestinal microbiomes in the pathogenesis of male infertility remains poorly understood. To test the hypothesis that the microbiome is associated with idiopathic male infertility, we explored the gut, urine, and semen microbiomes of infertile men and compared these to paternity-proven fertile controls using both marker-based gene sequencing and shotgun metagenomics.

DESIGN: We prospectively enrolled 25 men with primary infertility and 12 paternity-proven controls. We collected semen, midstream urine, and rectal swab specimens and positive/negative experimental controls.

MATERIALS AND METHODS: We performed a detailed history and physical exam, comprehensive semen testing, hormonal profiling, and 16S ribosomal RNA (rRNA) gene sequencing for quantitative taxonomic analysis at strain resolution. Using shotgun metagenomics, we then compared molecular functional pathway expression differences between fertile and infertile men.

RESULTS: We identified a diverse semen microbiome similar to urine but distinct from the rectal microbiome. Infertile men harbored decreased rectal *Anaerococcus* and increased seminal *Aerococcus* compared to fertile controls. *Prevotella* was inversely associated with sperm concentration, and *Pseudomonas* was directly associated with total motile sperm count. Several anaerobes were highly overrepresented in infertile, but not fertile, men with a varicocele. Oxidative stress and leukocytospermia were associated with only subtle differences in the microbiome. Vasectomy appeared to alter the seminal microbiome, suggesting a testicular or epididymal contribution. Metagenomics data from infertile men revealed significant differences in the S-adenosyl-L-methionine (SAM) cycle, which is involved in DNA methylation, antioxidant production, and polyamine synthesis and may play a multifaceted role in the pathogenesis of infertility.

CONCLUSIONS: This pilot study represents the first comprehensive investigation into the microbiome in male infertility and provides proof-of-principle for future mechanistic studies to explore causality and design future diagnostic and therapeutic strategies for men with this complex, costly, and emotionally debilitating disease.

O-230 2:05 PM Tuesday, October 20, 2020

INCREASING PATERNAL AGE IS NEGATIVELY ASSOCIATED WITH DONOR OOCYTE RECIPIENT SUCCESS: A PAIRED ANALYSIS UTILIZING SIBLING OOCYTES.

Kelly McCarter, MD,[1] Robert Setton, MD,[2] Alice Chung, BA,[2] Zev Rosenwaks, M.D.,[2] Steven Spandorfer, MD[2] [1]Weill Cornell Medicine, New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: Compared to maternal age, there is a less robust understanding of the effects of paternal age on pregnancy outcomes. Some studies have shown that increasing paternal age has a negative effect on assisted reproductive outcomes, while others have shown no clear association. However, many of these studies have been unable to adequately control for oocyte quality, which affects embryo quality and IVF success rates. ART using sibling-oocyte recipients (oocytes from the same donor stimulation transferred to two different recipients) offers a unique model that controls to the greatest degree possible for oocyte quality. We sought to determine if increasing paternal age has an adverse effect on implantation and pregnancy rates by analyzing outcomes in sibling-oocyte recipients.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients who underwent donor egg recipient (DER) cycles in which oocytes from a single controlled ovarian hyperstimulation cycle were split between two recipients were included. The two recipients of the single-donor oocyte cycle were paired and categorized based on paternal age of donor sperm (group A: <45 years old; group B: >45 years old). Patients with uterine factor and severe male factor infertility, including the use of surgically retrieved sperm, were excluded. The primary outcome was implantation rate. Secondary outcomes were positive pregnancy, live birth, and miscarriage rates. Statistical analysis included paired t-tests, and $p<0.05$ was deemed statistically significant.

RESULTS: A total of 1,013 patients who underwent DER cycles between January 2010 and December 2016 were screened for inclusion, of which 408 patients had received oocytes from a split donor oocyte cycle. There were 87 pairs of patients (174 recipients) who received sperm from men with discrepant age based on the pre-specified groups. The mean age was 39.8 years old for group A and 49.5 years old for group B. The groups were similar for gravity, parity, body mass index, number of embryos transferred, peak endometrial stripe, and prior uterine surgery. The implantation rates were found to be significantly higher in group A compared to group B (62.6% ± 4.6% vs. 47.7% ± 4.7%, p=0.026). Likewise, the positive pregnancy rates (82.8% ± 4.1% vs. 66.7% ± 5.1%, p=0.005) and live birth rates (66.7% ± 5.1% vs. 51.7% ± 5.4%, p=0.03) were significantly higher in group A, the younger age group. Miscarriage rates were similar for groups A and B (19.3% ± 5.5% vs. 25.0% ± 6.1%, p=0.44).

CONCLUSIONS: In this idealized model that controls to the greatest degree possible for oocyte quality by using paired recipients from the same

donor from the same stimulation cycle, we found that increasing paternal age had a negative effect on implantation, positive pregnancy, and live birth rates.

O-231 2:20 PM Tuesday, October 20, 2020

POST-MORTEM EXAMINATION OF THE EFFECTS OF SEVERE ACUTE RESPIRATORY SYNDROME (SARS) ASSOCIATED CORONAVIRUS (SARS-COV) ON TESTIS. Justin K. Achua, MS, Kevin Y. Chu, MD, Himanshu Arora, PhD, Oleksii Lakymenko, MD, Oleksandr N. Kryvenko, MD, Ranjith Ramasamy, M.D. University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: The coronavirus disease 2019 (COVID-19) caused by the SARS-CoV-2 quickly grew into a global pandemic. The virus has been known to impact the respiratory system; however, the extent of impact on testicular tissue remains unknown. It has been found that COVID-19 binds to angiotensin converting enzyme (ACE) 2 receptors, and since ACE2 expression is high in the testes we believe COVID-19 may be prevalent in testes tissue.

DESIGN: In the present study, we analyzed the pathological changes within the testes of three patients who died of COVID-19 pneumonia and sepsis.

MATERIALS AND METHODS: In the present study, autopsy collection was done according to the University of Miami protocol. Testes tissue we collected from COVID-19 positive men (n=3) as well as COVID-19 negative men (n=3) to be used as controls. Tissue was formalin fixed and paraffin embedded. Samples were sectioned to 5-micron sections and stained with hematoxylin and eosin (H&E) as well as subjected to various fluorescently labeled antibodies to specifically differentiate cells or fluorescently labeled COVID RNA hybridization strands within the testes tissue. Fluorescent-labeled tissue slides were imaged on a quantitative pathology scope with various zoom levels allowing for comprehensive qualitative and quantitative imaging.

RESULTS: Among pathological examination of H&E stained slides from COVID-19 positive men, one case demonstrated increased inflammation and leukocyte infiltration, as well as occasional seminiferous tubules comprised of only Sertoli cells. The other 2 showed no abnormal change. These 2 cases had no leukocyte or macrophage infiltration, no inflammation, no abnormal basement membrane thickening, or changes to spermatogenesis. There was little to no difference between the two COVID-19 positive cases and COVID-19 negative controls. Sectioned slides from both COVID-19 positive as well as COVID-19 negative men are currently undergoing fluorescent labeled antibody staining for COVID RNA with results pending.

CONCLUSIONS: This study suggests that, despite the increase in ACE2 receptor presence in testes tissue and the SARS-CoV-2 virus' propensity to bind to said receptor, the male reproductive tract may not be targets of COVID-19 infection in all men. Whether COVID-19 RNA is detected in testes tissue remains to be evaluated.

TOP TEN PRIORITIES FOR MALE INFERTILITY RESEARCH. James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Cindy Farquhar, FRANZCOG FRCOG MD MPH,[2] Priority Setting Partnership for Infertility. [1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop the top 10 research priorities for male infertility.

DESIGN: International consensus development study. Healthcare professionals, men with fertility problems, and others were brought together in an open and transparent process using formal consensus methods advocated by the James Lind Alliance.

MATERIALS AND METHODS: Potential research questions were collated from an initial international survey, a systematic review of male infertility guidelines, and Cochrane systematic reviews. A rationalized list of confirmed research uncertainties were prioritized in an international survey. Prioritized research uncertainties were discussed during a face-to-face consensus development meeting.

RESULTS: The initial survey was completed by 388 participants, from 40 countries, and 107 potential research questions were submitted. By reviewing five clinical practice guidelines and four Cochrane systematic reviews a further 18 potential research questions were identified. A rationalized list of 34 confirmed research uncertainties were entered into an interim prioritization survey completed by 317 respondents from 43 countries. The top 10 research priorities for male infertility were identified during a consensus development meeting involving 41 participants from 11 countries (Table 1).

TABLE 1. Top 10 research priorities for male infertility.

1	Are sperm tests other than bulk parameters useful in evaluating male fertility? If so, which?
2	What is the emotional and psychological impact of male infertility? Can addressing it improve outcomes?
3	Do environmental factors cause male infertility? If so, which?
4	Does treating specific causes of male infertility improve outcomes?
5	Can we improve surgical sperm extraction outcomes by using endocrine stimulation protocols?
6	What modifiable risk factors cause male infertility?
7	Does treating modifiable risk factors improve outcomes?
8	What co-morbidities are associated with infertility?
9	Does treating co-morbidities improve outcomes?
10	Are nutraceuticals useful in improving male reproductive potential? If so, which?

CONCLUSIONS: We anticipate the top 10 research priorities for male infertility will help research funding organizations and researchers to develop their future research agenda. Healthcare professionals, professional organisations and patient advocacy groups should champion the research priorities to highlight the many unanswered questions which need to be addressed in order to improve the outcomes of men with fertility problems.

THRESHOLDS FOR TESTICULAR SIZE DISCREPANCY IN FERTILE MEN WITH AND WITHOUT VARICOCELE. William T. Berg, MD,[1] Gabriella J. Avellino, MA, MD,[1] Kathleen Hwang, MD,[2] Mark Sigman, MD[1] [1]Brown University, Providence, RI; [2]University Pittsburgh, Urology, Pittsburgh, PA.

OBJECTIVE: The difference in testicular sizes between right and left testes is often utilized to determine the effect of pathology such as varicoceles on testicular growth. Furthermore, the normal testicular size differential in adult fertile men is currently unknown. We sought to characterize the testicular size distribution in fertile men with and without clinical varicoceles.

DESIGN: Cross-sectional retrospective cohort study.

MATERIALS AND METHODS: Records from men presenting for vasectomy consultation were evaluated. Men with a history of a solitary testicle, testicular torsion, or infertility were excluded. Only those men who fathered children were included. Testicular volume was measured using a modified Takihara orchidometer. The modified orchidometers were created using an ellipse formula and 3-D printing to make larger rings up to 60 cc to allow for measurements of testes beyond the original orchidometer ring size, which went up to only 34 cc. Testicular size measurement and the presence or absence of varicocele was determined by clinical exam by three fellowship trained male infertility specialists. Testicular size distribution and differential means were calculated. Reference ranges and differences in testicular size were calculated to include 95% of the patients. Comparisons were then made between those with and without varicoceles. Parametric statistics were used for normally distributed data (testicular sizes) while non parametric tests of significance were used for non-normally distributed data (difference s in testicular size).

RESULTS: Out of 3,235 men, 618 met inclusion criteria. In fertile men without a varicocele, the mean left testis volume was 31.4 cc (95% population range 17.5 – 48.6 cc) and the mean right testis volume was 32.5 cc (95 % population range 17.5 – 55.0 cc). Testicular size was greater on the right than on the left in 88% of men. A varicocele was present in 17.7% of patients. The presence of a varicocele was associated with decreased testicular size on both the left (31.4 cc vs 27.9 cc, $p<0.01$) and the right (32.5 cc vs 30.5 cc, $p=0.03$). In patients whose right testicle was larger than or equal to

the left testicle, the mean size discrepancy was 2.0 cc vs 3.2 cc in those without a varicocele compared to those with a varicocele ($p<0.001$). The mean percentage size discrepancy between right and left testicles in these patients was 5.8%. vs 10.3% ($p < 0.001$). In addition, 95% of these patients had a difference in testis volume of less than or equal to 8 cc and a percent difference in testicular size of less than or equal to 23%.

CONCLUSIONS: In fertile men, the normal reference limits for left testicular volume is approximately 17 cc to 50 cc. In addition, the normal upper reference range threshold for the difference in testicular size in fertile men without varicocele is 8 ml or 23%. This is the first study to date to establish population means and normal ranges for a cohort of fertile men without varicocele. In patients with a varicocele, testicular size can be expected to decrease accordingly. These reference ranges will serve as important guides when assessing male fertility status.

EVALUATION OF SERUM 17-HYDROXYPROGESTERONE AS PREDICTOR OF SEMEN PARAMETER IMPROVEMENT IN MEN UNDERGOING MEDICAL TREATMENT FOR INFERTILITY.

Thiago Fernandes Negris Lima, MD,[1] Premal Patel, M.D.,[2] Ruben Blachman-Braun, M.D., M.Sc.,[3] Evgeniya Rakitina, MS,[3] Ranjith Ramasamy, MD,[1] 17 ohp. [1]University of Miami, Miami, FL; [2]University of Manitoba, Winnipeg, MB, Canada; [3]University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: To identify infertile men with testosterone deficiency (TD) who will respond with semen parameters improvement to medical therapy with clomiphene citrate (CC) and human chorionic gonadotropin (hCG).

DESIGN: Prospective cohort study from July 2018 to January 2020.

MATERIALS AND METHODS: We included men with impaired semen parameters and TD. Men received either CC or CC/hCG if history of testosterone use. We assessed demographic information, serum testosterone (T), 17-hydroxyprogesterone (17-OHP) - maker of intratesticular testosterone (ITT), follicle-stimulating hormone (FSH), luteinizing hormone (LH), and semen parameters before and after therapy. Semen quality upgrading was based on assisted reproduction eligibility: in vitro fertilization (< 5 million), intrauterine insemination (IUI) (5-9 million), and natural pregnancy (> 9 million). Variables were compared using the U Mann Whitney or Wilcoxon rank test.

RESULTS: 31 men were included. Median follow-up was 3.7 [3.3 – 5.1] months. 16 men upgraded semen quality. 6/10 men with initial total motile sperm count (TMSC) of 0 had motile sperm after treatment, and 11/20 men with TMSC < 5 upgraded semen quality into the range of IUI / natural pregnancy. Low 17-OHP was the only factor that predicted semen quality upgrading. Men with 17-OHP ≤ 55ng/dL upgraded semen quality along with improving hormones, whereas men with 17-OHP > 55ng/dL did not upgrade semen quality. (Table 1)

CONCLUSIONS: Medical therapy for infertile men with TD resulted in the improvement of sperm concentration, TMSC, T and 17-OHP. Semen quality upgrading appears to be more significant in patients with low 17-OHP, suggesting that ITT can be used as a biomarker to predict semen parameters improvement.

DO OUTCOMES OF EMBRYO TRANSFERS DIFFER WHEN COMPLETED BY REPRODUCTIVE ENDOCRINOLOGY AND INFERTILITY (REI) FELLOWS VERSUS FACULTY? AN 11-YEAR RETROSPECTIVE REVIEW.

Colleen Miller, M.D.,[1] Samir Babayev, M.D.,[1] Yulian Zhao, Ph.D.,[2] Stephanie Duong, M.S.,[1] Amy Weaver, M.S.[1] [1]Mayo Clinic, Rochester, MN; [2]Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, MN.

OBJECTIVE: To compare the clinical pregnancy rate (CPR) and live birth rate (LBR) of embryo transfers performed by REI fellows versus faculty physicians.

DESIGN: Retrospective cohort analysis.

MATERIALS AND METHODS: All patients who underwent an embryo transfer (ET) at Mayo Clinic Rochester from 1/2009 - 1/2020 were identified. Only patients who denied research access to their records were excluded. First-year fellow ETs occurred only after completion of 30 mock transfers under faculty supervision. The primary outcomes, CPR and LBR, were evaluated based on fitting generalized linear regression models assuming a binomial distribution and the logit link function, with fellow/faculty as a random effect, and adjusted for patient age, autologous or donor oocyte, fresh or frozen embryo, and the number of embryos transferred.

RESULTS: Fifteen fellows completed 1,236 (39.9%) of 3,100 total transfers during the study period. A comparison of all fellow versus faculty transfers showed no statistically significant difference in the CPR or the LBR (Table 1). This was also true when differentiating between autologous and donor oocyte transfers. When outcomes were stratified by fellowship year (FY1, FY2, FY3), the CPR (43.6% vs. 43.3% vs. 44.8%, p=0.92) and LBR (38.4% vs. 38.7% vs. 36.0%, p = 0.92) were similar. Eleven fellows completed at least 30 ETs in their FY1. Comparing each fellow's initial 30 ETs to all future FY1 ETs found that the CPR (48.2% vs. 40.6%, p=0.018) and LBR (45.0% vs. 34.5%, p=0.001) were both significantly higher among the initial transfers. One explanation may be that fellows were more likely to transfer at least 2 embryos during their first 30 ETs as compared to subsequent transfers (60.6% vs. 45.7%, p<0.001).

CONCLUSIONS: To date, this is the largest and most extensively controlled study of outcomes of embryo transfers performed by REI fellows versus faculty physicians. We found no differences in clinical outcomes between fellow and faculty transfers. First-year fellows who were appropriately trained had success rates equal to more experienced fellows, even among their first 30 transfers. These data demonstrate that allowing fellows to perform live ETs would not have a detrimental effect on clinical outcomes.

TABLE 1. Comparison of hormones levels and semen parameters at baseline and follow-up according to baseline 17-OHP (ng/dL).

	17-OHP > 55			17-OHP ≤ 55		
	Baseline (n = 12)	Follow-up (n = 12)	p-value	Baseline (n = 19)	Follow-up (n = 19)	p-value

TABLE 1. Comparison of Outcomes of ETs Performed by REI Fellows vs. Faculty, Overall and Stratified by Autologous vs. Donor Oocyte

Outcome	Fellows	Faculty	p
CPR			
Overall	43.7% (540/1236)	41.3% (770/1864)	0.28
Autologous	43.7% (495/1132)	40.8% (665/1628)	0.26
Donor Oocyte	43.3% (45/104)	44.5% (105/236)	0.78
LBR[†]			
Overall	38.2% (435/1139)	36.2% (602/1665)	0.38
Autologous	38.2% (396/1038)	35.6% (514/1446)	0.36
Donor Oocyte	38.6% (39/101)	40.2% (88/219)	0.78

[†]Analysis of the LBR was restricted to the 2,084 transfers performed prior to 3/22/2019.

O-236 2:05 PM Tuesday, October 20, 2020

EVALUATING TRENDS IN AUTHORSHIP BY GENDER WITHIN *FERTILITY AND STERILITY*, 2005-2019. Chelsea Henshaw, MD, Jaden R. Kohn, MD, MPH, Melissa McHale, MD, Kristin Darwin, MD, Holly Rankin, MD, Shari M. Lawson, MD, MBA. Johns Hopkins University School of Medicine Department of GYN/OB, Baltimore, MD.

OBJECTIVE: To examine trends in academic mentorship in Reproductive Endocrinology and Infertility research by assessing the genders of first and last authors of publications in *Fertility and Sterility*.

DESIGN: A bibliometric analysis of *Fertility and Sterility*.

MATERIALS AND METHODS: This study included case series, original research, and systematic reviews from *Fertility and Sterility* from 2005-2019. Data was obtained from *Fertility and Sterility* through Web of Science. The genders of the first and last author were determined using a validated gender-inference algorithm to assign gender to the corresponding first name. For first names with less than 70% gender assignment accuracy, gender identities were confirmed using internet searches of the individual and/or name. Cochrane-Armitage test and linear regression were used.

RESULTS: Gender of first and last authors was identified for 6,692 of 7,754 publications in *Fertility and Sterility* from 2005-2019.

A woman fulfilled the first author position of 40.5% of publications from 2005-2019, which slightly increased to 48.8% from 2010-2019. Women were the last authors of only 21.9% of all publications from 2005-2009, with an increase to 30.8% from 2010-2019 ($p<.05$).

Women were both the first author and last author of 11.5% of all publications from 2005-2009, however this percentage has increased to 19.7% over the past decade and a half ($p<.05$). Men as a first and last author pairing for publications decreased from 49% in 2005-2009 to 36% of all publications in 2010-2019 ($p<.05$).

Overall from 2005-2019, a publication is 2.74 times more likely to have a female first author and male last author pair versus a male first author with a female last author pair. However, over time this gap has decreased.

CONCLUSIONS: Over the past nearly two decades, dramatic changes can be seen when evaluating the author gender trends of publications in *Fertility and Sterility*. This suggests an increase in representation of women as leaders in the field of Reproductive Endocrinology and Infertility. Although these advances are commendable, gender equity in this field of academia has not yet been reached.

Genders of first- and last- author pairs in *Fertility & Sterility, 2005-2019*

Year	Both male authors	Both female authors	First author female, Last author male	First author male, Last author female
2005	56	11	24	9
2006	52	10	24	14
2007	50	11	29	10
2008	50	11	29	10
2009	47	13	30	10
2010	43	16	29	11
2011	40	15	35	10
2012	36	19	31	13
2013	33	21	33	13
2014	35	20	32	14
2015	37	19	32	13
2016	30	20	37	13
2017	35	19	32	14
2018	32	26	32	9
2019	30	19	38	13

O-237 2:20 PM Tuesday, October 20, 2020

EXPERIENCE EQUALS EXPERTISE: OUTCOMES OF LIVE EMBRYO TRANSFERS (ET) BY REPRODUCTIVE ENDOCRINOLOGY AND INFERTILITY (REI) FELLOWS (FEL) COMPARED TO ATTENDING (ATT) PHYSICIANS. Jacquelyn Shaw, MD,[1] Carlos M. Parra, MD,[2] Jennifer K. Blakemore, MD,[1] Mary Elizabeth Fino, MD,[1] Frederick L. Licciardi, M.D.[2] [1]NYU Langone Prelude Fertility Center, New York, NY; [2]NYU Langone Health, New York, NY.

OBJECTIVE: Live embryo transfer is arguably the most important skill learned in REI fellowship, yet approximately half of 3rd year fellows perform <10 ETs prior to graduation.[1] Some educators believe ETs performed by trainees reduce pregnancy rates.[2] Our center employs a thorough ET education with vast live ET training. Our objective was to examine if ET outcomes differ by FEL and ATT REI physicians.

DESIGN: Retrospective cohort study of all ETs at a large urban university based fertility center from 7/2015-3/2020.

MATERIALS AND METHODS: Our center completes >500 ETs annually, with FELs directly involved from year one. All ETs are direct and ultrasound (US) guided. FELs perform the US for all ATT ETs throughout fellowship. FELs complete 50 IUIs and perform 10 supervised, US guided IUIs with ET catheter before initiating supervised live ET. FEL ETs were identified and compared to those performed by ATT. The primary outcome was clinical pregnancy (CP) rate per euploid ET. Secondary outcomes evaluated livebirth/ongoing pregnancy (LB/OP) and spontaneous abortion (SAB) rates in all types of ET and by FEL year. Statistical analysis was performed using Chi-square and, with $p<0.05$ considered significant.

RESULTS: 5534 total ETs were completed, with 252 (5%) performed by 4 clinical FEL. FEL performed 17% (42) fresh, 71% (179) frozen, 11% (28) donor egg, and 59% (149) euploid ETs, at similar rates compared to ATT ($p=0.17$). 26% (66) of ETs were performed by a 1st year, 28% (70) by a 2nd year, and 46% (115) a 3rd year FEL, with no difference in ET type ($p=0.25$). For euploid ETs performed by FEL compared to ATT physicians (respectively), the CP [68% (101/148) vs. 69% (2360/3413)], biochemical [12% (18/148) vs. 9% (300/3413)], and ectopic [0.7% (1/148) vs. 0.3% (11/3413)] rates were statistically the same ($p=0.37$). Euploid LB/OP rates (60% vs. 59%) and SAB rates (3% vs. 7%) were the same ($p=0.26$). For all ETs, the CP [65% (163/251) vs. 62% (3172/5082)], biochemical [11% (28/251) vs. 10% (501/5082)], and ectopic [0.4% (1/251) vs. 0.3% (16/5082)] rates were statistically similar ($p=0.55$), as were the LB/OP rates (53% vs 52%) and SAB rates (8% vs 8%) ($p=0.89$). Analysis of individual FEL year compared to ATT or other FEL years produced similar results with no statistical difference ($p=0.64$). The 1st 10 FEL ETs (40 total) resulted in slightly lower but not statistically different CP (63%) and LB (48%) rates, with higher biochemical (13%) and SAB (15%) rates ($p=0.31$-0.93). To ensure FEL clinical proficiency, defined as no more than 10% different from the 65% ATT CP rate with 95% confidence, an a priori power analysis approach determined that the minimum number of FEL live ETs needed is 45.

CONCLUSIONS: ETs performed by REI FELs produce the same clinical pregnancy and livebirth rates as ATT physicians, without increased rates of biochemical pregnancies, ectopic pregnancies or miscarriages. Live ETs are essential to fellowship training, can be taught effectively with hands-on experience, and can be performed without compromising patient outcomes. We suggest a well-defined educational pathway for FELs to gain proficiency with a goal of 45 live ET during fellowship.

O-238 2:35 PM Tuesday, October 20, 2020

FERTILITY PRESERVATION AND INFERTILITY TREATMENT IN MEDICAL TRAINING: AN ASSESSMENT OF RESIDENCY PROGRAM DIRECTORS' ATTITUDES ACROSS SPECIALTIES IN THE UNITED STATES. Megan B. Huynh, BS candidate,[1] Ange Wang, MD,[2] Lusine Aghajanova, MD PhD[3] [1]Georgetown University, Washington, DC; [2]Stanford University School of Medicine, Stanford, DC; [3]Stanford University, Stanford, CA.

OBJECTIVE: To assess knowledge and support of residency program directors (PDs) in the United States towards the reproductive needs of their residents.

DESIGN: Cross-sectional survey.

MATERIALS AND METHODS: An online survey emailed to residency PDs of various medical specialties in the US.

RESULTS: Respondents included 299 PDs, with the most represented specialties being Emergency Medicine (11.0%), Obstetrics & Gynecology (9.7%), and Family Medicine (9.0%). The most common lengths of parental leave were 6-8 weeks of maternity leave (30.4%) and less than two weeks of paternity leave (33.1%). The majority of PDs lacked knowledge of their program's specific fertility insurance policies; 57.2% did not know about coverage for infertility treatment and 68.6% reported not knowing coverage for fertility preservation. 52.2% of PDs surveyed were unaware if any of their residents were facing infertility or recurrent pregnancy loss. PDs reported offering fertility-related support in the forms of moral support (68.2%), time off for appointments (65.2%), and insurance coverage (36.1%). 56.2% of PDs felt that their personal level of support was aligned with their programs'. Regarding fertility preservation, the majority of PDs (66.2%) reported never having a resident express interest to them; main resources available to residents included moral support (59.2%) and time off for appointments (48.5%). Similar to infertility treatment policy, the majority of program directors (55.9%) felt that their personal level of support was aligned with their program's for fertility preservation. Most respondents felt it was important to increase resources for residents interested in infertility treatment and fertility preservation and believed the best ways to do so were increasing their own personal awareness of individual needs (47.5%), establishing official policies on fertility treatment (34.1%), and financial support (33.4%). PDs reported that time (32.1%) and costs (24.8%) were the primary barriers that prohibited residents from seeking treatment for fertility-related issues. Stratification of results by PDs in surgical and non-surgical specialties, as well as by gender, revealed differences in support level and knowledge. Surgical specialty PDs emphasized more the need for increased resources for their residents' fertility needs, and male PDs generally appeared less knowledgeable about their residents' fertility issues.

CONCLUSIONS: The study found wide variance regarding residency PDs' personal knowledge and levels of support for their residents' fertility needs. The majority of PDs were unaware of fertility issues that their residents may be going through but were commonly ready to offer moral support and time off for any fertility-related issues. While many PDs felt that their personal level of support was aligned with their program's, they also felt that it would be important to improve resources for their residents, through increasing their own awareness of these issues, creating policies related to fertility treatment, and providing financial support for the treatment.

O-239 2:50 PM Tuesday, October 20, 2020

IMPROVING RESIDENT EDUCATION AND MASTERY IN REPRODUCTIVE ENDOCRINOLOGY AND INFERTILITY FOR THE GENERALIST OB/GYN: A SURVEY-BASED STUDY. Emma V. Gilmore, MD,[1] Jennifer K. Blakemore, MD,[1] Susan Maxwell, MD,[2] Shannon Devore, MD[1] [1]NYU Langone School of Medicine, New York, NY; [2]Northwell Health, New York, NY.

OBJECTIVE: Exposure to Reproductive Endocrinology and Infertility (REI) varies widely among OB/Gyn residencies, with most depending on a single 3-4 week rotation. At our institution, residents provide care to an underserved infertility population through ovulation induction (OI). However, the system was not optimized for education, so a new PGY2-directed monitoring service was created in 2018. Our objective was to evaluate the new system in regard to REI education within a generalist training framework.

DESIGN: Anonymous quantitative and qualitative IRB-approved survey of residents at a large urban academic center.

MATERIALS AND METHODS: In brief, the new system, designed to supplement the REI rotation, assigned residents to a 2-hour daily monitoring session, 5 days/week, twice during their PGY2 year, for transvaginal ultrasounds (TVUS), evaluation and counseling of patients undergoing OI. Presentations were made via telephone to a remote REI fellow who reviewed the ultrasound and precepted their plan. One year after the program was introduced, all residents who participated in the new OI curriculum (participants, n=10) as well as those trainees who partook in the old REI curriculum without the monitoring addition (controls, n=17) were included and surveyed.

A 23-question survey was created and vetted by 2 REI-trained physicians to evaluate knowledge, TVUS skills, confidence gained, and educational experience. Quantitative data are reported as %; qualitative data as unedited free text. Statistical analysis included unpaired t-tests for continuous variables where appropriate, with $p<0.05$ considered significant.

RESULTS: 8 participants and 14 controls responded, for a response rate of 91.6%. Most participants (62.5%) strongly agreed that they acquired REI knowledge and skills, compared to 7.1% of controls. Subjects rated their confidence with TVUS pre/post their experience (scale 0-100). Participants reported a statistically significant confidence increase of 28-Pre to 82-Post compared to controls of 58-Pre to 63-Post (t -3.02, $p<0.03$). Subjects were asked if they would feel confident implementing 3 cycles of OI prior REI referral and 87.5% of participants strongly agreed compared to 78.5% of controls. All participants (100%) agreed that the curriculum helped achieve their educational objectives, and that a remote REI preceptor was helpful and informative. The same trends were observed in a sub-group analysis of subjects with or without subspecialty interests. Overall, subjects enjoyed the curriculum with two reporting "the curriculum is fantastic and the junior residents know so much more than I do!" and "even as a chief this year I gained so much experience and knowledge helping my junior residents ... This is a truly valuable resident education experience!"

CONCLUSIONS: This curriculum intervention provided residents with increased confidence in REI knowledge, enhanced education, and skill acquisition. A remote REI preceptor was helpful and could be implemented in programs even without on-site sub-specialists. Further study is needed to determine if this system can be applied to other programs.

O-240 3:05 PM Tuesday, October 20, 2020

AGE AND INFERTILITY: AN OPPORTUNITY FOR IMPROVING MEDICAL EDUCATION. Kathryn Smith, B.S.,[1] Anne P. Hutchinson, M.D.,[2] Elaine O. Cheung, PhD,[3] Jessica L. Thomas, A.M.,[1] Patricia I. Moreno, PhD,[3] Veronika Elisabeth Grote, B.S.,[3] Kara N. Goldman, M.D.,[2] Neil Jordan, PhD,[4] Eve C. Feinberg, M.D.[2] [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Department of Medical Social Sciences, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Mental Health Services & Policy Program, Chicago, IL.

OBJECTIVE: Assess female physicians' knowledge about age and fertility.

DESIGN: Survey followed by qualitative semi-structured interviews in a subset of participants.

MATERIALS AND METHODS: Eligibility survey links were presented at a Women in Medicine conference and on Facebook physician mom groups. Questions assessed knowledge of age-related fertility decline and respondents' experiences with infertility and assisted reproductive technology (ART).

Qualitative interviews were conducted in a subset of 10 respondents who fulfilled eligibility criteria: graduation from medical school 1999-2019, current job in academic medicine. Interviews were conducted in-person or remotely over video conference using a semi-structured interview guide. Open-ended questions assessed participants' knowledge of age-related fertility decline, sources of education, and recommendations for physician education in fertility and family planning. All transcripts were qualitatively coded by two research team members using Dedoose.

RESULTS: Of the 44 survey respondents (mean age 34.5y, SD 5.4), 31 were attendings, 2 were fellows, 10 were residents, and 1 left medicine. Ten (9 attendings and 1 fellow) were invited to complete qualitative interviews (age 34.4 ± 2.1).

All 44 respondents correctly identified peak fertility as <30y and that egg quality declines as women age. Eighty percent (35/44) correctly identified that fertility begins to decline in the early 30s. Twenty percent (9/44) incorrectly believed that fertility begins to decline between ages 35 and 39.

Almost half of women surveyed (21/44) experienced infertility, and 12 (27.3%) used in vitro fertilization to conceive. Fifteen women considered oocyte vitrification, 7 sought consultation with a reproductive endocrinologist, 4 completed an oocyte vitrification cycle, and 2 were actively engaged in fertility preservation.

All 10 women who underwent qualitative interviews expressed that preclinical medical education on age-related fertility decline was insufficient. Instead, participants reported learning about fertility through witnessing the infertility experiences of patients (n=3), family/friends (n=4), and/or their own struggles (n=4). To improve medical education regarding fertility and family planning, 9 of 10 recommended having frank discussions with trainees on fertility, family planning considerations, and their available options (e.g., parental leave, fertility preservation benefits, infertility coverage) specific to pursuing a career in medicine.

CONCLUSIONS: A survey revealed high rates of fertility knowledge but high ART utilization among female physicians due to delayed childbearing. Qualitative interviews revealed informal education through the experiences of patients, peers, or personal experience. Medical school provides an ideal gender-inclusive environment for more structured education on age-related fertility decline. Female physicians voiced a desire for transparent discussions of access to fertility care and family planning options during residency.

SUPPORT: This research was funded by the 2019 ASRM Research Grant, awarded to Eve Feinberg, M.D. and Elaine Cheung, Ph.D. (co-PI's),Â Northwestern University.

REGENERATIVE MEDICINE AND STEM CELLS

O-241 9:40 AM Wednesday, October 21, 2020

THE EMBRYONIC DEVELOPMENTAL COMPETENCE OF RECONSTRUCTED ZYGOTES USING A CLONED MALE GAMETE. Philip Xie, B.S., Aysha Trout, B.A., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To test the feasibility of ooplast-mediated male genome replication as a source of male gametes to generate full preimplantation embryos.

DESIGN: Through injection into an enucleated oocyte, we generated identical copies of male genomes. The resulting androgenetic pseudo-blastomeres were used as male gametes and fused to artificially activated oocytes to generate zygotes. Full embryonic development was assessed in a time-lapse system in comparison to control ICSI conceptuses.

MATERIALS AND METHODS: Metaphase II (MII) oocytes from B6D2F1 mice were exposed to cytochalasin B, enucleated under Oosight™ visualization, and then injected with individual sperm heads from the same strain. The resulting pseudo-blastomeres containing copies of male genomes were exposed to DNA polymerase inhibitor and fused to chemically activated oocytes. Control conceptuses were generated by piezo-actuated ICSI. The resulting embryonic development was observed up to 96h.

RESULTS: The enucleation of 30 oocytes yielded the same number of ooplasts. They were subsequently injected with individual spermatozoa resulting in a 73% survival rate, and all developed a single male pronucleus. Following 16h in culture, 21 (95%) androgenetic constructs cleaved to the 2-cell stage, yielding 42 male pseudo-blastomeres. Each pseudo-blastomere was then fused with 42 chemically activated oocytes, and 39 successfully fused (93%) into reconstituted biparental zygotes. Thirty-five unmanipulated oocytes were injected with sperm heads, resulting in 30 control embryos (86%). Both control and experimental zygotes were then cultured in a time-lapse incubator and monitored for full preimplantation development. The control zygotes developed into 2-cell (87%), 4-cell (83%), morula (80%), and blastocyst (80%) embryos, while comparable cleavage parameters were obtained in the experimental embryos (90%, 87%, 85%, and 77%, respectively), without noticeable morphokinetic impairment.

CONCLUSIONS: These results support the feasibility of generating multiple copies of male gametes from a single spermatozoon. Once embryo implantation and the health of the offspring are confirmed, this technique has potential for use in replicating scarce male gametes, allowing pre-fertilization genetic screening for heterozygous conditions, and in conjunction with heritable genomic editing.

SUPPORT: None

MALE NEOGAMETOGENESIS TO GENERATE FULLY DEVELOPED PREIMPLANTATION EMBRYOS. Sherina Lawrence, B.S., Philip Xie, B.S., Mounia Haddad, M.D., Allison C. Petrini, M.D., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To assess the feasibility of haploidizing epiblast-like cells (EpiLCs) derived from male mouse embryonic stem cells (mESCs) to generate full preimplantation embryos.

DESIGN: Male mESCs were propagated and differentiated in a novel 3D culture system by the direct spherification technique. After 3 days of exposure to differentiating medium, EpiLCs, confirmed by specific biomarkers and synchronized at G1, were fused with intact oocytes following activation and completion of biparental haploidization. Full preimplantation development of the zygotes was assessed by time-lapse imaging and compared to control ICSI conceptuses.

MATERIALS AND METHODS: Male mESCs were suspended in base spherification solution and encapsulated by exposure to sodium alginate. Each sphere containing approximately $6.0x10^5$ cells, with diameter ranging from 8 to 10 mm, was bathed in medium supplied with activin A, bFGF, and KSR. Differentiated EpiLCs were isolated by trypsinization to assess OCT4 and Nanog expression. An additional 1.5 μM aphidicolin was supplied to the media 24 h before fusing with oocytes. Individual EpiLCs treated by Sendai virus were injected in the perivitelline space of an oocyte. Resulting oocytes displaying 2 spindle complexes were activated by 10 μM calcium ionophore. Control embryos were generated by piezo-actuated ICSI. Embryonic developmental morphokinetic parameters were detected through time-lapse imaging.

RESULTS: Male mESCs, engulfed in 4 spheres and plunged in differentiating medium, aggregated into embryoid bodies with a mean diameter of 250 μm. After isolation by mechanically breaching the spheres followed by trypsinization, cells showed a positive expression of OCT4 (>90%) and a decreased Nanog positivity (<40%), confirming differentiation to EpiLCs. Sendai virus–mediated cell fusion was performed on 80 oocytes, with a 100% fusion rate. A total of 49 oocytes displayed biparental spindle complexes (61.3%). After oocyte activation, 37 zygotes extruded the second polar body alongside a third pseudo polar body (from the haploidized EpiLCs), and developed 2 pronuclei (75.5%). After 96 h in a time-lapse incubator, the control embryos developed into 2-cell (86.7%), 4-cell (83.3%), morula (83.3%) and blastocyst (83.3%) embryos. Meanwhile, embryos in the experimental group developed into 2-cell embryos at a lower rate (69.4%, $P < 0.001$). Further developments into 4-cell (49.0%), morula (32.7%) and blastocyst (32.7%) embryos were also lower in zygotes obtained from biparental haploidization ($P < 0.00001$).

CONCLUSIONS: Neogametogenesis was accomplished by differentiating mESCs to EpiLCs in a novel 3D culture system. Zygotes obtained from biparental haploidization yielded full preimplantation development to expanded/hatching blastocysts. Despite a lower rate of blastocysts development, embryo morphokinetic characteristics were comparable to the control ICSI conceptuses. Once the ability to generate healthy pups is confirmed, this model may represent an ideal option to treat men with germ cell aplasia or spermatogenic arrest.

O-243 10:10 AM Wednesday, October 21, 2020

SAFETY AND TOXICOLOGY STUDY AFTER INTRA-OVARIAN ENGRAFTMENT OF HUMAN BONE MARROW MESENCHYMAL STEM CELL IN CHEMOTHERAPY INDUCED POI MOUSE MODEL. Hang-Soo Park, PhD,[1] Rishi Man Chugh, PhD,[1] Amro Elsharoud, MD,[1] Mara Ulin, MD,[1] Sahar Esfandyari, DVM,[1] Lale Bakir, MD,[1] Alshimaa Aboalsoud, MD - Ph D,[2] Ayman Al-Hendy, MD, PhD[1] [1]The University of Illinois College of Medicine, Chicago, IL; [2]Faculty of medicine, Tanta university, Egypt, Tanta, Egypt.

OBJECTIVE: Primary ovarian insufficiency (POI) refers to the ovarian loss of function under the age of 40 years and lead those patients to

amenorrhea and infertility. Our previous study showed that transplantation of human bone marrow-derived mesenchymal stem cells (hBM-MSC) in chemotherapy-induced POI mouse ovary can reverse POI through correction of serum hormonal levels, promote follicular generation in the ovary, increase in granulosa cells population, and achieve pregnancy. According to this research, BM-MSC is a promising cell source to treat POI patients, however, there are still concerns about the potential risks of stem cell engraftment due to the route of administration. For further clinical application using allogenic hBM-MSC in POI, these reproductive, developmental and toxicity concerns should be addressed. Understanding the distribution of engrafted hBM-MSC in an animal model will explain how hBM-MSC interacts in the host animal and ensures the safety of allogenic hBM-MSC intra-ovarian transplantation.

DESIGN: We hypothesize that engrafted hBM-MSC remain in the ovary and do not distribute to any other organs.

MATERIALS AND METHODS: In this study, we induced POI in C57/BL6 mice by chemotherapy. We then engrafted hBM-MSCs (500,000 cells/ovary) by direct intra-ovarian injection. 2 weeks and 4 weeks after MSC treatment, we sacrificed the mice and collected the major organs to analyze the presence of human-specific ALU repeat in genomic DNA (10 animals/group). We also analyzed the transmission of human DNA with fetus genomic DNA (8 fetuses/ group). Moreover, we traced engrafted hBM-MSC using whole body cryo-imaging.

RESULTS: We found that human genes representing engrafted hBM-MSC were detected only in mouse ovaries and not in any of the major organs such as the heart, lungs, and liver. We also found that human DNA was not transmitted into the fetus during development. Pups delivered by the hBM-MSC treated mice had no abnormal morphology and developed normally.

CONCLUSIONS: Our data revealed that engrafted hBM-MSC via intra-ovarian injection was not migrated into other organs. Engrafted cells stayed in targeted organs after 2 weeks and 4 weeks. hBM-MSCs engraftment does not affect fetuses or pups development. Our study demonstrates the safety data for allogenic hBM-MSC transplantation as POI therapy for future translations research and clinical trials.

BONE MARROW-DERIVED MESENCHYMAL STEM CELLS UPREGULATE ENDOMETRIAL STROMAL CELL MIGRATION BUT NOT PROLIFERATION. Qingshi Zhao, PhD, Yahaira Naaldijk, PhD, Oleta A. Sandiford, BS, Nicole M. Marchetto, MD, MPH, Nataki C. Douglas, MD, PhD, Pranela Rameshwar, PhD, Sara S. Morelli, MD, PhD. Rutgers New Jersey Medical School Newark, NJ.

OBJECTIVE: Cyclic regeneration of the endometrium is crucial for successful reproduction. Bone marrow-derived mesenchymal stem cells (BM-MSC) traffic to the endometrium and have been implicated in endometrial regeneration and repair of the menstrual "wound". Precise mechanisms are unknown, but likely occur via paracrine action, since the BM-MSC secretome contains growth factors and cytokines that promote wound healing in other tissues. Our objective was to test the hypothesis that the BM-MSC secretome upregulates human endometrial stromal cell (HESC) migration and proliferation, and activates genes involved in cell motility and survival.

DESIGN: Laboratory in vitro studies utilizing telomerase-immortalized HESC cell line (T-HESC) and mesenchymal stem cells (MSC) cultured from the bone marrow aspirate of a healthy female donor.

MATERIALS AND METHODS: Flow cytometry was performed to confirm BM-MSC phenotype. Conditioned medium (CM) was collected from BM-MSC after 24h of monolayer culture. T-HESC were then cultured for 24h in BM-MSC CM or phenol red-free DMEM + 10% charcoal-stripped FBS as control. We determined the effect of the BM-MSC secretome on T-HESC expression of *CCL2,* a chemokine that enhances HESC survival and motility, and *BCL2*, a cell survival gene. Total RNA was extracted from T-HESC and qRT-PCR was performed using 18S rRNA to normalize. For migration assays, a scratch was made through a confluent T-HESC monolayer and wound area was measured at 0, 8, and 24h using ImageJ software. Percent wound closure was calculated from a mean of 5 wound area measurements per well. To assess T-HESC proliferation, immunohistochemistry was performed using a specific anti-Ki67 antibody. The percentage of T-HESC expressing Ki67 was calculated in 10 high power fields per experiment. All experiments were performed three times in duplicate or triplicate. Mann-Whitney test was used for analysis of nonparametric data and unpaired t-test for parametric data, with $p<0.05$ considered significant.

RESULTS: Flow cytometry demonstrated that BM-MSC expressed MSC markers CD29, CD44, CD73 and CD90, and lacked expression of the hematopoietic marker CD45. The BM-MSC secretome upregulated T-HESC expression of *CCL2* mRNA by 13.5±1.7-fold (median±IQR, $p<0.0001$), but did not change expression of *BCL2* mRNA (0.9 ± 0.1-fold, $p=0.6$). Exposure to the BM-MSC secretome increased T-HESC migration (% wound closure) at 8h (16.9±4.3% CM vs. 10.3±3.1% control [mean±SD], $p=0.002$) and at 24h (68.4±4.8% CM vs. 48.5±14.5% control, $p=0.001$). T-HESC proliferation was unchanged after exposure to BM-MSC CM for 24h; the percentage of T-HESC expressing Ki67 was 47.8±4.4% in CM and 45.4±0.9% in controls (mean±SD, $p=0.3$).

CONCLUSIONS: The BM-MSC secretome upregulates endometrial stromal cell migration, a cellular process required for endometrial regeneration and repair. Increased expression of *CCL2* mRNA in T-HESC implicates a novel mechanism by which BM-MSC may mediate HESC motility. These findings support a role for BM-MSC in supporting physiologic endometrial regeneration, and imply a potential role for BM-MSC in promoting endometrial repair after injury.

O-245 10:40 AM Wednesday, October 21, 2020

SINGLE CELL TRANSCRIPTOME ANALYSIS IDENTIFIES PUTATIVE CELL SURFACE MARKERS OF HUMAN SPERMATOGONIAL STEM CELLS. Sarah Munyoki, B.A.,[1] Adrienne N. Shami, B.S.,[2] Xianing Zheng, B.S.,[2] Qianyi Ma, Ph.D.,[2] Meena Sukhwani, Ph.D,[3] Sue Hammoud, Ph.D.,[2] Jun Z. Li, Ph.D.,[2] Kyle Orwig, Ph.D.[4] [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Michigan, Ann Arbor, MI; [3]Magee-Womens Research Institute, Pittsburgh, PA; [4]University of Pittsburgh, Pittsburgh, PA.

OBJECTIVE: Identify the protein markers of human and monkey spermatogonial stem cells (SSCs) and the signaling pathways regulating their self-renewal and proliferation, to facilitate the development of SSC-based therapies for the treatment of male infertility.

DESIGN: We performed high throughput, unbiased, single-cell RNA-sequencing of normal adult primate testicular tissue. Clustering analysis coupled with the evaluation of expression patterns identified potential marker genes of primate stem/progenitor spermatogonia. The expression of these candidate markers on human testicular tissue was evaluated by immunostaining techniques. SSC transplantation was used to determine the candidate markers that may be utilized to sort and enrich human SSCs for downstream clinical applications.

MATERIALS AND METHODS: We performed drop-seq single cell RNA sequencing of 5 human and 4 rhesus macaque healthy adult donor testicular tissue, generating ~13,560 and 20,242 single cell transcriptomes respectively. Principal component analysis (PCA) dimensionality reduction and T-distributed Stochastic Neighbor Embedding (tsne)/ Uniform Manifold Approximation and Projection(UMAP) unsupervised clustering analysis partitioned the primate cells into transcriptionally distinct populations, representing the known primate testicular cell types. Differential expression analysis identified marker genes of the undifferentiated spermatogonia cell populations, that were validated by immunoflourescence techniques. Fluorescence activated cell sorting (FACS) and human to nude mouse xenotransplantation was used to evaluate SSC colonization activity.

RESULTS: Our transcriptome data identified CDK17, MAGEB2, MORC1, TCF3, PIWIL4, GPX1,DNAJB6, FMR1 and TSPAN33 as candidate markers genes of primate stem/progenitor spermatogonia. These genes exhibited unambiguous staining of cells on the basement membrane of human seminiferous tubules and demonstrated overlapping expression with human undifferentiated spermatogonia UCHL1, and more limited overlap with the differentiation marker cKIT. Colometric staining revealed that expression of these markers is mainly restricted to Adark and Apale spermatogonia which are thought to represent the SSC population in primate testes. Flow cytometry analysis of cell surface proteins TSPAN33 and PLPPR3 found that ~3% and ~1.5% of human testicular cells express these proteins respectively. When FACS sorted TSPAN33+, TSPAN33- or PLPPR3+,PLPPR3- and unsorted control fractions were xenotransplantated into infertile recipient mice, we observed significant enrichment of SSC colonization activity in the TSPAN33+ and PLPPR3+ fractions.

CONCLUSIONS: We have identified putative marker genes of primate stem/progenitor spermatogonia. These genes are implicated in WNT, Hedgehog, FGF, BMP, MAP2K/AKT signaling as well as metabolism that may be important in regulating primate SSC growth dynamics in vivo and/or in vitro. Our transcriptome data may reveal markers/niche signaling pathways that can be exploited to isolate and enrich primate SSCs and expand them in vitro.

SUPPORT: Magee womens Research Institute (MWRI) T32 fellowship in reproductive sciences

CHROMATIN ACCESSIBILITY, TRANSCRIPTIONAL NETWORKS, AND FATTY ACID (FA) SYNTHESIS DURING ADIPOGENESIS IN SUBCUTANEOUS (SC) ADIPOSE STEM CELLS (ASCS) OF POLYCYSTIC OVARY SYNDROME (PCOS) WOMEN.

Gregorio D. Chazenbalk, Ph.D.,[1] Smriti Sanchita, B.S.,[2] Karen L. Leung, B.S.,[1] Catherine T. Pham, B.S.,[1] Tristan R. Grogan, M.S.,[1] Xinmin Li, Ph.D.,[1] Xiangming Ding, Ph.D.,[1] Matteo Pellegrini, Ph.D.,[1] Marco Morselli, Ph.D.,[1] Lucia Carbone, Ph.D.,[3] Brett Davis, M.S.,[3] Mariam Okhovat, Ph.D.,[4] Phillip A. Dumesic, M.D., Ph.D.,[5] Kevin J. Williams, Ph.D.,[1] Daniel A. Dumesic, M.D.[1] [1]UCLA, Los Angeles, CA; [2]UCLA, Los Angeles, CA, India; [3]OHSU, Portland, OR; [4]Oregon Health and Science University, Portland, OR; [5]Dana-Farber Cancer Institute, Boston, CA.

OBJECTIVE: To examine dynamic changes of chromatin accessibility, transcriptional regulation, and total vs. *de novo* fatty acid (FA) synthesis in subcutaneous (SC) adipose stem cells (ASCs) of normal-weight PCOS women vs. age- and BMI-matched controls.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: SC abdominal ASCs were obtained from 3 non-Hispanic Caucasian normal-weight PCOS women who had previously shown higher *PPARg* and *CEBPα* mRNA expression in newly-formed adipocytes compared to age- and BMI-matched controls. ASCs were cultured in adipogenic medium for 0-12 days. Chromatin and RNA were isolated at days 0, 3, 7 and 12 for Assay Transposase Accessible Chromatin (ATAC)- and RNA-sequencing (RNA-seq). Accessible regions and enriched transcription factor (TF) binding motifs were identified from ATAC-seq using MACS2 and Homer (Hypergeometric Optimization of Motif EnRichment), respectively. Differentially expressed genes identified from RNA-seq were filtered for significance ($p_{adj}<0.05$) and fold-change (>2-fold); gene ontology (GO) functions and canonical pathways were determined using Ingenuity Pathway Analysis, and gene set enrichment analysis (GSEA) was used to identify enriched cellular processes. A subset of ASCs were exposed to adipogenic medium containing ^{13}C-glucose 48 hours before cell harvest at days 7 and 12 to analyze *de novo* FA synthesis. Different FAs were detected by high pressure liquid chromatograph-mass spectrometry and quantified with Fatty Acid Source Analysis. Paired and unpaired t-test were used for statistical analyses.

RESULTS: PCOS cells showed a substantial shift in chromatin accessibility between days 0 and 12, when less accessible chromatin at day 0 became more accessible than control cells by day 12. In correspondence of open chromatin, binding motifs for crucial adipogenic TFs FRA1, ATF3, BATF, FRA2, JUNB, AP-1 and FOSL2 were significantly enriched at days 0, 3 and 12. RNA-seq indicated adipogenic genes (*PPARγ, CEBPα, ADIPOQ, AGPAT2, FABP4, LPL, PLIN1*; 2-6 fold changes) were upregulated in PCOS cells, while lipid oxidation and FA β-oxidation ($z>2$, $p<0.05$) were upregulated GO functions at days 3, 7, and 12. In parallel, up-regulated pathways in PCOS included oxidative phosphorylation and cholesterol biosynthesis at days 3, 7, and 12. GSEA confirmed significantly increased transcripts related to oxidative phosphorylation, peroxisome activity and adipogenesis at days 3, 7, and 12 in PCOS cells ($p_{adj}<0.05$). *De novo* FA synthesis was 30% of total FA content. During adipocyte formation at day 7, total and *de novo* synthesis of myristic, palmitic, palmitoleic, and oleic acid increased in ASCs of both female types (day 7 to 12, $p<0.02$), but were significantly greater in PCOS than control cells at day 12 ($p<0.05$).

CONCLUSIONS: ASCs of PCOS women exhibit dynamic changes in chromatin accessibility during adipogenesis, with little accessibility at day 0 to enhanced accessibility by day 12. These developmental programming events may enhance transcriptional activation of crucial adipogenic genes and pathways, promoting greater FA production and fat storage in mature adipocytes.

THIRD PARTY REPRODUCTION

O-247 9:40 AM Wednesday, October 21, 2020

INTRACERVICAL INSEMINATION AND INTRAUTERINE INSEMINATION FOR DONOR SPERM TREATMENT IN THE NATURAL CYCLE: A RANDOMIZED CONTROLLED TRIAL.

Petronella A. L. Kop, MD,[1] M. van Wely, Dr. PhD.,[1] Alexandre Soufan, PhD,[1] Annemieke Aagje de Melker, PhD,[1] Ben W. Mol, MD, PhD Prof,[2] Rob Bernardus, MD Ph D,[3] Michael De Brucker, MD, PhD,[4] Pim MW. Janssens, PhD,[5] Annemiek Nap, MD, PhD,[5] Ben J. Cohlen, MD, PhD,[6] Jacqueline J. P. M. Pieters, MD, PhD,[7] Sjoerd Repping, Prof., PhD.,[1] F. van der Veen, Prof. MD, PhD.,[8] Monique H. Mochtar, MD, PhD[1] [1]Amsterdam UMC, University of Amsterdam, Center for Reproductive Medicine, Amsterdam Reproduction & Development Research Institute, Meibergdreef 9, Amsterdam, Amsterdam, Netherlands; [2]Monash University, School of Medicine, Melbourne, VIC, Australia; [3]Nij Barrahûs, Wolvega, Netherlands; [4]University Hospital Brussels, Brussels, Belgium; [5]Rijnstate, Arnhem, Netherlands; [6]Isala, Zwolle, Netherlands; [7]Vivaneo Medisch Centrum Kinderwens, Leiderdorp, Netherlands; [8]Amsterdam University Medical Center, Amsterdam, Netherlands.

OBJECTIVE: Both ICI and IUI in the natural cycle are performed as first line treatments in women who are eligible for donor sperm treatment. IUI is more costly than ICI, due to the involvement of sperm processing. The aim of this study was to determine if six cycles of ICI are non-inferior to six cycles of IUI in donor sperm treatment in terms of ongoing pregnancy.

DESIGN: We performed a multicenter, non-blinded, non-inferiority randomized controlled trial in six fertility clinics in the Netherlands and Belgium. Based on our retrospective cohort study we assumed a live birth rate of 40% after six cycles of IUI. To assess a non-inferiority margin of 12%, we needed to include 416 women.

MATERIALS AND METHODS: All women scheduled for donor sperm treatment were eligible, regardless of the indication for treatment. Women were allocated to receive either ICI or IUI in a natural cycle during six cycles within a time horizon of eight months. Eligible women were informed about the study by their doctor or by a dedicated research nurse. After written informed consent women were randomized using a central password protected Internet-based randomization program.

In ICI cycles, one insemination was performed with unprocessed semen by straw or by cervical cap within 24 hours after the LH surge in urine or blood. In IUI cycles, one intra-uterine insemination was performed with processed semen one day after the LH surge in urine or blood.

The primary outcome was conception within eight months after randomisation leading to a live birth. Secondary outcomes were multiple pregnancy, miscarriage and time to ongoing pregnancy.

We calculated relative risks (RR) and risk difference (RD) and 95% CI. We analysed the data both on an intention to treat and a per protocol basis. The per protocol analysis was limited to women who were treated according to the study protocol, who did not switch treatment and who had either become pregnant or completed six treatment cycles in case of treatment failure.

RESULTS: Between June 2014 and February 2019, we included 421 women, of whom 211 women were randomly allocated to ICI and 210 to IUI. Women's age was on average 34 years (SD $\pm$ 4) in both groups. Ongoing pregnancy occurred in 52 women (25%) in the ICI group and 82 women (39%) in the IUI group (RR 0.63, 95% CI: 0.47 to 0.84). Live birth rate occurred in 51 women (25%) in the ICI group and 81 women (39%) in the IUI group (RR 0.63, 95% CI: 0.47 to 0.84)). ICI was inferior to IUI; the left boundary of the 95% confidence interval was minus 0.24 and crossed the pre-set absolute difference of 12% (RD of -0.14, 95% CI: -0.18 to -0.30).

In the per protocol analysis ongoing pregnancy occurred in 50 women (39%) in the ICI group and 80 women (56%) in the IUI group (RR 0.69, 95% CI: 0.53 to 0.90). Live birth rate occurred in 49 women (38%) in the ICI group and 80 women (56%) in the IUI group (RR 0.68, 95% CI: 0.52 to 0.88). The time to pregnancy was longer in the ICI group compared to the IUI group after six cycles (HR 0.58, 95% CI: 0.41-0.82).

CONCLUSIONS: In women undergoing donor sperm treatment in a natural cycle, ICI results in lower ongoing pregnancy rates than IUI. Therefore, IUI should be the preferred treatment.

SUPPORT: This trial received funding from the Dutch Organisation for Health Research and Development (ZonMw).

O-248 9:55 AM Wednesday, October 21, 2020

JUST OVER ONE-THIRD OF PATIENTS INTERESTED IN EMBRYO DONATION COMPLETE EMBRYO DONATION. Olivia Carpinello, MD,[1] B. Mitchell Bodily, MD,[2] Samad Jahandideh, PhD,[3] Morine Cebert, Ph.D., RN,[4] Joshua C. Combs, MD,[5] Micah J. Hill, DO,[5] Alan H. DeCherney, MD,[6] Kate Devine, MD[3] [1]Program in Reproductive Endocrinology and Gynecology, NICHD, NIH, Bethesda, MD; [2]Uniformed Services University, Bethesda, MD; [3]Shady Grove Fertility, Washington D.C., DC; [4]University of Pennsylvania & Philadelphia VA Medical Center, Philadelphia, PA; [5]Walter Reed National Military Medical Center, Bethesda, MD; [6]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

OBJECTIVE: To describe one infertility center's experience with embryo donation, which has recently become an option for family building.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Patients at a single infertility practice who expressed interest in embryo donation from 2015-January 2020 were referred to the practice's embryo donation team. Criteria for embryo donation included: embryos vitrified onsite at blastocyst stage on day 5 or 6, egg age <40 years, sperm age <50 years, PGT-M/SR excluded, PGT-A euploid permitted. Embryos were accepted if associated clinical data indicated ≥40-45% odds of live birth, assuming no recipient uterine factor. Patient characteristics were assessed using descriptive statistics, and comparisons were made between those who completed donation and those who did not to determine if certain characteristics were associated with likelihood to complete donation. To determine the differences between the groups, independent samples T tests were performed, and proportions were compared with Chi-square.

RESULTS: 438 patients expressed interest in donating supernumerary embryos. On average, initial donation inquiry occurred 5 years from the patient's initial visit. Mean age at donation inquiry was 40.7 years. 89.3% of all patients had either a live birth or ongoing pregnancy from ART, with a mean of 1.2 live births from ART. The majority of patients interested in embryo donation were Caucasian (70.1%). Nine (2.1%) were in same-sex relationships and 28 (6.4%) were single females. 49 patients (11.2%) used donor sperm and 185 (42.2%) used donor eggs for embryo creation. Ultimately, 173 (39.5% of those who expressed interest) completed embryo donation. There was no statistically significant difference in the use of donor gametes between those who donated and those who did not (13.9% versus 9.2% for donor sperm and 48.0% versus 39.0% for donor egg). There was no difference in mean age at inquiry, gravidity, parity, patient ethnicity, infertility diagnosis, or relationship status between those who donated and those who did not. Caucasians, black or African Americans, and Asians made up 68.0%, 10.1% and 10.1%, respectively, of those who completed donation. A mean of 2.9 supernumerary embryos were donated.

CONCLUSIONS: Just over one third of patients who expressed interest completed embryo donation. There are likely complex social, cultural, psychological, and ethical components to embryo donation. These data show that, ultimately, the majority of interested patients choose not to donate. A surprisingly large number of patients interested in donating embryos (42.2%), and of those who ultimately donated (48.0%), utilized donor eggs in embryo creation. These numbers are much higher than the approximate 10% of IVF cycles which utilize donor egg within the practice. It is possible that these patients have a less genetically-centered definition, and experience, of family, which makes them more inclined both to use donor eggs and to donate embryos. It is also possible that donor egg recipients are more likely to have a desire to "give back" and to donate embryos in order to help others achieve parenthood.

O-249 10:10 AM Wednesday, October 21, 2020

HEALTHCARE PROVIDER PREFERENCES RELATED TO DISTRIBUTION OF GAMETE DONOR MEDICAL HISTORY UPDATES. Lauren Isley, MS, CGC, Pamela Callum, MS, CGC. Generate Life Sciences Los Angeles, CA.

OBJECTIVE: Personal and family medical history is collected from gamete donors during their initial eligibility assessment for participation in a donor program. This medical information captures only a short period of time given that donors are required to be young and healthy at the time of donation. New diagnoses in a gamete donor, a family member or a donor-conceived individual could significantly impact the health management of other donor-conceived offspring. Thus, the ASRM Ethics Committee recently published recommendations for donor programs (1) to encourage donors and recipients to provide medical updates and (2) to develop policies which outline the mechanisms for collecting and distributing updates. Numerous stakeholders including recipients, donors, donor-conceived individuals, and all of their healthcare providers, can benefit from an exchange of long-term health information. The Ethics Committee recommendation does not include specific guidance as to how often, by what method, and to whom new medical information should be distributed. This study investigated reproductive medicine providers' experience with and preferences for receiving updated medical information on gamete donors.

DESIGN: An online survey was developed and distributed by the ASRM Genetic Counselor Special Interest Group to all members of the Nursing, Legal, Mental Health, and Reproductive Managers professional groups.

MATERIALS AND METHODS: Not applicable.

RESULTS: A total of 57 responses were received and included members of all of the professional groups surveyed. The majority of respondents were mental health professionals, followed by nurses/nurse managers and practice administrators. Forty percent of respondents indicated they are unaware of the terms under which the gamete providers they work with will notify them or their patients of significant new medical information. The majority (65%) would prefer the gamete facility provides updates to both the clinic and the recipient. Twenty-four percent of respondents prefer to receive updates by email, followed by a letter (21%) or an online portal (21%). The majority of respondents (72%) wanted notified of high risks to the donor's offspring (i.e. donor is a carrier of an X-linked condition and 50% of males will be affected) and 63% also desired updates which confer a low risk to the offspring (i.e. donor is a carrier for an autosomal recessive condition; offspring will not be affected unless recipient is also a carrier). Nearly half (47%) indicated they want to receive updated medical information on gamete donors for an indefinite period of time.

CONCLUSIONS: There are currently multiple models of managing new medical information involving gamete donors. It is important that healthcare providers and recipients are aware of the terms under which updated medical information may be actively communicated to them by their gamete providers. This study aids gamete providers in understanding the preferences and expectations of reproductive providers as stakeholders in these communications and can inform their policy development.

O-250 10:25 AM Wednesday, October 21, 2020

REPRODUCTIVE OUTCOMES OF WOMEN 40 AND OLDER UNDERGOING IVF WITH DONOR SPERM. Pietro Bortoletto, MD, Stephanie Willson, MD, Phillip A. Romanski, MD, Owen Davis, M.D., Zev Rosenwaks, M.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine if women ≥ 40 years old without a male partner utilizing donor sperm have the same reproductive outcomes as those with a male partner who utilize their partners sperm.

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: We included women ages 40 years and older undergoing their first COH cycle at our center followed by a fresh cleavage (day 3) or blastocyst (day 5) embryo transfer (ET). Patients were divided into two groups based on the ejaculated sperm source utilized: Donor sperm or partner sperm. Live birth rate was the primary outcome. Pregnancy rate was the secondary outcome. Multivariable logistic regression was performed with adjustment for age, developmental stage of embryo, and number of embryos transferred. Odds ratios (OR) with 95% confidence intervals (CI) for pregnancy & live birth were estimated. Statistical significance was denoted by $p<0.05$.

RESULTS: A total of 3,910 cycles in women ≥ 40 years were analyzed, of which 307 utilized donor sperm and 3,603 utilized their partners sperm to conceive. In the univariate analysis, patients utilizing donor sperm were found to have similar pregnancy rates as those utilizing their partners sperm (41.0 versus 39.8%, OR: 0.95, 95% CI: 0.75-1.20). After adjusting for age, number of embryos transferred, and developmental stage of embryos, the model estimates did not vary (aOR: 1.22, 95% CI: 0.95-1.56). Similarly, the univariate analysis for live birth did not demonstrate a difference between groups (19.2 versus 17.8%, OR: 0.91, 95% CI: 0.67-1.22). However, after

similar adjustment for confounders, the use of donor sperm was associated with statistically significant increased odds of live birth (aOR: 1.38, 95% CI: 1.01-1.88).

CONCLUSIONS: Women ≥ 40 years old who are unpartnered or in same sex relationships can be counseled that their odds of a live birth are slightly better than women in heterosexual relationships utilizing their partners sperm. These findings serve to further refine and individualize counseling regarding expected IVF outcome for women in this age group and social scenario.

O-251 10:40 AM Wednesday, October 21, 2020

ASSOCIATION OF OBSTETRIC AND NEONATAL OUTCOMES WITH GESTATIONAL CARRIER GUIDELINE ADHERENCE. Brett Stark, MD,[1] Amy Kaing, MD,[2] Kate Swanson, MD,[2] Evelyn Mok-Lin, MD[3] [1]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]REI UCSF, Center for Reproductive Health, San Francisco, CA.

OBJECTIVE: To assess whether criteria described by American Society for Reproductive Medicine (ASRM) guidelines for gestational carriers and additionally non-described factors are associated with an increase in poor obstetric and or neonatal outcomes.

DESIGN: This is a cross-sectional study of births from gestational carrier pregnancies at a single institution in San Francisco, California between 2008 and 2019.

MATERIALS AND METHODS: Violations of ASRM guidelines include age <21 or >45 years, nulliparity, prior stillbirth, tobacco or percutaneous drug use, >5 prior deliveries, >3 prior cesarean delivery (CD), major comorbidities or mental health conditions, BMI >35, and short interval pregnancy (<12 months). The primary outcomes were clinical pregnancy, biochemical pregnancy, preterm delivery, term delivery, and pregnancy complications. Associations were analyzed using Fisher's exact test, Chi-squared test as appropriate, and multivariate logistic regression.

RESULTS: A total of 194 gestational carriers were included in this analysis. Among gestational carriers, Twenty-five percent (50/194) did not meet ASRM criteria, with BMI >35 (38%) and age (mostly >45 or <21) (36%) being the most common criteria violated. Seventy-six percent of carrier pregnancies (148/194) were mediated through a Surrogacy Agency. Surrogates presenting from agencies were more likely to adhere to ASRM guidelines (OR 3.02, 95% CI 1.49 – 6.13, p= .002). After categorizing the gestational carriers into complete guideline adherence versus any guideline non-adherence groups, we found that complete adherence to ASRM Guidelines did not alter rates of antepartum complications, intrapartum complications, and postpartum complications. Those in the non-adherence cohort were found to have significantly increased risk of spontaneous abortion (OR 4.89, 95% CI 2.04-12.4, p= .001). In a multivariate logistic regression adjusting for each ASRM guideline factor, age >45 (aOR 3.98, 95% CI 1.22-15.00,p=0.005) and BMI > 35 (aOR 4.89, 95% CI 1.59-15.00, p=0.005) were notable predictors of spontaneous abortion in non-guideline adherent gestation carrier pregnancies. Whether adherent or non-adherent to guidelines, gestational carriers with a history of a prior spontaneous abortion were more likely to experience a biochemical pregnancy (OR 3.2, 95% CI 1.2 – 8.4, p=0.018), and those with a history of prior preterm birth were more likely to experience a spontaneous abortion (OR 3.19, 95% CI 1.1-9.2, p=0.031).

CONCLUSIONS: Nearly one in four gestational carrier pregnancies in this cohort did not meet ASRM guidelines. Guidelines are less likely to be followed when a gestational carrier is found through means other than an agency. Non-adherence to ASRM guidelines was associated with an almost 5-fold increase in odds of spontaneous abortion. In both guideline adherent and non-adherent gestational carriers, history of prior spontaneous abortion as well as history of prior preterm birth are significantly associated with poorer pregnancy outcomes; thus, are important historical factors to rigorously account for when making carrier selection.

FAMILIES CREATED THROUGH EGG DONATION: PARENTAL PSYCHOLOGICAL HEALTH IN EARLY CHILDHOOD. Joanna Lysons, MSc, Susan Imrie, PhD, Vasanti Jadva, PhD, Susan Golombok, PhD. University of Cambridge, Cambridge, United Kingdom.

OBJECTIVE: This study examined mothers' and fathers' psychological health in families who had conceived a child using egg donation (ED). Data are reported from phase two of a longitudinal study, when children were aged five.

DESIGN: Cross-sectional design using standardized questionnaires.

MATERIALS AND METHODS: Questionnaire data were obtained from 66 families who had a child through egg donation, and a comparison group of 46 families who had a child through IVF with own-gametes. The average ages of mothers were 47.06 years (ED) and 42.24 years (IVF); fathers' average ages were 48.08 years (ED) and 45.11 years (IVF). Questionnaires assessing parental psychological health (Trait Anxiety Index, Edinburgh Depression Scale), stress associated with parenting (Parenting Stress Index), marital quality (Golombok Rust Inventory of Marital State), social support (Multidimensional Scale of Perceived Social Support) and resilience (Brief Resilience Scale) were completed by mothers and fathers. Independent-samples t-tests and Mann-Whitney U-tests were used to analyse the data.

RESULTS: Preliminary results found that mothers and fathers in both groups scored within the normal range for all questionnaire measures of psychological health. No significant differences were found between ED and IVF mothers in reported levels of anxiety, depression or resilience. ED mothers reported significantly lower couple relationship quality than IVF mothers ($t(93) = 2.97$, $p = .004$). However, when mother's age was controlled for, the test was no longer significant. ED mothers reported significantly higher parenting stress than IVF mothers ($U = 1070.5$, $p = .02$) and significantly lower levels of perceived social support than IVF mothers ($U = 1037$, $p = .007$). No significant differences were found between ED and IVF fathers in reported levels of couple relationship quality, perceived social support or resilience. ED fathers reported significantly higher levels of parenting stress ($U = 766.5$, $p = .01$), anxiety ($t(88.95) = 2.45$, $p = .016$) and depression ($U = 798.5$, $p = .03$) than IVF fathers. However, group differences in depression were no longer significant after controlling for father's age.

CONCLUSIONS: Egg donation parents appear to be functioning within the normal range with regards to parental psychological health. However, egg donation mothers reported lower couple relationship quality, higher parenting stress and lower social support, and egg donation fathers experienced greater parenting stress, anxiety and depression, relative to their IVF counterparts. It is notable that ED mothers' lower couple relationship quality and ED fathers' higher levels of depression appear to be related to the older age of egg donation parents, rather than their use of egg donation *per se*. Possible explanations for the differences in psychological health between the ED and IVF parents will be discussed.

HIGH-SENSITIVITY C-REACTIVE PROTEIN (HS-CRP) LEVEL AND PREGNANCY OUTCOMES IN WOMEN WITH UNEXPLAINED INFERTILITY UNDERGOING OVARIAN STIMULATION WITH INTRAUTERINE INSEMINATION (OS-IUI) IN A MULTICENTER TRIAL. Sarah Z. Gavrizi, MD,[1] Sushila Arya, MD,[1] Jennifer D. Peck, PhD,[1] Jennifer F. Knudtson, MD,[2] Karl R. Hansen, MD PhD,[1] Reproductive Medicine Network. [1]University of Oklahoma College of Medicine, Oklahoma City, OK; [2]University of Texas Health Science Center San Antonio, San Antonio, TX.

OBJECTIVE: To determine if chronic inflammation, as assessed by basal hs-CRP level, was associated with pregnancy outcomes in women with unexplained infertility undergoing OS-IUI.

DESIGN: Secondary analysis of a prospective, randomized, multicenter clinical trial investigating pregnancy, live-birth, and multiple pregnancy rates following ovarian stimulation-intrauterine insemination treatments, the Assessment of Multiple Intrauterine Gestations from Ovarian Stimulation (AMIGOS) trial.

MATERIALS AND METHODS: Of the 900 AMIGOS participants, 778 were available for analysis after excluding patients with hsCRP levels ≥10 indicative of infection, ectopic pregnancies and those missing pregnancy outcome or baseline hs-CRP serum measures. Hs-CRP concentration was evaluated using two definitions: first by hs-CRP categories of < 2mg/L and 2 - 9.9 mg/L as previously defined in the literature, and second, by tertiles (tertile 1 ≤ 0.725 mg/L, tertile 2 0.725 to 2.42 mg/L, and tertile 3 > 2.42 mg/L)[1] . Risk ratios (RR) and 95% confidence intervals for the outcomes of live birth, clinical pregnancy, and pregnancy loss were estimated using modified

Poisson regression models with robust standard errors.Adjustment for covariates were examined in multivariable models. No covariate evaluated (age, duration of infertility, BMI, history of pregnancy loss, race, ethnicity, income, and treatment group) met the a priori criteria for confounding (>10% change in RR upon inclusion (or removal from) the model), and therefore were not retained in the final model.

RESULTS: Elevated hs-CRP levels (2 to 9.9 mg/L) were observed in 39% (95% CI 35.5-42.4) of study participants. We found no relationship between baseline hs-CRP level and live birth or clinical pregnancy outcomes. Risk of pregnancy loss was greater in patients with hs-CRP levels in the middle (RR 1.72, 95% CI 1.05-2.83) and upper tertiles (RR 1.56, 95% CI 0.93-2.61) compared those in the lowest tertile, although the confidence interval for the upper tertile included the null value. Collapsing the two upper tertiles under an assumption of homogeneous patterns of risk suggested greater risk of pregnancy loss for hsCRP >0.725 (RR 1.64, 95% CI 1.03-2.60). However, when evaluated using cutpoints reflecting inflammation, hs-CRP level of 2 to 9.9 mg/L was not associated with a significant increase in pregnancy loss compared to <2 mg/L.

CONCLUSIONS: Basal hs-CRP was not associated with live birth or clinical pregnancy outcomes in women with unexplained infertility undergoing OS-IUI. However, hs-CRP >0.725 mg/L was associated with an increased risk of pregnancy loss. Additional studies are needed to refine hs-CRP cutpoints associated with increased risk of pregnancy loss.

PD-1 RECEPTOR AND LIGANDS ARE CONCENTRATED IN THE EXOSOME FRACTION OF HUMAN OVARIAN FOLLICULAR FLUID.

Thanh Ha Luu, MD, Evelyn Mercedes Llerena Cari, M.S., John Rushing, M.D., Liesl Nel-Themaat, Ph.D., HCLD, Alex J. Polotsky, M.D., M.S., Joshua Johnson, PhD. University of Colorado Anschutz Medical Campus Aurora, CO.

OBJECTIVE: We have found that membrane bound and soluble variants of PD-1 and ligands are expressed by permanent constituent cell types of the human ovary and fallopian tube. We hypothesize that PD-1 signaling controls both immunomodulatory and non-immunomodulatory events in the ovary and tube. During our first evaluation of cell-free human follicular fluid (hFF), we detected full-length PD-1 receptor and also full-length ligands PD-L1 and -L2. Because secreted variants of PD-1 and ligands are produced by alternative splicing, it was unclear why full-length proteins were detectable in cell-free hFF. Here we have tested two hypotheses: first, that full-length proteins are packaged in exosomes in HFF, and second, that both immune and non-immune cells participate in *bona fide* PD-1 receptor:ligand interactions in the ovary and tube. Because initial evaluation of the reproductive tracts of Pd-l1 knockout mice revealed alterations in ovarian (corpus luteum) vasculature, we evaluated receptor:ligand interactions within human ovarian and tubal vasculature.

DESIGN: Biochemical assessments of human ovary and fallopian tube tissue specimens and hFF collected during *in vitro* fertilization treatment cycles.

MATERIALS AND METHODS: Immunostaining and western blots were performed using de-identified human ovary and tubal specimens and hFF. Cells were removed from hFF *via* centrifugation, followed by optionally processing using an exosome isolation kit to produce exosome-enriched and -depleted fractions. To detect receptor:ligand interactions *in situ*, proximity ligation analysis (PLA) was performed. Negative controls were performed where primary antibodies were omitted. Statistical difference of comparisons between groups was conducted using Welch’s two sample t-test. P-values <0.05 were considered statistically significant.

RESULTS: PD-1 and ligands are present in several ovarian and tubal cell types. These include oocytes, granulosa cells, cells of the CL, ovarian and tubal vasculature, and the tubal lumen. Further, soluble proteins are present in hFF at bioactive levels that can control T cell PD-1 activation and IFNγ production. Western blots of exosome and non-exosome hFF fractions show that receptor and ligands are mostly concentrated in the exosome fraction. Immunostaining showed that PD-L1 and PD-L2 were expressed prominently in the smooth muscle layers of arterioles and venules, and also in these layers of larger hilar ovarian vessels. PLA analysis supported direct PD-1:PD-L1 interactions within blood vessels and between other ovarian and tubal cell types.

CONCLUSIONS: PD-1 ligands are expressed throughout human ovarian vasculature, and *bona fide* receptor-ligand interactions (membrane-bound and/or soluble) are supported by PLA analysis. hFF exosomes were found to contain bioactive full-length PD-1 and ligands, suggesting that exosomal delivery of these proteins may modulate immune responses and regulate vascular development during ovulation and at other times during follicular development.

O-255 10:10 AM Wednesday, October 21, 2020

DO ENDOMETRIAL NATURAL KILLER AND REGULATORY T CELLS DIFFER IN INFERTILE AND CLINICAL PREGNANCY PATIENTS? AN ANALYSIS IN PATIENTS UNDERGOING FROZEN EMBRYO TRANSFER CYCLES.

May-Tal Sauerbrun-Cutler, MD,[1] Warren J. Huber III, MD, PHD,[2] Paula M. Krueger, BS,[3] James Sung, MD,[4] Phinnara Has, MS,[5] Surendra Sharma, MD PhD.[6] [1]Warren Alpert Medical School of Brown University Women & Infants Hospital, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Providence, RI; [2]Department of Obstetrics and Gynecology, LSUHSC School of Medicine, New Orleans, LA; [3]Warren Alpert Medical School of Brown University, Women & Infants Hospital, Department of Pediatrics, Providence, RI; [4]Warren Alpert Medical School of Brown University, Women & Infants Hospital, Department of Pathology, Providence, RI; [5]Warren Alpert Medical School of Brown University, Women & Infants Hospital, Department of Obstetrics and Gynecology, Division of Research, Providence, RI; [6]Warren Alpert Medical School of Brown University, Women & Infants Hospital, Department of Pediatrics, Providence, RI.

OBJECTIVE: To characterize proportional presence and phenotypic changes in endometrial and peripheral blood natural killer (NK) and regulatory T cells (Tregs) during frozen embryo transfer (FET) cycles.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Endometrial tissue was collected from patients with recurrent pregnancy loss or history of implantation failure undergoing frozen embryo transfer cycles as part of an ERA biopsy or endometrial scratch. Endometrial NK (eNK) and Treg cell density was compared based on pregnancy status in the subsequent frozen embryo transfer cycle.

Peripheral blood was also collected from a separate cohort of patients undergoing frozen embryo transfer cycles. There were three time points for blood collection: 1) follicular phase, 2) day of the embryo transfer, and 3) day of quantitative serum β-hCG analysis. Peripheral blood Treg cell phenotype and density were compared based on timing of the blood draw and then stratified by the presence/absence of a clinical pregnancy.

RESULTS: A total of 33 luteal phase endometrial tissue samples were analyzed. There were more endometrial Tregs, similar eNK cells and a trend toward lower CD 16+ eNK in women with an ongoing clinical pregnancy compared to non-pregnant women. There were no differences in eNK and Treg density in natural “scratch cycles” vs programmed cycles or in non-receptive vs receptive endometrium (ERA cycles). 35 patients were enrolled in the peripheral blood analysis portion of the study. In the pregnant group, peripheral blood Tregs were elevated on the day of serum β- hCG time point when compared to the non-pregnant group.

CONCLUSIONS: Higher levels of endometrial Tregs and lower levels of CD16+ eNK cells are positive prognostic factors for infertile women prior to frozen embryo transfer. Our work on phenotypic and proportional analyses of endometrial immune cells may complement the endometrial receptivity assay in predicting improved pregnancy rates in patients with implantation failure.

O-256 10:25 AM Wednesday, October 21, 2020

DOES TESTING FOR IMMUNOLOGICAL MARKERS IN REPEATED IMPLANTATION FAILURE HAS A SIGNIFICANCE IN PROGNOSTICATING OUTCOMES OF FRESH NON DONOR IN VITRO FERTILIZATION CYCLES? - A PROSPECTIVE OBSERVATIONAL STUDY.

Neeta Singh, MD,[1] Monikha Siva, MBBS, MD,[2] Alpana Sharma, MD,[3] Sunesh Kumar, MD,[4] Perumal Vanamail, PhD[5]
[1]All India Institute of Medical Sciences, Obstetrics & Gynaecology, New Delhi, India; [2]Junior Resident, New Delhi, India; [3]Professor, New Delhi, India; [4]Professor& Head Department of Obst. & Gynae, AIIMS, New Delhi, India; [5]Additional Professor Statistics, New Delhi, India.

OBJECTIVE: The purpose of study is to compare the various immunological markers (Pro Inflammatory markers -IL-6, IL-17,IFN γ and Anti-Inflammatory markers -IL-4,IL-10, Anti-cardiolipin antibody IgG and IgM, Lac, anti-beta2 glycoprotein) in serum of women with implantation failure with that of the women with successful implantation during IVF cycle and establishing the correlation between different immunological markers and implantation failure.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: IVF was performed using flexible antagonist stimulation protocol. Inclusion criteria were:. Age 25- 35 years, History of one or more previously failed IVF/ICSI cycle, Fresh non donor IVF cycles, BMI 23 -29 kg/m2, AMH > 2ng/ml, FSH <9IU, AFC >8, Normal uterine cavity. Embryo transfer was done on day 2/3/5.Participants were divided into controls(40 patients) and cases(40 patients) groups after testing for serum β hCG on day-16. Cases included women with one or more implantation failure who were found serum β hCG negative. Control group included women with positive serum βhCG. Blood sample of 2-3ml for each immunological marker was drawn . A highly sensitive sandwich ELISA kit was employed for the estimation of serum levels of IL-4, IL-6, IFN-γ, IL-10, IL-17, and LAC, aCL, β2 GP.

Data analysis was carried out using STATA version 12.0. Descriptive statistics such as mean, standard deviation and range values were calculated for normally distributed data with comparison of mean values tested using Student-t independent test. Bi-variate correlation analysis between optical density and concentration of IL-markers were performed. To assess significant risk factors for implantation failure, univariate and multivariate logistic regression analysis were carried out. Adjusted odds ratio with 95% confidence interval was presented. For all statistical tests a two-sided probability of P <0.05 was considered for statistical significance.

RESULTS: Baseline characteristics were matched between study and the control group. There was a significant increase in the pro-inflammatory markers (IL-17 and IFN-γ) in the study group when compared with the control group. ($p < 0.0001$). However the anti-inflammatory markers among both the groups were comparable with no statistical difference. The ratio of the pro-inflammatory /anti-inflammatory markers was detected and there was significant increase in the following ratios in the study group. IL-17/IL-4, IL-17/IL-10, IFN-γ/IL-4, IFN-γ/IL-10 ($p<0.0001$). Antiphospholipid antibodies were not detected in both groups. The distribution of embryo transfer day was statistically significant ($p<0.03$) and this was found to be a confounding factor. The adjusted odds ratio for day of embryo transfer was 10.1 (95% CI 2.30 – 44.34).

CONCLUSIONS: Immunological imbalance is associated with implantation failure in IVF cycles. Defining the evidence-based immunological studies is essential for the appropriate evaluation and prognostication of couples with implantation failure which may lead to newer treatment modalities.

O-257 10:40 AM Wednesday, October 21, 2020

CH50 COMPLEMENT PATHWAY ADJUST BY ANTI MÜLLERIAN HORMONE LEVELS AT INFERTILITY PATIENTS.

Hector S. Godoy, MD, Hilda Sanchez, MD, Jose M. Lozano, MD, Griselda C. Reyes, MD, Francisco M. Rojas, MD, Berenice Flores, Phsysician. ART reproducción, CDMX, DF, Mexico.

OBJECTIVE: To evaluate the importance of immunological screening (Ch50, C3, C4), to determine the correlation between ovarian reserve and complement pathway.

DESIGN: A prospective study with patients with infertility diagnosis who undergoing to IVF from January 2019-May 2020.

MATERIALS AND METHODS: We study 40 patients with normal distribution: we took basal blood samples (day 1-3 of menstrual cycle), measuring complement pathway: CH50 (CAE) , C3 (mg/dl) , C4 (mg/dl); to evaluate ovarian status. We quantify Anti Müllerian hormone (ng/dl) Multivariate analysis was performed with version 12, JMP ® for a comparison analyses a Spearman correlation test was achieved with a significant result ($P < 0.005$).

RESULTS: 40 female age from 28-48 years (mean=37.87 years), the value of CH50 65-268 CAE (mean=153.2 CAE), C3 13.9- 183mg/dl (mean=128.52 mg/dl), C4 11.5-106 mg/dl (mean=29.86 mg/dl), AMH 0.10-3.9 ng/dl (mean=1.32ng/dl). Multivariate analysis comparison was performed with significant results: AMH with age (Spearman correlation -0.6; P 0.001) and AMH with CH50 (Spearman correlation -0.4; P 0.0129), rest not significant. (Table 1).

Variable	Variables	Spearman	Prob > $\lvert\rho\rvert$	
CH50 (CAE 63-145)	Age	0.2641	0.1042	+++
C3 (mg/dl 83-193)	Age	0.0993	0.5476	+
C3 (mg/dl 83-193)	CH50 (CAE 63-145)	0.2458	0.1314	++
C4 (mg/dl 15-57)	Age	0.2038	0.2132	++
C4 (mg/dl 15-57)	CH50 (CAE 63-145)	0.0035	0.9829	
C4 (mg/dl 15-57)	C3 (mg/dl 83-193)	0.229	0.1608	++
AMH	Age	-0.5065	0.001	———
AMH	CH50 (CAE 63-145)	-0.3946	0.0129	——
AMH	C3 (mg/dl 83-193)	-0.2352	0.1494	–
AMH	C4 (mg/dl 15-57)	0.0938	0.5699	+

CONCLUSIONS: Anti Müllerian hormone levels correlates inversely with age and the increase of CH50 levels negatively correlate with AMH. The combination of AMH with CH50 levels, could be a marker of deficient response at this complement pathway. Nevertheless, we need further investigation to value the immune system in infertility patients.

INTRAUTERINE ADMINISTRATION OF PERIPHERAL BLOOD MONONUCLEAR CELLS INCREASES CLINICAL PREGNANCY RATES IN FROZEN-THAWED EMBRYO TRANSFER CYCLES OF PATIENTS WITH IMPLANTATION FAILURE.

Ghaya Merdassi, Dr,[1] Mustapha BenKhalifa, PhD,[2] Oualid Triki, Dr,[3] Khaled Boudhraa, Dr,[1] Nizar ben Aissia, Dr,[1] Khemais Ben Rhouma, Dr,[3] Sami Mahjoub, Dr,[1] Hatem Bahri, Dr[1] [1]Alyssa Fertility Group, tunis, Tunisia; [2]2- Faculty of sciences of Bizerte, Tunisia; [3]Alyssa Fertility Group, Tunis, Tunisia.

OBJECTIVE: Intrauterine administration of peripheral blood mononuclear cells (PBMC) has been proposed to improve implantation rates in women with implantation failure. Our aim was to observe the effects of intrauterine administration of maternal and paternal PBMC on clinical pregnancy rate (CPR) of patients who received frozen-thawed embryo transfer (FET).

DESIGN: Retrospective cohort study from January 2019 to January 2020.

MATERIALS AND METHODS: Patients who had not experienced successful pregnancy despite one or more IVF-ET sessions were enrolled in this study (n=66).

Based on the patient's treatment preferences, maternal and paternal PBMC were freshly isolated from each couples and then administered to the intrauterine cavity of that patient. FET was performed and the success of implantation in the group of patients with two or more implantation failure ($n = 28$) was compared with that in the control groups of patients with one implantation failure ($n = 38$).

RESULTS: Pregnancy rate per transfer was evaluated in only 59 patients. A beneficial effect of endometrium immunomodulation was observed in FET cycles of all the patients with 28 pregnancies obtained after intrauterine insemination of maternal and paternal activated PBMC.

Baseline clinical parameters, number and quality of embryos transferred were comparable in the two groups.

CPR were significantly higher in the RIF group compared to control groups (50 % vs 36, 8%; respectively p< .0,5)

CONCLUSIONS: Intrauterine administration of maternal and paternal PBMC improves CPR, in FET cycles of all patients. The treatment improves

significantly the pregnancy outcomes much more for women with two or more implantation failure.

IVF OUTCOME PREDICTORS 2

O-259 9:40 AM Wednesday, October 21, 2020

THE EFFECT OF OBESITY ON EUPLOIDY RATES IN WOMEN UNDERGOING IN VITRO FERTILIZATION (IVF) WITH PREIMPLANTATION GENETIC TESTING (PGT). Stephanie M. Hallisey, MD,[1] Reeva B. Makhijani, MD,[2] Jeffrey Thorne, MD,[3] Prachi N. Godiwala, MD,[2] John Nulsen, MD,[2] Claudio A. Benadiva, MD,[2] Daniel R. Grow, MD,[2] Lawrence Engmann, MD[2] [1]University of Connecticut Health Center, Center for Assisted Reproductive Services, Farmington, CT; [2]Center for Advanced Reproductive Services, University of Connecticut School of Medicine, Farmington, CT; [3]RMA of Philadelphia, King of Prussia, PA.

OBJECTIVE: Elevated body mass index (BMI) is associated with a higher risk of miscarriage and lower probability of live birth following IVF (1-3). The etiology underlying these disparities is currently unclear. It is plausible that obesity may be associated with higher rates of aneuploidy, which could result in worsened pregnancy outcomes, although this has not been previously studied. Thus, we examined the impact of BMI on euploidy rates in IVF cycles with PGT.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: This study included women aged ≤45 years who underwent IVF with PGT from 1/2013 to 2/2018 at a single academic fertility center. 533 cycles were divided into 3 cohorts according to BMI: 1) Normal: 18.5-24.9; 2) Overweight: 25-29.9; and 3) Obese: ≥30. The primary outcome was euploidy rate. Secondary outcomes included number of oocytes, fertilization rate, blastocyst development rate, number of blastocysts biopsied, and livebirth rate. Chi-Square and one-way ANOVA with post hoc Tukey tests were used for categorical and continuous variables respectively. Multiple linear regression analysis was performed to control for age, AMH, number of oocytes retrieved, blastocyte development rate, and number of blastocysts biopsied. A two-sided p-value of 0.05 was considered statistically significant.

RESULTS: Obese women were significantly older and had a lower blastocyst development rate than women with normal BMI. There was no difference in AMH, oocytes retrieved, fertilization rate, or embryos biopsied between BMI cohorts. There was no significant difference in euploidy rate between BMI cohorts (Table 1), which persisted after controlling for potential confounders. There were no differences in livebirth rate between normal weight (91/145; 62.8%), overweight (44/70; 62.9%) and obese (35/48; 72.9%) patients who underwent a subsequent transfer (p=0.41).

TABLE 1. IVF Outcomes by BMI Cohort in Patients Undergoing IVF with PGT

	BMI Cohorts			
Outcome (mean ± SEM)	Normal (n=301)	Overweight (n=118)	Obese (n=116)	P Value
Age (years)	37.4 ± 0.2[a]	37.9 ± 0.4[a,b]	38.5 ± 0.3[b]	0.03
AMH (ng/dl)	2.8 ± 0.2	3.1 ± 0.5	2.5 ± 0.3	0.42
Oocytes Retrieved (n)	14.1 ± 0.5	15.5 ± 0.8	14.2 ± 0.9	0.33
Fertilization Rate (%)	75.2 ± 1.0	71.3 ± 1.9	75.9 ± 1.5	0.09
Blastocyst Development Rate (%)	58.7 ± 2.0[a]	57.0 ± 3.3[a,b]	48.6 ± 2.3[b]	0.02
Blastocysts Biopsied (n)	4.6 ± 0.2	4.6 ± 0.3	3.8 ± 0.3	0.12
Euploid Rate (% ±)	33.5 ± 1.8	31.7 ± 2.9	33.7 ± 3.0	0.85

[a,b]Cohorts with different letters indicate significant differences between groups.

CONCLUSIONS: There was no significant difference in euploidy rates between BMI cohorts in women undergoing IVF with PGT. These findings suggest that the association between elevated BMI and unfavorable pregnancy outcomes may not be related to increased oocyte aneuploidy.

ADHERENCE TO ASRM SINGLE EMBRYO TRANSFER GUIDELINES IN FAVORABLE-PROGNOSIS PATIENTS UNDER 35 YEARS: A SART STUDY. Julian A. Gingold, MD, PhD,[1] Michelle Kappy, MD,[1] Rachel S. Gerber, MD,[1] Michelle Goodman, BS,[1] Melissa Fazzari, PhD,[1] Harry Lieman, MD,[1] Manvinder Singh, MD,[1] Staci E. Pollack, MD, MS,[2] Sangita K. Jindal, Ph.D.[1] [1]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.

OBJECTIVE: To measure adherence with 2013 ASRM guidelines recommending elective single embryo transfer (eSET) in favorable-prognosis patients.

DESIGN: Retrospective cohort from SART national patient registry.

MATERIALS AND METHODS: Inclusion criteria were IVF cycles from 2014-2016 in patients <35 years undergoing their first autologous fresh embryo transfer. Each cycle must have generated at least two blastocyst embryos, with at least one 3BB-grade or better transferred fresh. Cycles from PGT embryos and recurrent pregnancy loss patients were excluded.

Summaries of eSET and non-eSET live birth rate (LBR), gestational age at delivery, and birth weight were computed. Differences between groups were presented along with 95% confidence intervals. P-values were generated based on chi-square tests or t-tests, as appropriate.

RESULTS: The cohort included 28,311 favorable-prognosis fresh blastocyst transfers, of which 15,643 (55%) underwent eSET. Non-eSETs typically transferred two (n=12,609 (99.5%)), and rarely 3 (n=57) or 4 (n=2), blastocysts.

Age, BMI, parity, max FSH and AMH were clinically comparable between eSETs and non-eSETs. The infertility etiologies of non-eSETs were less likely than eSETs to be unexplained (1967 (15.5%) vs 3229 (20.6%)) and more likely to be male factor (5,287 (41.7%) vs 6,033 (30.6%)) (all p<0.001).

Multiple pregnancy, preterm delivery and birth weight <2500g were far more common in non-eSET than eSET births. However, LBR from non-eSET was also higher than from eSET cycles (Table 1, all p <0.001).

TABLE 1.

Cycle outcomes	Non-eSET (n=12668)	eSET (n=15643)	Absolute difference eSET vs. non-eSET (95% CI)
Clinical pregnancy, n (%)*	8698 (68.7%)	9436 (60.3%)	-8.5 (-9.6,-7.3)
Live birth, n (%)*	7809 (61.6%)	8254 (52.7%)	-8.9 (-10.0,-7.7)
Multiple pregnancy, n (%)*	3538 (27.9%)	147 (0.9%)	-27.0 (-27.8,-26.2)
Number of live births	11,443	8,403	
*Singleton**, n (%)*	4271 (37.3%)	8107 (96.4%)	59.2 (58.2,60.2)
*Twin**, n (%)*	6886 (60.2%)	290 (3.5%)	-56.0 (-57.0,-55.0)
*Triplet**, n (%)*	282 (2.6%)	6 (<.1%)	-2.4 (-2.7,-2.1)
*Quadruplet**, n (%)*	4 (<.1%)	0 (<.1%)	NS
*Delivery at <37 weeks** GA, n (%)*	3545(28.0%)	1603 (10.3%)	-17.7 (-18.7,-16.8)
*Birth weight (g)**, mean (SD)*	2795 (750)	3224 (697)	429 (409,449)
*Birth weight <2500g**, n (%)*	4642 (42.0%)	895 (10.6%)	-31.4 (-32.5,-30.3)

All p<0.001 except as noted with NS (not significant).
* Per embryo transfer. ** Per live birth.

CONCLUSIONS: There was widespread non-adherence with 2013 ASRM embryo transfer guidelines in favorable-prognosis patients. Despite slightly improved LBRs with non-eSET, the dramatically increased multiple pregnancy rates, preterm births and low birth weights should strongly discourage this practice.

LESS IS MORE: SART CORS STUDY COMPARING OBSTETRICAL AND NEONATAL OUTCOMES WHEN TRANSFERRING 1 VERSUS ≥2 PGT-A EMBRYOS.

Michelle Kappy, MD,[1] Rachel Schwartz Gerber, MD,[1] Melissa Fazzari, PhD,[1] Arielle H. Bayer, MD,[1] Julian A. Gingold, MD, PhD,[1] Michelle Goodman, BA,[2] Harry Lieman, MD,[1] Manvinder Singh, MD,[1] Staci E. Pollack, MD, MS,[2] Sangita K. Jindal, Ph.D.[1] [1]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.

OBJECTIVE: To compare obstetrical and neonatal outcomes following single embryo transfer (SET) versus (vs.) multiple embryo transfer (MET) from frozen-thawed embryo transfer cycles (FET) of autologous pre-implantation genetic tested for aneuploidy (PGT-A) embryos.

DESIGN: Retrospective cohort study from the SART CORS national database.

MATERIALS AND METHODS: Cycle data were obtained from the SART CORS database for all autologous FET cycles of PGT-A embryos between 2014-2016. The primary outcomes measured were live birth rate (LBR) and multiple pregnancy rate (MPR). Secondary outcome measures included rates of preterm delivery (<37 weeks, <34 weeks, and <28 weeks), low birth weight (LBW, <2500g) and very LBW (<1500g). Outcomes were compared between SET and MET groups using chi-square tests, with statistical significance defined as $p<0.05$.

RESULTS: There were 14,408 SET and 2,501 MET cycles. There were no clinically significant differences between groups in terms of age, BMI, parity, infertility diagnosis, or AMH levels. In the MET group, >99% transferred 2 embryos, and only 16 cycles reported 3 embryos transferred. While the LBR was greater with MET compared with SET (66.3% vs. 54.9%), the MPR was dramatically greater (46.8% vs. 1.7%) (Table 1). Preterm delivery (PTD) rates at <37 weeks (31.4% vs. 9.9%), <34 weeks and <28 weeks were significantly elevated in MET compared with SET cycles. Compared with SET, MET cycles were also associated with significantly higher rates of LBW (35.8% vs. 8.1%) and very LBW (5.6% vs. 1.3%) (Table 1).

CONCLUSIONS: Nearly half of the pregnancies resulting from PGT-A tested METs are multiples. Compared to SETs, METs are associated with significantly higher rates of neonatal morbidity, including PTD and LBW. Transfer of more than one PGT-A embryo should be strongly discouraged and patients should be counseled on the significant potential for adverse outcomes.

TABLE 1. Autologous FET PGT-A cycles*

Pregnancy and neonatal outcomes**	≥2 embryos transferred (n=2501)	Single embryo transferred (n=14,408)

ART TREATMENT HAS MINIMAL EFFECT ON COST OF HOSPITAL CARE IN CHILDREN TO AGE 4.

Dmitry Dukhovny, MD MPH,[1] Sunah S. Hwang, MD MPH,[2] Daksha Gopal, MPH,[3] Howard J. Cabral, PhD, MPH,[3] Hafsatou Diop, MD, MPH,[4] Judy E. Stern, PhD[5] [1]Oregon Health & Science University, Portalnd, OR; [2]University of Colorado School of Medicine, Aurora, CO; [3]Boston University School of Public Health, Boston, MA; [4]Massachusetts Department of Public Health, Boston, MA; [5]Dartmouth-Hitchcock, Lebanon, NH.

OBJECTIVE: To compare the cost of hospital care for children to age 4 among ART-treated, subfertile, and fertile women.

DESIGN: Retrospective evaluation of linked ART, birth certificate, and hospital data in Massachusetts.

MATERIALS AND METHODS: Cost of hospital care through age 4 was evaluated for singleton children born in Massachusetts between July 1, 2004 and December 31, 2012 to women ≥ 18 years of age with private insurance at delivery, born at ≥ 23 weeks gestational age (GA) who survived birth hospitalization to age 4. Data were obtained by linking ART deliveries from the Society for Assisted Reproductive Technology Clinic Outcome Reporting System (SART CORS) to the Pregnancy to Early Life Longitudinal (PELL) data system, which links birth certificates to hospital discharge records for mothers and infants in Massachusetts. We included hospitalizations, observational stays, and emergency room visits of children born to mothers of fertile (those without ART, other infertility treatments, or indicators of infertility), unassisted subfertile (UF: those without ART who had indicators of infertility and did not require any assistance with reproduction), non-ART medically assisted reproduction (MAR, required non-ART assistance with reproduction) and ART (deliveries linked to SART CORS). Costs prior to first discharge home from the birth hospitalization have been previously reported and were excluded. Outliers, or costs that were below the 1st or above the 99th percentile were recoded to 1st and 99th percentile, respectively. Multivariable gamma regression models comparing the ART, subfertile, and fertile groups were adjusted for age, race, education, chronic diabetes and hypertension, gestational diabetes and hypertension, low birthweight, prematurity, parity, gender, year of birth, and method of delivery. Costs are expressed in 2017 US Dollars. Statistical significance was noted where $P<0.05$.

RESULTS: There were 158,506 fertile, 3,168 UF, 1,912 MAR, and 6,667 ART children. Adjusted least square mean costs of care (± SE) without recoding top values were \$4,259 (±356), \$4,894 (±428), \$4,448 (±400), 4,005 (±341) respectively with only the unassisted subfertile group higher than the fertile ($P<0.01$) and the ART significantly lower than fertile ($P=0.0012$). When the 99th percentile was recoded, the adjusted costs were \$4,176 (±337), \$4,309 (±364), \$4,666 (±406), \$4,187 (±345) respectively with the MAR group having higher costs than the fertile group ($P=0.0007$). When selecting only those children born at <37 weeks GA only the MAR (\$6,799) group had higher average cost than the fertile group (\$6,116) ($P=0.0027$).

CONCLUSIONS: ART-treatment had minimal effect on cost of hospital care in children to age 4. Costs were increased slightly for children born to subfertile women.

CLOMIPHENE CITRATE EXPOSURE DOES NOT ADVERSELY AFFECT CLINICAL OUTCOMES IN SINGLE, EUPLOID FET CYCLES.

Carlos Hernandez-Nieto, MD,[1] Joseph A. Lee, BA,[1] Tamar Alkon-Meadows, MD,[1] Martha Luna-Rojas, MD,[1] Tanmoy Mukherjee, MD,[2] Alan B. Copperman, MD,[2] Benjamin Sandler, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: Clomiphene citrate (CC) is a selective estrogen receptor modulator utilized for OI and COH. Pharmacologically, CC has a half-life of 5 days; yet, it can be excreted after 6 weeks after initial administration[1]. CC is known to have antioestrogenic side effects which had been associated to a reduction in implantation rates for patients who undergo fresh IVF cycles[2]. However, evidence is scarce about the effect of CC on implantation potential in FET cycles. One study showed that patients who undergo a FET within 90 days after CC treatment had lower pregnancy rates compared with FET cycles that occur after 90 days of CC treatment [3]. Conversely,

another study did not find lower implantation rates in patients who undergo FET cycles, regardless of the time of CC administration [4]. To date, no study has analyzed CC exposure and subsequent transfer of euploid embryos. The objective of this study is to analyze implantation rates in patients exposed to CC prior to a single, euploid FET cycle.

DESIGN: Retrospective analysis.

MATERIALS AND METHODS: The study included patients who underwent a single, euploid FET from 2016 to 2020. PGT-A was performed by NGS. Cohorts were segregated in 2 groups according to duration between the last day of CC administration and FET day (Group 1: $\leq$90 days, Group 2: patients unexposed to CC or when exposure elapsed $>$ 90 days). Patients with genetic translocations, uterine factor, hydrosalpinx and RPL diagnosis were excluded from the analysis. Demographic characteristics and IVF outcomes were assessed. Comparative statistics and an adjusted multivariate analysis with a GEE framework were used for analysis. A sample size of 355 FET cycles per group was calculated to have an 80% power to detect a difference of 10% on implantation rates (α=0.05).

RESULTS: 433 FET cycles in which patients were exposed to CC within 90 days (Group 1) were compared with 5723 control cycles (Group 2). AMH levels were different among groups (3.5± 4 vs 3.5±3, p=0.02). The remaining demographic characteristics, including endometrial thickness at ET, were comparable among groups. Clinical pregnancy rate (CPR) (67.2% vs 61.4%, p=0.01) and ongoing pregnancy rate (OPR) (57.7% vs 51.5%, p=0.01) were significantly different among groups. No differences were found in implantation or clinical pregnancy loss (CPL) rates among groups. After adjusting for age, BMI, AMH, endometrial thickness at ET, embryo quality, and day of biopsy, there was no association with CC exposure and lower odds of implantation (OR 1.12,CI 95% 0.8-1.4,p=0.36), CPR (OR 1.21,CI 95% 0.9-1.5,p=0.09), OPR (OR 1.18,CI 95% 0.9-1.4,p=0.12), or higher odds of CPL (OR 0.96,CI 95% 0.6-1.3,p=0.85), when compared with controls. On a sensitivity analysis we also found no association within shorter CC exposure times (30 & 60 days) and IVF outcomes.

CONCLUSIONS: Although CC is a safe oral agent for ovarian stimulation, unfavorable effects on endometrial thickness are possible and could result in implantation failure during fresh IVF cycles. However, our study demonstrated no association between exposure to CC and adverse effect on IVF outcomes in patients undergoing a single, euploid FET cycle.t

SIMILAR PERINATAL OUTCOMES IN CHILDREN BORN AFTER FRESH OR FROZEN EMBRYO TRANSFER USING DONATED OOCYTES.

Filipa Rafael, MD, MSc,[1] Guillermo Mollá Robles, MSc,[2] Alfredo Muñoz Navarro, PhD,[2] Nicolas Garrido, PhD,[2] Juan A. Garcia-Velasco, MD, PhD,[3] Ernesto Bosch, MD, PhD,[4] Sofia Gouveia Nunes, PhD,[1] Sérgio Reis Soares, MD, PhD,[1] Samuel Santos-Ribeiro, MD, PhD[1] [1]IVI-RMA Lisbon, Lisbon, Portugal; [2]Fundación IVI, Valencia, Spain; [3]IVI-RMA Madrid, Madrid, Spain; [4]IVI Valencia, Valencia, Spain.

OBJECTIVE: Singletons born after fresh embryo transfer (ET) are associated with higher rates of preterm birth and low birthweight, while frozen embryo transfers (FET) seem to convey a higher risk of large for gestational age. However, studies comparing these outcomes using autologous oocytes are unable to adequately disentangle the potential effect of embryo vitrification from the possible consequences on endometrial receptivity caused by ovarian stimulation/preparation, prior to ET. Hence, the oocyte donation (OD) model is optimal for this differentiation and, so far, information available regarding neonatal outcomes is limited to either small and/or heterogeneous studies.

DESIGN: We performed a multicenter retrospective cohort study including 5848 singletons born between 2009 and February 2020 following OD and single blastocyst transfer, subdivided into fresh ET and FET groups.

MATERIALS AND METHODS: Patients with a first singleton livebirth after single blastocyst transfer were compared using multivariable regression analysis to account for potential confounding. The primary outcome was birthweight. Secondary outcomes were low birth weight (below 2500g and 1500g), birthweight z-scores, small/large for gestational age, prematurity, neonatal morbidity (Apgar scores and need for neonatal intensive care) and maternal morbidity (gestational hypertensive disorders, diabetes and cesarean delivery). The control variables included were female recipient/donor age, body mass index and smoking status, sperm source, endometrial thickness and preparation technique (natural or artificial cycle), serum estradiol and progesterone levels, and newborn gender. Continuous outcomes are presented with medians and interquartile ranges (IQRs) while dichotomous outcomes are shown using percentages and 95% confidence intervals (CIs).

RESULTS: There was no significant difference between the fresh ET and FET groups in terms of birthweight (3215 g, IQR [2900g, 3540 g]; versus 3200.0g, IQR [2860g, 3500 g]) and birthweight z-scores (0.03, IQR [-0.67, 0.73]; versus 0.1, IQR [-0.59, 0.71]), in both the unadjusted and confounder-adjusted models. However, artificial endometrial preparation was associated with a higher birthweight (3220 g, IQR [2900g, 3540 g]; versus 3105 g, IQR [2800g, 3450 g]) and birthweight z-scores (0.06, IQR [-0.63, 0.74]; versus -0.13, IQR [-0.73, 0.59]), even following confounder adjustment.

The premature birth rates ($<$37weeks) were, respectively, 9.9% (8.9%-10.8%) and 11.2% (9.8%-12.6%) for fresh ET and FET, while the very premature birth rates ($<$32 weeks) were 1.4% (1.0%-1.8%) and 1.9% (1.3%-2.5%), with no significant difference, even following confounder adjustment. There were also no statistically significant differences in other neonatal outcomes and maternal morbidity.

CONCLUSIONS: Perinatal outcomes did not seem to be affected by the embryo vitrification process in an OD model. Other factors may contribute to the hindered perinatal outcomes described, particularly the potential effect ovarian stimulation and endometrial preparation may have on endometrial receptivity.

STATE INSURANCE MANDATES AND TRENDS IN PREIMPLANTATION GENETIC TESTING (PGT) UTILIZATION IN THE UNITED STATES.

Bronwyn S. Bedrick, MD, MSCI,[1] Andrew D. Tipping, MA,[2] Katelin B. Nickel, MPH,[3] Joan Riley, PhD, HCLD,[4] Tarun Jain, MD,[5] Emily S. Jungheim, MD, MSCI[6] [1]Johns Hopkins University, Baltimore, MD; [2]Center for Administrative Data Research, St. Louis, MO; [3]Washington University School of Medicine, St. Louis, MO; [4]Washinton University School of Medicine, St. Louis, MO; [5]Northwestern University, Chicago, IL; [6]Northwestern Feinberg School of Medicine, Chicago, IL.

OBJECTIVE: To assess associations between insurance mandates for fertility care and PGT utilization over time

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Fresh, autologous IVF cycles from the 2007-2016 SART registry were analyzed in two periods due to changes in SART cycle definitions in 2013. Frozen, cancelled, and banking cycles were excluded. Cycles were categorized by level of insurance coverage mandated in the state they were performed as follows: comprehensive, partial, or no coverage. State census data were used to determine the population of reproductive age women and median household income. Log binomial regression was used to analyze change in proportion of PGT cycles over time relative to mandate type.

RESULTS: 875,567 cycles were included. The majority of IVF cycles occurred in states with no coverage. Per capita, IVF cycles were performed at higher rates in comprehensive coverage states (336 per 100,000 women in 2016) followed by partial (186) and no (142) coverage. For PGT cycles, comprehensive coverage states had the highest use per capita (98), followed by no (53) and partial coverage (34). However, beginning in 2009, the proportion of IVF cycles using PGT was actually highest in no coverage states. Median household income decreased with decreasing insurance coverage.

Between 2007-2013, there was a minimal, yet statistically significant yearly increase in the rate of PGT use (β= 0.05, SE= 0.003, $p<0.0001$). For partial and comprehensive coverage states, this increase was lower compared to no coverage states ($p<0.0001$). Between 2014-2016, there was a substantial increase in the use of PGT (β = 0.43, SE=0.005, $p<0.0001$). This rise was more substantial in partial coverage states (β = 0.11, SE= 0.03, $p<0.0001$).

CONCLUSIONS: This is the first study to examine the association between state mandated insurance coverage and PGT use. Across both time periods, there was a strong association between state mandate and PGT use. Additionally, PGT utilization increased substantially after 2013, corresponding to the publication of several influential papers on PGT. These trends may also be attributed in part to changes in SART definitions, state-level economics, PGT costs, and socioeconomic characteristics of women accessing IVF.

SUPPORT: The Center for Administrative Data Research is supported in part by the Washington University Institute of Clinical and Translational Sciences grant UL1 TR002345 from the National Center for Advancing Translational Sciences (NCATS) of the National Institutes of Health (NIH) and Grant Number R24 HS19455 through the Agency for Healthcare Research and Quality (AHRQ).

REDUCED WAITING TIMES AND IMPROVED EFFICIENCY FOR COUPLES ACCESSING PUBLIC, OUTPATIENT FERTILITY CLINICS IN THE NATIONAL MATERNITY HOSPITAL, DUBLIN, IRELAND.

Molly Walsh, MB BCh BAO,[1] Maebh Ann Horan, MB BCh BAO, MRCPI, MRCOG,[2] Mary Wingfield, MD FRCOG[3] [1]The National Maternity Hospital, Dublin, Ireland; [2]The Merrion Fertility Clinic, Dublin, Ireland; [3]Merrion Fertility Clinic, Dublin, Ireland.

OBJECTIVE: In Ireland there are difficulties accessing public outpatient services across all specialties. With a population of just under 5 million, it is estimated that there were 550,000 patients on waiting lists for first hospital outpatient visits at the end of 2019. Fertility services are particularly poorly resourced.

Fertility is very time sensitive, with the biggest prognosticator in terms of the success of assisted reproduction treatment being female age. Long wait times are therefore detrimental for these patients and international comparisons show that Irish patients are older when they access fertility treatment.

We noticed that there was a very poor attendance rate at our public infertility clinics, possibly exacerbated by the long wait time for an appointment. The aim of this study was to implement a new appointment strategy to address these unacceptably long waiting times and to reduce the "did not attend" (DNA) rate.

Ultimately reducing the number of clinic appointments per patient and reduced waiting time to treatment and pregnancy.

DESIGN: Retrospective comparative study

MATERIALS AND METHODS: Prior to 2019, referral letters from family doctors were triaged by hospital nursing staff. Patients were sent an appointment slot and asked to complete specific fertility investigations (hormone profile and semen analysis) at the hospital prior to their scheduled appointment.

From March 2019, all patients were asked to complete and return a lifestyle and medical history questionnaire and to have the required tests performed at the hospital. Only then was an outpatient appointment slot was scheduled.

The outcome of all referrals received between March and August 2019 (new system) was compared with that of patients referred between March and August 2018 (old system).

RESULTS: A total of 185 patient files were reviewed – n 78 (2018); 107 (2019)

Post implementation of the new system, the DNA (did not attend) rate was reduced from 32% to just 2%. Less than half of those initially referred (39%) returned the questionnaire and completed the required investigations therefore receiving an appointment.

For those who were given an appointment in 2019, the waiting time averaged 52 days compared to 178 previously. The total number of clinic visits needed to complete the basic work up reduced from two to one.

Disappointingly, it took, on average, 189 days to complete the basic investigations. However this is compared to almost a year (326 days) in 2018. The rate limiting factor contributing to this was the waiting time for a pelvic ultrasound, with the average wait being 120 days after initial consultation.

Period	1							2		
Year	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016
Total cycles	81512	82920	82776	83402	83894	82215	77364	92074	100318	109092
% of total cycles using PGT	4.9	4.6	4.4	4.6	5.2	5.4	6.4	17.4	25.7	33.7
% change in % PGT	-	-7.3	-4.5	5.9	11.7	3.8	18.7	-	47.1	31.4
% PGT – no coverage	4.8	4.7	4.6	5.1	5.8	5.9	6.9	19.4	28.5	37.0
% PGT – partial coverage	3.5	2.9	2.2	2.3	2.1	1.9	4.2	6.9	12.3	18.4
% PGT – comprehensive coverage	5.6	4.8	4.5	4.2	4.6	5.2	5.8	15.4	21.9	29.1

Almost one third of the women attending our clinic fell into the 35 – 39 age group category. Such a wait is not acceptable at this age.

CONCLUSIONS: By ensuring patients complete their basic investigations before they receive an appointment, we have drastically reduced waiting times and the DNA rate.

Now more than ever in this post COVID-19 era, we should aim to be streamlined and cost effective, prioritising our patients access to outpatient care. This approach could be adopted by other clinical services in Ireland to reduce clinic waiting times.

P-03 4:30 PM Saturday, October 17, 2020

CONSIDERING LOCATION IN ACCESS TO INFERTILITY SERVICES. Nathanael B. Stanley, MA University of South Florida, Tampa, FL.

OBJECTIVE: The objective of this research is to observe aspects of location in reference to the use of infertility services by U.S. residents, with the purpose of identifying instances of interstate and international travel related to accessing infertility services, and the locations of CDC reporting ART clinics in relation to population and birth density.

DESIGN: Place, location, and travel are important factors to consider when discussing accessibility of specialized healthcare, such as infertility services. The ability to observe differences in the locations of clinics is informative, but geographic proximity to a clinic does not equate to increased access to infertility services. Medicine in the United States is a business, so geographic spread of ART clinics will undoubtedly follow population density. When reviewing different national surveys available that include questions about residence and infertility services, such as the Society for Assisted Reproductive Technology (SART) and the National Survey of Family Growth (NSFG), the surveys did not ask the right questions that would give insight into the influence of location hypothesized to be influential, such as the type of employment (employment status, part time, full time, state in which people work) and whether people travel for services (*where* and *how far* people go to access infertility services).

MATERIALS AND METHODS: This research uses a survey instrument developed by the PI, and spatial analysis of 2017 CDC-reporting ART clinics in relation to population and birth density in the United States. The survey instrument includes questions about: employment, travel intentions and reasons, and state of residence. Frequency statistics calculated using SAS 9.4 will show variations in answers. Spatial analysis consists of geocoding CDC-reporting ART clinics, and comparing their location with population and birth density data at the Census Tract level. In order to identify spatial clustering of clinics, an Optimized Hot-Spot analysis of 2017 ART clinics was conducted in ArcPro 2.5.

RESULTS: Survey results from 134 persons in 33 states using infertility services reveal the majority of people accessing infertility services accessed those services in their same state of residence (88.3%), most people have not and are not considering traveling out of state (90.3%) or out of country (82.7%) to access infertility services. There were 440 ART clinics reporting data to the CDC in 2017. Optimized Hot Spot analysis revealed 147 output features statistically significant based on an FDR correction for multiple testing and spatial dependence, and those areas overlapped with the largest population and birth density census tracts.

CONCLUSIONS: Based on survey results, it does not appear that interstate or international travel for infertility services occur with high frequency for U.S. citizens. Spatial analyses revealed distinct spatial patterns regarding the location of CDC-reporting ART clinics and population and birth densities. Based on the nature of medicine in the United States as a business, it makes logical sense that ART clinics exist in areas with high population.

P-04 4:30 PM Saturday, October 17, 2020

EMERGENCY DEPARTMENT UTILIZATION FOR OVARIAN TORSION IN THE UNITED STATES (2006-2016). Jessie-Joyce Kue, MSCR,[1] Charley Jiang, MS,[1] Emma Giuliani, MD,[2] Chelsea N. Fortin, MD,[2] Erica E. Marsh, MD, MSCI, FACOG[2] [1]MD/MSCR candidate, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.

OBJECTIVE: Ovarian torsion (OT), a condition in which the ovary twists on its vascular and lymphatic support, can compromise the blood supply and lead to edema, ischemia, and eventually necrosis of the ovary. OT is a gynecologic emergency that requires prompt intervention. Although it is mainly diagnosed in the Emergency Department (ED), little is known about the utilization of EDs for this condition. The purpose of this study was to characterize use of United States (US) EDs for adult ovarian torsion patients.

DESIGN: Retrospective analysis of national database

MATERIALS AND METHODS: Data were extracted from the Nationwide Emergency Department Sample (NEDS), developed by the Healthcare Cost and Utilization Project of the Agency for Healthcare Research and Quality. ICD-9 and ICD-10 codes were used to identify women aged 18-65 years who were seen in the ED with a primary diagnosis of OT between 2006-2016. Other variables analyzed include payer type, income quartile by zip code, region, hospital teaching status, and hospital location. Descriptive statistics regarding ED utilization were obtained using SAS 9.4.

RESULTS: From 2006 to 2016, the number of ED visits for OT among 18 – 65-year olds increased from 2,791 to 4,420 ($p< 0.0001$). Approximately one-third of these visits were comprised of women aged 26 – 44 years. More than half of all ED visits were paid for by private insurance (56.6%), followed by Medicaid (20.3%) as the next largest payer. 31.5% of visits occurred in large metropolitan areas. Metropolitan teaching hospitals experienced a notable increase in ED visits for OT over the study period, during which time visits for OT doubled from 1,263 to 2,695. Conversely, the number of visits remained at about 1,662 cases per year at metropolitan non-teaching and non-metropolitan hospitals. ED charges for OT nearly quadrupled over the study period. The average charge for OT patients in 2006 was $5,134 and in 2016 was $19,012 – an average annual increase of 14.4% compared to an annual increase of 8.5% for all other diagnoses in age matched women. Hospital admission rates declined over the study period from 76% in 2006 to 38% in 2016 ($p< 0.01$).

CONCLUSIONS: The overall utilization of the ED for ovarian torsion increased significantly during the 11-year study period, despite a significant decrease in admission rates. Given that OT is considered a surgical emergency, this decrease in admission rate is quite surprising. The majority of patients were insured by private insurance, and metropolitan teaching hospitals saw a significant increase of OT cases from 2006 to 2016. Furthermore, the cost of ED visits for OT increased dramatically, with ED charges climbing from $5,000 to almost $20,000. Future studies are needed to elucidate the drivers behind the decrease in admissions for torsion.

P-05 4:30 PM Saturday, October 17, 2020

THE COST OF INFERTILITY (COIN) STUDY: ASSOCIATIONS WITH INCOME & BURDEN OF TREATMENT. Viji Sundaram, MD,[1] Jerrine R. Morris, MD, MPH,[1] Jake Anderson, MBA,[2] Martha Noel, MD[1] [1]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [2]FertilityIQ, San Francisco, CA.

OBJECTIVE: (1) To conduct an analysis in a national cohort of patients pursuing in vitro fertilization (IVF) to determine significant predictors for total out-of-pocket (OOP) cost; (2) To evaluate to what degree total OOP costs are determined by income; (3) To characterize how patients finance the cost of IVF

DESIGN: Cross Sectional Cohort

MATERIALS AND METHODS: In collaboration with a national fertility education company (FertilityIQ), a recruitment email was sent to all registered users of FertilityIQ who had undergone at least 1 cycle of IVF. Survey participants completed a web-based, anonymous, self-reported survey including questions regarding demographics, reproductive and IVF history, insurance information, financial details, opinions on legislation, and a standard Decision Regret Scale (DRS). Survey questions were created through an iterative process and revised to incorporate changes following pilot delivery to 10% of FertilityIQ users. Data analysis was performed with descriptive statistics; univariate logistic regression for dichotomous outcomes; and one-way analysis of variance (ANOVA) with pairwise comparisons using the Bonferroni adjustment for categorical outcomes.

RESULTS: Recruitment emails were distributed to 4,326 registered FertilityIQ users, with 1,568 people (36%) opening the email & 337 (8%) completing the survey. 66% of respondents were $\leq$34 years of age, and 85% were white. 40% had a household income of <$100,000, with 43% spending $25-70,000 on their total IVF care. Significant univariate predictors of total OOP cost included: education, income, insurance fertility coverage, length of time trying to conceive, use of an egg donor or gestational carrier, total egg retrievals and embryo transfers, and time spent on IVF. Patients with an annual household income of >$250k spent significantly more (median $55k) on their IVF care then patients making less (median $32,500, $p<0.01$), while families with an income of <$100k to $250k spent similar amounts. Of families making <$150k, 21-29% reported spending >50% of their disposable income on IVF. Common sources of funding for IVF regardless of income, included borrowing money, payment with credit cards, and delaying regular savings contributions. Those in lower-income groups relied on outside funding sources more than in higher-income groups,

including borrowing money, paying with credit cards, delaying home-buying, and delaying further education.

CONCLUSIONS: Funding for IVF creates a significant burden on families, even with incomes up to $250k. Patients making <$100,000 are able to fund IVF care through many different methods.

P-06 4:30 PM Saturday, October 17, 2020

ACCESS TO ART CARE AT A UNIVERSITY SATELLITE CLINIC: OUTCOME ANALYSIS OF PREGNANCY RATES, INCLUDING SINGLETON LIVE BIRTH RATES. Estefania Santamaria Flores, MD, MPH,[1] John Yeh, MD,[2] Shaila V. Chauhan, MD[3] [1]University of Massachusetts Medical School, Worcester, MA; [2]UMass, Worcester, MA; [3]U MassMedical School, Worcester, MA.

OBJECTIVE: The development of satellite clinics has improved the access of ART services to infertile patients. Little has been published about the pregnancy rates of such centers in comparison to the main centers with which they are connected. We investigated the first embryo transfer and subsequent embryo transfer outcomes in women cared for at our satellite center and compared these to rates of the main ART center and national data to better understand the utility of satellite clinics to improve access.

DESIGN: Retrospective, comparative cohort. This study was approved by the University of Massachusetts Institutional Review Board (#14573).

MATERIALS AND METHODS: All women ages 23 to 45 undergoing ART procedures in 2017 and 2018 at UMass Memorial Medical Center's infertility clinic were included. The patients had their ovulation induction managed at the satellite clinic and had their oocyte retrieval, embryo culture and embryo transfers at the main ART center. Positive pregnancy tests, clinical pregnancies, miscarriage rates, and live birth rates were calculated. The cases were divided into the following age groups: < 35, 35-37, 38-40, 41-42, and > 42. Using data published by the Society for Reproductive Technology Clinic Outcome Reporting System, we compared these rates to those of the affiliated main center and national data. The Student's t-test was used and $p < 0.05$ was considered statistically significant.

RESULTS: In 2017, 66 first embryo transfers and 28 subsequent embryo transfers were completed. Women < age 35 had a higher first embryo transfer singleton birth rate at our satellite clinic compared to the main center and national rates (61.2 % vs. 30.8 % vs. 35.4 %, respectively; $p < 0.05$). In 2018, 66 first embryo transfers and 34 subsequent embryo transfers were completed. For 2018, women < age 35 undergoing subsequent embryo transfers at our satellite clinic had higher live birth rates (70 % vs. 48.3 % vs. 47.1 %, respectively; $p < 0.05$). Analysis for all other categories for 2017 and 2018 demonstrated no other statistically significant differences when compared to both main center and national data.

CONCLUSIONS: Increased access to ART care was achieved by having our satellite clinic. We found that for women < age 35, there was a higher first embryo transfer singleton birth rate for 2017 and a higher subsequent embryo transfer live birth rate for 2018. No other statistically significant differences were noted for other categories for either year. These findings highlight the ability of satellite clinics to provide access to ART services and the continued need for quality improvement measures at satellite clinics to mirror the rates of their associated main centers.

P-07 4:30 PM Saturday, October 17, 2020

THE COST OF INFERTILITY (COIN) STUDY: MODELING DECISION REGRET. Viji Sundaram, MD,[1] Jerrine R. Morris, MD, MPH,[1] Jake Anderson, MBA,[2] Martha Noel, MD[1] [1]University of California, San Francisco, Department of Obstetrics and Gynecology, San Francisco, CA; [2]FertilityIQ, San Francisco, CA.

OBJECTIVE: To determine how much out-of-pocket (OOP) cost of in vitro fertilization (IVF) influences decision regret.

DESIGN: Cross Sectional Cohort

MATERIALS AND METHODS: In collaboration with a national fertility education company (FertilityIQ), a recruitment email was sent to all registered users of FertilityIQ who had undergone at least 1 cycle of IVF. Survey participants completed a web-based, anonymous, self-reported survey including questions regarding demographics, reproductive and IVF history, insurance information, financial details, opinions on legislation, and a standard Decision Regret Scale (DRS). Survey questions were created through an iterative process and revised to incorporate changes following pilot delivery to 10% of FertilityIQ users. Data analysis was performed with descriptive statistics; univariate logistic regression for dichotomous outcomes; Spearman's rank correlation; and one-way analysis of variance (ANOVA) with pairwise comparisons using the Bonferroni adjustment for categorical outcomes.

RESULTS: Recruitment emails were distributed to 4,326 registered FertilityIQ users, with 1,568 people (36%) opening the email & 337 (8%) completing the survey. 66% of respondents were ≤34 years of age, and 85% were white. 40% had a household income of <$100,000, with 43% spending $25-70,000 on their total IVF care. Mean DRS score in all survey participants was 25.4, consistent with moderate to severe regret. 3 out of 4 women had some degree of regret after undergoing IVF. Significant univariate predictors of moderate to severe regret included: total years spent on IVF (OR1.12, CI 1.02-1.24), if respondents had a live birth (OR 0.12, CI 0.06-0.25), number of live births using IVF (0.62, CI 0.47-0.81), and OOP costs of IVF treatment (OR 1.15, CI 1.04-1.28). The relationship between DRS score and total OOP cost was examined with a significant positive correlation noted (rho 0.127, $p=0.02$). Mean DRS scores reveal a significantly higher level of regret in those who did not have a live birth (41.74) following IVF compared to those who did (16.78, $p<0.0001$), which persisted regardless of total OOP cost spent on IVF.

CONCLUSIONS: Funding for IVF creates a significant burden on families, even with incomes up to $250k. Despite the large financial burden, regret around pursuing IVF is not associated with amount of money spent but entirely dependent on if a couple has a live birth.

P-08 4:30 PM Saturday, October 17, 2020

FINANCIAL ASSISTANCE OPPORTUNITIES FOR INFERTILITY TREATMENTS: MALE FACTOR INFERTILITY IS OFTEN FORGOTTEN. Darren J. Bryk, MD,[1] Sarah C. Vij, MD[2] [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH.

OBJECTIVE: Financial assistance opportunities (FAOs), in the form of grants and donated or discounted services or medications, can relieve the significant burden of fertility treatment costs on infertile couples. We analyzed the characteristics of fertility FAOs and hypothesized that FAOs for male factor infertility (MFI) would be less prevalent than those for female factor infertility (FFI).

DESIGN: Google search was performed for fertility FAO websites. Websites of all FAOs were then reviewed.

MATERIALS AND METHODS: Google search was performed and many aggregating websites that list fertility FAOs were found; cofertility.com had the most extensive list with links to each FAO's website. The websites for all FAOs found on cofertility.com were thoroughly reviewed. Those that only support adoption, that do not have a functioning website, or that have limited details listed on the website were excluded. Primary endpoint was evidence of financial support based on gender.

RESULTS: Eighty-six FAOs were reviewed. All 86 (100%) primarily support FFI; 72 include financial assistance for or discounted ART and intrauterine insemination (IUI), 16 for fertility preservation and egg cryopreservation, 4 for egg donation and 13 for fertility medications. None of the reviewed FAOs focus solely on MFI. MFI is mentioned in 27/86 (31.4%) of the FAOs; of these, 19 FAOs support ART or IUI related to MFI with 6 specifically noting surgical sperm retrieval or other procedures for MFI. Sperm cryopreservation and medications for MFI is supported by 5 and 4 FAOs, respectively. Among the entire cohort, specific populations that have dedicated FAOs are those in military (active duty, reserve or veteran) with 21/86 (24.4%) FAOs and current or prior-treated patients with cancer with 11/86 (12.8%) FAOs. Of the FAOs dedicated to military personnel, 7/21 (33.3%) include support for MFI. Of the FAOs dedicated to patients with a history of cancer, 5/11 (45.5%) include support for MFI. With regard to the type of financial assistance, 29/86 (33.7%) provide discounted or free fertility treatments or medications, 36/86 (41.9%) provide monetary grants (range $250 – $41,500) for fertility treatments, 1/86 (1.2%) FAO provides free fertility treatment and a monetary grant, 18/86 (20.9%) do not specify the type of assistance, and 1/86 (1.2%) provide a warranty if the IVF cycle is unsuccessful.

CONCLUSIONS: Couples with infertility due to a male factor have fewer opportunities for grants and discounted fertility treatments than do couples with FFI in the US. Further financial support may alleviate some of the burden on this subset of infertile patients.

SUPPORT: none

P-09 4:30 PM Saturday, October 17, 2020

ASSESSING TRANSPARENCY OF COSTS OF SPERM CRYOPRESERVATION ACROSS THE UNITED STATES. Johnny S. Su, BA,[1] Nicholas J. Farber, MD,[2] Yida Cai, BA,[1] Johnathan Doolittle, MD,[2] Sajal Gupta, MD,[3] Ashok Agarwal, PhD,[3] Sarah C. Vij, MD[2] [1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH; [3]American Center for Reproductive Medicine, Cleveland Clinic, Cleveland, OH.

OBJECTIVE: The objectives of our study are to assess the average cost of sperm cryopreservation and to determine the transparency in costs reported online in the U.S.

DESIGN: In March of 2020, we queried the Food and Drug Administration's Human Cell and Tissue Establishment Registration for facilities that have a registration to store semen products. Duplicate entries and those with no websites were excluded.

MATERIALS AND METHODS: Each facility was searched online for pricing data on sperm cryopreservation. Facilities were categorized by census region and facility type. Fisher's exact test and one-way analysis of variance were performed to compare online transparency and cost among different groups.

RESULTS: A total of 542 facilities were included, with only 96 facilities (17.7%) have any pricing information on sperm cryopreservation online. Of these, 16.7% (16/96) had price listings that were a part of fertility packages such as intrauterine insemination or in vitro fertilization. 12.5% (12) report transferring semen samples to another facility for long-term storage. 15.6% (15) charge their storage fee per client, while only 2.1% (2) charge by the number of semen specimens stored. 28.1% (27) offer storage plans longer than one year at reduced rates. Table 1 demonstrates the national cost of sperm cryopreservation. Online price transparency was different among the U.S. census regions: Northeast (21.2%), South (11.9%), Midwest (25.5%), and West (17.1%) (p=0.04). By facility type, 71.4% of biobanks had pricing information online compared to 34.5% of academic hospitals, 40% of non-university affiliated hospitals, and 6.3% of private practices (p<0.01). The Northeast had the highest annual storage fee (mean US$478) compared to the South ($443), the Midwest ($307), and the West ($395) (p=0.03). There were no differences in annual storage fee by facility type or in initial fee across groups.

CONCLUSIONS: Costs transparency of sperm cryopreservation is poor across the U.S., with less than one-fifth of registered facilities displaying any cost information online. The annual cost of storing sperm is highest in the Northeast, which could be attributed to differences in laboratory techniques, demographic patterns, or IVF insurance coverage. Achieving effective cost transparency can promote consumer decision-making and decrease the barrier for men seeking fertility preservation.

TABLE 1. National cost of sperm cryopreservation (in USD)

	Mean	Median	SD	# Reporting
Initial bank	389.12	350	225.06	80
Free storage (months)	9.5	12	4	14
Repeat bank	271.14	260	69.20	28
Storage - 1 month	46.87	48.00	11.24	23
Storage - 1 year	396.43	385.00	180.68	67
Thawing fees	170.98	150.00	143.69	29
Specimen retrieval	53.08	45.00	77.8	26
Infectious disease testing	171.22	140.00	58	9

P-10 4:30 PM Saturday, October 17, 2020

RURAL LOCALE PROTECTIVE FOR ETHNICALLY AND RACIALLY DIVERSE WOMEN AT RISK FOR GESTATIONAL DIABETES MELLITUS IN THE PACIFIC NORTHWEST. Kelsie Clausen, MA, OMSII,[1] Kathaleen Briggs Early, PhD, RDN, CDE,[1] David Gothard, MS,[1] Lizzie Lamb, MPH,[1] Laurene Enns, MA,[1] Esther Park-Hwang, MD, MBA[2] [1]Pacific Northwest University of Health Sciences, Yakima, WA; [2]MultiCare Health System, Tacoma, WA.

OBJECTIVE: Pregnancy-related complications like gestational diabetes mellitus (GDM) lead to adverse outcomes and increased chronic disease risk for both mother and fetus. Women living in rural and medically underserved communities are at especially high risk due to the inverse association of health outcomes with the social determinants of health and high rates of obesity. Prevalence of GDM in rural and non-rural areas has not been not been previously evaluated, and with co-morbidities leading to lifelong health implications, it is imperative to identify disparities to mitigate them. Our primary aim was to determine if there is a significant difference in GDM prevalence between rural and non-rural communities, and if there are certain variables that contribute as predictors for GDM risk.

DESIGN: This research is a retrospective, case-control study of the Center for Disease Control's (CDC) Pregnancy Risk Assessment and Monitoring System (PRAMS), years 2012-2015, Phase 7.

MATERIALS AND METHODS: We used SPSS v25.0 software to analyze data from PRAMS for AK, OR, and WA including birth certificate and core 7 questionnaire variables. The sample was weighted to be reflective of a population of 450,294.8 persons. Univariate analysis was performed to identify variables that were significantly different in rural or non-rural areas using a p-value threshold of 0.05. The significant variables were accounted for in a multivariable logistic regression model for GDM outcome to determine the additive influence of rural locale after adjustment for potentially confounding significant factors. Commonly known confounding risk factors, such as advanced maternal age, obesity, socioeconomic status, macrosomia, and caesarean section were controlled for in the model. Outcome measures were evaluated by adjusted odds ratios with 95% confidence intervals and tested for equivalence to 1.

RESULTS: Overall, rural locale was not significantly different than urban for GDM, but indicated a slightly increased odds ratio (p=0.690). Hispanic race was significant for increased prevalence in rural locations (p<0.001) and decreased risk of GDM (p=0.024). Combined, being Hispanic and having rural locale did not increase GDM risk (p=0.329). Additionally, the Kessner index, describing adequacy of prenatal care, was higher in rural locales and a predictor for decreased odds of GDM, though p=0.310. Post-hoc analysis revealed rural locale was significant for *reducing* risk for GDM among non-white women (aOR=0.562). Also, despite white race as a protective factor in general (p<0.001), white women were at increased risk of GDM in rural locations (p=0.031).

CONCLUSIONS: Overall, there was no difference in GDM prevalence between rural or non-rural areas of AK, OR and WA. White maternal race was a protective factor, but for non-white women, rural residence adds a significant protective influence on GDM risk. Several aspects could account for this, including social support practices, the quality and type of occupation, nutritional intake, or physical activity.

SUPPORT: None.

BARRIERS TO FAMILY BUILDING AND IMPACT ON CAREER TRAJECTORY FOR WOMEN IN MEDICINE. Anne P. Hutchinson, M.D.,[1] Kathryn Smith, B.S.,[2] Elaine O. Cheung, PhD,[3] Patricia I. Moreno, PhD,[3] Neil Jordan, PhD,[4] Kara N. Goldman, M.D.,[1] Jessica L. Thomas, A.M.,[2] Veronika Elisabeth Grote, B.S.,[3] Eve C. Feinberg, M.D.[1] [1]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Department of Medical Social Sciences, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Mental Health Services & Policy Program, Chicago, IL.

OBJECTIVE: Explore female physicians' perceptions and experiences of fertility, pregnancy, and parenthood in academic medicine, and their impact on family planning and career trajectory.

DESIGN: Qualitative semi-structured interview study

MATERIALS AND METHODS: Qualitative interviews were conducted in person or remotely over video conference using a semi-structured interview guide. The interviewer asked open-ended questions to elicit participants' knowledge, experiences and concerns as related to partnership, family planning, fertility, pregnancy and parenthood, and whether these factors had impacted participants' career paths. All interview transcripts were qualitatively coded by two members of the research team in Dedoose.

RESULTS: 10 female physicians in academic medicine (age M = 34.4, SD: 2.1, range: 28-38) completed qualitative interviews: 9 attending physicians, and 1 fellow.

All 10 women expressed frustration that leave, childcare, and fertility benefits were not openly discussed. The 4 women with children reported that they relied on peer mentorship, as opposed to Human Resources transparency, to navigate the process. Among the 6 women without children, 5 lacked information about their institution's parental leave policies.

Nine of 10 women interviewed reported delaying childbearing (range: 0.5-6 years). Among the women who delayed childbearing, 7 cited barriers in the training/work environment (lack of time, lack of flexibility in schedules, financial strain) as their primary reason for delay, and 2 cited the lack of a partner.

Six of 10 women reported frustration with their lack of schedule flexibility, and 7 of 10 perceived lack of peer support for parental leave, fertility, or childcare needs.

Nine of 10 women reported that they would decrease their clinical time to allow for additional flexibility with childbearing. Two would consider changing specialties or leaving medicine completely to accommodate childbearing and parenthood.

These stressors were notably diminished in women who selected their career paths with flexibility for childbearing in mind (e.g., hospital medicine) or were in divisions composed of predominantly young female physicians. These stressors were also diminished in women who reported having additional support for family and parenthood outside of the workplace (e.g., financial and/or childcare support provided by romantic partners and other family). While all participants agreed that their partner should share in parenting responsibilities, 8 reported that they would not expect their partner to make any changes to their career paths to facilitate family life.

CONCLUSIONS: This study identified several important barriers to female physicians interested in parenthood while pursuing careers in academic medicine. Young female physicians are bearing the brunt of the stressors of parenthood, and without proper social and institutional support they are at increased risk for burnout, turnover, or departure from medicine. These findings reinforce the importance of clear-cut, supportive policies and ongoing dialogue about these issues and available resources.

HUMID VS DRY CULTURE: DOES RELATIVE HUMIDITY AFFECT THE MORPHOKINETICS OF *IN VITRO* CULTURED EMBRYOS?. María de los Ángeles Valera, PhD Student,[1] Carmela Albert, PhD,[2] Lorena Bori, M.Sc,[2] Lucia Alegre, PhD,[2] Thamara Viloria, PhD,[2] Marcos Meseguer, PhD[2] [1]IVIRMA Global; IVI Foundation, Valencia, Spain; [2]IVIRMA Global, Valencia, Spain.

OBJECTIVE: The aim of this study is to compare the timing of the main development events of embryos cultured in humid (HC) or dry conditions (DC) in a time-lapse system (TLM) incubator.

DESIGN: In this retrospective study we analysed the morphokinetics of 7014 embryos belonging to 832 ICSI treatments performed during two consecutive years, from autologous (n=393) or ovum donation programs (n=439). Embryos were cultured in an incubator equipped with time-lapse monitoring system, in dry (3281 embryos) or humid conditions (n=3149). Timing of the main development events of each embryo were annotated and compared between the two study groups.

MATERIALS AND METHODS: Stimulation, oocyte pickup and fertilization were performed according to the standard procedures of the clinic. Fertilized oocytes were cultured in a Geri incubator (Genea Biomedx, Australia). This incubator has 6 separated chambers for individual patients, 3 of them operating with dry environment, and 3 adapted for culture in a high relative humidity atmosphere. Embryo cohorts were randomly assigned to DC or HC. Embryo development was monitored using Assess 2.0 TLM software from Geri and the main morphokinetic parameters were automatically annotated and compared between those incubated in dry vs humid conditions. Statistical analysis was performed using the Statistical Package for Social Sciences (SPSS) in search for significant differences between the two groups.

RESULTS: Morphokinetic parameters were compared between all embryos cultured in HC and DC, as well as only good morphology blastocysts and only transferred embryos. Significant differences ($p \leq 0,05$) were found in the mean values of **tPNf** (23,350h in HC vs 23,591h in DC), **t2** (26,809h in HC vs 27,149h in DC), **tM** (85,958h in HC vs 86,904h in DC) and **tEB** (114,727h in HC vs 113,805h in DC), being all except the latter lower in embryos cultured in HC. When comparing only good morphology blastocysts, **tPNf** (22,821h vs 23,165h), **t2** (25,569h vs 25,843h) and **tM** (85,226h vs 86,573h, $p \leq 0,001$) remained being significantly lower in HC, as well as **tSC** (98,499h vs 99,187h), but no significant difference was found in tEB. However, when comparing only transferred embryos (n=394), no significant differences in tPNf nor t2 were found, although **tM** remained significantly lower in HC (83,424h vs 86,020h in DC, p=0,002). Later developmental events occurred faster in transferred embryos cultured in HC than DC: **tSB** (95,806h vs 97,249h, p=0,042), **tB** (101,870h vs 103,662h, p=0,05) and **tEB** (108,086h vs 109,851h, p= 0,012), in contrast with the observed in the whole set.

CONCLUSIONS: Embryos cultured in HC had a slightly faster development than those cultured in DC, being the time to reach morulae stage the most affected parameter, which has been previously related with higher embryo quality and implantation potential (Goodman *et al*, 2016). These findings are consistent with previously published results (Albert *et al,* 2020) where embryos cultured in HC had higher ongoing pregnancy rates than those cultured in DC.

HOW LOW CAN YOU GO WITH OXYGEN CONCENTRATION?. Rachel Blair Danis, MD,[1] Jesse L. Stone, MS,[2] Jacqueline Ho, MD MS,[1] Trenton Place, DO, PhD,[1] Lynda K. McGinnis, PhD,[1] Ali Ahmady, PhD[3] [1]University of Southern California, Los Angeles, CA; [2]USC Fertility, Los Angeles, CA; [3]Keck School of Medicine, University of Southern California, Los Angeles, CA.

OBJECTIVE: The concentration of oxygen in the female reproductive tract gradually decreases from 5-7% in the fallopian tube to 2% in the uterus. A reduction in oxygen from atmospheric to physiologic levels improves cell number, decreases DNA fragmentation, and induces less oxidative stress on the blastocyst. However, studies investigating benefits of ultralow oxygen concentrations *in vitro* have shown inconsistent findings[2,4–8]. We sought to determine if culturing from single-cell stage embryos at various ultralow oxygen concentrations improved embryo development in the mouse model.

DESIGN: Basic science

MATERIALS AND METHODS: Cryopreserved single-cell stage mouse embryos ($B_6C_3F_1$ X $B_6D_2F_1$ strain; Embryotech, Haverhill, MA) were thawed and randomly divided into 5 oxygen treatment arms: 0.7-0.8% (n=173), 1.5% (n=176), 2% (n=166), 3% (n=171), and 5% (n=171, control arm). Embryos were cultured to the blastocyst stage in groups of 6 in 25μl droplets of Continuous Single Culture Complete (CSCC, Irvine Scientific) in an incubator (Heracell 150i) at 8% CO_2 and a pH of 7.3. Embryo development was evaluated by quantifying cell number over a 5-day period. Chi square test and logistic regressions were used to test associations where appropriate. A p-value of <0.05 was considered statistically significant.

RESULTS: Mouse embryos cultured at ultralow oxygen concentrations of 1.5%, 2%, and 3% had similarly high rates of blastocyst development, whereas those cultured at 0.7-0.8% had the lowest rate of blastocyst development (Table). Compared to cleavage-stage embryos cultured at 5%, mouse embryos cultured at 2% and 3% oxygen concentrations were more likely to become blastocysts, (OR 4.1 and OR 3.7, $p<0.05$, respectively), and those cultured at 0.7-0.8% were least likely to develop into blastocysts (OR 0.2, 95% CI 0.12-0.34, $p <0.001$; Table).

CONCLUSIONS: We demonstrated a unimodal distribution for optimal oxygen concentrations *in vitro*. Too low, 0.7-0.8%, resulted in poor blastulation, and the standard 5% did not improve embryo development. Oxygen concentrations at 2% and 3% resulted in optimal blastocyst development.

TABLE. Mouse embryo development at ultralow oxygen concentrations

Oxygen Tension	0.7-0.8%	1.50%	2%	3%	5%
Number of single-cell embryos on Day 1*	173	176	166	171	171
Number of cleavage* (%)	171 (98.8)	176 (100)	156 (94.0)	163 (95.3)	170 (99.4)
Number of blastocyst* (%)	94 (54.3)	159 (90.3)	150 (90.4)	156 (91.2)	146 (85.4)
Odds ratio of a cleavage stage mouse becoming a blastocyst	0.20*	1.5	4.1*	3.7*	1.0 (ref)

Logistic regression used; *significance $p<0.05$

These findings shed light on the potential benefit of ultralow oxygen concentration, particularly at 2-3%.

REALISTIC MEASUREMENT OF THE EFFECT OF SPERM DNA FRAGMENTATION ON REPRODUCTIVE OUTCOMES BY CUMULATIVE LIVEBIRTH RATES (CLBR) PER EMBRYO REPLACED AND OOCYTE EMPLOYED REVEALS ITS LACK OF RELEVANCE IN UNSELECTED MALES USING OWN OOCYTES. Irene Hervas, MSc,[1] Nicolas Garrido, PhD,[1] Rocio Rivera-Egea, PhD,[2] Cristina Gonzalez-Ravina, PhD,[3] David Amoros, PhD,[4] Fernando Quintana, Sr., PhD,[5] Maria Gil Julia, MSc, MRes,[1] Alberto Pacheco, PhD[6] [1]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [2]IVIRMA Valencia, Valencia, Spain; [3]IVIRMA Sevilla, Sevilla, Spain; [4]IVIRMA Barcelona, Barcelona, Spain; [5]IVIRMA Bilbao, Bilbao, Spain; [6]IVIRMA Madrid, Madrid, Spain.

OBJECTIVE: Sperm DNA fragmentation (SDF) effect on reproductive outcomes has been extensively studied and contradictory conclusions have been reached so far, probably caused by an inappropriate way of measuring reproductive success influenced by sperm biomarkers. Using clinical outcomes per embryo transfer is a biased measure of the impact of SDF on the embryonic cohort, since does not consider the surplus contribution of other cohort embryos and the best are firstly selected.We addressed this problem by studying raw live birth rates (LBR) at first embryo transfer (ET), in all ET (fresh + thawed), and CLBR, per ET, number of embryos replaced (EmbR) and oocytes consumed until reaching a first live, better assessing its actual effect.

DESIGN: Retrospective cohort multicenter study.

MATERIALS AND METHODS: Patients undergoing IVF/ICSIs with autologous oocytes (n=1055) from Jan 2000-Mar 2019, tested for SDF on ejaculated spermatozoa using TUNEL assay. Analysis groups were established to compare all main outcomes: SDF >15% (H, high) and in 10% SDF ranges: <10%, 10%-20%, 20%-30%, >30%, by X^2 square tests, and CLBR estimated with Kaplan-Meier and Mantel-Cox test, considering the total number of embryo transfers, embryos transferred, and oocytes needed to obtain the first livebirth.

RESULTS: 2759 embryo transfers were considered, and a total of 2469 embryos and 5657 consumed oocytes had been including. Overall population characteristics were comparable. No difference in LBR was shown neither at first embryo transfer nor in all, with high/low (L) SDF 41.9% vs 38.2% and 39.9% vs 36.5% respectively. LBR rates considering 10% SDF ranges were comparable in first and in all transfers. CLBR per ET performed showed non-significant differences between H or L fragmentation groups: 40.7% vs 46.9% (1st), 59.1% vs 66.4% (2nd), 69.9% vs 77.0% (3rd) and 86.7% vs 100.0% (5th). If compared by 10% SDF ranges, CLBR of the group with the lowest (<10%) SDF versus the highest (>30%) were 41.1% vs 38.9%, 59.0% vs 71.8% and 68.1% vs 78.8% with the first three ET respectively. Cumulative LBR according to the number of EmbR were similar (L vs H): for 2 EmbR (48.0% *vs* 54.3%) and 4 EmbR (67.5% *vs* 74.0%), as they were comparing CLBR by SDF groups, being 49.0% (<10%) and 53.3% (>30%) CLBR with 2 EmbR, or when up to 4 embryos were replaced, 66.0% (<10%) and 81.3% (>30%). CLBR per number of oocytes consumed was comparable in L group (43.3%, 67.3% and 81.9%), and in H group (46.0%, 68.35% and 87.3%) for 5, 10 or 15 oocytes used respectively. By SDF groups, CLBR was analogous, f.i. in <10% *vs* >30% groups: 43.5% *vs* 49.2% at 5 oocytes, 68.3% *vs* 77.4% at 10 oocytes, and 81.6% *vs* 88.7% at 15 oocytes consumed.

CONCLUSIONS: DNA fragmentation does not negatively affect the live birth rates of unselected patients undergoing an IVF-ICSI cycle with their own oocytes, neither per transfer, nor accumulated per transfer, embryo or oocyte, after the largest and most extensive data analysis done so far.

P-15 4:30 PM Saturday, October 17, 2020

EFFECT OF PENTOXIFYLLINE SUPPLEMENTATION ROUTINELY ADDED TO SPERM SUSPENSIONS IMMEDIATELY BEFORE INTRACYTOPLASMIC SPERM INJECTION. Rita C. S. Figueira, Ph.D.,[1] Sidney Verza, Jr., B.Sc.,[1] Vanessa C. F. Moreno, B.Sc.,[1] Sandro C. Esteves, M.D., Ph.D.[2] [1]Androfert, Campinas, Brazil; [2]ANDROFERT & University of Campinas (UNICAMP), Campinas, Brazil.

OBJECTIVE: Effects of PTX indiscriminate use have not been properly studied, and concerns exist of possible embryotoxicity. We investigated the clinical utility of routine PTX-sperm supplementation on the fertilizing ability and embryo development.

DESIGN: Prospective cohort study

MATERIALS AND METHODS: In the study group, 10μL of a commercially available PTX (20mg/mL; Vascer, União Qumica, Brazil) was added 1:1 v/v to the sperm suspension and this preparation was immediately transferred to a PVP drop in an ICSI dish. Motile sperm, preferentially those exhibiting hyperactivation, were selected to injection. Blastocysts were subjected to trophectodermal biopsy and comprehensive chromosomal screening. Statistical analysis was performed using Student T-test, Chi-square and multiple regression models. The primary endpoint was 2PN fertilization rates (FRs) and the secondary endpoints were embryonic outcomes.

RESULTS: In study periods 1 (July/18 - April/19, Control) and 2 (May/19 - December/19, PTX), 141 and 178 couples were subjected to 232 and 244 ICSI cycles without and with PTX supplementation, respectively. Demographic data were similar between control and PTX groups. PTX increased

FRs in the overall populations and subgroups, including azoospermic men, with a more pronounced effect when ICSI was carried out with testicular sperm. No apparent toxic effect was noticed concerning the rates of blastocyst formation and euploidy. Table 1 presents a summary of the results. Multiple regression models showed a significant and independent increment on fertilization ability when sperm samples derived from non-male factor cycles were PTX-incubated (β=6.01, p=0.03).

	Fertilization rate			Blastocyst rate			Blastocyst euploidy rate		
Cycles	PTX	Control	P	PTX	Control	p	PTX	Control	p
All	74.4	68.1	<0.001	49.6	49.3	0.88	40.8	40.9	0.97
Non-male factor	78.1	70.0	<0.001	52.8	54.0	0.64	39.1	40.1	0.84
Male factor	69.4	64.1	0.05	44.7	39.0	0.11	43.9	44.0	0.98
Azoospermia	65.6	52.1	0.01	35.5	33.7	0.79	50.0	41.7	0.65
Testicular sperm	63.6	46.5	0.005	32.0	32.1	0.99	43.8	42.9	0.96

CONCLUSIONS: Our findings indicate that the routine use of PTX enhances sperm fertilizing ability without compromising embryo development and genetic competence. Beside its positive effect on intracellular cyclic AMP concentrations, other mechanisms might be involved. The observed beneficial effect of PTX in our cohort warrants further investigation to confirm its efficiency and safety.

P-16 4:30 PM Saturday, October 17, 2020

SEPARATION OF NON-APOPTOTIC SPERM VIA MAGNETIC ACTIVATED CELL SORTING BEFORE INTRACYTOPLASMIC SPERM INJECTION IN AUTOLOGOUS OOCYTES INCREASED CUMULATIVE LIVE BIRTH RATES WITH LIMITED CLINICAL IMPACT. Maria Gil Julia, MSc, MRes,[1] Fernando Quintana, Sr., PhD,[2] David Amoros, PhD,[3] Alberto Pacheco, PhD,[4] Cristina Gonzalez-Ravina, PhD,[5] Rocio Rivera-Egea, PhD,[6] Irene Hervas, MSc,[1] Nicolas Garrido, PhD[1] [1]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [2]IVIRMA Bilbao, Bilbao, Spain; [3]IVIRMA Barcelona, Barcelona, Spain; [4]IVIRMA Madrid, Madrid, Spain; [5]IVIRMA Sevilla, Sevilla, Spain; [6]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: The benefit of using magnetic activated cell sorting (MACS) to select annexin V negative, non-apoptotic sperm before intracytoplasmic sperm injection (ICSI) has been a matter of controversy. One reason might be the bias caused by embryo selection in each transfer and measuring success only on the first attempt. The aim of this study is to retrospectively evaluate MACS when using autologous oocytes, measuring success by cumulative rates per embryo transferred and oocyte consumed until a first child is born, overcoming the classical limitations.

DESIGN: Multi-center retrospective observational cohort study.

MATERIALS AND METHODS: Data was extracted from the results of ICSI cycles with autologous oocytes (Jan 2008-Feb 2020) which used semen samples processed by standard preparation protocols (control) or the standard procedure plus an added MACS step. Descriptive variables were compared by t-tests and gestational outcomes per embryo transfer (ET) and, in case of live birth rates (LBR) also per cycle, by Fisher's exact test. Kaplan-Meier (K-M) estimates reported cumulative LBR (CLBR) per ET and metaphase II oocyte (MII) in both groups. Mantel-Cox tests were performed to compare the plotted curves for each group. The threshold for statistical significance was set at p-value<0.05.

RESULTS: Overall cycle and patients characteristics were similar between groups.

When computed per ET, MACS group (n=2802 transfers) had a 46.9% biochemical pregnancy rate, a 39.7% clinical pregnancy rate and a 32.4% ongoing pregnancy rate, while the control group (n=60503) showed 45.4%, 38.7% and 31.8% respectively. None of these differences were statistically significant.

In terms of LBR, MACS group showed a 29.3% LBR per ET and a 38.8% per cycle (n=2115 cycles). The control group exhibited a 29.2% LBR per ET and 37.4% per cycle (n=60503). Neither of the comparisons were statistically significant.

CLBR per ET was 63.6% (60.1, 66.8) for two transfers, 80.6% (75.5, 84.6) for three in the MACS group, whereas the control group presented a rate of 59.6% (58.9, 60.4), 72.3% (71.2, 73.3) respectively.

CLBR per embryos transferred was 21.5% (19.4, 23.6) for one embryo, 55.5% (52.6, 58.2) for two, 65.4% (62.0, 68.5) for three and 83.3% (78.9, 86.7) for four, while the control group's CLBR was 15.0% (14.7, 15.4), 49.1% (48.6, 49.7), 58.0% (57.3, 58.7) and 73.3% (72.5, 74.1). Both CLBR measures displayed K-M curves with a statistically significant difference.

If computed per MII used, control group showed a CLBR of 13.1% (12.8, 13.5) for five MII, 39.8% (39.2, 40.4) for ten and 62.7% (62.00, 63.4) for fifteen, while the MACS group had a CLBR of 11.0% (9.6, 12.4), 36.6% (33.9, 39.1) and 59.8% (56.3, 63.0). K-M curves had a statistically significant difference.

CONCLUSIONS: Considering the largest sample size for this type of studies yet, the findings suggest that the separation of annexin V negative non-apoptotic sperm through MACS prior to ICSI using their own oocytes decreases the number of embryos needed to achieve the first live birth, but not the oocytes. However, the overall clinical relevance remains low.

P-17 4:30 PM Saturday, October 17, 2020

OOCYTE IN VITRO MATURATION DOES NOT ADVERSELY AFFECT THE PROGRESSION OF THE FIRST MEIOTIC DIVISION. Marga Esbert, PhD,[1] Cristina Garcia, MSc,[1] Georgina Cutts, MSc,[2] Evelin Lara-Molina, MD,[1] Emre Seli, MD,[3] Agustin Ballesteros, MD,[1] Nicolas Garrido, PhD,[4] Mariona Quera, MSc,[1] Richard Thomas Scott, Jr., MD,[3] Dagan Wells, PhD,[2] Elpida Fragouli, PhD[2] [1]IVI RMA Barcelona, Barcelona, Spain; [2]JUNO GENETICS, Oxford, United Kingdom; [3]IVI RMA New Jersey, Basking Ridge, NJ; [4]IVI Foundation - IIS La Fe Biomedical Research Institut, Valencia, Spain.

OBJECTIVE: Immature oocytes account for 15% of all oocytes collected and are usually discarded during IVF. There is little information on the aneuploidy frequency of *in vitro* matured (IVM) oocytes derived from young fertile women, and a standardized protocol enabling effective IVM is lacking. Our study aimed to: 1. Assess whether the addition of autologous cumulus cells (CCs) improves IVM rates; 2. Perform a comprehensive analysis of aneuploidy frequency and type in oocytes cultured in the presence or absence of autologous cumulus cells (CCs) during IVM.

DESIGN: This is a prospective randomized study including 390 oocytes [116 metaphase II (MII) and 274 immature oocytes] from 91 donors undergoing ovarian stimulation in one clinic between March-July 2019. The immature oocytes underwent IVM in the presence (n=137) or absence of CCs (n=137) according to a randomization plan. The MII oocytes served as a control for the IVM groups.

MATERIALS AND METHODS: Oocyte donors (mean age 25.57 $\pm$ 4.47) had a normal karyotype and did not have fertility problems. Biopsy of the 1st polar body (PB) was performed directly after denudation for MII oocytes, or after IVM for immature ones. IVM took place in a time-lapse incubator until 1st PB extrusion, or for 50 hours. CC suspension (1ul) was added to the culture well of 137 of the immature oocytes. The cytogenetics of oocytes and their 1st PBs was examined via a well-validated next generation sequencing (NGS) strategy. Our sample size calculation indicated that 74 MII were required per group (with an Alpha risk of 5%, a Beta risk of 20%) to reach statistical significance.

RESULTS: CC co-culture did not enhance IVM rates. Overall, 62.77% of oocytes co-cultured with CCs matured to MII, compared with 71.53% of oocytes cultured without CCs. A significantly higher number of mature MII oocyte-PB pairs (86.28%) yielded NGS results, compared to the IVM pairs (77.90%, P = 0.01). Reciprocal results between oocyte and their 1st PBs were obtained for most (77.84%) of the samples. A similar euploidy rate was observed for the MII oocytes (81.97%), and the IVM oocytes cultured in the presence (80.00%) or absence (85.42%) of CCs. Abnormalities resulting from loss or gain of whole chromosomes or of individual chromatids occurred at a similar rate for MII and IVM oocytes.

CONCLUSIONS: Our data suggest that CC supplementation does not enhance IVM. The IVM process does not seem to affect the accuracy of the first meiotic division and there were no statistical differences observed in the various types of meiotic error. Since DNA degradation is one of the principle reasons for failure of NGS analyses, the lower proportion of IVM oocytes/PBs that yielded results during this study may indicate reduced DNA integrity following IVM, a possibility that warrants further investigation. To our knowledge, this is the largest study employing NGS to provide a definitive insight into the chromosome constitution of IVM oocytes.

P-18 4:30 PM Saturday, October 17, 2020

ASSESSING THE CLINICAL VIABILITY OF MICRO 3PN ZYGOTES. Albert Li, BA,[1] Rose Marie Roth, MSc, TS(ABB), CLT (NYS),[1] Richard Slifkin, BA, TS(ABB), CLT(NYS),[1] Christine Briton-Jones, PhD, HCLD,[1] Joseph A. Lee, BA,[1] Daniel E. Stein, MD,[2] Alan B. Copperman, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: Following intracytoplasmic sperm injection (ICSI) of an oocyte in vitro, fertilization is evaluated using morphological assessment and count of pronuclei (PN). Normal fertilization is characterized by the appearance of 2 PN, observed 13-19 hours post-ICSI. Occasionally, a 3rd "micro" PN can be observed in the zygote. This finding has traditionally been interpreted by embryologists to be an abnormality that is consistent with embryonic aneuploidy, including triploidy [1,4]. Reproductive biologists have demonstrated that the appearance of a 3rd micro PN following injection of a single spermatozoon can result from the retention of the second polar body, oocyte meiotic failure, or sperm abnormalities [2, 3]. Embryos resulting from tri-pronucleated zygotes have also been found to be euploid, perhaps due to self-correction during subsequent cell division [4]. This study aims to evaluate the clinical viability of micro 3PN zygotes by assessing rates of embryo ploidy and frozen embryo transfer (FET) outcomes.

DESIGN: Retrospective

MATERIALS AND METHODS: Micro 3PN zygotes were identified from patients who underwent IVF with ICSI and pre-implantation genetic testing for aneuploidy (PGT-A). On day 3 of development, embryos underwent laser assisted hatching to breach the zona pellucida. At the blastocyst stage of development (day 5, 6 or 7), a trophectoderm biopsy was performed on any embryo(s) that met biopsy criteria ($\geq$5 trophectoderm cells herniating, $\geq$grade "C" inner cell mass and trophectoderm). Samples of biopsied trophectoderm were sent to a commercial laboratory for genetic analysis using a next generation sequencing method. Embryos were vitrified post-biopsy, and euploid embryos were subsequently thawed for FET.

RESULTS: A total of 107 micro 3PN zygotes were evaluated between March 2018 and January 2020. After culturing to the blastocyst stage,16.8% (n=18) of the embryos were biopsied, and 72.2% (n=13) of those displayed diverse types of aneuploidy, although triploid embryos were not found. A euploid rate of 27.8% (n=5) was detected, with 60% (n=3) of those transferred in a FET cycle. A clinical pregnancy rate of 66.7% (n=2) was achieved. One patient reported a livebirth and the other pregnancy is currently ongoing.

CONCLUSIONS: This study demonstrates the reproductive potential of micro 3PN zygotes within an IVF setting. Although there is a high rate of embryonic aneuploidy in micro 3PN-derived blastocysts, our study shows a proportion of these embryos are euploid, can be selected for embryo transfer, and lead to a positive pregnancy outcome. We suggest extending culture of micro 3PN zygotes due to their capability of having a normal genetic profile. With the validation of genetic screening, patients can be assured that normal pregnancies can be sourced from micro 3PN zygotes.

EFFECTS OF A23187 AND IONOMYCIN ON OOCYTE ACTIVATION IN PATIENTS WITH PREVIOUS TOTAL FERTILIZATION FAILURE OR SEVERE OLIGO-ASTHENO-TERATOZOOSPERMIA: A 9-YEAR RETROSPECTIVE STUDY. Lei Jia, Master,[1] Shujing He, MM,[2] Wenlong Su, MS,[3] Cong Fang, PHD, MD[4] [1]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [3]Sixth Affiliated hospital of Sun Yat-Sen University, Guangzhou, China; [4]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To assess effects of the applications of Ca^{2+} ionophore A23187 and Ionomycin on fertilization rate, embryonic developmental potential and clinical outcomes in patients with a history of total failed fertilization/lower fertilization rate or severe oligo-astheno-teratozoospermia.

DESIGN: A 9-year retrospective study was conducted with clinical-based data at Reproductive Medicine Research Center of the Sixth Affiliated Hospital of Sun Yat-sen University from May 2010 to December 2019.

MATERIALS AND METHODS: The indications for assisted oocyte activation (AOA) in our center were: (1) patients with total failed fertilization (0%)/lower fertilization rate (fertilization rate <33.3%) in previous ICSI cycles (at least three mature oocytes on the day of oocyte retrieval); or (2) severe oligo-astheno-teratozoospermia including globozoospermia, cryopreserved micro-dissection testicular sperm extraction (MD-TESE) and cryopreserved rare human spermatozoa. The AOA procedure was performed as follows: the oocytes were exposed to either the ready-to-use A23187 solution (GM508, Cult-Active, Gynemed) or 10μM ionomycin (407952,Sigma-Aldrich) after ICSI. All patients were categorized into two groups: A23187-AOA group and Ionomycin-AOA group. And each group was divided into two subgroups according to origin (ejaculated or testicular sperm). Statistical analyses were performed by SPSS 22.0 with the chi-square test, Yates' correction, or Fisher's exact probabilities accordingly when comparing frequencies or proportions. P <0.05 were considered to be statistically significant.

RESULTS: A total of 65 patients whose oocytes were exposed to either the A23187-(n=39) or Ionomycin-AOA (n=26) protocol were included in the final analysis. Significantly higher 2PN fertilization rate (55.0% vs. 43.3%, P<0.01), 2PN cleavage rate (97.4% vs. 90.4%, P<0.05) and blastocyst formation rate (69.1% vs. 45.2%, P<0.05) were observed in Ionomycin-AOA group compared with those in A23187-AOA group. In ejaculated spermatozoa subgroup, 2PN cleavage rate (97.1% vs. 85.8%, P<0.05) and rate of D3 transferable embryos (92.6% vs. 73.6%, P<0.01) in Ionomycin-AOA group were higher than those in A23187-AOA group; In testicular spermatozoa subgroup, the 2PN fertilization rate(55.4% vs.37.7%, P<0.05), blastocyst formation rate(93.3% vs.20.0%,P<0.01) and cumulative clinical pregnancy rate(66.7% vs.10.0%, P<0.05) in Ionomycin-AOA group were higher than those in A23187-AOA group. A total of 20 healthy neonates were delivered in 65 patients and 9 pregnancies were ongoing. None of congenital anomalies (birth defects) was found in fetuses following AOA.

CONCLUSIONS: Ionomycin may be superior to A23187 for improving fertilization rate and embryonic developmental potential. And compared with A23187, Ionomycin provides better clinical outcomes for patients with testicular-origin severe oligo-astheno-teratozoospermia.

INCREASED BLASTOCYST EUPLOID RATE USING A NOVEL SINGLE-STEP CULTURE MEDIUM. Rebecca Holmes, PhD, HCLD,[1] Rebecca Kile, MS,[2] Courtney Grimm, MS,[2] William B. Schoolcraft, MD,[2] Jason E. Swain, PhD, HCLD,[3] Rebecca L. Krisher, PhD[4] [1]CCRM Boston, Newton, MA; [2]Colorado Center for Reproductive Medicine, Lone Tree, CO; [3]CCRM IVF Network, Lone Tree, CO; [4]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: The objective of this study was to compare the impact of a novel single-step culture medium versus a commercial sequential media on cycle outcomes following sibling oocyte splits.

DESIGN: Prospective randomized trial using sibling oocytes.

MATERIALS AND METHODS: All procedures were conducted at a single IVF center and all PGT-A results were from a single genetics lab. After ICSI all injected oocytes were evenly and randomly distributed between two dishes containing either a novel single-step medium (CCRM Single Step) or a commercial sequential media (Sage media, Cooper Surgical). All media were supplemented with the same lot of 10% SPS protein and cultured under oil in the same benchtop incubator under oil using ~6% CO_2, 5% O_2. All embryos were treated identically except for the culture medium used. In phase 1, media were exchanged following 24h, 72h and 120h of culture for both the sequential and single-step media. In Phase 2 the single step medium was exchanged at 72h, while the sequential media was changed at 24h, 72h and 120h. Data were analyzed using Fisher's Exact Test

RESULTS: In Phase 1, more good quality blastocysts (GQB) were obtained on day 5 and in total with the single step medium. This resulted in a significantly increased blastocyst rate of 10% and an increased euploid/2PN of 5% for single step medium compared to sequential.

In Phase 2, GQB on D5 was again higher in the single step medium, although overall GQB percentage was similar in both media systems. However, overall blastocyst development was lower in single-step. The percentage of euploid embryos/2pn remained higher in the single step medium

PHASE 1	# 2PN	%D5 GQBL/2PN	%Total GQBL/2PN	% Total BL/2PN	euploid/ 2PN
SAGE CM/BM	164	21%	47%	57%$_a$	28.5%
Single Step	191	29%	51%	67%$_b$	33.8%
PHASE 2					
SAGE CM/BM	99	18%	46%	57%	26.0%
Single Step	111	25%	46%	50%	32.9%

CONCLUSIONS: A novel single-step medium performed as well as, if not better than, a commercial sequential media. In phase 1, using the same number of media exchanges, the single step media outperformed the sequential media, suggesting superiority of the media formulation to meet the developmental needs of the preimplantation embryos. Fewer media exchanges were performed in Phase 2 with the single step medium to reduce handling and test if this might further improve outcomes. While still yielding higher good quality D5 blastocyst rates, reduced handling using the single step medium did not further enhance outcomes, suggesting that embryo handling/media exchanges were not a significantly detrimental factor. In our hands, this single step medium results in more D5 blastocysts, more blastocysts available for biopsy, and more euploid embryos - ultimately benefiting the patient.

ASSISTED HATCHING (AH) IN COLLAPSED BLASTOCYSTS IS ABLE TO RESTORE THE IMPLANTATION RATES: A RETROSPECTIVE STUDY. Alberto Tejera, PhD,[1] Lucia Alegre, PhD,[1] Amparo Mifsud, PhD,[1] Jose Maria De los Santos, PhD,[1] Marga Esbert, PhD,[2] Marcos Meseguer, PhD[1] [1]IVIRMA Global, Valencia, Spain; [2]IVI RMA Barcelona, Barcelona, Spain.

OBJECTIVE: Blastocyst contraction has been extensively described by Time-Lapse monitoring systems, affecting approximately 20% of the embryos, decreasing their implantation potential to 10% (Scorio et al. 2020). Our objective is to demonstrate whether performing AH for those collapsed blastocysts (CB) may help to restore their implantation potential. To demonstrate our hypothesis we calculated the implantation rate as well as pregnancy rate (PR) of CB with AH comparing these results to those blastocysts with collapse but without AH.

DESIGN: Retrospective Cohort Study.

MATERIALS AND METHODS: We analyzed 208 blastocyst from oocyte donation program during one consecutive year(January 2019-January 2020) that were distributed in two groups**:** the control group (107 CB without AH) and the study group (101 CB with AH). All blastocysts included in the study were cultured in a time-lapse system to identify the collapse episode ($\geq$50% of the surface of the trofoctoderm separated from the zona pellucida), being verified the collapse through the Embryo Viewer^{TM} or Asses 2.0 workstations. Both study and control group were formed by frozen blastocyst where the collapse episode was retrospectively identified before warming. AH was achieved in the study group through laser (eliminating one quarter part of the zona pellucida). All embryos were incubated for 3-4 hours before being transferred. Pregnancy and implantation rates were analyzed and compared in both groups by X^2 test and regression logistic analysis(RLA) was performed considering body mass index, maternal age, blastocyst vitrification day(D5 vs D6) and blastocyst morphology as confounding factors to weight the effect of AH on ongoing pregnancy rate(OPR).

RESULTS: Considering cases with known implantation, after applying AH in the collapsed blastocysts(101) resulted higher pregnancy rates(PR) compared to those without AH(107): 54.5% vs 40.6% for PR with p=0.049; 45.5% vs 31.7% for clinical pregnancy rate(CPR) with p= 0.043 and 35.6% vs 20.8% for OPR with p=0.019. When we only selected SET cases (177) the benefits were equally effective for CB with AH (84) compared to CB without AH(93), getting higher OPR (34.5% vs 17.2% p=0.008). The blastocysts were categorized by morphology (ASEBIR) into A, B or C. After performing a RLA , AH presented an odds ratio of 3.23 (CI95% 1.491-6.979) for OPR (p=0.003).

CONCLUSIONS: Our findings support the use of AH for CB to improve up to three times the OPR. Maybe the strong contractions suffered by the blastocysts during the embryo development imply a waste of energy necessary for the implantation process. This behaviour would explain the decreased of the implantation of those embryos without AH. Performing AH in CB could recover the implantation capacity impaired by the collapse. Also irrespective of either blastocyst morphology or vitrification day a benefit was observed and quantified after carrying out AH.

P-22 4:30 PM Saturday, October 17, 2020

A REDESIGN OF THE PROTEX TO HARVEST FREE OXYGEN SPECIES APPEARS TO IMPROVE OVERALL SEMEN PARAMETERS. Samuel D. Prien, PhD,[1] Melissa Sillivent, M.S.,[2] Lindsay L. Penrose, PhD[1] [1]Texas Tech University Health Sciences Center, Lubbock, TX; [2]Texas Tech University, Lubbock, TX.

OBJECTIVE: Previous research from this laboratory has demonstrated that semen quality, both physiological and biochemical, can be improved via a simple redesign of the semen collection cup. The redesign termed the Device for Improved Semen Collection (DISC – trade name ProteX), maintains a stable environment during and after collection, preventing cell shock and preserving cell function. However, the original design did nothing to prevent DNA fragmentation. Recently the system underwent a redesign incorporating a proprietary method to harvest free oxygen radicals, an identified cause of DNA fragmentation. The object of this study was to determine the effects of the redesign on all cellular functions.

DESIGN: Lab-based study of standard semen parameters

MATERIALS AND METHODS: In these initial studies, frozen bovine semen was thawed and processed similarly to an IUI sample to yield a final 6 mL sample containing approximately 20 million cells/mL. Two milliliters of the cell suspension was then transferred to a standard specimen cup (SSC), the original ProteX device (PRO), or the redesigned system (Pro+), and the sample maintained on a benchtop at room temperature. At times 0, 1, 3, 6, 9, 24, and 48 hrs, the samples were briefly vortexed, and aliquots used to prepare slides for semen analysis, acrosome reactions, and DNA fragmentation. Semen analyses were performed on a Hamilton Thorn IVOS unit, and acrosome and DNA fragmentation determined using standard techniques. Resulting data were analyzed using ANOVA with repeated measures.

RESULTS: As expected, all semen analysis parameters decreased over time ($P < 0.001$). However, cells stored in the Pro and Pro+ maintained significantly higher cellular activity for all semen parameters when compared to the SSC after as little as 6 hrs ($P < 0.005$). This difference can be seen easily at 48 hrs were the Pro and Pro+ maintained over 20% of the initial motility and rapid cells while the SSC had dropped to 7% and 1%,

respectively ($P < 0.001$). Further, while the motility and rapid cells were similar between the Pro and Pro+, other semen parameters, such as linearity and straightness, indicated the cell stored in the Pro+ possessed better overall activity than in the Pro ($P < 0.01$). Acrosome and DNA fragmentation data are pending.

CONCLUSIONS: The ProteX semen collection system continues to be a superior collection system for andrology samples than a standard specimen cup. Further, the redesigned ProteX appears to provide additional protection to overall sample quality, which should result in healthier cells for all ART procedures.

VOLATILE ORGANIC COMPOUND PROFILE OF MINERAL OIL AFFECTS EMBRYO DEVELOPMENT.

Courtney K. Grimm, MS,[1] Rebecca L. Krisher, PhD,[2] Jason E. Swain, PhD, HCLD,[3] William B. Schoolcraft, MD,[1] Linxing Yao, PhD,[4] Amy Sheflin, PhD[4] [1]Colorado Center for Reproductive Medicine, Lone Tree, CO; [2]CCRM Colorado, Lone Tree, CO; [3]CCRM IVF Network, Lone Tree, CO; [4]Colorado State University, Fort Collins, CO.

OBJECTIVE: A high quality mineral oil overlay is an essential component of a successful in vitro embryo culture system. Mineral oils may contain impurities and by-products from manufacturing such as volatile organic compounds (VOCs) that have the potential to leach into culture medium and disrupt embryo development. The aim of this study was to investigate the VOC content of four commercial oils, and to assess whether oil VOC content affects mouse embryo development and developmental kinetics.

DESIGN: Research study

MATERIALS AND METHODS: Mouse embryos (ND4, 4-8 wks) were produced by in vitro maturation (IVM) and fertilization (IVF). Zygotes were cultured in an EmbryoScope (Vitrolife) under one of four commercial oils: Vitrolife Ovoil, Life Global Paraffin Oil (LGPO), Sage Oil for Tissue Culture, or Spectrum USP Mineral Oil (four replicates, n=48/oil). Spectrum and LGPO were also tested in individual embryo culture in 2uL drops (four replicates, n=69 and 67, respectively). Triplicate samples of the four oils were analyzed using gas chromatography-mass spectroscopy (GC-MS) to assess relative VOC content.

RESULTS: There were no significant differences in embryo developmental kinetics due to type of oil overlay at any of the time points examined (pronuclear fade, first cleavage, morula compaction, appearance of the blastocoel, blastocyst, expansion, and hatching). There were also no differences in embryonic development to first cleavage, blastocyst, or hatching blastocyst in the Embryoscope. In microdrop culture, however, there were significant differences in development to blastocyst at 96 hours of culture (LGPO=13±6%, Spectrum=65.6±26%; p=0.028) and to hatching blastocyst at 112 hours of culture (LGPO=7.8±9.7%, Spectrum=50±27%, p=0.045). The GC-MS results showed four distinct VOC profiles by brand. VOC levels were significantly higher in LGPO for heptadecane (LGPO=9.8x106 ±2.9x106, Spectrum=2.8x106±1x105; p=0.0288) and for decane (LGPO=2.6x107±2.1x106, Spectrum=8.8x106±2.7x106, p=0.00013). Tetradecane, undecane, and dodecane were found in LGPO but were not detectable in Spectrum.

CONCLUSIONS: Although the four oils tested had distinct VOC profiles, there were no differences in development or developmental kinetics data for embryos cultured in the EmbryoScope under each oil. There were, however, significant developmental differences for single embryo culture in microdrops under LGPO and Spectrum oils, suggesting that this may be a more sensitive assay for assessing oil toxicity. Heptadecane, decane, tetradecane, undecane, and dodecane content of LGPO oil may be responsible for the significantly reduced development observed in microdrop culture. Oil containing elevated levels of these VOCs should be avoided for human embryo culture.

P-24 4:30 PM Saturday, October 17, 2020

STRONTIUM-INDUCED OOCYTE ACTIVATION IN NON-MALE FACTOR ICSI CYCLES AND ADVANCED MATERNAL AGE.

Rita C. S. Figueira, Ph.D.,[1] Sidney Verza, Jr., B.Sc.,[1] Vanessa C. F. Moreno, B.Sc.,[1] Sandro C. Esteves, M.D., Ph.D.[2] [1]Androfert, Campinas, Brazil; [2]ANDROFERT & University of Campinas (UNICAMP), Campinas, Brazil.

OBJECTIVE: Abnormal calcium (Ca2+) oscillations in aged oocytes may adversely affect fertilization and subsequent embryonic development. Strontium (Sr2+) induces Ca2+ oscillations via the InsP3 receptor and PLCζ activation. However, unlike the sperm factor and calcium ionophore induced Ca2+ oscillations, Sr2+ does not require putative maternal machinery. We investigated the role of Sr2+ for artificial oocyte activation (AOA) in aged oocytes among non-male factor infertility couples undergoing assisted reproduction technology (ART).

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: This study included infertility couples with non-male factor infertility and advanced maternal age (40 years and over) with at least one previous non-AOA failed ICSI cycle. Ovarian stimulation and laboratory protocols were similar between non-AOA and the Sr2+-AOA, except for the use of AOA. In the study group (Sr2+-AOA cycles) all injected oocytes were stimulated using 10 mM SrCl (Sigma-Aldrich, St Louis, MO, USA) for 60 min, immediately after ICSI. The zygotes were cultured up to the blastocyst stage, and the resulting embryos were subjected to trophectoderm biopsy for preimplantation genetic testing for aneuploidies using next-generation sequencing. Comparisons between Sr2+-AOA and previous non-AOA cycles were performed using the paired Student's t-test. The primary endpoint was 2PN fertilization rates and the secondary endpoints were embryonic outcomes. Statistical analyses also included generalized linear and binary logistic regression models.

RESULTS: Between September 2019 and March 2020, we performed 18 Sr2+-AOA cycles in 13 couples who have undergone an average of 1.9 previous failed ICSI without AOA (range 1–6 cycles). The 2PN fertilization rate after Sr2+-mediated AOA was significantly higher than that of the routine non-AOA ICSI procedure (81.0% vs. 67.1%, p=0.04). Adjusted linear regression models showed that fertilization rates were significantly and independently associated with Sr2+-AOA (β=19.85, p=0.007). Sr2+-mediated AOA had no negative impact on blastocyst formation rate (30.9% vs. 34.5%, p=0.67) and on the likelihood of having at least one euploid blastocyst for transfer (OR=1.46, 95% IC: 0.26-8.27).

CONCLUSIONS: Age-related oocyte activation defects might adversely impact fertilization rates by ICSI, thus affecting the number of resulting embryos. Our results suggest that Sr2+-mediated AOA improves fertilization rates in aged oocytes, probably related to a sperm-independent activation. Our data corroborate previous studies on the safe utilization of Sr2+ on gametes and embryos cultured to the blastocyst stage. However, large-scale studies are warranted to evaluate the effectiveness of Sr2+-mediated AOA on pregnancy outcomes.

P-25 4:30 PM Saturday, October 17, 2020

MIGRATION SPEED OF NUCLEOLAR PRECURSOR BODIES IN PRONUCLEI: A NOVEL PARAMETER FOR PREDICTING LIVE BIRTH.

Taketo Inoue, Ph.D.,[1] Sayumi Taguchi, M.S.,[1] Mikiko Uemura, Ph.D.,[2] Yoshiko Tsujimoto, M.S.,[1] Kazunori Miyazaki, Ph.D., M.D.,[1] Yoshiki Yamashita, Ph.D., M.D.[1] [1]Umeda Fertility Clinic, Osaka, Japan; [2]Kansai University of Welfare Science, Kashiwara, Japan.

OBJECTIVE: Nucleolus precursor bodies (NPBs) are dynamic and the characteristic NPB pattern changes within a short time during the syngamy process on time-lapse imaging. However, the relationship between NPB migration speed and human IVF outcomes remains unclear.

DESIGN: Migration of 262 NPBs from 47 zygotes (12 patients) were prospectively analyzed after ICSI, and embryonic development was observed until blastocyst (blastocyst: $n = 25$; arrest: $n = 22$). The relationship between NPB migration and pregnancy was retrospectively analyzed from live birth/ongoing pregnancy (> 22 wks) (LB/OP, $n = 30$) and negative clinical pregnancy patients ($n = 30$) in frozen-thawed single ICSI-derived blastocyst transfer cycles. The zygotes were cultured in a time-lapse incubator (Geri+; CO_2; 6% O_2, 5% at 37°C and 80±20% humidity), and images were recorded every 5 min.

MATERIALS AND METHODS: The mPN and fPN were identified by appearance location in a zygote (fPN appearance: just below polar bodies). The central coordinates of mPN, fPN, and 2–5 NPBs/PN were measured by motion capture software. The migration distance of NPBs between two sequential images was calculated as the standard of central coordinates of PN, and then the migration speed of NPBs was calculated thereafter. A univariate logistic analysis was used to analyze the relationship among blastocyst development and 25 factors including time of cleavage and cleavage interval from termination of ICSI to day 3. Subsequently, multivariate logistic analysis was used to analyze the relationship among the blastulation and

migration speed of NPBs in factors that were $P < 0.15$ after univariate logistic analysis. Receiver operating characteristic curve analysis was used to calculate the cutoff values of blastocyst development and LB/OP.

RESULTS: The migration speed of NPBs was significantly faster in the blastocyst developed group than in the arrested group (mPN: $P < 0.001$; fPN: $P = 0.024$). The timing of blastocyst formation was correlated with the migration speed of NPBs in mPN ($rs = -0.633$, $P < 0.001$). In the arrested group, 68.2% embryos were arrested until day 3. The blastulation was related to the migration speed of NPBs in mPN and fPN, tPNf, tPNf-tPNa, t2, t3-t2, and t3-tPNf ($P < 0.05$) in a univariate logistic analysis, while the factor associated with blastocyst development was the migration speed of NPBs in mPN (OR: 5.14, 95%CI: 1.20–21.90, $P = 0.027$) in multivariate logistic analysis. As regards blastocyst development, the cutoff value of the migration speed of NPB in mPN was 3.70 μm/h (AUC: 0.81, 95%CI: 0.68–0.95). Compared to the negative clinical pregnancy patients, the migration speed of NPBs in LB/OG patients was significantly faster (mPN: $P < 0.001$; fPN: $P = 0.045$). As regards LB/OP, the cutoff value of the migration speed of NPB in mPN was 4.56 μm/h (AUC: 0.75, 95%CI: 0.63–0.88). The LB/OP rate in $\geqq$ cutoff value was significantly higher than that in $<$ cutoff value groups (75.0% vs. 33.3%, $P = 0.002$).

CONCLUSIONS: The migration speed of NPBs is a novel predictor of human embryo development and clinical outcomes.

P-26 4:30 PM Saturday, October 17, 2020

IS THERE A CLINICAL IMPACT OF BLASTOCYST SHRINKAGE PRIOR TO VITRIFICATION?. Kana Murakami, M.S., Hiroya Kitasaka, Ph.D., Tomokuni Yoshimura, B.S., Noritaka Fukunaga, Ph.D., Yoshimasa Asada, M.D., Ph.D. Asada Ladies Clinic, Nagoya, Japan.

OBJECTIVE: Blastocyst vitrification is an essential technique when carrying out preimplantation genetic testing (PGT) due to the time it takes to receive the results of the biopsy. An important point for blastocyst vitrification is to confirm that penetration of the equilibration solution is sufficient and this can be observed by the shrinkage and re-expansion of the blastocyst. It can however be difficult to observe re-expansion of a shrunken blastocyst just before vitrification. Shrunken blastocysts may have exceeded an optimal time in the equilibration solution and there are some concerns about the negative effects of the cryoprotectant. In this study, we examined the impact on blastocysts that had shrunken just before vitrification on subsequent clinical performance.

DESIGN: Retrospective study.

MATERIALS AND METHODS: We examined 11247 cycles in which vitrification–warming single embryo transfer was performed from 2013 to 2018. The blastocysts (graded $\geq$3BB) were vitrified on day 5 or day 6. First, we compared the clinical performance with shrunken blastocysts just before vitrification (S group) and non-shrunken blastocysts (N-S group). Secondly, we compared the rate of re-expansion with the S group and N-S group after 4h warming.

RESULTS: The patient age in these the groups was similar (S group 34.9$\pm$3.7; N-S group 34.7$\pm$3.8). The pregnancy rate of the S group (36.3%,53/146) was significantly lower (P<0.05) than that of N-S group (45.8%,5055/11034). The miscarriage rate of the S group (35.8%,19/53) was significantly higher(P<0.05) than that of N-S group (21.9%,1106/5055). The rate of S group's re-expansion after warming (79.5%,116/146) was significantly lower (P<0.05) than N-S group (91.9%,10142/11034). The pregnancy rate of blastocysts in the S group with re-expansion (44.0%,51/116) was the same as that of N-S group (47.8%,4848/10142). The miscarriage rates in these same groups was similar (S group 35.3%,18/51; N-S group 21.8%,1057/4848). However, the pregnancy rate of blastocysts in the S group which did not re-expand (6.7%,2/30) was significantly lower(P<0.05) than N-S group (23.2%,207/892).

CONCLUSIONS: In view of the significantly lower pregnancy rate of S group blastocysts, we conclude that there was an impact on blastocysts that had shrunken just before vitrification on subsequent clinical performance. In addition, the rate of re-expansion in S group blastocysts after warming was also significantly lower. It is possible that there was a negative impact on blastocyst shrinkage caused by the cryoprotectant. As a next step, we need to examine the time change of shrunken blastocyst in equilibration solution, so that the vitrification method may be improved leading to a higher clinical performance.

SUPPORT: None.

MORPHOKINETICS OF MORULA STAGE EMBRYO FAIL TO PREDICT BLASTOCYST FORMATION AND BLASTOCYST QUALITY. Nabil Sayme, Dr. med,[1] Thomas Krebs, Dipl.-Biol,[1] Dieter H. A. Maas, Prof. Dr. med.,[1] Marija Kljajic, Master of Biology Science[2] [1]Team Kinderwunch Hannover, Hannover, Germany; [2]Saarland University Medical Center, Homburg, Germany.

OBJECTIVE: In the last decade, the introduction of time-lapse technology enables almost continuous monitoring of embryo development. This technology generates comprehensive information regarding morphology and kinetics of embryo development and facilitates observation of dynamic, and often transient, events occurring between static observation periods. Together, these have been defined as 'morphokinetic' variables. Although for the past five years, there has been a rapid rise in the use of 'morphokinetic' variables, some disagreement concerning widely applied of this method into an embryo selection model is still present.

DESIGN: In the present study, cell cycle duration is calculated using time-lapse, according to a single cell division. The injection time of ICSI was designated as "time zero" (t0), and computer software was used to calculate the time frame between the injection and the moment of pronuclei disappearance (tPNf), as well as the time frame between injection and compaction process of morula (tM). Besides the mentioned time frames, the software also calculated the cleavage interval from the moment when PN disappear (tPNf) to the moment when morula is reached as well as the cleavage interval (t2M) from the two-cell stage to the morula and from the four-cell stage to the morula (t4M). Obtained results of those embryo cycle duration were later associated with the embryo capability to forming a blastocyst as well as with blastocyst quality.

MATERIALS AND METHODS: A total of 87 blastocysts from 20 patients undergoing an antagonist cycle for ICSI treatment between November 2019 and December 2019 were evaluated. All blastocysts were cultured in Embryoscope™ according to the manufacturer's specifications (Vitrolife, Sweden). The Gardner and Schoolcraft scoring system was used to describe blastocyst quality. Correlations between the data were calculated using logistic regression analysis. Statistical significance was defined as p<0.05. All statistical analyses were performed using SAS software.

RESULTS: Morphokinetic data showed that the time of pronuclei disappearance (tPNf) was significantly different (p<0.01) in successfully formed blastocysts (21.36 $\pm$2.23) versus arrested or non-blastulating embryos (22.80$\pm$2.27). Furthermore, this parameter as well significantly affect blastocyst quality (p<0.05). On the other hand, the time necessary for the compaction process/fully reached morula stage (tM) between embryos which successfully reached the blastocyst stage and those embryos that did not, were not statistically significant (tM: p>0.05).

Neither cleavage intervals (t2M) from the two-cell stage to morula, and from the four-cell stage to morula (t4M) did not show a significant impact on blastocyst formation. What is more, blastocyst quality neither was affected by presented morphokinetic (tM; t2M; t4M) parameters.

CONCLUSIONS: Obtained results as we believe are helpful for a better understanding of the association between embryo morphokinetic parameters and blastocyst development and potentially can be incorporated into an embryo classification model.

P-28 4:30 PM Saturday, October 17, 2020

QUALITY CONTROL VIA ASSESSMENT OF CONSISTENCY IN EMBRYOLOGY AND CLINICAL ENDPOINTS BETWEEN MULTIPLE LABS USING A SINGLE DONOR EGG BANK. Jason E. Swain, PhD, HCLD,[1] Rebecca L. Krisher, PhD,[2] William B. Schoolcraft, MD[2] [1]CCRM IVF Network, Lone Tree, CO; [2]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: Quality control is an essential component of a quality management program for an IVF laboratory. Instrumental in this process is performing routine monitoring to ensure measured outcomes are falling within acceptable standards and established ranges. It can be difficult to identify causative factors within a single lab due to variation in the infertile patient population, especially when laboratory volume is low. Having a series of related laboratories utilizing the same culture system and standardized protocols with regular peer group comparisons can offer a benefit in quickly

identifying and isolating possible issues within the IVF culture system or differences in clinical practices. This troubleshooting can be further improved via examination of a control, fertile population using oocyte donors.

DESIGN: Retrospective data analysis

MATERIALS AND METHODS: Data was collected over a 2 year period from frozen donor oocyte warms performed in 8 clinical IVF laboratories utilizing the same donor egg bank. Oocyte cryosurvival, fertilization and blastocyst conversion rates were compared. Additionally, rates of blastocyst aneuploidy and pregnancy rate were determined. Means and SEMs were calculated for each laboratory and also combined to help establish a higher acceptable threshold for future quality improvement. Differences were compared using one way ANOVA and Bonferroni pairwise comparisons

RESULTS: Comparison of laboratories demonstrated consistency between locations. One laboratory had significantly lower cryosurvival than two other labs (p=0.004). All other labs had similar oocyte survival upon warming. There were no differences in fertilization per survived oocyte or blastocyst conversion rates per fertilized zygote between labs. Rates of blastocyst aneuploidy were also similar between labs. No significant difference in number of embryos transferred per recipient between locations was apparent, and resulting pregnancy rates were comparable (p=0.25). Per thawed egg, there was a trend (p=0.099) for one laboratory to have reduced total blastocyst development compared to three others. Combining data from all laboratories yielded an overall mean and SEM for each endpoint assessment (Survival: 90.3±0.8%, Fert: 80.1±1.2%, Total GQB: 50.5±1.7%, Total Blast: 65.7±1.6%, Euploid rate: 67.7±2.3%, Ongoing CPR: 75.7±4.2%).

CONCLUSIONS: Having the ability to compare outcomes between related IVF laboratories utilizing identical products and similar protocols provides a powerful model for ongoing quality control assessment. Examining outcomes from a donor oocyte population from a single donor egg bank can further improve this quality control approach. Having more data and points of comparison from a control patient population within an IVF laboratory peer group can help quickly identify issues within the lab and provide insight as to whether they may be related to lab consumables, local embryology technique or clinical approaches. This model, along with consistent periodic review, provides the ability to implement corrective action in a timely fashion.

P-29 4:30 PM Saturday, October 17, 2020

BENEFITS OF DAY 7 BLASTOCYST CULTURE?: A COMPARISON OF CONVERSION AND EUPLOIDY RATES BETWEEN RELATED IVF LABORATORIES WITH DIFFERENT VOLUMES. Jason E. Swain, PhD, HCLD,[1] William B. Schoolcraft, MD,[2] Rebecca L. Krisher, PhD[2]
[1]CCRM IVF Network, Lone Tree, CO; [2]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: Traditional culture systems grow embryos for up to 6 days to the blastocyst stage. The assumption is that after this point, the potential for good quality and/or euploid blastocyst development is minimal. However, several studies have shown that blastocysts with the ability to support live birth can develop in vitro on Day 7. Day 7 culture may be a source of additional embryos for patients to further increase their reproductive potential following IVF and may vary based on size of the IVF program due to differences lab procedure timings. The objective of this study was to compare rates of Day 7 blastocyst development and resulting euploid rates between related IVF labs of differing sizes.

DESIGN: Retrospective analysis

MATERIALS AND METHODS: Embryos from all patients undergoing PGT-A over the same 2 year time period in 11 related IVF programs were cultured to Day 6 and blastocysts of grade 3BB or better were cryopreserved. In an effort to balance desire for additional embryos with laboratory logistic and impact on incubator capacity, any patient undergoing PGT-A with no blastocysts on day 5/6 or who had remaining morulae or early stage blastocysts by day 6, were kept in culture for one additional day to determine if additional good quality blastocysts were available on day 7. Good quality embryos were biopsied for PGT-A and frozen. Data were analyzed using pairwise comparisons and regression analysis

RESULTS: Each laboratory was able to cryopreserve day 7 blastocysts. The number of blastocysts and resulting euploid rate varied by location. No correlation was apparent between number of retrievals and percentage of day 7 blastocysts, R^2=0.003.

CONCLUSIONS: Culturing blastocysts to day 7 in select patients is a feasible approach to increase the number of additional euploid embryos available for transfer, while balancing the impact of laboratory workflow and resources. In a related network of labs using similar protocols, no correlation was apparent between day 7 blastocyst development and cycle volume, indicating that both large and small programs can benefit from this approach. However, it should be noted that larger laboratories with many procedures that go later in the day or who may not be able to be as strict on procedure timings may potentially find more blastocysts on day 7 than smaller labs.

TRANSFER STRATEGY OF OBTAINING FEWER THAN 3 EGGS IN IVF CYCLE. Tingting Li, Doctor
Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To explore the strategy of embryo transfer with ≤3 eggs in IVF cycles.

DESIGN: A retrospective study

MATERIALS AND METHODS: A retrospective study was conducted with clinic-based data in the Reproductive Medicine Centre of the Sixth Affiliated Hospital of Sun Yat-sen University from Jan 2017 to Apr 2019. A total of 1 600 cycles were divided into 3 groups: fresh D3 embryo transfer (Group 1, *n*=615), frozen D3 embryo transfer (Group 2, *n*=525), frozen blastocyst transfer (Group 3, *n*=460). We compared the general character of patients and clinical outcomes among the 3 groups.

RESULTS: There were no significantly differences found in age, AMH, and basal FSH among the 3 groups, Biochemical pregnancy, clinical pregnancy and live birth rates (38.2% *vs.* 29.3%, 34.5% *vs.* 25.9%, 18.2% *vs.* 11.2%) were significantly higher in group 1 than those in group 2. These differences were statistically significant. When patients canceled fresh embryo transfer due to various reasons, better biochemical pregnancy, clinical pregnancy and live birth rates were achieved in group 3 than group 2 (36.7% *vs.* 29.3%, 33.4% *vs.* 25.9%, 13.7% *vs.* 11.2%). These differences were also statistically significant. Through multivariate regression analysis, after controlling for potential confounding factors such as age, AMH and embryo transfer grade, the live birth rate of group 1 was still significantly higher than that of group 2 (OR=1.906(1.272-2.857), P=0.002, and the live birth rate of group 3 was still significantly higher than that of group 2 (OR = 3.388 (1.876-6.118), P = 0.000)

HOW TO OPTIMIZE CULTURE MEDIA OSMOLALITY IN IVF TREATMENTS. Renata de Lima Bossi, PhD, Brenda Campos Villa Pinto, BSc, Marcos Sampaio, MD PhD, Marco Tulio Vaintraub, MD MSc, Selmo Geber. Professor, ORIGEN, Belo Horizonte, Brazil.

OBJECTIVE: Study aim was compare osmolality in sequential and single step culture media, covered with two types of oil mineral and paraffin, in two types of incubators, dry and humid.

DESIGN: A prospective observational study was performed from March to November 2019. For each incubator, humid water jacket (Forma 4130, Thermo Scientific) and dry bench top (G185, K-Systems), both trigas, a total of 30 dishes were prepared with sequential (Cleavage Medium, Cook) and single step media (CSCM, Irvine Scientific), covered with paraffin oil (Ovoil, Vitrolife). Another 30 dishes were prepared as mentioned above, covered with mineral oil (Light Mineral Oil, Irvine Scientific). Statistical analysis was performed using ANOVA.

MATERIALS AND METHODS: Twenty 35x10 millimeters dishes (Falcon), at a time, were prepared in a laminar flow hood at room temperature, using 25 microliter droplets of CSCM and Cleavage Medium. Ten were covered with 3,0 mL mineral oil and ten with paraffin oil. Half of the dishes were incubated in a dry incubator and another half in a humid. Osmolality (mOsm/kg) was measured using osmometer (Advanced Instruments) on day 1, 3, 5 and 7, one drop per day.

RESULTS: Humid incubator is better for maintaining the osmolality of culture media, regardless of the type of oil used. CSCM has lowest levels of osmolality on day 1 when compared to Cleavage (263 X 286, p<0.0001) and maintained statistically lowest levels of osmolality on day 3, 5 and 7. In humid incubator, both culture media using paraffin or mineral oil, had similar osmolality on day 3 (269 X 270, P=0.391 for CSCM; 293 X 292, P=0.759 for Cleavage) , day 5 (270 X 271 P=0.978 for CSCM; 292 X 293 P=0.914 for Cleavage) and day 7 (271 X 271 P=0.999 for CSCM; 294 X 292 P=0.624 for Cleavage). Paraffin oil provided greater protection against evaporation, maintaining lower levels of osmolality, in a dry incubator, for CSCM media in D3 (281 x 284, P<0.001), D5 (287 x 293, P<0.001) e D7 (298 x 304, P<0.001). No significant difference was observed for Cleavage osmolality on day 3 and 5 (304 X 306, P=0.213) (314 X 314, P=1.0) comparing two types of oil, in a dry incubator. On day 7 paraffin oil is better to maintain osmolality (322 X 325, P=0.003).

CONCLUSIONS: Our study demonstrated that combination of humid incubator and paraffin oil are better for maintaining osmolality level of single step media, which can improve continuous and undisturbed embryonic culture. Comparing humid versus dry benchtop incubators, using different types of oils and culture media, is necessary for better IVF results.

P-32 4:30 PM Saturday, October 17, 2020

PREDICTION OF IMPLANTATION RATE IN SINGLE EUPLOID FROZEN-THAWED BLASTOCYST TRANSFER CYCLES BY CULTURE TIME AND/OR RE-EXPANSION RATE AFTER TROPHECTODERM BIOPSY. Vasileios Stolakis, MSc, PhD, MLS (ASCP)CM Kofinas Fertility Group, New York, NY.

OBJECTIVE: To examine whether the culture time and/or re-expansion rate after trophectoderm (TE) biopsy can predict implantation rate in single euploid frozen-thawed blastocyst transfer (seFET) cycles.

DESIGN: Retrospective cohort study in a private assisted reproductive technology (ART) program.

MATERIALS AND METHODS: In this retrospective cohort study 397 blastocysts (Day-5 and -6) from 344 patients (35.8 ± 4.2 years of age) were characterized as euploid after preimplantation genetic screening by array comparative genomic hybridization or next generation sequencing. The TE biopsies and the (seFET) cycles were performed at the Kofinas Fertility Group ART clinic from January 2016 to January 2020. All aneuploidy screenings were authorized by patients after consultation. The euploid blastocysts of all participants were divided in two groups: (i) those that were cultured for 1-4 h after TE biopsy (Cultured Group; CG, n=184) and (ii) those that were cryopreserved immediately after TE biopsy (Non-Cultured Group; NCG, n=213). In addition, the CG was further divided in two subgroups based on the re-expansion rate after TE biopsy in relation to the initial blastocoel expansion rate; these subgroups were either: (i) partially re-expanded (pRE) blastocysts (blastocoel formation, but not full re-expansion) or (ii) fully re-expanded, hatching or completely hatched blastocysts (fRE). Implantation rate was assessed in the examined groups and subgroups.

RESULTS: No significant difference was detected in the overall implantation rate between the two examined groups, CG and NCG (70% *vs* 69%, respectively) and between the two subgroups of the CG group, pRE and fRE (70% *vs* 71%, respectively). In contrast, Day-5 euploid blastocysts that belong to the pRE subgroup demonstrated a significantly higher implantation rate compared to Day-6 euploid blastocysts belonging to the same subgroup (78% *vs* 52%, respectively, $p<0.01$). Most importantly, euploid blastocysts cultured for ≤2h after biopsy belonging to the fRE subgroup were characterized by a significantly higher implantation rate when compared with euploid blastocysts cultured for more than 2h after biopsy belonging to the pRE subgroup (83% *vs* 54% respectively, $p<0.05$).

CONCLUSIONS: Implantation rate in seFET cycles can be improved by selecting blastocysts that are able to achieve full re-expansion when cultured for ≤2h after TE biopsy, instead of blastocysts that are cultured for >2h after TE biopsy and they have only partially re-expanded. Further studies are required in order to shed more light on the optimal culture time and/or re-expansion rate after TE biopsy.

P-33 4:30 PM Saturday, October 17, 2020

EMBRYONIC CHROMOSOMAL CHANGES AND EMBRYONIC MORPHOLOGY: WHAT IS THEIR RELATIONSHIP TO THE CHOICE OF THE BEST EMBRYO. Mariana Moraes Piccolomini, MS,[1] Edson G. Lo Turco, PhD,[2] Lucas Yamakami, MD,[3] Helio Sato, PhD,[3] Fernando Prado Ferreira, MD, PhD,[3] Renato Tomioka, MD,[3] Orcar Duarte, MD[4] [1]Senior Embryologist, São Paulo, Brazil; [2]IonMedicine - Precision Medicine, Sao Paulo, Brazil; [3]Clinical Chief, São Paulo, Brazil; [4]Clinical Chief in Lab For Life Laboratory, São Paulo, Brazil.

OBJECTIVE: The embryonic morphology is an important factor while evaluating embryonic potential. With the advances in the field of genetic analysis techniques, it is known that the decision to transfer an euploid embryo is related to higher pregnancy rates. However, genetic evaluation is an invasive exam, which does not occur with the morphology evaluation, which can be considered an advantage. Nonetheless, it is not yet known whether it is possible to associate embryonic quality with euploidy, and the literature are very controversial. Because of this, we aimed to evaluate the effects of embryo quality on the aneuploidy.

DESIGN: Prospective study.

MATERIALS AND METHODS: Data from 1037 blastocysts were collected that were cultivated in continuous culture medium in incubators at 37oC, CO_2 8%, and O_2 5%. The blastocyst morphology was classified by SART criteria and the best quality embryos (3-6; A and B) were denominated top-quality embryos. The blastocysts were biopsied, and the cells were sending to PGT-A, subsequently being cryopreserved. According to the results, the embryos were separated into three groups: >75% aneuploidy (G1), between 74,9%-24,9% aneuploidy (G2), and <25% aneuploidy (G3). 320 couples undergoing *in vitro* fertilization in 2019 agreed to participate in the study. The female partners underwent controlled ovarian stimulation and had their oocytes recovered and subsequently inseminated. The fertilized embryos were cultivated in the group with the CSCM (Irvine) culture medium. In the stage of the blastocyst, they were biopsied and the preimplantation genetic diagnosis was performed by next-generation sequencing. Besides that, the embryos were evaluated for their quality through the morphological assessment.

RESULTS: Considering the morphologic variables, the G3 group (<25% aneuploidy) presented a significant ($p<0.01$) higher rate of top-quality embryos (55.1%±39.1%) when compared with the G1 group (35.9%± 41.9%). No significant difference was found when compared to the G3 group with the G2 group (46.4%±40.0%), and the G2 group with the G1 group, concerning the rate of top-quality embryos. These results show that embryos with better morphology assessment end up being euploid, which would allow the association of morphology evaluation with the embryo genetics status. However, this study has the same weakness that other blastocysts morphological studies, the evaluation always can be influenced by the observer, in addition to the possible loss of events due to time of analysis.

CONCLUSIONS: Because of this, further studies are necessary to establish whether it is safe to predict ploidy through embryo morphological analysis, also with the support of new technologies such as time-lapse. However, this study shows the relation between blastocyst aneuploidy and embryo quality on day 5/6. Our results are close to the routine of the vast majority of laboratories in the world, which do not have the resources of time-lapse technology, and It is possible to think of a joint strategy that allows the association of the morphological analysis to choose the better embryos to do the biopsy.

MITOCHONDRIAL SUPPORT OF EMBRYOS FROM WOMEN OF ADVANCED MATERNAL AGE DURING ART. Rebecca Kile, MS, Deirdre M. Logsdon, MS, Catherine Nathanson, BS, Sue McCormick, BS, William B. Schoolcraft, MD, Rebecca L. Krisher, PhD Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: The supplementation of MitoTempo and mitoquinol (MTQ) in mouse embryo culture results in better quality blastocysts by supporting mitochondrial function. Women of advanced maternal age have reduced oocyte quality due in part to dysfunctional mitochondria. The aim of this study was to determine the effect of supplementation of mitochondrially targeted antioxidants (MTQ) during human embryo culture for women of advanced maternal age (≥35 yr).

DESIGN: Prospective clinical trial with sibling embryos.

MATERIALS AND METHODS:: After oocyte retrieval, cumulus oocyte complexes (COC) were denuded of cumulus cells. Mature oocytes (MII) were fertilized by ICSI and randomly allocated into sequential culture medium, 2/3 to control and 1/3 to medium with MTQ. Zygotes were moved into second step medium on day 3 and cultured for 5-7 days, at which time good quality blastocysts were biopsied for PGT-A and vitrified. MTQ was present throughout the culture period.

RESULTS: A total of 11 patients with advanced maternal age (AMA) (average age 39.4 yr, range 35-46) were included in this study. Post ICSI, 143 presumptive zygotes were placed in control medium and 66 in medium supplemented with MTQ. Normal fertilization, determined by presence of 2 pronuclei (2PN), was 83% in control and 91% in MTQ ($p=0.11$). There were no differences between control and MTQ treatment in D5 (control, 18%; MTQ, 20%) or total (control, 48%; MTQ, 45%) good quality blastocyst (≥grade 3BB) development (per 2PN), or total blastocyst development (control, 63%; MTQ, 62%). There was also no difference in the percentage of euploid blastocysts (control, 33%; MTQ, 30). To date, four euploid blastocysts from the control treatment and one from the MTQ treatment have been transferred individually to a total of 5 patients, all resulting in ongoing pregnancies with fetal heart beat.

CONCLUSIONS: In this preliminary study, we did not note any improvement in good quality or euploid blastocyst development due to inclusion of MTQ in the culture media. Both treatments resulted in an equal percentage of transferrable euploid embryos per oocyte injected with sperm. One embryo has been transferred after MTQ treatment, resulting in a healthy ongoing pregnancy. These data suggest that MTQ treatment of human embryos in culture is safe, although at this point it does not appear to be effective in increasing blastocyst development for women of AMA. However, further research is required to determine if there are any positive effects of MTQ treatment on implantation and/or pregnancy loss that are not yet evident from this initial trial.

P-35 4:30 PM Saturday, October 17, 2020

IN-VITRO FERTILIZATION TECHNIQUES COULD INCREASE MONOZYGOTIC TWINS RATE IN SINGLE EMBRYO TRANSFERS. Sofia Ana Dominici, Gynecologist, Estefania Navall, Gynecologist, Valentina Torres Monserrat, Embryologist, Maria Cecilia Delpiccolo, Embryologist, Nicolas Carizza, Gynecologist, Trinidad Leiva, Gynecologist, Maria Noelia Lardizabal, Embryologist, Ariadna Sol Ruiz, Gynecologist, Carlos Carizza, Medical Director Fertya, Rosario, Argentina.

OBJECTIVE: The objective of this study is to determine monozygotic twins rate in single embryo transfer of IVF cycles and analyze the associated factors of this event.

DESIGN: A retrospective analysis of blastocyst single embryo transfer in fresh and freeze-thaw cycles of all patients enrolled in IVF treatments in Fertya, since October 2015 until March 2019. Patients were divided in two groups: Group 1 (G1), 442 fresh blastocysts single embryo transfer, and Group 2 (G2), 597 freeze-thaw blastocysts single embryo transfer. The main outcomes studied were clinical pregnancy, multiple pregnancy and live birth rates for each group. The second outcome analyzed was the incidence on monozygotic twins pregnancy with the use of high complexity laboratory techniques and patients age.

MATERIALS AND METHODS: Embryos obtained in fresh IVF cycles were grown until day five or six in K-System® G-185 or Thermo Fisher Scientific® Heracell 150i incubators with Sage® or Global Total® mediums and then vitrified and warmed with Kitazato® Kits. Blastocysts were vitrified only when full expansion with a blastocele >50% of the embryo was observed. Blastocyst's morphology was assessed using Istanbul Consensus scoring. Chi square independence test and Fisher's exact test were used to compare the results of the two groups, statistical difference represented by a $p<.05$.

RESULTS: We observed that in fresh blastocyst single embryo transfers our clinical results are clinical pregnancy rate 38,23 % (169/442), multiple pregnancy rate 3,55 % (6/169) and live birth rate 34,61 % (153/442). Analyzing single blastocyst freeze-thaw transfers there were no statistical differences compare to G1, clinical pregnancy rate 37,02 % (221/597), multiple pregnancy rate 3,62 % (8/221) and live birth rate 31,65 % (189/597). *Analyzing only monozygotic twin pregnancies, abortion rate was 42,86 % and live birth rate 50 % (6 produced two births and 2 a single birth).*

Monozygotic twin pregnancy occurred only in under 35 years old patients. When analyzing the techniques used in the laboratory, in 57,0 % of the multiple pregnancies assisted hatching with laser was performed previous to embryo transfer and, when comparing the employed culture media, 50 % was cultured in GLOBAL TOTAL ® and 50% in SAGE ®. When carrying out hypothesis contrast over the twin rate in comparison to the values of spontaneous monozygotic twins pregnancies of the general population of 0,4 %, a value of p<0,0001 was obtained.

CONCLUSIONS: Our blastocyst single embryo transfer in IVF cycles shows an increase in monozygotic twins rate in comparison to the general population. All our cases occurred in women ≤35 years old. When considering laboratory high complexity techniques employed, neither vitrification, culture media nor the assisted hatching technique seem to affect the rate of twins. However, the main limitation of this work is the low number of cases analyzed.

COMPARISON OF EMBRYO MORPHOKINETICS FOLLOWING ASSISTED SPERM FUSION INSEMINATION AND RESCUE INTRACYTOPLASMIC SPERM INJECTION. Shota Hatakeyama, Master,[1] Yasuyuki Araki, Ph.D.,[2] Yasuhisa Araki, Ph.D.,[2] Shirei Ohgi, M.D.,[1] Atsushi Yanaihara, M.D.[1] [1]Yanaihara Women's Clinic, Kamakura, Japan; [2]Gunma Paz University, Takasaki, Japan.

OBJECTIVE: In a previous study, assisted sperm fusion insemination (ASFI), which is a fertilization method using a single motile sperm without breaking the oocyte membrane, yielded fertilization rates and blastocyst formation rates similar to those obtained by rescue intracytoplasmic sperm injection (ICSI) (1). In this study, we assessed embryo development following ASFI and rescue ICSI via a time-lapse system.

DESIGN: A retrospective observational study using a time-lapse system was used to monitor 33 blastocysts from 25 patients undergoing ASFI (N=13 blastocysts) or rescue ICSI (N=20 blastocysts) between April 2019 and March 2020.

MATERIALS AND METHODS: Three hours after conventional in vitro fertilization, all inseminated oocytes were denuded of cumulus cells and the presence of the second polar body was confirmed. Oocytes with a single polar body were incubated for another 3 hours. Oocytes exhibiting only one polar body were defined as unfertilized oocytes and used for ASFI or rescue ICSI. Rescue ICSI was performed following conventional ICSI procedures. For ASFI, a motile sperm bound to the zona pellucida was collected using an injection needle and this sperm was pressed onto the membrane of an unfertilized oocyte for 30 seconds. Following fertilization, the oocytes were cultured and imaged using a time-lapse system.

RESULTS: The mean and standard deviation of ages of the women in the ASFI and rescue ICSI groups were 37.3±4.0 and 35.3±4.4 years, respectively, which was not significantly different (p>0.05). The ASFI and rescue ICSI groups showed no statistical difference in the time of pronuclei appearance (4.8±1.1 vs. 5.2±1.2 hours), pronuclear fading (20.9±2.3 vs. 21.1±2.3 hours), formation of eight-cell stage (54.4±7.4 vs. 56.7±8.1 hours), initiation of blastulation (92.1±8.1 vs. 95.4±7.1 hours), and full blastulation (100.6±7.9 vs. 104.1±7.9 hours).

CONCLUSIONS: This observational study showed that there were no differences in the morphokinetic parameters of embryo development between ASFI and rescue ICSI. For more general applications, further studies using a larger number of patients are necessary.

THE OOCYTE MATURATION FAILURE AND EMBRYO ARREST: A RETROSPECTIVE STUDY IN THE THIRTEEN-YEAR PERIOD. Lada Diachenko, MSc, Pavlo Mazur, MSc, Dmytro O. Mykytenko, MD, DSc, Valery Zukin, MD, PhD Clinic of Reproductive Medicine "Nadiya", Kyiv, Ukraine.

OBJECTIVE: Oocyte maturation and embryo arrest are well-known cases in clinical practice but this issue is still not sufficiently analyzed. According to investigations on animal models more than 35 genes have been found to be associated with abnormal early embryonic development. It has already been confirmed that five human genes, such as TUBB8, TLE6, PATL2, PADI6 and KHDC3L, have the similar functions. According to the Istanbul consensus, arrested embryos are those that have not cleaved during a 24-h period. There is a group of patients for whom the embryo arrest is a stable problem and recurs in subsequent IVF cycles. Patients with inability to obtain mature, morphologically normal egg that can be fertilized are rarer.The aim of the study was to evaluate the frequency of embryo arrest and oocyte maturation arrest within patients under 37 years of age.

DESIGN: Retrospective study.

MATERIALS AND METHODS: Cycles of 6015 patients in the thirteen-year period (2006-2018) were analyzed in this retrospective study. Only patients under 37 years of age, who underwent routine stimulation protocols, were included in the investigation. The embryo and oocyte maturation arrest group included patients who did not receive any blastocysts during all their stimulations.

RESULTS: The analysis showed that the group with embryo and oocyte maturation arrest reached to 3.34 % (n =201). Additionally two groups of poor (n=851) and good responders (n=5164) were assessed. It was shown that the percentage of patients with embryo and oocyte maturation arrest in the group of good responders was 1.8% (n=92) compared with the poor responders group – 12.8% (n=109). This study included a group of patients from only one IVF clinic. For clearer understanding of this issue there is a need of similar analysis among different groups within different populations. According to our assumptions, the results may be the same.

CONCLUSIONS: It is important to analyze other populations for more accurate evaluation of embryo and oocyte maturation arrest frequency. Moreover, it is crucial to assess the genetic background of such conditions. The identification of new genes that play a key role in early embryonic development will allow to create a new genetic screening panel.

POSTER SESSION: ART LAB: OUTCOME PREDICTORS

P-38 4:30 PM Saturday, October 17, 2020

BIRTH OF HEALTHY BABIES FROM BLASTOCYSTS DERIVED FROM MONO-PRONUCLEAR ZYGOTES FOLLOWING INTRACYTOPLASMIC SPERM INJECTION. Haruhisa Tsuji, M.S., Hiroya Kitasaka, Ph.D., Noritaka Fukunaga, Ph.D., Yoshimasa Asada, M.D., Ph.D. Asada Ladies Clinic, Nagoya, Japan.

OBJECTIVE: We have previously reported that 80.7% of 1PN zygotes derived from IVF or ICSI had a biparental chromosome, and some of these developed to the blastocyst stage (Tokoro et al. ASRM 2013). However, it has also been demonstrated that all embryos derived from 1PN-ICSI zygotes are chromosomally abnormal and these zygotes should be discarded, though 1PN zygotes derived from IVF(1PN-IVF) could be used for reproductive purposes (Mateo et al. Fertil Steril. 2013; 99: 897-902). In addition, it has been reported that zygotes derived from 1PN-ICSI produced blastocysts but did not lead to pregnancies (Igashira et al. ASRM 2016). In this study, we examined mono-pronuclear zygotes derived after ICSI (1PN-ICSI) can develop normally and result in a healthy live birth.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: This was a retrospective study including 2482 ART patients treated in 2814 cycles and where 3618 zygotes formed 1PN after ICSI. The time period was 72 months (January 2013 to December 2018). Patients seeking infertility treatment in a well-established private IVF clinic. Blastocyst rates, clinical pregnancy and miscarriage rates after a single blastocyst embryo transfer following the culture of 1PN-ICSI zygotes were compared with data on 1PN-IVF or normal 2PN zygotes during the same time period. Furthermore, follow up information was obtained on the health status of live births derived from 1PN-ICSI zygotes. Statistical significance was determined using the chi-square test (level of P<0.05).

RESULTS: The formation rate of 1PN-ICSI was 2.8%(3618/127728), significantly lower (P<0.05) than 1PN-IVF (4.6%; 1044/22799). The blastocyst rate of 1PN-ICSI zygotes (14.8%; 525/3547) was significantly lower (P<0.05) compared to 1PN-IVF zygotes (26.5%; 274/1035) or normal 2PN (62.0%, 22420/36189) . The clinical pregnancy rate of 1PN-ICSI transferred zygotes (24.4%; 53/217) was significantly lower (P<0.05) compared to 1PN-IVF transferred zygotes(36.6%; 41/112) or normal transferred zygotes from 2PN (40.2%; 4802/11947). However, the miscarriage rates were not significantly different (respectively, 30.2%, 34.1% and 23.3%) 21 healthy newborns were obtained from the successful pregnancies after embryo transfer of 1PN-ICSI blastocysts.

CONCLUSIONS: These results suggest that not all 1PN-ICSI zygotes are abnormal, and these can result in a viable pregnancy and healthy live birth. Continued culture to blastocyst of 1PN-ICSI zygotes should be carried out in order to further assess their potential for transfer.

ALL TWIN PREGNANCIES ARE NOT THE SAME: EFFECT OF MATERNAL PARITY ON OUTCOMES OF TWIN PREGNANCIES CONCEIVED SPONTANEOUSLY VERSUS WITH ASSISTED REPRODUCTIVE TECHNOLOGY. Rachel S. Mandelbaum, MD, Meghan Brooke Smith, MD, Brittany L. Klooster, MD, Rachel Blair Danis, MD, Lynda K. McGinnis, PhD, Jacqueline Ho, MD MS, Kristen Bendikson, MD, Richard J. Paulson, MD, MS University of Southern California, Los Angeles, CA.

OBJECTIVE: Multiple gestations are a leading cause of preterm birth and neonatal morbidity, and reducing rates of multiple gestation with assisted reproductive technology (ART) has been a key focus over the past decade. Previous literature has suggested that parity may affect outcomes in multiple gestations, however this has not been studied with regards to the ART population.[1] Therefore, this study sought to evaluate the effect of maternal parity on neonatal outcomes of twin pregnancies conceived spontaneously versus with ART.

DESIGN: A retrospective populational study using Centers for Disease Control and Prevention (CDC) National Center for Health Statistics (NCHS) Natality database, which is derived from the birth certificates of United States residents.

MATERIALS AND METHODS: Data for all twin gestations between 2016 and 2018 was extracted. Pregnancies affected by hypertensive disorders, pre-eclampsia, gestational or pre-gestational diabetes, or a history of preterm birth were excluded. Cases were stratified by the use of ART, and pregnancies in which the use of ART was unknown or not recorded were also excluded. Primary outcomes included gestational age at delivery, birth weight, and NICU admission. Student's t-test was used for continuous variables and chi squared test for dichotomous variables.

RESULTS: A total of 268,710 twin gestations met criteria for inclusion in the study, 22,677 (8.4%) of which were conceived via ART. 64,547 (24.0%) women overall were primiparous; there were 9,146 (38.7%) primiparous women with ART twin pregnancies compared to 55,762 (22.7%) primiparous women with spontaneously conceived twin pregnancies. Average gestational age and birthweight at delivery was 34.8 $\pm$ 3.8 weeks and 2,265.0 $\pm$ 657.3 grams, respectively, for primiparous women compared to 35.4 $\pm$ 3.1 weeks and 2,407.1 $\pm$ 604.5 grams, respectively, for multiparous women ($P<0.001$, both). Rates of NICU admission were significantly higher among twin neonates born to primiparous women compared to multiparous women (40.1% vs. 33.8%, $P<0.001$). Among ART pregnancies in particular, gestational age at delivery, birthweight, and NICU admission rates were similar to that of the overall cohort. Gestational age at delivery and birthweight remained significantly higher and NICU admission rates significantly lower in multiparous women with ART twin pregnancies compared to primiparous women ($P<0.001$, all). Average age of women with ART pregnancies was significantly higher than those with spontaneously conceived pregnancies ($P<0.001$).

CONCLUSIONS: Outcomes of twin gestations are improved in multiparous women compared to primiparous women in both ART and spontaneously conceived pregnancies, including higher birth weight and gestational age at delivery with lower rates of NICU admission. Counseling women about the risk of multiple gestation and associated neonatal morbidity with ART must include consideration of prior parity.

EFFECT OF CO-INCUBATION OF SPERMATOZOA WITH HUMAN ENDOMETRIAL CELLS ON ASSISTED REPRODUCTION OUTCOMES. Rumiana Ganeva, MSc, Dimitar Parvanov, PhD, Ivaylo Rangelov, MSc, Silviya Gogeva, MSc, Georgi Stamenov, MD/PhD Nadezhda Women's Health Hospital, Sofia, Bulgaria.

OBJECTIVE: To evaluate the effect of the co-incubation of spermatozoa with human endometrial cells prior ICSI on the assisted reproduction outcomes (fertilisation rate, proportion of high quality embryos, implantation rate and live birth rate) in couples with unexplained infertility.

DESIGN: Prospective.

MATERIALS AND METHODS: 110 couples fulfilled the inclusion criteria of unexplained infertility and males with normozoospermia or teratozoospermia. All patients have signed written informed consent. Couples were randomly allocated to study group (n=55) and control group (n=55).

After liquefaction all fresh semen samples were washed and were subjected to swim up. Semen samples from the study group were co-incubated for 2 hours with endometrial cell culture, obtained from their partners' endometrial biopsy. All patients underwent standard ICSI protocol. Embryo transfer was performed in 42 couples of the control group and on 40 couples in the co-incubation group.

Main outcomes were fertilisation rate, proportion of high quality embryos, implantation rate and live birth rate. Statistical analyses were performed using SPSS v21. $P>0.005$ was considered significant.

RESULTS: The study group and the control group were comparable in terms of female age, male age, count of unsuccessful IVF cycles, oocyte count and oocyte quality. There were no significant differences in the fertilisation rate (78$\pm$9% vs. 80$\pm$8%, $p>0.05$) and the proportion of high quality embryos (62$\pm$12% vs. 65$\pm$9%, $p>0.05$) between the co-incubation group and the control group. However, the implantation rate after sperm co-incubation with human endometrial cells was significantly higher when compared to the control group (46% vs. 33%, $p<0.05$). The live birth rate of the successfully implanted embryos was also significantly higher in the co-incubation group in comparison to the control group (95% vs. 40%, $p=0.003$).

CONCLUSIONS: Co-incubation of spermatozoa with endometrial cell culture has no effect on fertilisation rate and proportion of high quality embryos, but leads to higher implantation rate and live birth rate in comparison to conventionally prepared semen for ICSI. These results indicate that couples with unexplained infertility can benefit from sperm co-incubation with endometrial cells before performing ICSI.

P-41 4:30 PM Saturday, October 17, 2020

OVERVIEW OF 2018 U.S. ASSISTED REPRODUCTIVE TECHNOLOGY (ART) TREATMENT OUTCOMES AND CONTRIBUTION OF ART TO MULTIPLE BIRTHS AND PRETERM BIRTHS IN THE UNITED STATES. Saswati Sunderam, M.A PhD,[1] Dmitry M. Kissin, MD, MPH,[1] Yujia Zhang, PhD,[1] Amy Jewett, MPH,[1] Sheree L. Boulet, DrPH,[2] Lee Warner, PhD,[3] Charlan D. Kroelinger, PHD,[3] Wanda D. Barfield, MD[3] [1]Centers for Disease Control and Prevention, Chamblee, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Centers for Disease Control and Prevention, Atlanta, GA.

OBJECTIVE: To assess national and state-specific ART utilization and outcomes and the contribution of ART to multiple births and prematurity.

DESIGN: Population-based cross-sectional analysis

MATERIALS AND METHODS: Data for ART procedures and birth outcomes in 2018 were obtained from CDC's National ART Surveillance System (reporting years 2017 and 2018). Data for all infants born in the U.S. were obtained from 2018 CDC's National Vital Statistics System. The number of ART procedures performed per million women 15-44 years of age (ART utilization); rates of single embryo transfers (SET) among women <35 years, 35-37 years, >37 years; rates of preterm (<37 weeks gestation) and multiple births among ART-conceived infants and all infants; and proportions of U.S. multiple births and preterm births that are ART-conceived were calculated for 50 States, District of Columbia, and Puerto Rico, classified by mother's state of residence. The proportion of infants who were small for gestational age (SGA) (born at <10th percentile of birthweight for gestational age) was calculated for singleton births (22–44 weeks gestation) for ART and all infants.

RESULTS: Among 3,813,136 infants born in the U.S. in 2018, 2.0% (74,926) were conceived with ART (range: 0.4% in Puerto Rico to 5.1% in Massachusetts). ART utilization ranged from 484 (Puerto Rico) to 7,438 (Massachusetts) procedures per million women aged 15-44 years. The national SET rate among women <35 years was 74.1% (range: 28.2% in Puerto Rico to 89.5% in Delaware). The national SET rates among women 35-37 years and >37 years were 72.8% (range: 30.6% in Puerto Rico to 93.7% in Delaware) and 66.4% (range: 27.1% in Puerto Rico to 85.3% in Delaware), respectively. The rates of infants that are

multiple births and preterm births were 21.4% and 26.1% among ART infants versus 3.3% and 10.0% among all infants, respectively. Nationally, the proportion of U.S. multiples and preterm infants that are ART-conceived was 12.5% and 5.1%, respectively. The percentage of ART-conceived singletons that were SGA was 7.3%; the corresponding percentage among all singletons was 9.4%.

CONCLUSIONS: In the U.S., a higher proportion of ART-conceived infants are multiples or were born preterm compared to all infants. Wide variations were observed among states and territories in the rates of ART utilization and SET. Greater utilization of SET, where appropriate, could reduce the contribution of ART to multiple births and preterm births. Rates of SGA for singletons were lower among ART-conceived infants compared with all infants, possibly indicating better health behaviors and care among ART patients.

SUPPORT: None.

P-42 4:30 PM Saturday, October 17, 2020

IMPACT OF ENDOMETRIAL PATTERN ON LIVE BIRTH RATE AND SUBSEQUENT DEVELOPMENT OF HYPERTENSIVE DISORDERS OF PREGNANCY.

Valerie A. Flores, MD,[1] Dawn A. Kelk, PhD, HCLD,[2] Sarah Bjorkman, MD,[3] Pinar H. Kodaman, MD/PhD[3]
[1]Yale School of Medicine, Oange, CT; [2]Yale University, Orange, CT; [3]Yale School of Medicine, New Haven, CT.

OBJECTIVE: Recent studies suggest that FET cycles are associated with a higher incidence of hypertensive disorders of pregnancy (HTN). In FET cycles, endometrial thickness and pattern have been used as indicators of endometrial receptivity, although the ability of these measures to predict clinical pregnancy rate (CPR), live birth rate (LBR), and pregnancy complications remains unclear. The current study examines the influence of endometrial pattern (EP) and thickness on CPR, LBR, and HTN.

DESIGN: Prospective cohort study

MATERIALS AND METHODS: A total of 257 consecutive FET cycles in women aged 24-40 years were assessed at a single academic center. Cycles using donor egg-derived embryos, PGT embryos and natural thaw were excluded. EP was classified as one of three types: EP-A (Trilaminar), EP-B (Intermediate), or EP-C (Homogenous). EP and thickness were assessed prior to progesterone start. A multivariate regression model was used to assess the relationship between endometrial pattern. We adjusted for age at embryo cryopreservation, BMI, estradiol (E2) level, days on oral estradiol, and number of embryos transferred and thickness with CPR, LBR, HTN, birth weight, and gestational age at delivery.

RESULTS: There were no significant differences in patient age between the different pattern groups. EP-A was positively associated with CPR and LBR, while EP-C negatively correlated with these outcomes ($p<0.05$). Endometrial thickness was associated with CPR ($p<0.05$). The multivariate regression model showed: Odds of CPR were 2 times greater (95% CI [1.6, 6.1]) with EP-A than C. The odds of LB were 3 times greater (95% CI [1.3, 5.0]) with pattern A than with C. EP was a predictor of ongoing pregnancy with nearly half of pregnancies with +hCG in the pattern C not resulting in a live-birth (LB). Women with endometrial pattern C who did have a LB were significantly more likely to develop HTN ($p<0.05$) compared to women with EP-A (OR 4.8 (95% CI [1.4, 16.2])). No other factors in our model were associated with HTN. EP was not related to birth weight, gestational age at delivery, or multiple gestation.

Pattern Type	# patients	Avg. Age	+hCG (%)	CP (%)	LB (%)	HTN*
A	118	33.7	78.8	64.4	52.5	20.7
B	78	34.8	73.1	55.1	47.4	30.3
C	61	34.4	60.7	41.0	31.1	50

*HTN data available for 109 subjects: (EP-A n=58; EP-B n=33; EP-C n=18)

CONCLUSIONS: EP may serve as a biomarker of endometrial receptivity. Trilaminar EP (Type A) independently predicts CPR and LBR in FET cycles, with a 3-fold increase odds of LB. Abnormal EP (i.e. Type C) increases the risk of HTN, which may be linked to poor implantation. Further studies are needed to understand the mechanism by which endometrial pattern contributes to a healthy pregnancy.

P-43 4:30 PM Saturday, October 17, 2020

IMPACT OF OVARIAN STIMULATION AND IN VITRO FERTILIZATION ON LIPID PROFILE OF MICE BLASTOCYSTS.

Thalita S. Berteli, MSc,[1] Eduardo D. Borges, MSc,[1] Caroline M. Luz, MSc,[1] Christina R. Ferreira, PhD,[2] Alessandra A. Vireque, PhD,[3] Paula A. Navarro, MD, PhD[1] [1]Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo - Departamento de Ginecologia e Obstetrícia, Ribeirão Preto-SP, Brazil; [2]Purdue University - Metabolite Profiling Facility, Bindley Bioscience Center, IN; [3]Invitra – Assisted Reproductive Technologies LTD, Supera Innovation and Technology Park, Ribeirão Preto-SP, Brazil.

OBJECTIVE: To evaluate the impact of ovarian stimulation (OS) and OS plus in vitro fertilization (IVF) procedure on lipid profile of mice blastocysts by comparing the lipid profile of blastocysts originated from natural mating with or without previous superovulation and blastocysts from oocytes of superovulated females subject to IVF.

DESIGN: Experimental study.

MATERIALS AND METHODS: Blastocysts were recovered from C57BL/6J females (8 weeks) that were mated with males after confirmation of the estrous cycle (natural in vivo control group - N) or after superovulation with 5 UI equine chorionic gonadotropin followed by 5UI human chorionic gonadotropin (superovulation in vivo control group – S). For the IVF group (IVF), oocytes collected from superovulated females were inseminated with $1x10^6$ sptz/ml and cultivated for 96 hours in continuous culture media *(KSOM, Cosmo bio co., LTD)* incubated at 37°C with 5% CO_2. Blastocysts of each group were individually fixed in methanol/water. Lipids of 9 blastocysts per group were extracted using *One Step Methanol* protocol. Individual samples containing the lipid extracts of blastocysts were then diluted and flow injected into the triple quadrupole spectrometer equipped with an electrospray ion source. Lipids were analyzed using the multiple reaction monitoring profiling (*MRM*-profiling) method and values of relative intensities of ions detected in each group were compared using univariate (one-way ANOVA, volcano plot) and multivariate analysis (PCA, PLS-DA, hierarchical cluster analysis).

RESULTS: One-way ANOVA (p-value ≤ 0.05) showed that 95 out of the 125 lipids were differently expressed among the three groups. The top five important features identified by partial least square discriminant analysis (PLS-DA) variables of importance (VIP) scores (>1.32) were free fatty acid C28:0, sphingomyelin (SM d18:1/14:0), phosphatidylserine PS(20:4), phosphatidylcholine PCo(36:5), and phosphatidylethanolamine PE(14:1), all of which were more abundant in the IVF group, followed by S and N, respectively. This pattern was observed in all top 50 features selected by PLS-DA VIP (>1). PCA and heatmaps generated by hierarchical cluster analysis suggested that IVF was further separated from the other groups. This was confirmed by two by two-group analysis using volcano plot (p-value ≤ 0.05, fold change ≥ 1.5) that detected 15, 57, and 99 significant features between N vs. S, IVF vs. S, and IVF vs. N, respectively.

CONCLUSIONS: While ovarian stimulation alone promotes some alterations in lipid profile of in vivo originated blastocysts when compared with in vivo blastocysts from natural cycles, mainly on phosphatidylcholines, IVF process using oocytes from superovulated mice was responsible for more extensive changes observed on the lipid profile of the studied blastocysts, related to overall increased abundances in the relative concentration of specific membrane phospholipids and fatty acids.

METABOLIC IMAGING OF CUMULUS CELLS AND EMBRYO OUTCOME.

Marta Venturas, M.Sc.,[1] Kishlay Kumar, PhD,[2] Xingbo Yang, PhD,[1] Dagan Wells, Ph.D.,[3] Catherine Racowsky, PhD,[4] Dan Needleman, Ph.D.[1]
[1]Harvard University, Cambridge, MA; [2]University of Oxford, Oxford, United Kingdom; [3]Juno Genetics, Oxford, United Kingdom; [4]Brigham and Women's Hospital, Boston, MA.

OBJECTIVE: Bidirectional metabolic cooperativity between the human oocyte and its surrounding cumulus cells is essential for successful

development. However, the relationship between cumulus cell metabolism and oocyte viability is not well established. Our aim was to determine whether non-invasive metabolic imaging of cumulus cells mitochondrial function is associated with the clinical outcome of the corresponding oocyte.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: Cumulus cell clusters (n=458 from 177 patients, mean age 36.7y) were dissected from cumulus oocyte complexes prior to assisted reproduction technique treatment. Morphology of embryos was assessed on day 3. Grades were stratified as excellent (n=89), good (n=79), fair (n=43) and poor morphology (n=62). Clinical outcomes of the corresponding oocytes were tracked. Embryos were transferred on day 3 or 5, either fresh (n=48 and 10) or after warming (n=7 and 20). Cumulus cell metabolism was assessed non-invasively using fluorescence lifetime imaging microscopy (FLIM) to measure the autofluorescence of NADH and FAD+, two key metabolites in cellular respiration and glycolysis. This approach enabled quantitative information to be obtained on concentrations of these coenzymes and on metabolite enzyme engagement. Overall a single FLIM measurement provides a total of 8 metabolic parameters (4 for NADH and 4 for FAD+). An additional parameter, the Redox Ratio can also be acquired (NADH intensity / FAD+ intensity). We used multilevel models to investigate the association of cumulus cell metabolic parameters with day 3 embryo morphology and clinical outcome.

RESULTS: Of the cumulus samples analyzed, 62 corresponded to embryos that did not implant, and 23 led to a clinical pregnancy. We found significant associations between cumulus cell FAD+ fraction bound to enzyme (p =0.02) and FAD+ short lifetime (p <0.001) and the clinical outcome of the corresponding embryo. There were no significant associations between cumulus metabolic parameters and embryo quality assessed at day 3.

CONCLUSIONS: Cumulus cell metabolic parameters are significantly associated with embryo outcome, although not with day 3 embryo quality. These findings suggest that metabolism and morphology provide complementary information. We are working to develop an embryo selection algorithm using machine learning based approaches that combines cumulus cell metabolic data, patient clinical characteristics (age, BMI, AMH levels), and morphological assessment of embryo quality.

SUPERIOR SPERM SELECTION? MICROFLUIDIC SPERM SORTING IMPROVES EUPLOID EMBRYO ONGOING PREGNANCY RATE COMPARED TO DENSITY GRADIENT CENTRIFUGATION.

Katherine L. Palmerola, MD,[1] Sabrina A. Gerkowicz, MD,[2] Ineabelle Collazo, BS,[1] Himanshu Arora, PhD,[3] Maria Bustillo, M.D[1] [1]IVFMD, South Florida Institute for Reproductive Medicine, MIAMI, FL; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL; [3]University of Miami Miller School of Medicine, Miami, FL.

OBJECTIVE: Euploid embryo pregnancy failures are frustrating for clinicians and patients alike and remain a poorly understood aspect of infertility. Novel sperm selection techniques using microfluidic sorting devices are reported to improve embryo quality and pregnancy outcomes, though existing data is limited by small sample size. This study aims to compare euploid embryo ongoing pregnancy rates from embryos generated with the use of microfluidic sperm sorting (MSS) versus standard density gradient centrifugation (DGC).

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: All IVF/PGT-A cycles resulting in embryo biopsy between January and October 2019 at a large, multicenter, private practice were included in analysis. Our center transitioned to use of MSS devices for all IVF cycles mid-way through this time period. PGT-A cycles were divided into two cohorts based on sperm preparation technique prior to ICSI: MSS (n = 167 cycles) and DGC (n = 167 cycles). Primary outcome was ongoing pregnancy rate following euploid embryo transfer. Secondary outcomes included fertilization rate, biopsiable blastocyst rate, and euploidy rate. Statistical analysis included two-tailed Student's t-test for continuous variables and Chi-square test for categorical variables, with $p < 0.05$ defining statistical significance.

RESULTS: Demographics, including oocyte age, body mass index, and baseline sperm parameters, were similar between MSS and DGC cohorts with the exception of AMH: mean 2.5 ng/mL in MSS versus 3.4 ng/mL in DGC, p=0.01. Euploid embryo transfers following MSS demonstrated higher ongoing pregnancy rate (86.1%) compared to DGC (70.8%), p=0.02 (Table 1). Fertilization, biopsiable blastocyst and euploidy rates were equivalent in MSS and DGC groups. Of note, MSS resulted in a trend towards greater percentage of Day 7 biopsies (5.1%) versus DCG (2.6%).

TABLE 1. MSS versus DGC Primary & Secondary Outcomes

	Microfluidic Sperm Sorting (MSS)	Density Gradient Centrifugation (DGC)	P-value
Fertilization Rate (%)	69.7	71.5	0.38
Biopsiable Blastocyst Rate (%)	54.8	51.2	0.17
Euploidy Rate (%)	47.4	50.2	0.45
Pregnancy Rate (%)	80.9	82.3	0.85
Ongoing Pregnancy Rate (%)	86.1	70.8	0.02
Biochemical Pregnancy Rate (%)	22.2	16.7	0.16
Clinical Miscarriage Rate (%)	5.6	10.4	0.4

CONCLUSIONS: Despite equivalent fertilization, embryo progression, and euploidy rates, microfluidic sperm sorting results in a higher ongoing pregnancy rate following euploid embryo transfer compared to standard density gradient centrifugation. Our findings may be explained by the lower DNA fragmentation and hence improved embryo quality of resultant embryos.

P-46 4:30 PM Saturday, October 17, 2020

STAGE OF TRANSFERRED BLASTOCYST MAY AFFECT PREGNANCY OUTCOMES WHEN TIMED WITH ENDOMETRIAL RECEPTIVITY ASSAY (ERA).

Rae vanTol, BS,[1] Robert Colver, MD,[2] Bradford Bopp, MD,[2] Matthew Will, MD,[2] Erica Anspach Will, MD,[2] Glen Adaniya, PhD[1] [1]Ovation Fertility, IN; [2]Midwest Fertility Specialists, Carmel, IN.

OBJECTIVE: ERAs have become popular tests in fertility patients with recurrent implantation failure and is used to personalize the timing of the transfer of embryos based on endometrial receptivity. Our study was performed to determine if blastocyst (BL) stage, at time of transfer, influences pregnancy outcomes when transferred based on ERA recommendations.

DESIGN: We performed a retrospective analysis of 200 single, euploid frozen embryo transfers (FETs) from patients who underwent ERA testing between 2018-2020. FET cycles were divided into groups based on stage of BL post thaw, early BL (B) (n=68), expanded BL (ExB) (n=56), hatching BL (HB) (n=42), and fully hatched BL (fHB) (n=34). Differences in implantation rates (IR), ongoing pregnancy rates (PR), and biochemical rates (BR) were statistically compared between groups.

MATERIALS AND METHODS: Between January 2018 and February 2020, 200 ERA timed, single euploid FETs were performed. Cycles that resulted in the transfer of two embryos or non-tested embryos were excluded. Pictures of embryos taken post thaw, 2+ hours before transfer, were analyzed and cycles were divided into 4 groups based on BL stage post thaw.

Group I – (B), 0% hatching out of zona
Group II – (ExB), <25% hatching out of zona
Group III – (HB), ≥25% hatching out of zona
Group IV – (fHB), embryo fully hatched out zona

Results were analyzed by Chi square analysis. A P value of $<.05$ was considered statistically significant.

RESULTS: The synchronization between the developing embryo and endometrium is essential for successful pregnancy. Transfers were divided into groups of B, ExB, HB, and fHB, achieving IR of 44%, 71%, 55%, and 50%, respectively, and PR were as follows, 35%, 50%, 38%, 24% (Table 1).

ExB did have significantly higher IR than B ($p<0.001$). ExB also had significantly higher PR compared to fHB ($p<0.05$). There was no significant difference in BR among groups.

TABLE 1.

Blastocyst Stage	FETs #	Implantation Rate # (%)	Pregnancy Rate # (%)	Biochemical Rate # (%)
B (Group I)	68	30 (44)[a]	24 (35)	4 (6)
ExB (Group II)	56	40 (71)[a]	28 (50)[b]	5 (9)
HB(Group III)	42	23 (55)	16 (38)	5 (12)
fHB(Group IV)	34	17 (50)	8 (24)[b]	4 (12)

[a] Group II implantation rate significantly different than group I. [b] Group II pregnancy rate significantly different than group IV

CONCLUSIONS: The transfer of an ExB based on ERA timing was associated with higher IR and PR compared to other BL stages. Personalized medicine has been promoted with individualized stimulation protocols and ERAs, which have improved results through identification of the optimal "window of implantation". The embryo remains another major factor and success can further be improved by personalizing embryo transfers based on BL stage at time of transfer. Further investigation is required to confirm these initial findings.

THE EFFECT OF EMBRYO CATHETER-LOADING TECHNIQUE ON PREGNANCY AND IMPLANTATION RATES IN FROZEN EMBRYO TRANSFER CYCLES.

Tamar Matitashvili, MD,[1] Seifeldin Sadek, MD,[1] Hadi Ramadan, M.D.,[2] Gerard Celia, Jr., PhD[3] [1]Jones Institute, Norfolk, VA; [2]Eastern Virginia Medical School, Norfolk, VA; [3]EVMS, Norfolk, VA.

OBJECTIVE: The purpose of the study was to compare the implantation and clinical pregnancy rate when using a medium-only catheter loading technique versus an air-fluid method in frozen embryo transfer (FET) cycles.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: 113 women undergoing FET were included in our study. Group 1 (n=70) had FET done between 6/1/19 and 9/30/19 using an air-fluid technique of embryo loading. Group 2 (n=43) had FET done between 1/1/20 and 4/30/20, when a fluid-only method was implemented.

In Group 1, loading was done by filling the catheter with 15-20μL of medium and then aspirating 10μL air followed by 5-10μL of medium containing embryo(s). Loading was completed by adding 10μL of air at the tip of the catheter.

In Group 2, loading was performed by filling the catheter with 15-20μL of medium followed by an additional 5-10μL containing embryo(s), without air.

In both groups the catheter was flushed with 1ml of Global Total (Cooper-Surgical, Denmark) prior to loading and embryos were aspirated in Embry-oGlue (Vitrolife, Sweden).

Embryo transfer technique was identical in both groups and was standardized among physicians based on current ASRM practice guidelines.

Data was analyzed using unpaired Student's t-test to compare quantitative variables and chi square test for qualitative variables.

RESULTS: No statistical difference was detected between the groups with regard to age, body mass index, diagnosis, FET and ovarian stimulation cycle characteristics, number and quality of embryos transferred (all P >0.05).

113 FETs resulted in 59 positive pregnancy test results and 49 clinical pregnancies - defined as documented intrauterine gestational sac with fetal pole and positive fetal heartbeat on ultrasound.

There was no statistical difference between Group 1 and Group 2 in clinical pregnancy (45.7% vs 39.5% P=0.38) and implantation rate (55.7% vs 46.5% P= 0.35).

CONCLUSIONS: No difference was found between groups with respect to implantation and clinical pregnancy rates.

We conducted this study to gain more insight into potential differences between two techniques, as only 2 prospective trials with similar sample size, conducted in fresh cycles, were reported more than 20 years ago. Even though no significant difference in pregnancy rate was demonstrated at that time, routine use of air brackets is still controversial. While it may offer some psychological comfort to the doctor, as the echogenic air droplet makes it easier to visualize the procedure on ultrasound, there exists a theoretical assumption that reactive oxygen species may cause damage to the embryo, given the fact that the introduction of air is non-physiologic.

Currently, no studies have utilized a sample size large enough to demonstrate a statistical difference between methods. Additionally, transfer guidelines and advances in ART techniques have changed dramatically since the earliest reports. We intend to increase our sample size to achieve sufficient statistical power.

MICROFLUIDIC DEVICE-BASED SEMEN PREPARATION INFLUENCES EUPLOIDY RATES OF HUMAN BLASTOCYSTS.

Zeki Beyhan, Ph.D.,[1] Sally Abboud, M.S.,[1] Jordan A. Moliver, B.A., J.D.,[1] Farah S. Chuong, M.D.,[2] Fernando M. Akerman, M.D.,[1] Michael H. Jacobs, M.D.,[1] fertility and IVF Center of Miami[1]Fertility and IVF Center of Miami, Miami, FL; [2]8950 N Kendall Drive, Miami, FL.

OBJECTIVE: The study has been conducted to assess preimplantation development of human embryos following ICSI with two different sperm separation techniques. Zymot, a microfluidic sperm separation device (MFSS), which was based on motility within a micro-environment, and density gradient centrifugation (DGS) which was based on centrifugal force. The study was carried out between 2018 and 2019.

DESIGN: Retrospective

MATERIALS AND METHODS: A total of 371 ART-cycles were included in the study. Semen samples from patients with severe male pathology, TESE, MESA, and donor semen were excluded. Fresh ejaculated specimens from consenting men were collected for standard semen analysis in accordance with WHO 2015 guidelines. DGC (Control Group, n=220) and MFSS (Treatment Group, n=151) were used to isolate motile spermatozoa based on cell motility and fluid dynamics. 1802 blastocysts were biopsied and analyzed to determine ploidy status . Patient characteristics such as male and female age, number of retrieved oocytes, number of embryos were comparable between control and treatment groups. All oocytes were inseminated by ICSI and cultured following standard embryo culture protocols. Trophectoderm biopsies were performed on Day 5 or 6 of development and screened for euploidy using NGS. Experimental end points of the study were fertilization, blastocyst conversion and euploidy rates of preimplantation embryos. Ch-square and regression analyses were used to compare treatments and to identify factors affecting ploidy status of blastocysts.

RESULTS: Fertilization and blastocyst conversion rates were comparable between the sperm prep methods tested. Regression analysis of the factors influencing the ploidy status of the blastocysts indicated that use of MFSS method, ZyMot increases the number of euploid embryos by 0.44/cycle, controlling for other known characteristics of patient sets (p: 0.05 *).

Semen Prep Method	ICSI Cycles (N)	ICSI Oocyte (n)	Fertilization %	Blastocysts Biopsied (%)	Euploid Blastocyst (%)
DGS	220	2058	1667 (81.0)	1050 (51.0)	620 (59.0)
MFSS	151	1419	1078 (76.0)	752 (53.0)	474 (63.0) *

CONCLUSIONS: This study suggests that the use MFSS for sperm preparation for ICSI ccyles could improve the number of euploid embryos, modestly. Although the morphology and DNA integrity were not assessed in this study directly, widely reported improvements in these aspects by the MFSS may explain the improvements in PGT-A outcomes. The findings of our study should to be considered in the light of some limitations, such as a modest sample size and absence of morphology and DNA integrity data. These need to be addressed in future studies to provide a more complete assessment of the treatments.

SORT-TERM *IN VITRO* MATURATION (IVM) CULTURE OF CUMULUS-OOCYTE COMPLEXES IMPROVES SUBSEQUENT EMBRYONIC DEVELOPMENT IN STIMULATED CYCLES. Ya-Nan Shi, PhD,[1] Yi Zhou, Master,[2] Lei Jia, Master,[1] Yingying Liu, Master,[1] Cong Fang, PHD, MD,[3] Xiao-yan Liang, M.D., Ph.D.[3] [1]Laboratory of Reproductive Endocrinology, The Research Center of Reproductive Medicine, The 6th Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China; [2]492459979@qq.com, Guangzhou, China; [3]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To determine the effect of short-term culture in IVM medium on oocyte maturation, subsequent embryonic development and the clinical outcome.

DESIGN: A prospective study was conducted under the following background. Current standard stimulation protocols use gonadotropins (recombinant or hMG) combined with LHRH agonists to prevent the problem of premature ovulation with the aim of obtaining an average of 10–15 mature oocytes per retrieval. However, it is quite often containing some immature oocytes retrieved with mature oocytes even after triggering of LH surge. Practically those immature oocytes retrieved were discarded. Insemination is performed normally after approximately 41 h of HCG injection. Therefore, there is a few hours (3-5 h) after oocyte retrieval before insemination in fertilization medium (FM). We do not know whether or not FM is suitable for final oocyte maturation.

MATERIALS AND METHODS: Forty-five infertile women under 35 years of age were enrolled in this study. All the patients underwent autologous intracytoplasmic sperm injection (ICSI) cycles with more than 2 cycles failed previously. GnRH antagonist protocol was used for controlled ovarian hyperstimulation. Twelve patients were enrolled in the treated group, the COCs were cultured in balanced IVM medium (IVM Kit, SAGE, Coopersurgical, USA) immediately after retrieval for 4 hours in 5% CO_2, 5% O_2, 90% N_2at 37°C incubator before ICSI. Those thirty-there untreated patients underwent conventional ICSI with a similar duration of incubation in FM before ICSI. The oocyte maturation rate was compared in the two groups, and subsequent fertilization rate, early embryonic development and the pregnancy rate were also determined.

RESULTS: The maturation rate was 72.1%(98/136) and 69.8%(233/334) in treated and untreated groups. The fertilization rate, usable embryo rate, good quality embryo rate, blastocyst formation rate as well as biochemical and clinical pregnancy rate were 72.4%(71/98) vs 69.1%(161/233), 78.9%(56/71) vs 59.0%(95/161) (P<0.1), 52.1%(37/71) vs 33.5%(54/161) (P<0.1), 60.6%(20/33) vs 57.9%(22/38), 57.1%(4/7) vs 35.7%(10/28) and 42.9%(3/7) vs 35.7%(10/28) respectively.

CONCLUSIONS: Short-term IVM culture of COCs remarkably improves the usable embryo rate and good quality embryo rate, subsequently could obtain higher proportion of good quality embryos for transfer, thereby improves pregnancy rate.

P-50 4:30 PM Saturday, October 17, 2020

EFFECT OF RE-EXPANSION IN FROZEN-THAWED EMBRYO TRANSFERS ON PREGNANCY OUTCOMES. Kathryn D. Coyne, MD, Mabel Lee, MD, Lauren Alexis Palavos, BS, James Hamrick, BS, Brooke A. Belvin, BS, Rachel S. Weinerman, MD, Rebecca Flyckt, MD, James H. Liu, M.D., Sung Tae Kim, PhD, HCLD University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH.

OBJECTIVE: To evaluate the effect of blastocyst re-expansion on frozen-thawed embryos at time of transfer on pregnancy outcomes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients undergoing frozen-thawed embryo transfer (FET) from January 2017 to March 2020 in our center were included. Following a standard FET protocol, vitrified blastocysts were re-warmed on the day of ET and images of the thawed embryo were taken prior to transfer. Images were reviewed by at least two embryologists and the degree of expansion at least 1 hour post thaw at time of FETs was documented and included: 1) fully re-expanded 2) partially re-expanded 3) non re-expanded. Primary outcomes included: high quality embryo, defined by minimum grades of B for both trophectoderm and inner cell mass by Gardner's blastocyst grading scale; pregnancy; clinical pregnancy; miscarriage; and, ongoing pregnancy and live birth. Statistical analyses were done using ANOVA for continuous data and Chi Square for dichotomous outcomes.

RESULTS: A total of 645 single FET cycles were analyzed in the study. There were 301 fully re-expanded (46.7%), 274 partially re-expanded (42.4%), and 70 non re-expanded (10.9%) embryos at the time of transfer. The mean age, BMI, and endometrial thickness was not significantly different between the groups (p=NS). There was a significantly higher rate of embryo quality (56.8% and 58.0% vs. 44.3%; p=0.034), pregnancy rate (68.4% and 68.2% vs. 55.7%; p=0.048), clinical pregnancy rate (62.1% and 62.8% vs. 55.7%; p=0.030), and ongoing or live birth rate (50.2% and 51.8% vs. 38.6%; p=0.048) in frozen-thawed embryos that were fully or partially expanded at the time of transfer versus non re-expanded, respectively. No difference was noted in miscarriage rate between the groups (10.6%, 10.9%, 10.0%; p=0.9). The majority of thawed embryos were at least partially re-expanded (89.1%). The non re-expanded group has fewer high quality embryos (56.8% and 58.0% vs. 44.3%; p=0.034). When the high quality embryos were analyzed alone, there were no significant differences (p=NS) in pregnancy rates (70.2% vs. 72.5% vs. 64.5%), clinical pregnancy rates (64.9% vs. 67.5% vs. 54.8%), ongoing or live birth rates (52.6% vs. 58.8% vs. 41.9%) or miscarriage rate (10.0% vs. 8.8% vs. 12.9%) between the fully, partially, and non re-expanded groups, respectively.

CONCLUSIONS: Transferring a non-re-expanded blastocyst, as compared to a fully or partially expanded blastocyst, at the time of FET is associated with a lower ongoing pregnancy and live birth rate in our study. However, embryo quality appears to have a greater effect on pregnancy outcomes than re-expansion, as there were no differences in outcomes between the groups when considering only high-quality blastocysts.

EFFECTS OF CULTURE TIME ON PREGNANCY OUTCOME OF FROZEN-THAWED D5 BLASTOCYST. Junxia Liu, MD,[redacted] Guoning Huang, M.D[2] [1]ChongQing Health Center for Women and Children; [2][redacted].

OBJECTIVE: To explore the effect of culture time on pregnancy outcome of frozen-thawed D5 blastocysts, and to optimize the blastocyst transfer strategy.

DESIGN: A retrospective cohort study.

MATERIALS AND METHODS: A retrospective cohort study of 1576(age<38) frozen-thawed high quality blastocyst transfer cycles vitrified on day 5, were divided into 2 ~ 4 h (group A, n = 677) and 16 ~ 20 h (group B, n = 899) according to culture time after thawed.

RESULTS: The implantation rate (64.58%), clinical pregnancy rate (77.99%) and ongoing pregnancy rate (71.79%) in group A were higher than those in group B (51.35%, 67.96%, 58.39%), the difference was statistically significant ($P = 0.000$). The early miscarriage rate in group A (6.44%) was lower than that in group B (11.13%, $P = 0.000$).

CONCLUSIONS: D5 thawed blastocysts cultured for 2~4 hours had better pregnancy outcomes.

IS THE BIGGEST IMPACT ON CLINICAL IVF OUTCOMES OBTAINED BY IMPLEMENTATION OF CONTINUOUS MEDIA, TIME-LAPSE INCUBATOR OR BOTH?. Teija Peura, PhD,[1] Andrew Murray, MSc,[2] Natalie Hesketh, MSc,[2] Sarah Dalati, PhD,[2] Mark Bowman, MB BS PhD,[2] Steven J. McArthur, BSc[2] [1]Genea Biomedx, Sydney, NSW, Australia; [2]Genea, Sydney, NSW, Australia.

OBJECTIVE: The objective of this work was to explore which change has the biggest impact on clinical IVF outcomes; implementation of continuous media, timelapse incubator or a combination of the two.

DESIGN: Separate prospective sibling oocyte studies were conducted to compare embryo culture in continuous medium vs. sequential media, and in timelapse incubator vs. benchtop incubator. Subsequently a change in embryo culture system was introduced across a chain of clinics and retrospective comparative data of outcomes of old (sequential + benchtop) vs. new (continuous media + timelapse) system were collated and analysed. Altogether 970 and 42,892 embryos were included in prospective and retrospective studies, respectively, between 2014-2019.

MATERIALS AND METHODS: Patients with min. 2 or 1 fertilised oocytes were included in prospective and retrospective studies, respectively. Embryos were culture in Gems® Cleavage and Blastocyst Medium or Geri Medium (Genea Biomedx) in Geri® incubator, or in MINC™ benchtop (Cook Medical) or Geri® timelapse incubator (Genea Biomedx) in Gems Sequential media. Retrospective follow-up included patients with comparable ages, fertilisation methods (IVF vs ICSI) and PGT prevalence and outcomes. Cumulative pregnancy outcomes were collated over a two-year period.

RESULTS: No statistical differences in grade 1 or 2 utilisable blastocysts by Day 5 or 6 (26.9 vs. 26.2%) or cumulative live births/on-going pregnancies for 112 patients (16 vs. 21) were observed between sequential vs. continuous media in prospective media studies. The tendency for more embryos being vitrified at Day 5 for PGT in continuous media group resulted in more cryo-PGT transfers in that group despite comparable euploidy outcomes between groups. In incubator studies, the corresponding embryo development rates were significantly higher (43.3 vs. 27.5%, $p<0.001$) in Geri incubator compared to MINC benchtop. In addition, more embryos reached grade 1 or 2 by day 5 in Geri than in MINC (93% vs. 76%). Cumulative live births/ongoing pregnancies for 80 patients were also higher in Geri than in MINC (14 vs. 25, $p<0.05$). In retrospective follow-up, the combination of Geri continuous media + Geri timelapse incubator led to significantly higher embryo development (38.7 vs. 29.1%, $p<0.001$) and cumulative live births/ongoing pregnancies (30.3 vs. 34.1%, $p<0.001$) than Gems sequential media + MINC benchtop. Overall, data from >42,000 embryos showed statistically highly improved ($p<0.00001$) outcomes both in utilisable embryo development as well cumulative pregnancy rates. Although groups were balanced for PGT cases, the overall increase in NGS PGS over the years with associated embryo manipulations and impact on patient cohorts could have been expected to have a negative impact on outcomes under the new, later adopted system. However, the new system still proved superior.

CONCLUSIONS: Although both the change into continuous media and timelapse incubation separately had some positive impacts on outcomes, the true benefits emerged more clearly when the two were combined.

P-54 4:30 PM Saturday, October 17, 2020

IS THERE A DIFFERENCE IN IVF DEVELOPMENTAL OUTCOMES BETWEEN OOCYTES RETRIEVED IN ROOM TEMPERATURE OOCYTE COLLECTION MEDIUM OR MEDIUM MAINTAINED AT 37oC?. Sarah Dolisca, MD,[1] Karissa C. Hammer, MD,[2] Stylianos Vagios, MD,[2] Jennifer Hsu, MD,[2] Caitlin Sacha, MD,[2] Irene Souter, MD,[2] Manoj Kumar Kanakasabapathy, MS,[3] Prudhvi Thirumalaraju, BS,[3] Charles L. Bormann, PhD,[2] Hadi Shafiee, PhD[3] [1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: Analyzing the impact of collection medium temperature during egg retrievals on IVF outcomes using convolutional neural networks (CNN) and preimplantation genetic testing for aneuploidy (PGT-A)

DESIGN: A retrospective review of 206 IVF-ICSI cycles at a single institution between 2016-2019 comparing oocyte retrieval medium at room temperature to medium at 37oC. The percentage of normally fertilized MII oocytes (2PN) was measured 16-18 hours post-insemination (hpi). A CNN model trained to classify images of embryos at 113 hpi compared D5 embryo development. A trained CNN predicted the implantation potential of PGT-A embryos calculated the average implantation potential for each embryo imaged per cycle.

MATERIALS AND METHODS: Using a dataset comprised of 1971 embryos cultured and imaged in the EmbryoScope comparisons were made after varying the temperature management of collection tube media between two cohorts: 1) room temperature and 2) 37oC. Comparisons were made regarding the percentage of normal fertilization (2PN), D5 embryo development, average implantation potential for each embryo, percentage of euploid blastocysts per cycle, and average number of euploid embryos per cycle.

RESULTS: Room temperature and 37oC treatment groups were comparable by age (36.5, 37.5 years, respectively), and all cycles had at least one blastocyst available for PGT-A (room temperature N=32, 37oC N=173).

Both groups were comparable for rate of normal fertilization, 76.9% for room temperature and 77.9% for 37oC ($p=0.711$). There were no differences in D5 embryo development between the two groups, 55.5% room temperature and 60.7% at 37oC ($p=0.122$). Similarly, there were no significant differences in percentage of high quality D5 blastocyst development between the two groups, 31.1% at room temperature and 33.0% at 37oC ($p=0.544$).

The average implantation potential for each embryo imaged was comparable between the two treatment groups at 41.0% per embryo for room temperature and 43.0% per embryo at 37oC ($p=0.189$). The percentage of euploid embryos per cycle were similar as well, 35.8% at room temperature and 42.1% at 37oC ($p=0.335$). No differences were observed between the average number of euploid embryos per cycle: 1.4 at room temperature and 1.7 at 37oC ($p=0.308$).

CONCLUSIONS: Patients who underwent oocyte retrieval with collection tube medium warmed to 37oC had comparable outcomes to those at room temperature. These findings suggest that room temperature collection tube medium is equally efficacious for IVF procedures.

THE EFFECTS OF TEMPERATURE VARIATION TREATMENTS ON MOUSE EMBRYO MORPHOKINETICS AND METABOLISM.

Doris Ferreira Moriyama, M.Med.Sci,[1] Dimitra Makri, M.Med.Sci,[2] Mary-Naya Maalouf, M.Med.Sci,[2] Petra Adamova, M.Med.Sci,[2] Walid Maalouf, PhD,[2] Edson G. Lo Turco, PhD[3] [1]Sao Paulo Federal University, School of Medicine, Department of Surgery, Division of Urology, Human Reproduction Section, Sao Paulo, Brazil; [2]University of Nottingham, School of Medicine, Division of Child Health, Obstetrics, and Gynaecology, Nottingham, United Kingdom; [3]IonMedicine - Precision Medicine, Sao Paulo, Brazil.

OBJECTIVE: This study aimed to evaluate the effects of temperature variation treatments on mouse embryo morphokinetics and metabolism.

DESIGN: Prospective study.

MATERIALS AND METHODS: Frozen-thawed hybrid B6C3F1 x B6D2F1 mouse embryos (N=161) were cultured in time-lapse system incubators under 3 temperature variation treatments: Treatment 1 (T1) at 37°C during the day and 35.5°C during the night, Treatment 2 (T2) at 38.5°C during the day and 37°C during the night and Control (C) with constant 37°C. For this study, 3 time-lapse system incubators were used (one for each study group), temperature was changed in the set-up function every 12 hours (9am and 9pm) and embryo culture was performed at 6% CO_2, in dry atmosphere. Experiments terminated at 9am of Day 5 (96 hours post-thaw) and culture media was collected individually for metabolomics. The following morphokinetics events were annotated: first cleavage (t2), division to 3-cells (t3), 4-cells (t4), 5-cells (t5) and 8-cells (t8), start of blastulation (tSB), full blastocyst (tEB) and hatching of the blastocyst (tHB). All the time points were normalized to pronuclear fading (tPNf). Based on the pre-compaction time points annotated it was calculated the duration of the second (ECC2) and third cell cycle (ECC3), as well as, the synchronicity of the second (s2) and third cell cycle (s3). With blastocyst time points it was also calculated the duration of blastulation (dB). The Targeted Metabolomics was performed with a HPLC coupled with an Amino Acid Analyzer. The amino acids library (23 metabolites) was based on the dynamic metabolism of a developing mouse embryo, from zygote to blastocyst stage.

RESULTS: Considering the morphokinetics variables (N=161 blastocysts) it was found statistical differences for the variables: t2, t3, t4, ECC2, t5, t8, tSB, tB, tHB, with the embryos from T1 (low temperature) group consistently showing a lower rate of development when compared to both T2 and C group. On the other hand, the rate of development of T2 (high temperature) group was very similar to the control group, with no statistical differences for all variables between these 2 study groups. The individual metabolomics of culture media (N=81 samples) showed that the amino acids L-histidine, ammonium chloride, valine, L-ornithine, tryptophan, L-alpha-aminoapidic acid, L-threonine, L-aspartic acid, L-isoleucine, cystine, L-methionine, L-alanine, glutamic acid, phenylalanine and serine were highly expressed in the T1 (low temperature) group, indicating a more stressed metabolism, while both T2 and C group showed a low expression of the same metabolites.

CONCLUSIONS: In summary, considering normal metabolism and morphokinetics events throughout embryonic development, culturing embryos at 37°C during the day and 35.5°C during the night (T1) showed negative effects, such as low rate of development and stressed metabolism. In contrast, the second temperature variation treatment with 38.5°C during the day and 37°C during the night (T2) seemed to be as efficient as the control group for *in vitro* mouse embryo culture.

SUPPORT: This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nvel Superior – Brasil (CAPES) – Finance Code 001.

AMH IS NOT ASSOCIATED WITH HIGH-GRADE EMBRYO QUALITY AS ASSESSED BY DAY 3 AND DAY 5 MORPHOLOGY.

Rhea Chattopadhyay, MD,[1] Salomeh M. Salari, MD MS,[2] Salina Zhang, MD,[3] Valerie Libby, MD,[1] Channing Burks, MD,[1] Rebecca Flyckt, MD,[1] Rachel S. Weinerman, MD[1] [1]University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH; [2]University Hospitals Cleveland Medical Center, Cleveland, OH; [3]Case Western Reserve University School of Medicine, Cleveland, OH.

OBJECTIVE: The purpose of this study was to determine if there is a correlation between AMH and the quality of day 3 and day 5 embryos in patients undergoing fresh IVF cycles.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: All fresh IVF cycles at a single academic center in 2016 were evaluated. Patients with an AMH level documented within one year prior to stimulation who proceeded to retrieval were included in our analysis. Patients without AMH levels drawn before stimulation were excluded. Experimental perimeters included age, BMI, #eggs retrieved, #mature eggs, # fertilized embryos (2pn), #day 3 blasts, and # day 5 blasts. A morphological grading system was used to determine the quality of day 3 and day 5 embryos. Criteria for high quality day 3 (HQD3) embryos were: 7-10 cells, <10% fragmentation, and no fragmentation or scattered fragmentation. For high quality day 5 blastocysts (HQD5) criteria were: 1) presence of a blastocyst that is expanding, fully expanded, or hatching with 2) an inner cell mass that is loosely grouped with several cells or tightly packed with many cells, and 3) the trophectoderm described as containing few cells forming loose epithelium or many cells forming a cohesive epithelium, and the absence of necrotic cells. Multiple linear regression analysis was performed to assess if embryo quality, (defined as #HQD3/#2pn or #HQD5/#2pn) is associated with AMH level, controlling for patient's age and BMI. Significance was determined at a p-value of 0.05.

RESULTS: 292 cycles met inclusion criteria and were analyzed. Higher AMH levels were associated with significantly younger patients (r^2=0.09, $p<0.001$) and significantly more oocytes retrieved (r^2= 0.13, $p<0.001$). After controlling for age and BMI, there was no significant relationship between AMH level and embryo quality as defined by the study's parameters for percentage of high quality Day 3 and Day 5 embryos.

CONCLUSIONS: In our study, we did not find AMH to be a predictor of embryo quality. This information is important when counseling patients on the utility of AMH. While AMH levels predict the number of oocytes retrieved during an IVF cycle, it may not predict the quality of embryos, which is an important distinction for patients and clinicians.

HEALTHY BABIES CAN ALSO BE OBTAINED FROM BLASTOCYSTS WITH DIRECT CLEAVAGE.

Fumiya Kondo, M.S., Hiroya Kitasaka, Ph.D., Noritaka Fukunaga, Ph.D., Yoshimasa Asada, M.D., Ph.D. Asada Ladies Clinic, Nagoya, Japan.

OBJECTIVE: Direct cleavage (DC) of an embryo has been reported to decrease blastocyst formation, but if such an embryo does go to blastocyst, viability can be similar to normally dividing one.However, whilst there are some reports of live births from DC embryos, there is still unsufficient clarity on the relationship between DC and outcome. Therefore we compared the prognosis of normally dividing and DC embryos in blastocyst transfer.

DESIGN: This was a retrospective analysis of embryos that were cultured in time-lapse incubators between December 2016 and December 2018 and then a single frozen-thawed blastocyst was replaced.

MATERIALS AND METHODS: Part 1: After confirming the 2 pronuclei, we targeted 1177 embryos that had been cultured at time lapse for up to 7 days and were frozen in blastocysts (Blast3 ≦, not including CC) and

transferred by singly.The pregnancy and miscarriage rates were compared for three groups: normally dividing embryos (normal division group, n=933), Abnormal direct cleavage at the first division (DC1 group, n=164) and Abnormal direct cleavage at the second division (DC2 group, n=80).Part 2: We compared the prognosis of the three groups in 176 cases. We examined the average body weight (37-41 weeks of term birth), male-female ratio, birth defect rate, preterm birth rate, Caesarean section rate, and average apgar score.Statistical significance was analyzed by Ryan method and Steel-Dwass test multiple comparisons.

RESULTS: Part 1: The pregnancy rate was 49.0% (457/933), 35.4% (58/164), and 48.8% (39/80) in the normal division group, DC1 group, and DC2 group, DC1 group was significantly lower than that in the normal division group. ($p < 0.05$)The miscarriage rates were 19.9% (91/457), 20.7% (12/58), and 25.6% (10/39), respectively, showing no difference.Part 2: Average body weights were 3141.6 ± 486.6 ($n = 130$), 3097.3 ± 331.9 ($n = 17$), 2823.3 ± 468.6 ($n = 10$) in the normal divided, DC1, and DC2 group, respectively. Male-female ratio (male / female) was 1.20 (79/66), 1.25 (10/8), 1.75 (7/4), congenital anomaly rate was 2.7% (4/147), 0% (0/18), 0 % (0/18), premature birth rate was 9.2% (12/143), 5.9% (1/18), 10.0% (1/11), Caesarean section rate (Caesarean section / total) was 32.6% (47/144) , 27.8% (5/18), 45.5% (5/11), and the average apgar score was 8.4 ($n = 114$), 8.0 ($n = 15$), 7.9 ($n = 11$), showing no difference between the 3 groups.

CONCLUSIONS: The DC1 embryo had a lower pregnancy rate than the normal dividing embryo, but the miscarriage rate was not different between the DC1 embryo and the normal dividing embryo. DC2 embryos were not different from normal division embryos in terms of pregnancy and abortion rate. From the prognosis of childbirth, it was suggested that both DC1 and DC2 embryos may have the same results as normal dividing embryos.These results demonstrate that the pregnancy rate of blastocysts from DC1 embryos was lower, however if the blastocyst stage is reached in DC1 and DC2 embryos replacement should be considered if there are no other blastocysts available.

P-58 4:30 PM Saturday, October 17, 2020

THE COMPARABLE BIRTH OUTCOME OF YOUNGER AND OLDER PATIENTS. IS THIS POSSIBLE?. Oscar Perez, Ph.D.,[1] Hannalie Adriaanse, BS,[1] Gabriella Navarrete, BS,[1] Breanna Tilley, MSc,[1] Linda Lay, BS,[1] Lucille M. Little, BS,[1] Jessica Kozlowski, B.S.,[1] Ravi Gada, MD,[2] Laura Lawrence, MD,[2] Karen Lee, M.D.,[2] Mika R. Thomas, MD,[2] Samuel J. Chantilis, MD[2] [1]Dallas Fertility Center, Dallas, TX; [2]Dallas-Fort Worth Fertility Associates, Dallas, TX.

OBJECTIVE: Women of advanced age (≥ 41 years old) are an expanding reproductive age group; however, it is well known that fertility is remarkably reduced with the increasing age of women using assisted reproductive technologies (ART). Technology tools such as preimplantation genetic testing (PGT) offer the possibility to combine ART procedures for selecting embryos with higher implantation potential. The objective of this study was to compare the implantation rate and birth outcome of patients ≤ 34 years old (younger patients) and patients 41-44 years old (older patients) that underwent frozen embryo transfer (FET).

DESIGN: Data were prospectively collected over four years for all patients (n=1299) undergoing FET.

MATERIALS AND METHODS: Patients using autologous oocytes who underwent primary and secondary FET's from January 2016 to August 2019 were divided into four groups. Younger patients with PGT (n=393), younger patients without PGT (n=775), older patients with PGT (n=85), and older patients without PGT (n=46). The FET's were a combination of primary and secondary transfers. For patients with a primary frozen embryo transfer, the rates were 55% for the younger and 56% for the older patient groups. Vitrified blastocysts were thawed using rapid warm™ Blast (Vitrolife) and cultured in G2™ (Vitrolife) plus 20% protein for one hour and then transferred to the transfer dish containing hyaluronan for at least 3 hours before the embryo transfer. Chi-square analysis was applied to detect differences in the clinical and birth endpoints.

RESULTS: As expected, differences were observed in the implantation rates between younger patients and older patients with FET without PGT treatments. Similarly, the birth outcomes in patients without PGT treatment showed the same result. The implantation rates and birth outcomes for FET and PGT procedures are summarized in the table 1.

CONCLUSIONS: Data from this study suggest that implantation rate and birth outcome when offering FET and PGT are increased in older patients. These outcomes were constant for over four years. Patients between 41 and 44 years old who have euploid frozen embryos can obtain similar high implantation and birth outcomes when compared with younger patients in the ≤ 32 years old group.

P-59 4:30 PM Saturday, October 17, 2020

PROGNOSTIC VALUE OF OOCYTE QUALITY IN *IN VITRO FERTILIZATION* OUTCOMES: A SYSTEMATIC REVIEW. Nicole Mercado Fischer, MPH,[1] Ha Vi Nguyen, MD,[2] Bhuchitra Singh, MD, MPH, MS,[3] Valerie L. Baker, MD,[4] James Segars, MD[3] [1]Johns Hopkins University School of Medicine, Division of Reproductive Endocrinology and Infertility, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]10751 Falls Road, Lutherville, MD.

OBJECTIVE: The development of an objective and accurate test to assess human oocyte quality remains an important goal of reproductive medicine. The aim of this study was to survey and critically assess current methodological innovations used to test oocyte quality that have prognostic value in predicting *in-vitro* fertilization (IVF) outcomes.

DESIGN: Systematic review.

MATERIALS AND METHODS: Following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, we surveyed published literature between January 1st, 2010 and December 31st, 2019 using PubMed, Scopus, and Embase databases. Two reviewers screened for English-language articles regarding the predictive value of oocyte quality markers for IVF outcomes of interest including fertilization rate, embryo quality, implantation rate, pregnancy, continued pregnancy, and live birth rate. Articles that did not mention oocytes, or focused on non-human subjects, oocyte aging, oocyte maturation, embryo quality markers, oocyte quality interventions, or specific clinical diagnoses (endometriosis and polycystic ovarian syndrome) were deemed outside the scope of this analysis and excluded.

RESULTS: Twenty-seven relevant articles were identified, including 19 prospective and 8 retrospective cohort studies (n=3,472 patients). We identified three general approaches for oocyte quality assessment: morphological evaluation by embryologist (12 papers), genomics and proteomics (13 papers), and artificial intelligence classification systems using oocyte images (2 papers). Morphologic assessment, while a mainstay of clinical practice, did not show a consistent pattern of strong predictive value in IVF outcomes (7 papers in favor of its predictive value, 5 against). A considerable proportion of genomic and proteomic articles identified potentially promising biomarkers that may predict pregnancy and live birth rates (12 in favor, 1 against). Artificial intelligence is a more recent and rapidly growing method which minimizes subjectivity while potentially improving predictive ability (2 in favor).

CONCLUSIONS: Modern oocyte quality assessment research largely entails morphological evaluation, genomics/proteomics, and artificial

TABLE 1. Implantation rate and birth outcome in younger (≤ 34 years old) and older patients (41-44 years old).

	Implantation Rate n (%)		Birth Outcome n (%)	
Age Group	FET and Non-PGT	FET and PGT	FET and Non-PGT	FET and PGT
≤ 34 Years Old	549/976 [a] 56%	276/438 [a] 63%	376/775 [a] 49%	211/393 [a] 54%
41-44 Years Old	24/69 [b] 35%	61/97 [a] 63%	12/46 [b] 26%	47/85 [a] 55%

The numbers within columns with different superscripts indicate significant differences ($P<0.05$).

intelligence to predict reproductive success. Contemporary reproductive scientists, embryologists, and clinicians should be familiar with these strategies, which have the potential to move the field forward with substantial improvement in predicting patient reproductive outcomes and identifying potential targets for future therapies. Although there remains a lack of consensus on optimal methods, artificial intelligence and genomics demonstrate promise in improving understanding of oocyte quality assessment and prognostication.

ASSOCIATION OF MITOSCORE AND TIME TO BLASTULATION: EVALUATION AS PREDICTORS OF REPRODUCTIVE OUTCOMES AFTER SINGLE FROZEN EMBRYO TRANSFER. Janet Bruno-Gaston, MD, Luwam A. Ghidei, MD, Yadav Ghanshyam, MD, Chellakkan Selvanesan Blesson, PhD, William Gibbons, MD Baylor College of Medicine, Houston, TX.

OBJECTIVE: Evaluate the correlation of mitoscore and time to blastulation (TTB) among euploid embryos and its predictive value on reproductive outcomes

DESIGN: Single-center retrospective cohort study

MATERIALS AND METHODS: We performed a retrospective chart review of patients who underwent IVF with ICSI and pre-implantation genetic testing for aneuploidy (PGT-A) with mitoscore (Igenomix) from 10/2017 to 12/2019. Embryos were cultured in a time-lapse incubator and timing to blastulation (TTB) was recorded. Medical records were reviewed for patient demographics and FET cycle characteristics. The primary outcome was to assess correlation of mitoscore and TTB. Secondary outcomes included implantation and ongoing pregnancy, defined as cardiac activity on ultrasound at 10wks gestation or later. Spearman correlation analysis was performed to assess association of mitoscore and TTB, and a $p < 0.05$ was considered statistically significant. Statistical analyses were done between patient groups using t-test or Mann-Whitney U test. Logistic regression was applied to assess predictors of implantation and pregnancy.

RESULTS: We identified 137 patients with 465 embryos and 145 frozen embryo transfers (FET). We found an overall implantation rate of 68.3% (n=99) and ongoing pregnancy rate of 53.7% (n=78). A significant correlation between Mitoscore and TTB ranking were found among all embryos (ρ=0.54, p< .0001, 95%CI 0.47-0.60). This positive correlation persisted amongst patients with implantation (ρ=0.52, p<0.001, 95% CI 0.36-0.65) and no implantation (ρ=0.44, p<0.002, 95% CI 0.17-0.65) following single FET. We noted no differences in mitoscore or TTB among patients with or without implantation (Mitoscore p=0.61, 95%CI -2.31 to 1.43: TTB p=0.41, 95%CI -3.77-1.55) or ongoing pregnancy (Mitoscore p=0.28, 95%CI -2.66-7.60: TTB p=0.92, 95%CI -2.29-2.52). Logistic regression of demographics, FET cycle characteristics, mitoscore and TTB revealed no predictors of implantation. Factors including age, BMI, parity, endometrial thickness, and FET protocol were not different between implanted vs. non-implanted groups.

CONCLUSIONS: Mitoscore and TTB are correlated amongst euploid embryos. However, neither was found to be an independent predictor of implantation. Continued efforts to refine embryo selection outside of ploidy status may help address implantation failure following single euploid FET.

P-61 4:30 PM Saturday, October 17, 2020

OFFSPRING GENDER RATIO AFTER SPERM CO-INCUBATION WITH ENDOMETRIAL CELLS PRIOR IVF. Rumiana Ganeva, MSc, Dimitar Parvanov, PhD, Kristina Nikolova, MSc, Georgi Stamenov Stamenov, MD/PhD Nadezhda Women's Health Hospital, Sofia, Bulgaria.

OBJECTIVE: To observe and compare the offspring gender ratio in couples who had co-incubation of spermatozoa with human endometrial cells prior IVF and patients with conventionally performed IVF.

DESIGN: Observational.

MATERIALS AND METHODS: Data on the offspring gender of 106 couples who had sperm co-incubation with the partners' endometrial cells prior IVF (study group) and 104 couples who reached labour after conventional IVF (control group) was recorded.

Cells obtained from endometrial biopsies were cultivated in DMEM F12 10% FBS for 48 hours at 37oC and 5%CO_2. On the day of the follicular punction washed semen was incubated for 2 hours with the confluent endometrial cells followed by conventional IVF protocol.

Statistical analysis was performed by Chi-square test using SPSS v.21. P<0.05 was considered significant.

RESULTS: The conventional IVF group and the sperm co-incubation group were comparable in age, BMI, oocyte quality and number of unsuccessful ART procedures.

The female to male ratio in the conventional IVF group was 1:1.08 (female:male) with 48.1% females and 51.9% males.

Live births after sperm co-incubation with endometrial cells prior IVF resulted in significantly more female than male babies (63.2% vs. 36.8%, respectively, p<0.05) with gender ratio 1.71:1 (female:male).

When the gender ratios were compared between the two groups, female proportion was significantly higher in the co-incubation group in comparison to the control group (p<0.05).

CONCLUSIONS: Our data show that spermatozoa co-incubated with endometrial cells prior IVF skews the sex ratio of the offspring to favor females. This observation suggests that co-incubation of spermatozoa with endometrial cell culture may lead to preferential hyperactivation of human spermatozoa bearing X chromosome. More studies are needed to analyze the effect of the endometrial cell culture on spermatozoa.

P-62 4:30 PM Saturday, October 17, 2020

EXCESSIVE TRIMMING OF CUMULUS CELLS IS ASSOCIATED WITH LOWER FERTILIZATION RATES AFTER CONVENTIONAL INSEMINATION. Carlos A. Guerrero, Ph.D., Jennifer A. Rodriguez, B.Sc., Daniel Skora, M.D., Rebecca A. Chilvers, M.D., Satin S. Patel, M.D., Jerald S. Goldstein, M.D. Fertility Specialists of Texas, Frisco, TX.

OBJECTIVE: Trimming of cumulus cells during the oocyte retrieval procedure is a common practice. The objective of this study was to evaluate the effect of excessive trimming of cumulus cells on normal and abnormal fertilization rates after conventional insemination.

DESIGN: Retrospective analysis of data collected from January 2018 through January 2020. Patients were divided into two treatment groups based on different levels of cumulus cell trimming after follicular aspiration: A) minimal trimming (most layers of cells remain) and B) excessive trimming (few layers of cells remain). Laboratory end points were analyzed using t-test and Chi-square test as appropriate.

MATERIALS AND METHODS: Patients ≤35 years old undergoing IVF with conventional insemination (n=291) were used in this study. Oocytes

TABLE 1. Effect of cumulus cell trimming on fertilization and blastocyst rates.

Cumulus Cell Trimming Level	# of Patients	Avg. # Mature Oocytes	Normal Fertilization Rate (%)	Abnormal Fertilization Rate (%)	Blastocyst Rate (%)
Minimal Trimming	120	14.1[a]	1291/1613 (80%)[a]	139/1613 (8.6%)[a]	881/1291 (68%)[a]
Excessive Trimming	171	14.4[a]	1841/2589 (71%)[b]	287/2589 (11.1%)[b]	1230/1841 (67%)[a]

[a,b] Different superscripts within columns indicate significant differences (P<0.05)

were trimmed using two 25g needles immediately after follicular aspiration. Oocytes were then inseminated with 150 m/ml motile sperm 4-6 hours post oocyte retrieval and cultured overnight in P-1 medium. Fertilization was assessed 17-19 hours post insemination. Zygotes were cultured in sequential G-1/G-2 media under 6% CO_2, 5% O_2 and 89% N_2 at 37.1℃. Patients with abnormal semen parameters based on WHO 5th Edition guidelines were excluded from this study.

RESULTS: There was a higher normal fertilization rate when oocytes were minimally trimmed during the oocyte retrieval procedure. In addition, abnormal fertilization increased when cumulus cells were trimmed excessively (Table 1). No difference was noted between treatment groups for patient age, average number of mature oocytes and blastocyst rate.

CONCLUSIONS: These findings suggest that cumulus cells should be minimally trimmed during the oocyte retrieval procedure to increase normal fertilization rates and reduce the number of oocytes fertilized abnormally.

SUPPORT: None.

P-63 4:30 PM Saturday, October 17, 2020

EMBRYO CULTURE WITH SEQUENTIAL VS SINGLE STEP MEDIA: EFFECT ON EUPLOID RATES?. Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology, Gayathri Gedela, Master in Clinical Embryology, Durga Gedela Rao, Sr., MRCOG, Sandeep Karunakaran, Sr., MS, PGDHM, PGDMLE Oasis fertility, Hyderabad, India.

OBJECTIVE: The aim of this study was to see whether the mode of embryo culture based on the kind of media use (Sequential Vs Single step media) had an effect on the euploidy rate

DESIGN: Retrospective Case Control Comparative Study. Private Fertility Clinic

MATERIALS AND METHODS: Patients who have opted to go for Pre-Implantation Genetic Testing for Aneuploidy (PGT-A) for selection of embryos were included in the study (May 2014 - January 2020) (n=335). The total number of embryos biopsied was 1323 embryos

All the biopsies and tubing were performed by one operator and the embryos were cultured in the bench top incubator with low oxygen culture condition. All things being constant, the only variable was the media used for culturing the embryos. Sequential media was from COOK Medicals & Single step media was from Cooper Surgicals, Origio. The patients were divided into 2 groups: Group A (n=167): Sequential Media, Group B (n=168): Single Step Media. All the oocytes were subjected to ICSI. They were cultured till Blastocyst and on Day 5 TE biopsy was done and frozen as per our clinics standard operating protocols. The biopsied samples were sent for PGT-A testing, done by next generation sequencing (NGS). The euploidy rate was calculated in both the groups. Study groups were further sub classified based on age of women (<37 years - young age & >37 years - advanced maternal age) and euploidy rates were assessed. This was done to eliminate bias from age.

RESULTS: The mean embryo euploidy rate was calculated in both the groups (Group A) 35.30% and (Group B) 36/6%.

Euploid rates based on age stratification were:

Group A - Younger women had euploidy of 39.74% Vs Older women 27.2 %

Group B - Younger women had euploidy of 40 % Vs Older women 28 %

Choice of culture media does not seem to affect the euploid status of the embryos. We did an age stratification to rule out age related decrease in the euploidy status. Advanced maternal age with either sequential or single step media did not seem to affect the euploid rates of the embryos.

CONCLUSIONS: Sequential or Single step culture media in the embryo culture system do not seem to have an effect on the policy status of an embryo. Based on the data from this study we can opt to use any system of media for embryo culture.

P-64 4:30 PM Saturday, October 17, 2020

IMPACT OF BLASTOCYST MORPHOLOGY GRADING ON PREDICTING IMPLANTATION OF EUPLOID EMBRYOS IN GESTATIONAL CARRIERS. Jordana Mashiach Friedler, MD MHA,[1] Michal Dviri, MD,[2] Anjila Roumia, MD,[3] Noga Fuchs Weizman, MD,[1] Shira Baram, MD,[1] Clifford Lawrence Librach, MD[1] [1]CReATe Fertility Centre, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]CReATe fertility centre, Toronto, ON, Canada.

OBJECTIVE: Our study aimed to investigate the correlation between static morphology of euploid embryos and pregnancy outcome in the optimal setting of sFET to a Gestational carrier (GC).

DESIGN: Retrospective cohort study. We reviewed all the single FET using euploid embryos and GCs at CReATe fertility center, Toronto Canada between Jan 2017 and Mar 2019. Mosaic embryo transfers were excluded. Only GC were included to eliminate other factors that may impact implantation.

MATERIALS AND METHODS: Blastocysts were graded immediately before TE biopsy according to the degree of expansion and ICM and TE morphology. using a modified SART method. The grading was as follows: ICM A-round/oval, tightly packed/compacted cells; B- not oval, partly spread and some tight cells; C-small/few cells and loosely group; D-seldom scattered cells, no visible cohesion, empty and degenerating. TE: A-many highly compacted cells, cohesive epithelium; B- few, slightly larger cells, continuous epithelium; C-less, larger cells, no continuous epithelium; D-very few cells, around 2-5 cells, degenerating. All embryologists are trained in order to minimize inter-observer variability in embryo grading, and standardize their biopsy technique. All PGT samples were analyzed using standard NGS methodology and reported as euploid, aneuploid or mosaic. The GCs have all had at least one successful pregnancy of their own, and went through an evaluation that included a medical assessment, lab testing and anatomical investigation of their uterus via pelvic ultrasound and sonohysterography. All FET were preformed using a HRT primed protocol of estrogen either PO, trans-dermal or both. After achieving a sufficient endometrial thickness of at least 7mm, progesterone, either IM or vaginal was added and timed with the embryo transfer. Ongoing pregnancy (OGP) is defined as a pregnancy passed 12 weeks gestation. Implantation was regarded as all patients that had either biochemical pregnancies, early miscarriages and OGP or Live birth.

RESULTS: 319 euploid embryo transfers to GCs were identified. The following data was collected: age at OPU, type of HRT preparation and endometrial thickness at day of Progesterone initiation. We compared pregnancy and implantation rates in groups according to ICM grade , TE grade and built a three tier system in which AA,AB,BA were regarded -GOOD; CA,CB,AC,AB were regarded FAIR; CC, DA, DB, DD, AD, BD, CD were regarded POOR - P>0.05 . Implantation and pregnancy rates of the euploid embryos were similar in all groups regardless of the morphology grading.

CONCLUSIONS: In euploid embryos morphologic grading of ICM or TE alone or in combination was not found to be a predictor of implantation or pregnancy. Therefore, other strategies for prioritization of euploid embryos should be explored to help prioritize embryos and maximize pregnancy rates per transfer.

P-65 4:30 PM Saturday, October 17, 2020

EFFECT OF LASER-ASSISTED HATCHING ON CLINICAL AND NEONATAL OUTCOMES IN PATIENTS UNDERGOING SINGLE VITRIFIED-WARMED BLASTOCYST TRANSFERS. Yuji Endo, Ph.D,[1] Yoshitaka Fujii, Ph.D,[2] Shingo Mitsuhata, M.S.,[2] Momoko Hayashi, B.Sc.,[2] Hiroaki Motoyama, MD.[3] [1]Chief Embryologist, Kurashiki, Japan; [2]Embryologist, Kurashiki, Japan; [3]Chief doctor, Kurashiki, Japan.

OBJECTIVE: The American Society for Reproductive Medicine recommends minimal use of assisted hatching (AH) procedures for all patients undergoing *in vitro* fertilization (IVF), due to poor live-birth data and increased risk of multiple pregnancies (1). However, it can still be disputable considering that no comparison was made between various techniques of AH, different stages of embryo, and types of cycle. Thus, there is a clash of viewpoints in term of AH effectiveness. Furthermore, very few follow-up studies of newborns after AH have been reported. This study aims to determine the effect of laser-AH on clinical and neonatal outcomes in patients undergoing IVF using single vitrified-warmed blastocyst transfers.

DESIGN: A retrospective, observational study.

MATERIALS AND METHODS: During June 2014 and March 2018, a total of 453 warmed blastocyst transfer cycles, including 279 patients (mean age = 34.0±3.9) were analyzed; of which, 231 cycles were treated by laser-AH and 222 cycles with no treatment were used as control. The day 5 blastocyst before vitrification that was expanded and had a good quality was enrolled in this study. During blastocyst warming, multiple laser beams cut off a small section of the zona pellucida (ZP) area where empty perivitelline space was found. After an overnight culture, a re-expanded blastocyst that had survived was transferred and followed up until the delivery of a

newborn. The primary outcome was live-birth rate. Secondary outcomes were completely hatched rate, clinical pregnancy rate, and neonatal outcomes, including the average gestational weeks, birth weight, malformation rate, and twin-birth rate.

RESULTS: Following overnight culture, the completely hatched rate was significantly higher in AH treatment group than in the nontreatment control group (90% versus 3%, respectively, P<0.01). The quality of the transferred blastocysts was comparable between the two groups. However, statistically, AH group had a significantly higher clinical pregnancy (49% versus 37%, P<0.01) and live-birth delivery (42% versus 27%, P<0.01) rates compared to the control group. Neonatal data were collected from 84 babies in the AH group and 55 babies in the control group. No differences were observed between both groups with respect to the average gestational weeks (39±1.6 weeks vs. 38±3.5 weeks), birth weight (3029±411 g vs. 3003±702 g), and malformation (0% vs. 2%) in newborns, respectively (P>0.05). All of them were single live births.

CONCLUSIONS: The laser-AH treatment increased live-birth rate after the transfer of a vitrified-warmed blastocyst and had no adverse effects on neonatal outcomes. The warmed blastocyst with partially removed ZP encouraged the hatching processes without cell trapping and slitting. The laser-AH did not increase the risks of multiple pregnancies after single blastocyst transfer; however, the low number of outcomes limits this interpretation. Our findings are consistent with the findings of Alteri et al. (2) who systematically evaluated the AH results of all available publications.

SHORT ABSTINENCE IS A GOOD STRATEGY FOR TREATING VERY SEVERE OLIGOASTHENOTERATOSPERMIC (OAT) COUPLES.

Patrizia Maria Ciotti, BSc,[1] Nilla Calza, BSc,[1] Silvia Zuffa, Lab Technician,[1] Leonardo Notarangelo, BSc,[2] Elena Nardi, PhD,[2] Giuseppe Damiano, MD,[1] Linda Cipriani, MD,[1] Eleonora Porcu, MD[3] [1]University-Hospital S.Orsola - Bologna, Bologna, Italy; [2]University of Bologna, Bologna, Italy; [3]Infertility and IVF Center, S.Orsola University Hospital, Medical and Surgical Sciences Department (DIMEC) University of Bologna, Bologna, Italy.

OBJECTIVE: Sexual abstinence is considered one of the several factors that influence sperm quality. Recent studies show that a shortening could be beneficial mostly in OAT patients. The present study has the objective to study the efficiency of a second semen sample produced after a short abstinence in severe OAT infertile patients.

DESIGN: retrospective study. 127 cycles performed at our University Hospital Infertility Center (May 2014 - May 2018) were divided into two groups:

Group 1 (Study Group): 75 cycles. Very severe OAT patients with the following characteristics on the day of treatment:

1) count < 0.2x106/ml, without progressive motility;
2) count > 0.2x106/ml, and no total or progressive motility;
3) 0% normal morphology.

Two samples were requested.

Group 0 (Control Group): 52 cycles. Normospermic or light OAT patients programmed for treatment the same day of at least one couple of Group 1.

Semen parameters and outcomes were compared between Groups.

MATERIALS AND METHODS: Group 1: 75 cycles (59 fresh, 16 with thawed oocytes), Group 0: 52 cycles (43 fresh, 9 with thawed oocytes). Ovulation was induced with r-hCG administered 36h before oocytes retrieval. Oocytes cryopreservation were carried out by vitrification/warming. ICSI was utilized as insemination technique for all oocytes.

RESULTS: women's mean age Group 1 (36.96±3.95) and Group 0 (37.4±3.92) and men's mean age Group 1 (40.57±5.49) and Group 0 (40.56±5.41) were not significantly different ($P = .834$, $P = .954$ respectively). Conventional semen parameters were compared between sample of Group 0 vs 1° sample of Group 1. All parameters, excluding volume, resulted significantly different (*P<.001)*. The same comparison was done between 1° and 2° sample of Group 1. Significant differences were found between volume, total and progressive motility ($P < 0.001$).

The percentage of utilization of Group 1 semen samples for ICSI was as follows: 1° sample (6/70) 8.6%; 1°+2° samples (18/70) 25.7%; 2° sample (46/70) 65.7%.

A total of 383 oocytes (321 fresh and 62 thawed) were inseminated.

Fertilization, pregnancy rate/transfer, implantation and miscarriage rates were 63% and 86% ($P<.001$), 34.8% and 30.6% ($P = .78$), 23.3% and 17.5 ($P = .35$), 25% and 20.0% ($P = .002$) in Group 1 and Group 0 respectively.

CONCLUSIONS: Results show that short abstinence in severe OAT patients allows us to obtain sperms with better motility to be used for ICSI. The request of a second semen sample in couples with extreme semen parameters is a valid and simple strategy that helps to obtain the same probability of pregnancy compared to a Control Group. Furthermore, it allows us to utilize fresh sperms avoiding to resort to cryopreserved reserve or testicular surgery.

GDF9 IN DAY 3 EMBRYO CULTURE MEDIUM IS A STRONG PREDICTOR OF EMBRYO QUALITY.

Jing Yu Li, PhD,[1] Guoning Huang, M.D[2] [1]Chongqing Key Laboratory of Human Embryo Engineering,-Chongqing Reproductive and Genetics Institute, Chong Qing, China; [2]ChongQing Health Center for Women and Children.

OBJECTIVE: To explore the whether the concentration of GDF9 in Day 3 culture medium can be used as non-invasive biomarker for predicting embryo quality.

DESIGN: Prospective study.

MATERIALS AND METHODS: A total of 70 patients who obtained at least 2 transferable and 2 untransferable embryos with 6-12 blastomeres at Day 3 were enrolled into the present study. Four spent culture medium corresponding to the 2 good quality embryos and 2 bad quality embryos from each patient were collected. The concentration of GDF9 in embryo culture medium was quantified by ELISA. Statistical analyses defined correlations between GDF9 concentration and embryo quality.

RESULTS: Good-quality embryos exhibited a significantly lower concentration of GDF9 compared with bad-quality embryos, suggesting that GDF9 in culture medium is an objective marker for embryo quality assessments. The GDF9 concentration in the medium increased with the increasing of embryo fragmentation. The receiver operating

characteristic curve for good-quality embryos by GDF9 concentration in the culture medium had an area under the curve of 0.785, and using a threshold of 796.5 pg/ml, sensitivity and specificity values were 61.31 and 89.47 %, respectively.

CONCLUSIONS: The determination of GDF9 concentration in the culture medium can be used to predict good-quality embryos.

SUPPORT: No

COMPARABLE PREGNANCY OUTCOMES BETWEEN HIGH-SCORE BLASTOCYSTS WITH LOWER EXPANSION GRADE ON DAY 5 AND HIGHER EXPANSION GRADE ON DAY 6: AN ANALYSIS OF 1751 FROZEN-THAWED CYCLES.

Yingchun Guo, M.D., Tingting Li, Doctor, Yi Zhou, Master, Lei Jia, Master, Cong Fang, Ph.D. Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To identify blastulation and expansion grade predictive of pregnancy and live births outcomes with high-score blastocysts in frozen-thawed transfer cycles.

DESIGN: A retrospective study was conducted with clinic-based data in the Reproductive Medicine Centre of the Sixth Affiliated Hospital of Sun Yat-sen University from February 2014 to April 2020.

MATERIALS AND METHODS: High-score blastocysts frozen on day 5 (grade 3AA, 3AB, 3BA or 3BB) or day 6 (grade ≥4 and neither C grades in the evaluations of ICM nor TE) using vitrification-freezing protocol were included. Endometrial preparation was carried out with natural cycle, hormone replacement cycle or controlled ovarian hyperstimulation cycle accordingly. Progesterone administration was commenced when the thickness of endometrium reached 8 mm or more. Single embryo was transferred on day 5 after ovulation or progesterone supplementation. Difference in baseline characteristics, characteristics of embryo transfer cycles and clinical outcomes between two groups were assessed. Statistical analyses were performed stratified by age and anti-Müllerian hormone (AMH).

RESULTS: A total of 617 blastocysts in day 5 group and 1134 blastocysts in day 6 group were assessed. As a whole, patients in day 5 group were

younger than patients in day 6 group (34.22 versus 34.73, P = 0.041). No significant differences were observed in characteristics of transfer cycles, clinical pregnancy rate and live birth rate between groups. Stratified analyses showed that the biochemical pregnancy rate and clinical pregnancy rate were higher in day 5 group for patients aged below 30 years (60.6% versus 43.8%, P = 0.001 and 55.8% versus 38.2%, P < 0.001, respectively) when basic patient demographics were comparable, while rates of miscarriage, ongoing pregnancy and live birth were similar between groups. No significant differences were found in pregnancy outcomes for patients in other subgroups (31 to 35 years, 36 to 40 years, > 40 years). Stratified by AMH (< 1.1 ng/ml or ≥1.1 ng/ml), pregnancy outcomes were all comparable between day 5 group and day 6 group.

CONCLUSIONS: In frozen-thawed transfer cycles, the pregnancy potential of high-score blastocysts with lower expansion grade on day 5 and higher expansion grade on day 6 are comparable for patients aged above 30 years.

P-69 4:30 PM Saturday, October 17, 2020

EFFECT OF TROPHECTODERM GRADE OF BLASTOCYST AT EMBRYO TRANSFER ON PREGNANCY OUTCOMES.

Kathryn D. Coyne, MD, Mabel Lee, MD, Lauren Alexis Palavos, BS, James Hamrick, BS, Brooke A. Belvin, BS, Rachel S. Weinerman, MD, Rebecca Flyckt, MD, James H. Liu, M.D., Sung Tae Kim, PhD, HCLD University Hospitals Fertility Center/Case Western Reserve University, Beachwood, OH.

OBJECTIVE: To evaluate the effect of trophectoderm vs. inner cell mass grade of blastocyst at time of embryo transfer on pregnancy outcomes.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients undergoing both fresh and frozen-thawed single embryo transfer (ET) from January 2017 to March 2020 in our center were included. Following a standard FET protocol, vitrified blastocysts were rewarmed on the day of ET and images of the thawed embryo were taken prior to transfer. Similarly, images of fresh embryos prior to transfer were taken. These images were reviewed by at least two embryologists and each were assigned a grade by Gardner's blastocyst grading scale. High quality grades were defined as A or B grades. Fair quality grades were defined as C grades. Groups for analysis included blastocysts with both high quality inner cell mass and trophectoderm grades (group A), blastocysts with high quality inner cell mass grade and fair trophectoderm grade (group B), and blastocysts with fair quality inner cell mass grade and high trophectoderm grade (group C). Primary outcomes included: pregnancy, clinical pregnancy, miscarriage, and ongoing pregnancy and live birth. Statistical analyses were done using ANOVA for continuous data and Chi Square for dichotomous outcomes.

RESULTS: A total of 531 fresh and frozen single ET cycles were analyzed in the study. There were 384 group A embryos, 129 group B embryos, and 18 group C embryos. The mean age, BMI, and endometrial thickness was not significantly different between the groups (p=NS). There were no significant differences in pregnancy rates (70.1% vs. 69.0% vs. 66.7%; p=NS), clinical pregnancy rates (63.3% vs. 59.7% vs. 61.1%; p=NS), ongoing or live birth rates (53.4% vs. 48.8% vs. 38.9%; p=NS) or miscarriage rate (8.6% vs. 10.1% vs. 22.2%; p=NS) between group A, B, and C, respectively. The majority of transferred embryos were of high quality inner cell mass and trophectoderm grades (72.3%).

CONCLUSIONS: There appears to be no difference in pregnancy outcomes when comparing high quality inner cell mass grade with fair quality trophectoderm grade vs. fair quality inner cell mass quality and high quality trophectoderm grade. Thus, this study demonstrates that the grade of trophectoderm does not have a greater impact than that of the inner cell mass on pregnancy outcomes, as had been hypothesized and shown in other studies. Further, embryos with both fair inner cell mass and trophectoderm grades have potential for good pregnancy outcomes. Morphology evaluation is subjective and dependent on embryologist assessment; therefore, each center should perform their own data analysis in order to establish a morphology standard for embryo selection for transfer.

P-70 4:30 PM Saturday, October 17, 2020

IS IT POSSIBLE TO PREDICT THE RESULT FOR THE TUNEL ASSAY FROM A ROUTINE SPERMOGRAM ANALYSIS?.

Roxana Vanina De Caro, Medical Doctor,[1] María Pía Zappacosta Villarroel, Medical Doctor,[1] Belen Garcia Ojeda, Medical Doctor,[1] Mercedes Leticia Guidobono, Embryologist,[2] Raymond Joseph Osés, Medical Doctor,[2] Alberto Kenny, Medical Doctor,[1] Roberto Inza, Medical Doctor[1] [1]IFER, Ciudad Autonoma de Buenos Aires, Argentina; [2]IFER, Ciudad Autónoma de Buenos Aires, Argentina.

OBJECTIVE: to investigate the spermogram parameters which might have an association with sperm DNA fragmentation.

DESIGN: cross-sectional study.

MATERIALS AND METHODS: This study was performed between December 2013 and December 2019. Routine spermograms and sperm DNA fragmentation tests (TUNEL) were performed in 600 samples by the same observer in a Fertility Center in Buenos Aires. Spermogram parameters were recorded according to WHO guidelines. The dependent variable was the TUNEL test, which was confronted to the rest of the spermogram parameters. To estimate the predictive value for the TUNEL test we used the multiple linear regression analysis. Statistical analysis was performed with Stata 12, considering p <0.05 as a significant value.

RESULTS: The parameters associated with the possibility of predicting the TUNEL test result were: patient's age (more than 45 years old), semen volume, percentage of progressive motility and total sperm retrieved in the swim up. The model showed a significant difference (test F <0,0001) and the variables included had a p < 0.05 value.

CONCLUSIONS: There is an association between some spermogram parameters and the TUNEL test. These parameters were: patient's age, semen volume, percentage of progressive motility and total sperm retrieved in the swim up. This mathematical model is particularly suited to this data set, but with a high predictive value. These results cannot be taken properly exhaustive, but as an hypothesis generator for future studies and perhaps councelor when requesting a TUNEL test. A larger sample study is required to validate these findings.

REPRODUCTIVE & PERINATAL OUTCOMES OF FRESH VERSUS FROZEN TESTICULAR SPERM IN NON-OBSTRUCTIVE AZOOSPERMIA MEN.

Sakshi A. Longani, Masters in Biotechnology,[1] Krishna Mantravadi, Sr., MBBS, PGDHOM, Masters in clinical embryology,[2] Durga Gedela Rao, Sr., MRCOG,[2] Sandeep Karunakaran, Sr., M.B.B.S, MS, PGDHM, PGDMLE,[1] Rajesh Mani Raghupathy, MBBS, PGDCE,[1] Yedluri Rupasree, M.Sc Biotechnology, PhD Biotechnology, PGDCE,[2] Afsha Firdouse, M.Sc Biochemistry, PGDCE[2] [1]oasis fertility, Hyderabad, India; [2]Oasis fertility, Hyderabad, India.

OBJECTIVE: To investigate Reproductive & Perinatal Outcomes of Fresh or Frozen-thawed surgically retrieved sperms (SRS) in Non-Obstructive Azoospermia (NOA) individuals

DESIGN: Retrospective data Analysis of (n=108) patients undergoing SRS during January 2013 to June 2019.The study group was divided into two groups, Fresh SRS (n=60) and Frozen SRS (n=48) in our private IVF clinic.

MATERIALS AND METHODS: **Study Design and Duration-**Retrospective data Analysis of (n=108) patients undergoing SRS during January 2013 to June 2019.The study group was divided into two groups, Fresh SRS (n=60) and Frozen SRS (n=48) in our private IVF clinic.

Inclusion-Couples undergoing Assisted Reproductive Technique (ART) cycles where the women were < 37 years old and male partners had NOA and had a successful retrieval of sperm, were included. Only self-gamete cycles were considered.

Exclusion –Advanced maternal age (>38yrs), People with no sperm retrieval, People who did not have viable sperms after freezing and thawing.

Women underwent controlled ovarian stimulation and oocyte retrieval (OPU) as per our clinic's standard operating procedure (SOP). Male partner's

underwent SRS and testicular sperms were either used for ICSI if done at OPU or frozen and thawed for use in subsequent cycles as per SOP. Embryos cultured till blastocyst stage and freeze all policy was adopted. Couples underwent Frozen embryos transfers with two blastocysts and reproductive outcomes were evaluated.

Primary Outcome- Blastocyst Rate (BR), Implantation Rate (IR), Live Birth Rate (LBR).

Secondary Outcome-Fertilization Rate (FR), Miscarriage Rate (MR), Clinical Pregnancy Rate (CPR), Perinatal Outcomes.

RESULTS: The Reproductive outcome for Fresh and Frozen Surgically Retrieved Sperms, respectively were, **Fertilization Rate** was 92.72 % v/s 92.74 % (p value 0.9968)

Blastocyst Rate was 46.74 % v/s 35.57 % (p value 0.2444)

Implantation Rate was 43.97 % v/s 47.27 %(p value 0.7334)

Clinical Pregnancy Rate was 59.67 % v/s 73.33 % (p value 0.1390)

Live Birth Rate was 45.16 % v/s 63.33 % (p value 0.0612)

Miscarriage Rate was 4.84 % v/s 3.33 % (p value 0.6978)

Perinatal Outcomes

Both study groups had comparable perinatal outcomes with no concerning trends.

Congenital anomalies - Only One baby from fresh SRS had Anglemans syndrome.

There isn't a marked difference in the outcomes between Fresh or Frozen SRS. Freezing testicular sperms doesn't seem to alter reproductive and perinatal outcomes.

CONCLUSIONS: Frozen Testicular Sperm seem to offer comparable outcomes with Fresh Testicular sperms in ART cycles. All trial attempts for sperm retrieval should be backed up with cryopreservation.

P-72 4:30 PM Saturday, October 17, 2020

IMPACT OF SEMEN PARAMETERS IN INTRACYTOPLASMIC SPERM INJECTION (ICSI) OUTCOME IN FRESH OVODONATION PROGRAM. Maria Cecilia, Delpiccolo, Embryologist, Valentina Torres, Monserrat, Embryologist, Maria Noelia, Lardizabal, Embryologist, Nicolas Carizza, Gynecologist, Trinidad Leiva, Gynecologist, Estefania Navall, Gynecologist, Sofia Ana, Dominici, Gynecologist, Ariadna Sol Ruiz, Gynecologist, Carlos Carizza, Medical Director Fertya, Rosario, Argentina.

OBJECTIVE: The main objective of this study is to analyze the relationship between semen parameters and fertilization, blastulation and implantation rate in donated fresh oocytes.

DESIGN: A retrospective study comparing results obtained in fertilization, blastulation and implantation rates using fresh oocytes from young and healthy donors microinjected in the period 2017-2018. We included a total of 98 patients in the analysis, who received at least five fresh oocytes from our egg bank undergoing ICSI treatment using their partners´semen samples. Considering a successful treatment those whose fertilization rate were $\geq$70% and blastulation rate were $\geq$40%, we defined different groups of treatments (successful vs. unsuccessful, regarding fertilization or blastulation rates) and analyzed the semen parameters according to WHO (World Health Organization) within groups. We also evaluated if implantation rate was related to semen quality obtained in a previous semen analysis.

MATERIALS AND METHODS: Embryos obtained from fresh oocyte cycles of ICSI in our private clinic were incubated in K-System® G-185 incubator or ThermoFisher Scientific® Heracell 150i incubator with Sage® Medium or Global Total® Medium. Semen samples were washed and prepared using density gradient Irvine® media. The different semen parameters were previously analyzed using the software computer-aided sperm analysis (CASA) Ivos II™ Hamilton Thorn® and the Halosperm® technique to evaluate the sperm DNA damage. The Chi square independence test and Fisher's exact test was used to compare groups regarding implantation, blastulation, fertilization (2PN) rates and the different semen parameters previously analyzed in the seminogram. Statistical difference was represented by a $p<.05$.

RESULTS: Our results show that there is no statistical difference in sperm concentration between groups, considering both fertilization rates (p-value= .118) or blastulation rates (p-value= .815). The same results were obtained for sperm morphology related to successful fertilization (p-value= .459), and blastulation (p-value= .970). No relationship was obtained between DNA fragmentation and successful fertilization (p-value= .566) or blastulation (p-value= .385). An interesting result was obtained for spermatozoa motility, which shows a statistical difference in total motility related to successful fertilization rate (p-value= .039) but no difference to blastulation rate (p-value= .872). In addition, we analyzed if there was a relationship with altered seminograms values (semen analysis which shows at least one altered parameter) and implantation rate, the result showed no statistical difference (p-value= .858).

CONCLUSIONS: Analyzing different covariates we only found statistical difference in favor of total sperm motility and successful fertility rate but no statistical difference in blastulation rate. Based on our results, we can conclude that semen quality seems not to be decisive or determinant for the success of the fertilization, blastulation and implantation rate using oocytes of healthy and young patients in ICSI treatments.

P-73 4:30 PM Saturday, October 17, 2020

EFFECT OF CULTURE MEDIUM ON BLASTOCYST DEVELOPMENT. Deepti Tiwari, MS,[1] Caroline McCaffrey, PhD,[1] Roberto Olivares, BS TS,[1] Barry Witt, MD[2] [1]NYU Langone School of Medicine, New York, NY; [2]Greenwich Fertility and IVF Center, Greenwich, CT.

OBJECTIVE: To compare a commercial medium with our established medium in the IVF lab in terms of blastocyst formation, utilization and development.

DESIGN: Medium I was assessed for performance alongside our standard culture Medium G in a pilot sibling oocyte study. Having confirmed successful performance of Medium I a prospective comparison of both media was undertaken to compare development of thawed donor eggs. Chosen KPIs for comparison were Blastocyst Formation (BFR), Blastocyst Utilization (BUR) rates and BUR on Day 5.

MATERIALS AND METHODS: In the sibling oocyte comparison a total of 19 patients were selected based on sufficient numbers of eggs to split (N = 12). On Day 1 following fertilization check zygotes displaying 2PN from sibling oocytes were split between Media I and G, both supplemented with 10% protein supplement and equilibrated in conditions yielding manufacturers' recommended pH values. Embryo assessment was conducted on days 5, 6 and 7. Trophectoderm biopsy and subsequent blastocyst vitrification was carried out on good quality blastocysts on Days 5 through 7 as appropriate.

In the second phase of the study thawed donor eggs were placed in either Medium I or Medium G immediately following ICSI and cultured through day 7. All other culture conditions such as incubator conditions, culture dishes, culture drop volume, oil overlay etc were maintained constant in all stages of the comparison.

RESULTS: In the sibling oocyte study 19 patients yielding a total of 218 x 2PN were separated into 2 groups for culture in medium I or G. BFRs of 64% (51/80) vs 55% (72/131) (p = 0.94), BURs of 56% (45/80) vs 47% (62/131) (p = 1.0) and EU of 21% (17/ 80) vs 17% (23/131) (p = 0.83) were achieved in Medium I & G respectively. There was no significant difference in % blastocysts that developed to usable blastocysts on Day 5 in Medium I (33%) when compared to Medium G (23%) despite a trend suggesting that Media I supported a higher Day 5 blastocyst development.

The table below shows the results for the thawed donor eggs.

	Medium I	Medium G	Sig
Egg thaw N cycles	7	6	
Fert rate (2pn / # ICSI'd)	35/43 (81%)	30/49 (61%)	0.04 (Sig)
BFR (# Blast/ # ICSI'd)	23/43 (54%)	20/49 (41%)	0.30 NSD
BUR Day 5 (Usable Blasts/ # ICSI'd)	11/43 (26%)	6/49 (12%)	0.11 NSD
BUR Total (Usable Blasts / # ICSI'd)	17/43 (40%)	17/49 (35%)	0.67 NSD

CONCLUSIONS: Both culture media supported a similar proportion of blastocyst formation and utilization. Although there was no significant difference in BFR, BUR or BUR on day 5 between the 2 media this allowed the lab to maintain redundancy with culture conditions should an emergency arise with a single supply chain. In addition, it provides an extra level of QC in the lab with a media comparison

SUPPORT: No Financial support.

P-74 4:30 PM Saturday, October 17, 2020

EFFECT OF MEDIA CHANGE PARADIGMS ON THE EFFICACY OF A SINGLE STEP CULTURE MEDIUM. Rebecca Holmes, PhD, HCLD,[1] Jason E. Swain, PhD, HCLD,[2] William B. Schoolcraft, MD,[3] Rebecca L. Krisher, PhD[4] [1]CCRM Boston, Newton, MA; [2]CCRM IVF Network, Lone Tree, CO; [3]Colorado Center for Reproductive Medicine, Lone Tree, CO; [4]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: Sequential and single step culture media are both popular choices embryo culture. The objective of this study was to compare the impact of sequential versus single step culture media on outcomes following different media exchange paradigms.

DESIGN: Prospective randomized trial using sibling oocytes.

MATERIALS AND METHODS: All procedures were conducted at a single IVF center and all PGT-A results were from a single genetics lab. Our objective was to study the impact of the culture medium itself so all other variables were controlled for. After ICSI, sibling oocytes were randomly allocated between two dishes containing either an in-house formulated sequential media or a single-step media (CSCM-NX, Irvine Scientific). All media were supplemented with the same lot of 10% SPS protein and cultured in a K systems G210 incubator under 4 mL oil with ~ 6% CO2 and 5% O_2. In phase I, media was exchanged following 24h (PN check), 72h (D3) and 120h (D5) of culture. In Phase II media was only exchanged at 72h. Data were analyzed using Fisher's Exact Test

RESULTS: In phase 1 with media changes on days 1, 3 and 5, although not statistically significant more blastocysts were observed in the single-step media on day 5, 6 and 7, including good quality blastocysts. However a higher aneuploidy rate was observed in the single step medium resulting overall in no more usable blastocysts. In phase II with a single media change on D3, the sequential system yielded more euploid blastocysts compared to the single step medium.

	Phase I		Phase II	
Media type	Sequential	Single step	Sequential	Single step
# patients	13	13	26	26
# oocytes	60	64	178	192
fert rate	86.7	82.8	85.4	82.8
%day 5 blasts	46.2	62.3	58.6	57.2
% day 7 blasts	61.5	73.6	70.4	71.7
% ≥3BB day 5	23.1	32.1	28.9	31.4
% ≥3BB day 7	46.15	56.60	46.7	50.9
% Euploid blast	54.17	43.33	59.6_a	45.3_b

CONCLUSIONS: A 10% increase in usable blastocysts was observed in the single-step medium when refreshed every 48. However PGT-A revealed a >10% decrease in euploid blastocysts in the single-step medium resulting in no overall difference in the percentage of transferable euploid embryos per zygote. When media refresh was done on day 3 only, there was no significant difference in usable blastocysts between the media systems. However, a significant decrease in the percentage of euploid blastocysts was observed using the single-step medium.

In our hands, this single-step media with multiple media changes results in more blastocysts available for biopsy, but did not result in more euploid blastocyst available for transfer. With a single media change there was no advantage in blastocyst development while reduced euploidy persisted. This data suggests that embryo ploidy can be affected by culture medium and sequential media is preferred based on the two media tested here.

P-75 4:30 PM Saturday, October 17, 2020

SINGLE-LAYER DENSITY GRADIENT CENTRIFUGATION IS A SIMPLE AND EFFECTIVE SPERM PREPARATION APPROACH IN DECREASING THE INCIDENCE OF THE CONTAMINATION ORIGINATED IN THE POTENTIAL PATHOGENS IN HUMAN SPERM SAMPLES DURING IVF PRACTICE. Yongrui Du, Ph.D. Tianjin Central Hospital of Gynecology Obstetrics, Tianjin, China.

OBJECTIVE: The aim of this study was the evaluation of single-layer density gradient centrifugation, compared with swim-up step, on decreasing the occurrence of the embryo contamination from purified sperm pellets in couples undergoing conventional IVF.

DESIGN: a retrospective cohort study

MATERIALS AND METHODS: Patients less than 45 years of age who participated in a fresh IVF-ET cycle from January 2017 to May 2020 were included in this study. Poor responders with less than three mature oocytes were excluded. Patients were requested to abstain for three days sexually. G-IVF medium (GIM) was used in combination with Single-layer density-gradient centrifugation (SDGC) or swim-up (SUP) methods for sperm preparation. A total of 2565 fresh conventional IVF cycles were grouped according to methods used for sperm preparation and retrospectively analyzed (SDGC, n=997; SUP, n=1568) differences in the incidence of bacterial embryo contamination originated in purified sperm pellets and some key performance indicators (fertilization rate, good quality embryo rate, and pregnancy rate).

RESULTS: With SDGC, we identified no patient's embryos contaminated (0/997) from purified sperm pellets during conventional IVF. With swim-up, we identified 14 (14/1568) patients' embryos bacterial contaminated. Total fertilization rates were not statistically different between the SDGC and SUP groups (86.7% vs. 83.1%, respectively, p=0.248); while significant differences were found in 2PN fertilization rate (75.8% vs. 63.5%, p=0.045), and good embryos rates (47.1% vs. 41.9%, p=0.028).

CONCLUSIONS: Centrifugation through single-layer density gradient centrifugation efficiently diminished the bacterial contamination if strict aseptic techniques were also used.

P-76 4:30 PM Saturday, October 17, 2020

INCREASING THE AMOUNT OF LEARNING DATA FOR DEEP LEARNING IS EFFECTIVE IN IMPROVING THE AUTOMATIC PRONUCLEUS NUMBER DETECTION SYSTEM FOR HUMAN EMBRYOS. Hiroya Kitasaka, Ph.D.,[1] Noritaka Fukunaga, Ph.D.,[1] Sho Sanami, Ph.D.,[2] Hiroyuki Watanabe, M.S.,[1] Yuji Tsuzuki, M.S.,[2] Yuta Kida, M.S.,[1] Seiji Takeda, M.S.,[2] Fumiya Kondo, M.S.,[1] Sho Takeda, B.S.,[1] Yoshimasa Asada, M.D., Ph.D.[1] [1]Asada Ladies Clinic, Nagoya, Japan; [2]Dai Nippon Printing Co., Ltd., Tokyo, Japan.

OBJECTIVE: Deep Learning (DL) technology is a set of machine learning techniques to train artificial neural networks, which are systems that mimic interactions of human nerve cells. By using a neural network with multiple layers, it is possible to learn features included in data and to obtain capability to recognize images. We have already reported the development of the first automatic system to detect pronuclear number for human embryos by using DL technology. However, the detection accuracy was low in 1PN and 3PN human embryos. In this study, we examined whether the detection accuracy could be improved by increasing the amount of training data of 1,3PN embryos.

DESIGN: Prospective study using DL technology. The pronuclear number detection algorithm was constructed by using neural networks.

MATERIALS AND METHODS: Embryo images for the training data were acquired by a time-lapse incubator of the fertilization phenomena from ICSI oocytes. The captured interval was 15 minutes over 18 hours, and 32152 images taken over the time period were used. The same embryos (n=983) were used for comparison of two networks trained with different amounts of training data. A network was trained with 0PN: 14652, 1PN: 469, 2PN: 15788, 3PN: 154 images from time-lapse images in which the embryologist had visually determined the pronuclear number. Another network was trained with same number of 0PN and 2PN images and with an increased number of 1PN: 990 and 3PN: 722 images. The pronuclear number detection rates were then compared.

RESULTS: The detection rate of the pronuclear number before the increase in number of training data vs. after the increase was 100% vs 98.1% for 0PN, 29.2% vs 53.6% for 1PN, 95.0 vs 89.9% for 2PN and 0% vs 21.9% for 3PN. By increasing the amount of training data, 1PN detection rate was higher and the detection rate for 3PN was significantly improved (P <0.01, Fisher's exact test).

CONCLUSIONS: By increasing the amount of training data we have demonstrated that the accuracy of automatic pronucleus detection can be improved for 1PN and 3PN embryos. By exposing DL technology to increasingly larger amounts of data improved performance of the automatic system can be obtained. This can be usefully applied for automation of tasks such as

evaluating human pronuclear oocytes and hence it can be a powerful support tool for embryologists.

AUTOMATED IDENTIFICATION OF DEGRADED AREAS WITHIN BLASTOCYSTS BY MEANS OF ARTIFICIAL VISION.

Alejandro Chavez-Badiola, MD,[1] Adolfo Flores-Saiffe Farias, Sr., MSc, PhD,[2] Gerardo mendizabal-Ruiz, PhD,[3] Roberto Valencia, MSc, PhD,[2] Andrew J. Drakeley, MD FRCOG[4] [1]IVF 2.0 LTD, Maghull, United Kingdom; [2]IVF 2.0 LTD, Liverpool, United Kingdom; [3]Universidad de Guadalajara, Guadalajara, Mexico; [4]Liverpool Women's Hospital, Liverpool, United Kingdom.

OBJECTIVE: to assess an artificial vision system's capabilities to identify degraded areas within blastocysts in an automated fashion, and based on information extracted from single blastocysts' micrographs.

DESIGN: prospective analysis of blastocysts' micrographs retrospectively obtained from two IVF clinics.

MATERIALS AND METHODS: images of degenerated blastocysts were retrospectively collected from a six consequtive month period. A senior embryologist manually segmentedthe degradated zones of 341 high-quality micrographs of blastocysts. From this ground truth, 10% of the images and their segmentation masks were randomly selected for testing porpuses. All images were preprocessed in four steps, and later passed through 21 different filters (e.g. entropy, Gaussian blur, Laplacian, and Sobel), convolved by 41 texture energy-kernels each, resulting in 861 textures per image. Data augmentation was used on the training set. 50 pixels were randomly selected per zone (background, embryo, and degradated) for each micrograph, and texture-based feature vectors extracted (total database of 140,600 data points), used to train a neural network (three layers with 100 nodes each, Adam optimizer and categorical cross-entropy as the loss function), during 500 epochs with a validation split of 10% of the original datasize, a callback of learning rate reduction (factor of 0.5, patience of 25 epochs, and validation loss as the monitor), and early stopping callback (patience of 60 epochs, validation loss as monitor, and a minimal delta of 0.001). With this texture-based model we computed and concatenated the five masks per image, and trained an autoencoder (AE) consisting of three convolutional and three max-pooling layer for encoding, plus three convolutional and three up-sampling layers for decoding. Model was trained with a mean squared error as the loss function, RMS prop as the optimizer, early stopping and learning rate reduction callbacks (100 epochs), with a 10% validation split. Testing dataset was assessed using Sorensen-Dice coefficient (SDC).

RESULTS: after applying data augmentation techniques, a total of 1228 images became available both for training and validation. After testing, the model obtained a mean SDC of 0.93 on all of the zones; 0.99 when using the background mask alone; 0.72 for the cell mask; and 0.77 for the degraded mask.

CONCLUSIONS: we report an accurate and automated identification of degraded areas within blastocysts, extracted from single static images, and by means of artificial vision. Although a pilot study, successful identification of degenerative patterns within a blastocyst could pave the way to improving already existing embryo classification, and time-lapse algorithms. Further identification of degenerative patterns could help to make better decisions when faced against cryopreserving extremely poor-quality embryos, or discarding "bad looking" embryos with unknown potential. The present tool could also help in the increasing interest around patterns of degradation given different protocols. A larger cohort will be needed for future studies.

USING AN ARTIFICIAL NEURAL NETWORK (ANN) FOR PREDICTING NUMBER OF MATURE OOCYTES AT RETRIEVAL.

Baruch Abittan, M.D.,[1] Jill Karten, M.D.,[2] Alixandra Domney, M.D., M.P.H.,[2] Jesse Stewart, B.A.,[3] Oren Segal, PhD.,[3] Randi H. Goldman, M.D.[1] [1]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Hofstra University, Hempstead, NY.

OBJECTIVE: To develop a prediction model for number of mature oocytes at retrieval using an artificial neural network (ANN).

DESIGN: This was a model-prediction study based on a retrospective cohort of patients who underwent first fresh autologous in vitro fertilization cycles resulting in oocyte retrieval between the years 2016-2019 at a single academic center. Patients were included if anti-Müllerian hormone (AMH) and follicle stimulating hormone (FSH) were recorded within one year of stimulation and were excluded if an aromatase inhibitor was used during the cycle.

MATERIALS AND METHODS: Our dataset consisted of 1011 cycles and was organized into 5 training (n=808) and test (n=203) sets using K-fold cross validation. An ANN was built with the Keras API for TensorFlow and trained on this data. The neural network approximates a function which maps patient- and cycle-specific data (i.e., number of follicles, AMH values, etc.) to the main outcome measure/target variable, number of MII oocytes, using linear regression. Standard regression prediction modeling was also performed and model accuracies were compared by root mean square error (RMSE).

RESULTS: A model for predicting the number of MIIs at oocyte retrieval using parameters available on the day of trigger was designed, implemented, and is currently being beta tested online. Examples of the predicted number of MIIs according to patient- and cycle- specific parameters is shown in the Table. ANN-prediction modeling outperformed standard regression prediction modeling (RMSE: 4.3, and 4.5, respectively). When cycles were limited to those with 12 or fewer MII oocytes retrieved, the RMSE improved to 2.4.

CONCLUSIONS: We have developed a counseling tool to predict the number of mature oocytes at retrieval based on patient-and cycle-specific characteristics available on the day of trigger shot using an ANN, which outperforms standard regression prediction models, and allows for continuous prospective testing and refinement. This tool will be made available to the public following beta testing and we hope that it enhances personalized patient counseling.

	Age (y)	AMH (ng/ml)	FSH dose	Follicles >14mm	Peak E2 (pg/mL)	No. predicted MIIs
Patient 1	35	1.0	5000 IU	10	1700	7
Patient 2	35	3.0	2000 IU	10	3500	12
Patient 3	35	8.0	1500 IU	10	3700	14

P-79 4:30 PM Saturday, October 17, 2020

ARTIFICIAL NEURAL NETWORKS APPLIED FOR PREDICTION OF THE IMPLANTATION POTENTIAL BY USING EMBRYO MORPHOLOGY DYNAMICS.

Lorena Bori, M.Sc,[1] Elena Paya, PhD, Student,[2] María de los Ángeles Valera, PhD, Student,[1] Jose Alejandro Remohi, MD, PhD,[3] Valery Naranjo, PhD,[4] Marcos Meseguer, PhD[5] [1]IVIRMA Global, Valencia, Spain; [2]IVIRMA Global, Instituto de Investigación e Innovación en Bioingeniera (I3B), Valencia, Spain; [3]IVI Foundation IVIRMA, Paediatrics, Obstetrics and Gynaecology Department, Valencia University, Valencia, Spain; [4]Universitat Politécnica de Valencia, Valencia, Spain; [5]IVIRMA Global, Valencia, Spain, Valencia, Spain.

OBJECTIVE: To describe novel embryo morphology dynamics features capable of predicting implantation potential as input data for an artificial neural network (ANN) model.

DESIGN: A retrospective cohort study was performed including 637 patients, from the oocyte donation program of IVI Valencia, who underwent single blastocyst transfer during two consecutive years. All the embryos were cultured in a time-lapse incubator (Embryoscope Plus®). The study was divided into two phases. Phase1: analysis of the impact of novel embryo parameters on implantation. Phase 2: development of an ANN algorithm for implantation prediction

MATERIALS AND METHODS: All the embryos were evaluated with the Embryoviewer®. Novel morphodynamic parameters were measured with the drawing tools, including: distance and speed of pronuclear migration, blastocyst expanded diameter, inner cell mass area and trophectoderm cell cycle length. Conventional morphokinetic parameters (tpb2, tPNa, tPNf, t2, t3, t4, t5, t6, t7, t8, tSC, tM, tSB, tB, tEB, tHiB) and novel proposed morphodynamic parameters were used as input data for the ANN, in the following

manner: ANN1, conventional morphokinetic parameters; ANN2, novel embryo parameters; ANN3, conventional and novel embryo parameters; and ANN4, those parameters which had significant differences between implanted and non-implanted embryos. The architecture of the ANN was a multilayer perceptron (MLP) with two hidden layers and 15 neurons in each one. Dataset was divided into 85% for learning process by using 5-fold-cross-validation approach and 15% for testing the algorithm. The predictive power was measured by using the area under the curve (AUC) of the receiver operating characteristic (ROC) curve.

RESULTS: Out of the total parameters (novel and conventional morphokinetics), t4, t6, t7, t8, t9, tSC, tM, tSB, tB, tEB, blastocyst expanded diameter and trophectoderm cell cycle length had statistically different values in implanted and non-implanted embryos ($p<0.05$). The results in terms of sensitivity, specificity, accuracy, F-Score and area under the curve for the four ANN models in the testing dataset are represented in the Table I. The higher predictive power was achieved by ANN3 with an AUC of 0.77.

TABLE I.

Artificial Neural Network	Sensitivity	Specificity	Accuracy	F-Score	AUC
ANN1	0.88	0.46	0.71	0.78	0.64
ANN2	0.86	0.58	0.75	0.80	0.73
ANN3	0.82	0.67	0.76	0.80	0.77
ANN4	0.85	0.57	0.74	0.79	0.68

CONCLUSIONS: The novel proposed embryo features have influence on the implantation potential and their combination with conventional morphokinetic parameters is effective as input data for a predictive model based on artificial intelligence.

SUPPORT: The authors' research is supported by The Ministry of Science, innovation and Universities CDTI (IDI-20191102), Industrial PhD grant (DIN2018-009911) and Agencia Valenciana de Innovació (INNCAD00-18-009) awarded to M.M. and E.P.

IMPACT OF A COMMERICALLY AVAILABLE SPERM SEPERATION DEVICE (ZYMŌT MULTI) ON SPERM DNA QUALITY COMPARED TO DENSITY GRADIENT SEPERATION WITH SWIM UP.

Alexander Lagunov, MSc,[1] William B. Schoolcraft, MD,[2] Jason E. Swain, PhD, HCLD[3] [1]CCRM Toronto, Toronto, ON, Canada; [2]CCRM Fertility Network, Lone Tree, CO; [3]CCRM IVF Network, Lone Tree, CO.

OBJECTIVE: Isolation of high quality sperm is a pre-requisite for IVF/ICSI to ensure proper fertilization, embryo development and to obtain successful clinical outcomes. The quality of sperm not only entails sufficient motility and morphology, but also involves isolating sperm with high DNA integrity. Various sperm isolation methods exist and some may be superior to others with regard to obtaining sperm with intact DNA. This study compared DNA integrity of sperm isolation using a novel sperm separation device that uses sperm motility and a separation membrane (ZYMŌT Multi) or the traditional density gradient separation (DGS) followed by swim-up approach.

DESIGN: Prospective trial

MATERIALS AND METHODS: Semen samples were obtained from 30 men. All samples were split and processed using both the ZYMŌT MULTI device as well as DGS + swim-up. Briefly, the ZYMŌT preparation entailed adding raw semen to the device inlet port and obtaining isolated sperm from the outlet. DGS + swim-up entailed layer raw semen over the top of a 40%/80% gradient (Puresperm) and spinning the sample at 300xg for 20 minutes followed by two 8 minute washes (Quinn's sperm wash) at 300xg. The pellet was then overlaid by GIVF medium and motile sperm isolated from the top fraction ~1hr later. DNA fragmentation (DFI) was assessed on all isolated samples and also to the raw semen using the TUNEL assay**.** Data were analyzed using ANOVA and Tukey analysis, $p<0.05$.

RESULTS: The DFI of the raw semen was assessed. Use of both sperm separation techniques examined in this study resulted in isolation of sperm with significantly improved sperm DNA integrity compared to sperm from raw semen. There was no statistically difference in in resulting sperm DFI levels between use of ZYMŌT MULTI and DGS + swim up.

	Raw Semen	DGS +Swim-up	ZYMŌT MULTI
Avg Sperm DFI	19.2 ±2.4[a]	7.2±0.9[b]	6.7±0.9[b]

different superscripts represent statistically significant differences between treatments, $p<0.05$

CONCLUSIONS: Different sperm separation techniques can improve sperm DNA integrity compared to sperm found in raw semen. Use the commercial sperm separation device provided no increase in improvement in resulting sperm DNA fragmentation compared to careful sampling of sperm prepared via proper DGS followed by swim-up. Future studies will examine impact of the novel sperm separation device on resulting fertilization, embryo development/aneuploidy and clinical outcomes.

MACS TECHNOLOGY APPLIED FOR SPERM SELECTION IMPROVES BLASTOCYST QUALITY; A CONTINIOUS EMBRYO MONITORING STUDY.

Laura Romany, PhD,[1] Thamara Viloria, PhD,[2] Belén Aparicio-Ruiz, PhD,[1] Diana Beltrán, Master,[3] Jose Alejandro Remohi, MD, PhD,[3] Marcos Meseguer, PhD[4] [1]IVIRMA, Valencia, Spain; [2]IVIRMA Global, Valencia, Spain; [3]IVIRMA Valencia, Valencia, Spain; [4]IVIRMA Global, Valencia, Spain, Valencia, Spain.

OBJECTIVE: To compare the effect of Anexin-V (Magnetic Activated cell sorting) MACS sperm selection method in morphokinetic markers of embryo development, blastulation rate, blastocysts quality, implantation and fertilization rates by using time-lapse monitoring system incubators.

DESIGN: Secondary analysis from a prospective trial.

MATERIALS AND METHODS: A total of 478 patients were distributed in two groups: MACS (MG) n=243 (Swim-up+MACS) vs.Control group (CG) (swim-up)n=235 before ICSI treatment from our oocyte donation program. With the use of Time-lapse technology (Geri, Genea; Australia), we did a complete embryo follow-up with further morphokinetic analysis.

RESULTS: A total of 5232 oocytes were microinyected that were giving rise to 2437 Blastocyst in Day 5 (67.2%) in the MG and (67.9%) (P=0.664). No notable differences between morphokinetic parameters when compared both groups (MG and CG) particularly at early cleavage stages embryos t2(28.36 (95% CI28.05-28.67)-(28.36 (95%CI28.04-28.68)), t3(38.35 (95% CI38.03-38.67)- 38.40 (95%CI38.04-38.76)) and t4(40.84 (95%CI40.40-41.18)-41.37(95%CI40.97-41.77)) were demostrated. These differences were found in t5(51.15 (95%CI50.70-51.60)-53.09(95%CI52.52-53.67)), t8(62.25(95%CI61.62-62.88)-65.31(95%CI64.57-66.05)), and time for Blastulation in both groups. To reach blastocyst complete development, the morphokinetic parameters analysed, tEB (Expanded Blastocyst) (113.65(95% CI112.85-114.45)-113.57(95%CI(111.55-115.59)) and tHB (hatched blastocyst) (118.92 (95%CI (116.67-120.30)-73.80 (95%CI1.76-145.83)) showed comparable results in both groups.

A slight trend towards higher embryo quality was observed in optimal blastocyst rate (A and B) based on inner cell mas quality when compared MG 86.1% (95% CI83.83-88.37) and 51.2% (95%CI35.55-56.85) and CG 83.8 (95% CI81.21-86.39) and 60.0 (95%CI54.99-65.0), respectively. Regarding optimal blastocyst rate based on trophoectoderm quality TE, the data showed a significance increase of blastocyst with higher quality in MG 80.2 (95%CI77.61-82.79) compared with CG 71.0 (95%CI67.87-74.13) in day 5. Considering outcome results a total of 422 blastocyst were transferred, with a mean number of 1.56 (95% CI 1.49-1.63) embryos transferred per cycle in MG and 1.73 (95% CI 1.67-1.80) in CG. A total of 406 blastocyst were cryopreserved, 205 in MG and 201 in CG, a mean number of 2.55 (95% CI 2.28-2.82) embryos were vitrified in the MG and 3.66 (95% CI 3.36-3.96) in the CG per cycle. In both cases showed a significant decrease in MG. Regarding fertilization rate 70.0% (95% CI63.85-76.15) and 75.1(95%CI63.23-86.97) and implantation rate 55.19 (95% CI 49.08-61.30) and 53.20 (95% CI 47.36-58.67) in MG and CG respectively were achieved with comparable results.

CONCLUSIONS: Despite the higher quality of embryos related to the MACS technology application this effect was not detected when morphokinetics were analyzed. Additionally reproductive outcome were comparable. Our results are supported by a consistent sample size.

P-82 4:30 PM Saturday, October 17, 2020

EXTERNAL VALIDATION OF AN AI SYSTEM FOR BLASTOCYST IMPLANTATION PREDICTION. Chloe Hardy, MSc,[1] Spilios Theodoratos, MSc,[2] Georgia Panitsa, PhD,[2] Jeanette Walker, BA,[2] Stephen Harbottle, BSc,[1] Ioannis A. Sfontouris, PhD[3] [1]Cambridge IVF, Cambridge, United Kingdom; [2]Business Insight Corporation, Cambridge, United Kingdom; [3]University of Nottingham, Nottingham, United Kingdom.

OBJECTIVE: To assess the performance in a clinical setting of IVFvision.ai, an artificial intelligence (AI) system for blastocyst selection

DESIGN: Retrospective analysis of single blastocyst transfer (SBT) images

MATERIALS AND METHODS: Convolutional Neural Networks were used to develop IVFvision.ai, an algorithm that differentiates between Day-5 blastocysts with a positive or negative implantation outcome. Implantation was confirmed by the presence of an embryonic sac with heartbeat.

External validation of IVFvision.ai was performed at a University IVF Clinic using 113 anonymised Embryoscope images of SBT. Assessed images were taken at 116±h hours post-insemination at the equatorial focal plane.

The predictive ability and reliability of IVFvision.ai to correctly classify blastocysts according to implantation outcome were compared to the KIDScoreD5 v2 prediction algorithm, as well as three expert Clinical Embryologists.

AUC for each predictor was estimated using ROC curve analysis. Sensitivity, specificity, PPV, NPV and accuracy were calculated using crosstabs. Reliability of IVFvision.ai and embryologist assessments was calculated by the Interclass correlation coefficient (ICC). Stepwise logistic regression was used to model predictors significantly associated with implantation controlling for maternal age and fertilisation method.

RESULTS: IVFvision.ai had higher AUC and overall accuracy in predicting implantation compared to KIDScoreD5 and all embryologists (Table 1). The reliability of IVFvision.ai was perfect (ICC = 1.00, 95% CI 1.00 to 1.00), consistently returning the same classification after a triple reading process. The reliability between 3 embryologists was moderate (ICC = 0.744, 95% CI 0.606 to 0.838), significantly lower than that of IVFvision.ai.

Stepwise logistic regression showed that only IVFvision.ai prediction (p=0.008) and fertilisation method (p=0.051) were significantly associated with implantation. The combined model IVFvision.ai+Fert had an AUC 0.740.

CONCLUSIONS: IVFvision.ai is a comprehensive AI system that identifies implantation outcome with high ability, outperforming all human experts and the KIDScore prediction algorithm. The system paves the way for clinical trials to improve the accuracy and efficiency of embryo selection in IVF.

SUPPORT: None

TABLE 1. Predictive characteristics

	AUC	95% CI	Sensitivity %	Specificity %	PPV %	NPV %	Accuracy %
IVFVision.ai	0.675	0.530-0.821	61.9	73.2	54.2	78.9	69.4
KIDScoreD5	0.672	0.538-0.807	66.7	65.9	50	79.4	66.1
Embryologist 1	0.570	0.414-0.725	28.6	85.4	50	70	66.1
Embryologist 2	0.663	0.517-0.809	61.9	70.7	52	78.4	67.7
Embryologist 3	0.628	0.477-0.778	52.4	73.2	50	75	66.1

FIRST APPLICATION OF ARTIFICIAL NEURONAL NETWORKS FOR HUMAN LIVE BIRTH PREDICTION ON GERI TIME-LAPSE MONITORING SYSTEM BLASTOCYST IMAGES. Lucia Alegre, PhD,[1] Lorena Bori, MSc,[1] María de los Ángeles Valera, PhD Student,[2] Marcelo Fábio Gouveia Nogueira, PhD,[3] André Satoshi Ferreira, Undergraduate,[3] José Celso Rocha, PhD,[3] Marcos Meseguer, PhD[4] [1]IVIRMA Global, Valencia, Spain; [2]IVIRMA Global; IVI Foundation, Valencia, Spain; [3]Universidade Estadual Paulista (UNESP), Faculdade de Ciências e Letras (Câmpus de Assis), Assis - SP, Brazil; [4]IVIRMA Global, Valencia, Spain, Valencia, Spain.

OBJECTIVE: To introduce the analysis of blastocysts images from alternative time-lapse monitoring systems (TLM) by using Artificial Intelligence in the prediction of live birth (LB).

DESIGN: Retrospective cohort Study.

MATERIALS AND METHODS: We used image analysis technology as a tool to evaluate TLM images of 244 blastocyst stage embryos at 111.5 ± 1.5h post ICSI. The embryos were cultured in Geri-TLM incubator (Genea, Australia) until day 5 of development. Of the 244 blastocysts analyzed, from a single embryo transfer program, 200 were used for training (82%) and 44 for a blind test (18%) for prediction of LB by using AI. It was built a model of artificial neuronal network (ANN) to produce a predictable outcome of LB. Several independent numerical variables extracted from standardized TLM images as an input data were used. The efficacy of prediction of live birth was quantified and assessed using confusion matrices (True Positive-TP, True Negative-TN, False Positive-FP, False Negative-FN; Positive Prediction Value-PPV and Negative Prediction Value-NPV), ROC curves and AUC.

RESULTS: The accuracy (ACC) of prediction of live birth by AI using an ANN model was 85.2% (208/244; TP= 68, TN= 140, FP= 19, FN= 17). In the training dataset the ACC was 90.5% (181/200; TP= 58, TN= 123, FP= 14, FN= 5, AUC= 0.868), and in the blind test dataset, ACC was 61.4% (27/44; TP= 10, TN= 17, FP= 15, FN= 12, AUC= 0.634). The PPV, precision with which the ANN model was able to classify correctly a positive LB was 78.2%. In training dataset, the precision was 80.6% for LB+, and in blind test dataset 66.6%. Likewise, the overall NPV, capacity to classify correctly a negative LB, was 89.2%. In training dataset, the NPV was 96.0%, and in blind test dataset 58.6% for LB-. The AUC in the Blind test for positive and negative LB were very similar, 0.634 and 0.618 respectively.

CONCLUSIONS: This is the first ANN model using images from Geri TLM incubator as a target in image analysis technology. The model shows a competitive accuracy, predictive power and precision to improve the efficacy of embryo selection performed by the standard morphology and increasing the odds of LB per embryo transfer.

SUPPORT: The authors' research is supported by grants # 2017/19323-5 from São Paulo Research Foundation (FAPESP).

NOVEL ARTIFICIAL INTELLIGENCE ALGORITHM FOR IMPROVING EMBRYO SELECTION COMBINING MORPHOKINETICS AND NON-INVASIVE MEASUREMENT OF OXIDATIVE STRESS. María de los Ángeles Valera, PhD Student,[1] José Celso Rocha, PhD,[2] Lorena Bori, M.Sc,[3] Lucia Alegre, PhD,[3] Marcelo Fábio Gouveia Nogueira, PhD,[2] Dóris Spinosa Chéles, Masters Student,[2] Marcos Meseguer, PhD[4] [1]IVIRMA Global; IVI Foundation, Valencia, Spain; [2]Universidade Estadual Paulista (UNESP), Faculdade de Ciências e Letras (Câmpus de Assis), Assis - SP, Brazil; [3]IVIRMA Global, Valencia, Spain; [4]IVIRMA Global, Valencia, Spain, Valencia, Spain.

OBJECTIVE: The aim of this study is to develop an artificial intelligence (AI) model able to predict the life-birth probability of *in-vitro* cultured embryos, combining morphology and morphokinetic (MK) information of their development with their oxidative stress level.

DESIGN: This retrospective study includes 131 transferred embryos (fresh and frozen-thawed) cultured individually in an Embryoscope

(ESD) incubator (Vitrolife, Denmark) until day 5/6. They belong to 100 ICSI cycles performed between May 2017 and December 2018, using autologous or donated eggs. After transfer, the oxidative status of the culture media was assessed by the Thermochemioluminiscence (TCL) Analyzer™ (Carmel diagnostics, Israel) as an indirect measurement of their metabolic activity. A machine learning algorithm was trained using MK data obtained using the *time-lapse* monitoring system, the TCL values and the clinical outcome of each embryo, generating a predictive model of life-birth probability.

MATERIALS AND METHODS: Fertilization was performed following the standard protocol of the clinic. Scoring and selection for transfer/freezing were performed according to the ASEBIR criteria, combining morphological and MK assessment. The oxidative status of 15 μL aliquots of media was measured by the TCL Analyzer, which counts the photons emitted per second (cps) as result of the heat-induced oxidation and modification of the sample. TCL parameters used were H1, H2 and H3 (TCL amplitude at 55, 155 and 255 seconds after heating, respectively), as well as their "sm" variants, resulting from applying a smoothing algorithm to normalize the data. The AI analysis was performed using machine learning algorithms, combining different sets of variables. Data from 105 embryos was used for the training of the machine, and 26 for the simulation.

RESULTS: Properly timed development and higher TCL parameters directly related to higher chances of achieving life-birth, as previously published. Five datasets were formed using different combinations of MK and TCL parameters with the stronger statistic correlation with life-birth result: MK+H1+H2+H3, MK+H1sm+H2sm+H3sm, MK+H1sm, MK+H2sm and MK+H3sm. They were compared to a reference model using only MK. The combination with the highest predictive capacity was MK + H2sm. In the training, the model achieved a 93.6% accuracy for predicting positive life-birth (LB+) and 86.2% for negative (LB-), compared to the 97.9% LB+ and 94.8% LB- using solely MK. The blind test of MK + H2sm model had a stronger predictive power (83.3% LB+, 85.7% LB-) than only MK (66.7% LB+, 85.7% LB-). Other combinations of oxidation variables did not show an improved predictive capacity when compared to the MK algorithm.

CONCLUSIONS: The presented AI algorithm combining MK and TCL parameter H2sm scores a higher predictive power for life-birth than using only MK data. This supports the relevance of the oxidative status of the culture media as an indirect measurement of metabolic activity, higher in embryos that achieve birth. This AI algorithm provides an upgraded score system to assist embryo selection, potentially improving clinical results.

THE USE OF DEEP CONVOLUTIONAL NEURAL NETWORKS (CNN) TO OBJECTIVELY ASSESS THE ROLE OF ABSTINENCE ON IVF DEVELOPMENTAL OUTCOMES.

Stylianos Vagios, MD,[1] Irene Souter, MD,[1] Caitlin Sacha, MD,[1] Manoj Kumar Kanakasabapathy, MS,[2] Prudhvi Thirumalaraju, BS,[2] Charles L. Bormann, PhD,[1] Hadi Shafiee, PhD[2] [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: Scientific literature suggests that prolonged abstinence of men negatively impacts sperm parameters, potentially leading, among other, to motility and increased DNA fragmentation. For this reason, the World Health Organization recommends a 2-7-day abstinence period prior to collection for standard semen evaluation. However, it is unclear whether the length of abstinence affects IVF developmental outcomes when utilizing intracytoplasmic sperm injection (ICSI) for fertilization. The aim of this study is to use CNN to objectively assess whether a man's period of abstinence prior to ICSI affects ART developmental outcomes.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS:

Setting: Academic fertility center.

Data from 165 couples undergoing 193 IVF/ICSI/PGT-A cycles from 08/2014 to 12/2019 were analyzed. Freshly ejaculated samples were used for ICSI. Cycles were stratified in three groups based on male partner's abstinence period: 1-2.9 days (Group1, N=110), 3-4.9 days (Group2, N=69), $\geq$5 days (Group3, N=14).

Outcome measures: % of blastocysts and high-quality blastocysts developed on day 5 (D5) (assessed by CNN), predicted % of blastocyst and high-quality blastocyst development (assessed by CNN on D3), % euploid blastocysts, predicted implantation potential (assessed by CNN on D5). Previously validated, highly accurate deep CNN algorithms were used to evaluate the above CNN related outcome measures[1,2].

Statistics: Parametric and non-parametric tests were used as appropriate. P-values $<$0.05 were deemed significant.

RESULTS: The three groups did not differ significantly in male and female partner's ages, incidence of male factor infertility diagnosis, any specific semen analysis parameters, or response to stimulation, the latter assessed by the number of retrieved oocytes. The % of embryos that were classified as blastocysts on D5 did not differ significantly between groups [mean (95%CI): 59.8% (56.2-63.4), 55.3% (50.2-60.3), and 64.4% (51.1-77.8), p: 0.200, groups 1-3, respectively] neither did the predicted % of embryos developing to blastocysts [mean (95%CI): 64.2% (60.4-67.9), 60.2% (54.6-65.8), and 72.8% (62.9-82.7), p:0.174; groups 1-3, respectively]. Similarly, neither the % of embryos that developed to high-quality blastocysts on D5 nor the predicted % of embryos developing to high-quality blastocysts differed significantly between groups. When controlling for maternal age, euploidy rates [Group1: 42.1% (35.8-48.4), Group 2: 44.7% (36.2-53.3), and Group 3 38.9% (18.3-59.5), p:0.836] were, also, not associated with male's abstinence period. Finally, the CNN-predicted implantation potential for each embryo did not differ significantly among our groups [mean (95% CI): 42.8% (41.1-44.6), 40.4% (38.3-42.5), and 43.8% (38.1-49.5), p:0.149; groups 1-3, respectively].

CONCLUSIONS: Our findings do not support a negative impact of prolonged male abstinence on euploidy rates and other ART outcomes, as assessed by a highly accurate and previously validated deep-learning CNN in the setting of ICSI. Such findings could prove of significant value for the counseling clinician.

THE USE OF DEEP-LEARNING CONVOLUTIONAL NEURAL NETWORKS (CNN) TO OBJECTIVELY COMPARE TWO DIFFERENT EMBRYO CULTURE MEDIA.

Irene Dimitriadis, MD,[1] Stylianos Vagios, MD,[1] Irene Souter, MD,[1] Caitlin Sacha, MD,[1] Manoj Kumar Kanakasabapathy, MS,[2] Prudhvi Thirumalaraju, BS,[2] Charles L. Bormann, PhD,[1] Hadi Shafiee, PhD[2] [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: One of the most critical aspects of assisted reproductive technology are the laboratory embryo culture conditions. Little is known about developmental outcome effects of culture media used in IVF. Recently, a rather controversial study comparing in vivo and in vitro derived embryos demonstrated that in vitro embryos had lower morphology than those developed in utero, however there were no differences in aneuploidy rates[1]. Apparently, there is still room for improving IVF culture environments. Many commercially available culture systems claim superiority. Meaningful differences could be identified by eliminating embryologist-grading biases and using CNN-platforms and preimplantation genetic testing for aneuploidy (PGT-A) to compare developmental and genetic outcomes from these systems. The purpose of this study is to assess two different culture media,

Continuous Single Culture (CSC)-Complete and CSC-NX-Complete (Fuji-Film,Irvine,Ca), on embryo developmental outcomes using a validated deep convolutional neural network (CNN) and PGT-A.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Setting: Academic fertility center.

The study population consists of 1767 embryos derived from 204 ART ICSI cycles between 04/2019 and 12/2019 and cultured in the following media: CSC-Complete (349 embryos, 19.8%) and in CSC-NX-Complete (1418 embryos, 80.2%). PGT-A was performed on 755 embryos (175 cultured in CSC-Complete and 610 cultured in CSC-NX-Complete).

Embryos were cultured in 30 μl drops of medium, overlaid with mineral oil (Ovoil, Vitrolife) and cultured at 37ºC, 5% O_2, 6.5% CO_2 and balanced N_2.

All embryos were cultured and imaged in the Embryoscope™.

Outcome measures: fertilization rate, % of blastocysts and high-quality blastocysts developed on day-5 (D5) (classified using a $CNN^{2,3}$), % of D3-embryos predicted to develop to blastocysts and high-quality blastocysts (measured using a $CNN^{2,3}$), % euploid blastocysts, D5-predicted implantation potential (measured using a $CNN^{2,3}$).

RESULTS: The % of D5 embryos that developed to the blastocyst stage (62.5% and 59.0%, respectively in CSC-Complete vs. CSC-NX-Complete groups, p:0.240) or high-quality blastocyst stage (33.5% vs. 32.6%, respectively in CSC-Complete vs. CSC-NX-Complete groups, p:0.737) did not differ significantly between the two different culture media neither did the predicted % of embryos developing to either blastocysts (66.5% vs. 63.3%, respectively in CSC-Complete vs. CSC-NX-Complete groups, p:0.262). The CNN-predicted implantation potential of embryos did not differ between the CSC-Complete and the CSC-NX-Complete culture systems (42.8% ± 9.7% and 42.6% ± 8.9%, respectively, p:0.933). For biopsied embryos, similar euploidy rates (40.5% ± 33.3% vs. 40.5% ± 33.4%, respectively, p:0.858) were achieved in the CSC-Complete and CSC-NX-Complete media.

CONCLUSIONS: A highly accurate deep CNN found no significant differences between CSC-Complete and CSC-NX-Complete culture media. Therefore, one could argue that both single-step culture media are equally effective for culturing ICSI-derived embryos.

P-87 4:30 PM Saturday, October 17, 2020

A PROSPECTIVE MULTI-CENTER, RANDOMIZED STUDY TO COMPARE THE IMPLANTATION RATE (IR) OF EMBRYOS CULTURED AND ASSESSED USING TIME-LAPSE TECHNOLOGY (TLT) VS A CONVENTIONAL INCUBATOR (CI) SYSTEM.

Xiaodong Zhang, MSc,[1] Guoning Huang, BSc,[1] Yingpu Sun, PhD,[2] Haixiang Sun, PhD,[3] Xiaohong Wang, PhD,[4] Song Quan, MSc,[5] Qi Yu, PhD,[6] Ruizhi Liu, PhD[7] [1]Chongqing Medical Center for Women and Children, Chongqing, China; [2]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [3]Nanjing Drum Tower Hospital, Jiangsu, China; [4]Tangdu Hospital of the Fourth Military Medical University, Shaanxi, China; [5]The First Affiliated Hospital of South Medical University, Guangdong, China; [6]Peking Union Medical College Hospital, Beijing, China; [7]The First Affiliated Hospital of Jilin University, Jilin, China.

OBJECTIVE: To investigate if embryo culture and assessment by TLT leads to better clinical outcomes compared with CI with static morphological assessment.

DESIGN: A prospective, randomized, controlled, multicenter study enrolled 1224 women from 7 sites in China (July 2016 to August 2019).

MATERIALS AND METHODS: Women aged ≤35 years with normal ovarian response and uterine cavity, undergoing their first in vitro fertilization/intracytoplasmic sperm injection cycle (standard long protocol), with ≥8 follicles >14 mm per ultrasound on triggering day were eligible. Participants were randomized (1:1) to the Genea Embryo Review Instrument® (GERI®) TLT or CI groups (n=612 each). Embryos were cultured and assessed either in CI with standard morphological grading or GERI® TLT with GERI Assess® 1.2 software, an embryo assessment tool that annotates classification with atypical phenotypes. The two highest quality embryos were transferred on Day 3 and outcome information were collected until 10–12 weeks to verify ongoing pregnancy. The primary endpoint was IR as determined by ultrasound at 5–8 weeks of gestation. Secondary endpoints included number and quality of embryos cultured on Day 3, and clinical pregnancy outcomes. A power analysis indicated that a sample size of 612 subjects per group would provide ≥80% power with two-sided α=0.05 to detect a 27% relative difference in IR between groups. The IR for each treatment group and its asymptotic 95% confidence interval was calculated. Continuous variables were compared by t-test and categorical variables were compared by chi-square test, with a two-sided significance level of 0.05.

RESULTS: In total, 801 participants completed the study (TLT, n=398; CI, n=403). In the TLT group, 358 embryos were transferred, resulting in 246 ongoing pregnancies; in the CI group, 361 embryo transfers resulted in 228 ongoing pregnancies. The calculated IR (95% asymptotic confidence intervals) was 52.1% (48.4–55.8) in the TLT group and 45.7% (42.1–49.4) in the CI group. The between-group difference of 6.4% (1.2–11.6) was statistically significant (P=0.016). Across secondary efficacy indicators, higher clinical pregnancy (n=266/507 vs n=252/506) and multiple pregnancy rates (n=105/246 vs n=81/228) were observed in the TLT group vs the CI group, although the difference was not significant. No statistically significant differences were observed in embryological outcomes, biochemical pregnancy rate, ongoing pregnancy rate, ectopic pregnancy rate, and spontaneous abortion rate. No conclusions can be drawn regarding TLT effect on the live birth rate as patients were only monitored for ongoing pregnancy for 10–12 weeks after transfer.

CONCLUSIONS: The overall IR in the TLT group was statistically significantly higher than that in the control CI group. This may be attributable to the lack of disturbance in the culturing system and greater amount of embryo development information by time-lapse classification with atypical phenotypes vs CI. To our knowledge, this is the first reported assessment of GERI® TLT in China. Chinese Clinical Trial Registry: ChiCTR-IIR-16008758.

A COMPUTER-VISION BASED TOOL FOR THE AUTOMATIC IDENTIFICATION OF BLASTOCYSTS' REGIONS. A STEP CLOSER TO DECODING TIME-LAPSE?.

Alejandro Chavez-Badiola, MD,[1] Adolfo Flores-Saiffe Farias, Sr., PhD,[2] Roberto Valencia, MSc, PhD,[2] Gerardo Mendizabal-Ruiz, PhD,[3] Andrew J. Drakeley, MD FRCOG,[4] IVF 2.0[1]IVF 2.0 LTD, Maghull, United Kingdom; [2]IVF 2.0 LTD, Liverpool, United Kingdom; [3]Universidad de Guadalajara, Guadalajara, JA, Mexico; [4]Liverpool Women's Hospital, Liverpool, United Kingdom.

OBJECTIVE: to assess the capabilities of a computer-vision method to automatically identify blastocysts´ regions, from static blastocysts' micrographs

DESIGN: Prospective analysis of retrospectively obtained blastocysts' micrographs from two IVF centers

MATERIALS AND METHODS: a carefully curated dataset of 370 blastocyst images was created from the first 500 images generated at two IVF clinics over six consecutive months. All images were manually segmented identifying regions of interest. From this ground truth, 10% of the images were selected testing. All images were preprocessed, and then passed through 21 different filters (e.g. entropy, Gaussian blur, Laplacian, and Sobel) and convolved by 41 texture energy-kernels each, to identify a total of 861 textures. Data-augmentation was performed on the training set. 50 pixels were randomly select per blastocyst's region of interest , and its texture-based feature-vectors extracted (database of 300,400 data-points), used to training a neural-network (three 400 nodes layers, Adam optimizer, and categorical cross-entropy as the loss-function), during 500 epochs (validation split of 10%), a callback learning-rate reduction (factor of 0.5, patience of 25 epochs,

and validation loss as monitor) and an early stopping callback (patience of 60 epochs, validation loss as monitor, and a minimal delta of 0.001). With this texture-based model we computed five masks for each image within the training-set, and then trained an autoencoder (AE) using the ground-truth masks. This AE consist of three convolutional and three max-pooling layer for the encoding, three convolutional, and three up-sampling layers for the decoding. This model was trained with mean squared error as the loss-function, RMS prop as optimizer, early stopping, and learning rate-reduction callbacks (100 epochs), with a validation-split of 10%. The testing dataset was assessed using the Sorensen-Dice coefficient (SDC).

RESULTS: Following data-augmentation, a total 1,332 images became available for training the system. Overall, the model yield a mean SDC of 0.8744. The blastocoele, background, inner cell mass, trophectoderm, and zona pellucida respectively achieved 0.8399, 0.9690, 0.5684, 0.6586, and 0.7424 respectively.

CONCLUSIONS: Fully automation of the decision making process when using time-lapse has been challenging, partly due to the difficulties that automated blastocyst segmentation present. In this study, we present with an innovative approach to the challenge of blastocyst segmentation with encouraging. The accurate identification of blastocyst regions presented in our results, suggest that blastocyst micrograph segmentation is feasible with a combination of artificial-vision techniques, and an autoencoder to improve its initial result. This approach could pave the way for building further computational tools that might automatically track the regions of interest through time of any given blastocyst.

P-89 4:30 PM Saturday, October 17, 2020

IMPROVEMENT OF AN AUTOMATIC PRONUCLEAR DETECTION SYSTEM BY DEEP LEARNING TECHNOLOGY USING MULTI-SLICE IMAGES. Yuta Kida, M.S.,[1] Noritaka Fukunaga, Ph.D.,[1] Sho Sanami, Ph.D.,[2] Hiroyuki Watanabe, M.S.,[1] Yuji Tsuzuki, M.S.,[2] Hiroya Kitasaka, Ph.D.,[1] Seiji Takeda, M.S.,[2] Fumiya Kondo, M.S.,[1] Sho Takeda, B.S.,[1] Yoshimasa Asada, M.D., Ph.D.[1] [1]Asada Ladies Clinic, Nagoya, Japan; [2]Dai Nippon Printing Co., Ltd., Tokyo, Japan.

OBJECTIVE: We are developing an automatic PN detection system utilizing DL with the aim of establishing a more objective embryo evaluation. We have suggested that the embryo evaluation accuracy in PN number by DL using single-slices on the Z-axis of TL images was able to approach that of an embryologist and also reported the detection accuracy of PN can be improved through updating the algorithm(ASRM 2019). In this study, we have constructed a new algorithm by DL using 11 slices on the Z-axis images which were obtained using a new TL device, CCM-iBIS NEXT (NEXT;astec, Japan) and evaluated the detection accuracy.

DESIGN: We constructed the two algorithms of an automatic PN detection system.

Algorithm 1 was constructed by deep learning a total of 588 sequences of TL images (0PN:23, 1PN:27, 2PN:501, 3PN:37) using single slices on the Z-axis of TL images.

Algorithm 2 was constructed by deep learning a total of 920 sequences of TL images (0PN:43, 1PN:40, 2PN:782, 3PN:55) using 11 multi-slices on the Z-axis of TL images.

MATERIALS AND METHODS: We compared the evaluation accuracy of the two algorithms using 982 sequences of TL images (0PN:52 1PN:34 2PN:857 3PN:39) which were not used for learning. The PN number of all the above was assessed by an experienced embryologist who provided the evaluation and used as the correct answer.The chi-square test or Fisher's exact test were used for determining statistical significance.

RESULTS: The accuracy rate of Algorithm 1 was 2PN:70% (601/857), 0PN:92% (48/51), 1PN: 38% (13/34), and 3PN: 46% (18/39), respectively.The accuracy rate of Algorithm 2 was 2PN:90% (765/805), 0PN: 100% (51/51), 1PN: 29% (7/24), and 3PN: 0% (0/36), respectively.Comparing the accuracy rates using a single slice or multi-slice, there was no significant difference between 0PN and 1PN.However, for 2PN, the detection rate was significantly improved in the multi-slice($P<0.05$), in 3PN, the detection rate was significantly lower in the multi-slice($P<0.05$).

CONCLUSIONS: In this study, we have validated an improved detection rate of 90% for 2PN using an automatic pronuclear detection system employing multi- slices of TL images. The 1PN and 3PN embryo appearance rate is low at 3-5%. So, the detection rate is probably low because the small number of these images that can be used for learning. Through the addition of more images for learning, it is hoped that this can be addressed in future research. Further improvement of the accuracy can be expected by continuing to employ deep learning to the acquired TL images, adjusting the learning method and improving the algorithm.

NEXT-GENERATION SEQUENCING DEMONSTRATES THAT IDENTIFICATION OF PRESUMED ROUND SPERMATIDS BASED SOLELY ON MICROSCOPIC APPEARANCE IS FREQUENTLY INACCURATE. Brent M. Hanson, MD,[1] Xin Tao, Ph.D,[2] Tianhua Zhao, MD,[3] Andrew F. Carmody, BA,[3] Brian K. Ackerman, MBS,[3] Julia G. Kim, MD, MPH,[1] Kathleen Hong, MD,[1] Philip J. Cheng, MD,[1] James Hotaling, MD,[4] Richard Thomas Scott, Jr., MD[5] [1]IVI-RMA New Jersey, Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ; [3]IVIRMA, Basking Ridge, NJ; [4]University of Utah School of Medicine Andrology and IVF Laboratories, Salt Lake City, UT; [5]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: A subset of men with azoospermia lack mature spermatozoa at the time of surgical sperm extraction. Unfortunately, options for these patients are limited. It has been reported that round spermatids, which are haploid precursors to mature spermatozoa, can be successfully injected into human oocytes resulting in healthy offspring (1). However, the success of round spermatid injection (ROSI) relies on the accurate identification of spermatids. Identification is generally guided by cellular appearance during microscopy. This study seeks to evaluate whether next-generation sequencing (NGS) confirms the expected haploid status of cells which are presumed to be round spermatids based on visual characteristics.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: This study was performed at a university-affiliated fertility practice between October 2019 and April 2020. Frozen-thawed testicular tissue samples obtained from men with non-obstructive azoospermia via microsurgical testicular sperm extraction were evaluated for the presence of round spermatids. A cell was presumed to be a round spermatid if it met visual criteria previously described by Tanaka et al., including a diameter of 6-8 μm, an indistinct nuclear membrane, and a lack of distinct nucleoli or pseudopodia (2). Presumed round spermatids were isolated and placed in a hypotonic solution. Samples then underwent targeted NGS to a sequencing depth of 200-300, allowing for single nucleotide polymorphism (SNP) analysis. Ploidy status of the samples was assessed.

RESULTS: A total of 103 presumed round spermatids were analyzed. Overall, 19 samples (18.4%) had unamplified results with targeted NGS and 36 samples (35.0%) yielded nonconcurrent results. Of the 48 samples (46.6%) with interpretable results, 18 (37.5%) were found to be diploid, indicating that visual classification as a round spermatid was incorrect. The remaining 30 out of 48 samples (62.5%) were classified as haploid, consistent with the expected ploidy status for a round spermatid.

CONCLUSIONS: For the population of azoospermic men who only possess immature precursors to spermatozoa, ROSI serves as an opportunity to father biological offspring. However, this study demonstrates that in its current form, ROSI is limited by an inability to accurately distinguish round spermatids from diploid cells with a similar microscopic appearance. In order to improve fertilization rates and provide patients with the highest potential for reproductive success, investigation should focus on the development of new techniques for round spermatid identification.

FUTURE OF AUTOMATION: USE OF DEEP CONVOLUTIONAL NEURAL NETWORKS (CNN) TO IDENTIFY PRECISE LOCATION TO PERFORM LASER ASSISTED HATCHING ON HUMAN CLEAVAGE STAGE EMBRYOS. Nicholas Kelly, BA,[1] Charles L. Bormann, PhD,[1] Jessica Dickinson, BA,[1] Andrew D. Meyer, BA,[1] Manoj Kumar Kanakasabapathy, MS,[2] Prudhvi Thirumalaraju, BS,[3] Hadi Shafiee, PhD[3] [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Division of Engineering in Medicine, Department of Medicine, Brigham and Women's Hospital, Cambridge, MA; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: To determine whether a Deep-Learning Artificial Intelligence algorithm can be used to accurately identify the precise location to perform laser assisted hatching on cleavage stage embryos.

DESIGN: Laser assisted hatching (AH) is a procedure designed to enable embryo escape from the zona pellucida (ZP). Studies show that AH may increase the chance of pregnancy in older women with repeat IVF failure and in frozen embryo transfer cycles. This procedure is also widely used on cleavage stage embryos to facilitate herniation and biopsy of trophectoderm cells for Preimplantation Genetic Testing. AH utilizes a 1.48-μm diode laser that can damage embryos if applied too close to blastomeres. Therefore, it's critical for embryologists to only apply AH on a region of the ZP that is furthest away from healthy cells.

MATERIALS AND METHODS: Using a retrospective dataset of human embryos, a deep CNN model was trained and tested to classify between 12 classes at the cleavage stage (70 hours post insemination). Twelve classifications resembled the pattern of digits on a clock, spaced 30 degrees apart to provide an accurate location for laser AH to be applied.

We developed a deep convolutional neural network that was trained with 13908 annotated images of cleavage stage embryos. We classified the location of AH based on the greatest distance between the ZP and healthy blastomeres. The validation test containing 1908 images served to ensure the program training was complete. The developed network was evaluated using another independent set of 3888 cleavage stage embryos images with known AH location classifications

RESULTS: The deep learning CNN was able to correctly identify the appropriate region to apply laser AH on the zona pellucida with 99.41% accuracy with a 95% confidence interval (CI) ranging between 99.11% to 99.62% (n=3888). Furthermore, a receiver operator characteristic (ROC) revealed micro and macro area under the curves (AUC) of 1, which confirmed that the AI can accurately pinpoint the correct location to perform AH.

CONCLUSIONS: The AI trained network can be used to accurately identify the correct location on the ZP to perform laser AH. This study demonstrates the extraordinary power and potential for utilizing CNNs in an ART laboratory to perform complex tasks such as laser AH. Findings from this study may allow for the automation of micromanipulation procedures.

EVIDENCE FOR SUPERIOR BLASTOCYST COHORT RANKING USING ARTIFICIAL INTELLIGENCE BASED ON RETROSPECTIVE CLINICAL PREGNANCY RESULTS. Matthew David VerMilyea, PhD,[1] Milad A. Dakka, PhD,[2] Jonathan MM. Hall, PhD,[3] Sonya M. Diakiw, PhD,[2] Tuc Van Nguyen, PhD,[2] Don Perugini, PhD,[2] Kaylen Silverberg, MD,[4] Michelle Perugini, PhD[2] [1]Ovation Fertility, San Antonio, TX; [2]Presagen and Life Whisperer, Adelaide, SA, Australia; [3]Australian Research Council Centre of Excellence for Nanoscale Biophotonics, Adelaide, SA, Australia; [4]Texas Fertility Center, Austin, TX.

OBJECTIVE: To establish evidence for superior ranking of blastocysts using artificial intelligence (AI) that assesses viability based on Day 5 embryo images. A simulated cohort study was performed to establish a measure of Time-to-Pregnancy (TTP), using AI to rank embryos within cohorts then calculating how many transfers are needed before a successful clinical pregnancy occurs.

DESIGN: Retrospective analysis in private reproductive technology programs.

MATERIALS AND METHODS: An AI model (Life Whisperer) for classifying Day 5 embryo images in terms of viability was developed by training and testing on datasets totaling 3,900 images with a known pregnancy outcome, sourced from 16 clinics across 5 countries.

A simulated cohort study was designed whereby retrospective embryo images from a blind test dataset with known pregnancy outcomes were randomized into 116 groups. Each group represented a simulated patients' cohort of embryos, using cohort sizes based on a known clinical distribution. The AI was used to rank embryos in each cohort from most to least likely to be viable.

We defined a new measure, TTP, as the position of the first embryo in the ranked cohort to give a positive pregnancy outcome. If the first embryo in the cohort resulted in a positive pregnancy, the TTP for that cohort was 1; if the first embryo was negative but the second embryo was positive, the TTP was 2, etc. A lower TTP was interpreted as a superior ranking outcome. Mean TTP value of the AI ranking was compared to the result expected from random chance, since all embryos in the dataset were already chosen by an embryologist and transferred.

RESULTS: The 3,900 embryo images were randomized into 116 simulated cohorts 1,000 times, and the entire set of cohorts were used to provide a bootstrapped statistical analysis. A mean TTP value of 1.506 and standard error of 0.003 was observed for the AI model, compared to a mean TTP of 1.750 and standard error of 0.004 for ranking based on random chance. The differences in mean TTP distribution were modeled as an asymmetric Laplace distribution. Overall, these results translated to a 13.6% improvement in TTP using AI compared to that of random chance, with statistical significance.

CONCLUSIONS: An AI model trained on clinical pregnancy data showed superior ranking ability and a shorter TTP compared with random chance, for simulated cohorts of transferred embryos. Out-of-pocket expenses for IVF are estimated at $19,000 for the first cycle and $7,000 for each additional cycle (Wu, et al. 2014). Given this, the reduction in TTP means a potential cost saving of $1,200 per patient and clinic revenue increase of $4,600 per treatment through the ability to service more higher value first cycle patients. In the USA with 300,000 annual IVF cycles, AI could achieve total patient savings of $360M, and $1.38B increase in revenue for IVF clinics. Globally with over 2.5M cycles, AI could achieve global patient savings of $3B and $13.8B increase in revenue for IVF clinics.

EFFECT OF THE GERI INCUBATOR ON CLINICAL OUTCOMES IN FRESH TRANSFER ART CYCLES. Conor Harrity, MRCOG, MRCPI,[1] Hans Arce, Medical doctor,[2] Rafie Ebrahimi Ghaei, MB BCh BAO LRCPI LRCSI,[1] Declan Keane, MSc, MBA,[3] Claire Moran, PhD[3] [1]ReproMedIreland, Dublin, Ireland; [2]34 Larkfield Way, Dublin, Ireland; [3]ReproMed Ireland, Dublin, Ireland.

OBJECTIVE: The GERI (Genea) incubator combines a closed culture system to provide stable conditions for the embryo, along with timelapse monitoring to aid selection. Although there are strong theoretical arguments that these interventions can improve outcomes, as with other "add ons" there is limited data to demonstrate if they can actually benefit patients.

Assessment of embryo morphology has traditionally required repeated removal from conventional incubators, exposing embryos to fluctuations in environment. Time-lapse Systems (TLS) such as GERI offer two potential advantages:

- Assessment without the need for physical disturbance (closed culture)
- Additional information regarding embryo development, acquired through continuous monitoring

Although there are strong theoretical arguments that these interventions can improve clinical outcomes, there is limited data to demonstrate true benefit to patients, with a Cochrane review (2019) concluding insufficient good quality evidence of any difference between TLS and conventional incubation.

Study question: Does embryo culture in the GERI system have any influcence on blastulation, implantation and pregnancy rates in fresh IVF/ICSI cycles

DESIGN: A retrospective cohort study of all fresh IVF/ICSI blastocyst transfer cycles from Jan 2016 to Dec 2019 was performed. Cleavage stage transfer, elective freeze-all, cycles with no embryos, and female age 42+ were excluded.

MATERIALS AND METHODS: All treatments were in a tertiary level university affiliated reprodictive medicine centre, and 578 cycles met the inclusion criteria. Treatments were divided into those where embryo culture was in standard incubators, and those using GERI. Clinical outcomes were calculated and compared using Chi square analysis for proportions and t-test for means.

RESULTS: Clinical Pregnancy rates were similar between groups (45.0% vs 38.1%, p=0.09), however significantly more embryos were transferred in the traditional incubator cases (1.44 vs 1.17, p<0.0001). There was a significantly higher implantation rate with the GERI cultured blastocysts (38.2% vs 26.1%, p =0.0004). More embryos were available for cryopreservation in the GERI cohort (p=0.0081)

Although age, AMH, number of oocytes retrieved were the same between groups, the fact this this was a retrospective analysis means that bias and the impact of confounding factors cannot be excluded.

CONCLUSIONS: The GERI system has the potential to help outcomes by the use of a closed culture system which could benefit embryo development, along with timelapse monitoring and use of morphokinetics to aid embryo selection and shorten the time to pregnancy.

Although no improvement in pregnancy rate was seen, a significant improvement in implantation rate was found, and less embryos were transferred, possibly indicating improvements in embryo selection in patients who used the GERI incubator system

A SYNTHETIC DATA SET OF 3D OOCYTE IMAGES AND MACHINE LEARNING ALGORITHM AS A MODEL TO ASSESS THE REPRODUCTIVE POTENTIAL OF OOCYTES.

Gerard Letterie, MD,[1] Nathan Kundtz, PhD[2] [1]Seattle Reproductive Medicine, Seattle, WA; [2]Rendering AI, Bellevue, WA.

OBJECTIVE: to design a deep convolutional neural network model using synthetic data sets of human oocytes to predict the reproductive potential of real-time oocyte images

DESIGN: development and description of new software for 3 D image analysis of oocytes.

MATERIALS AND METHODS: Real time data sets derived from a library of 2,500 oocyte images with known outcomes were used as models. Simulated images of human oocytes were then generated incorporating a spectrum of attributes associated with outcomes ranging from no fertilization to blastocyst formation. Metadata for the 3 D model was generated using the open source rendering engine, Lux Core Renderer, in an Amazon Web Services-based compute environment. Image variability was controlled through custom software produced by Rendered.AI. Image analysis was performed using a convolutional neural net UNet for biological segmentation image analysis.

RESULTS: We generated a reliable and robust 3 D simulation environment and a superimposable library of procedural generative mesh effects (or synthetic oocyte images) that incorporate real time oocyte features associated across a spectrum of reproductive outcomes noted above. Using this library and a scalable compute environment, we developed fully synthetic 3 D baseline reference datasets of 1,000 3 D oocytes containing representative samples of oocyte imagery and attributes associated with various clinical outcomes. The proposed algorithm is based on a convolutional neural network (CNN) and task specific software to extract attributes from the 2 D image. The algorithm can rapidly expand the image library and add or subtract endless oocyte features into the 3 D model. Run time to generate novel and unique oocyte images is 20 seconds. The software is capable of generating up to 5,000 oocyte images per day depending on feature adjustments.

CONCLUSIONS: Synthetic data sets offer a novel way to develop a limitless library of multi-faceted oocyte images for comparison to real time data images acquired in the embryology lab. We describe a synthetic data set and reference library of 3-D computer-generated oocyte images and an algorithm for feature extraction to predict fertilization of real time 2 D oocyte images. Our software model opens the possibility of using inexpensive synthetic data for training neural networks to identify oocytes with the highest reproductive potential while avoiding the need to collect large amounts of hand-annotated real-time oocyte images and data typically required for training and development. This capability lays groundwork for quantifying and exploring any observable oocyte properties in diverse datasets and eliminates the need and expense for large, annotated libraries to develop image analysis tools to assess oocytes. By using CNN-based machine vision techniques and the software we designed for this purpose, we suggest that these tools may be basically a simpler tool than the current labor intensive and expensive practice of collecting and annotating real time datasets for purpose of image analysis.

AUTOMATIC IMAGE SEGMENTATION AND QUANTITATIVE COMPONENT MEASUREMENTS ON HUMAN BLASTOCYST IMAGES USING ARTIFICIAL INTELLIGENCE (AI) IN ASSESSING MORPHOLOGY GRADING AND PREDICTING IMPLANTATION AND LIVE BIRTH OUTCOMES.

Jason KM. Au, MSc,[1] May Tian, MSc,[1] Reza Moradi, Ph.D.,[2] Parvaneh Saeedi, PhD,[2] Jon C. Havelock, MD, FRCSC, DABOG[1] [1]Pacific Centre for Reproductive Medicine, Burnaby, BC, Canada; [2]Simon Fraser University, Burnaby, BC, Canada.

OBJECTIVE: The present study aimed to identify the correlations between morphology and quantitative parameters of blastocyst components segmented on a still blastocyst image using the Blast-Net AI model and to determine which quantitative parameters would be the most predictive of implantation and live birth.

DESIGN: This is a retrospective cohort study analyzing blastocyst images acquired at 116 ± 2 hours post-insemination between 2012 and 2017, a six-year period. 415 blastocysts from 315 single or double embryo transfers from patients at mean age of 33.3 ± 3.3 years (range: 23 – 38) with a receptive uterine environment were included. All blastocysts were assessed with the Gardner[1] blastocyst scoring system at image acquisition and they were later confirmed by two experienced embryologists. All images analyzed have known implantation and live birth outcomes associated.

MATERIALS AND METHODS: All 415 images were analyzed with the Blast-Net automatic segmentation model as previously described.[2] Each image was segmented into the background, Zona Pellucida (ZP), Inner Cell Mass (ICM), Blastocoel, and Trophectoderm (TE). Each component was then quantitively measured using mathematical algorithms and converted into μm or μm^2 for data analysis. The Blast-Net model provides a confidence score on the segmentation of each component. 22 images (5.3%) failed to meet the 90% confidence inclusion cutoff for ICM and 2 images (0.5%) for ZP. 391 images were included for the determination of average blastocyst radius (BR), average ZP thickness, ZP area, TE area, ICM area and ratio of ZP thickness relative to BR (ZP/BR). The correlations of these parameters and morphology grading were assessed and logistical regression analysis was used to determine the Odds Ratio for each parameter in predicting implantation and live birth.

RESULTS: Among ZP area, average ZP thickness, average BR, and ZP/BR, ZP/BR has the best goodness of fit to the blastocyst expansion. The mean ZP/BR for size 2 expansion is 0.197, 95%CI [0.191, 0.203], size 3 is 0.153, 95%CI [0.149, 0.158], and size 4 is 0.080, 95%CI [0.075, 0.084], and they are significantly different ($p<0.0001$). ICM area and TE area are both significantly different between grade A and B ($p<0.0001$ and $p<0.005$, respectively), but not against grade C, due to the small number of grade C ICM or TE transferred. Mean ICM area for grade A ICM is 3170.4 μm^2, 95%CI [3080.6, 3260.2] and grade B is 2560.9 μm^2, 95%CI [2403.4, 2718.3]. Mean TE area for grade A TE is 4265.8 μm^2, 95%CI [4171.6, 4360.0] and grade B is 4052.6 μm^2, 95%CI [3940.5, 4164.7]. Among ZP/BR, ICM area, and TE area, only ZP/BR is indicative of implantation (OR = 2.59, 95%CI [1.10, 6.10]) and live birth (OR = 2.39, 95%CI [1.02, 5.61]). Blastocysts with a ZP/BR below 0.144 have significantly higher implantation rate (59% vs 48%, $p<0.04$) and live birth rate (53% vs 43%, $p<0.05$) than ones above this threshold.

CONCLUSIONS: Automatic segmentation and quantification of various components of a blastocyst image using the Blast-Net model can potentially offer automation in morphology assessment as well as embryo selection with improved implantation and live birth outcomes.

EMBRYOLOGIC OUTCOMES IN INTRACYTOPLASMIC SPERM INJECTION (ICSI) CYCLES UTILIZING SPERM SELECTED VIA A MICROFLUIDICS DEVICE COMPARED TO STANDARD

SELECTION. Prachi N. Godiwala, MD, Jane L. Kwieraga, BSc TS, Reeva B. Makhijani, MD, Chantal Bartels, MD, Alison Bartolucci, PhD, Daniel R. Grow, MD, John Nulsen, MD, Claudio A. Benadiva, MD, Lawrence Engmann, MD Center for Advanced Reproductive Services, University of Connecticut School of Medicine, Farmington, CT.

OBJECTIVE: Microfluidics sperm sorting allows for improved selection of normal sperm compared with conventional sperm preparation, but blastulation rate after its use has not been studied. We aim to compare the high-quality blastulation rate in cycles in which sperm was chosen via a microfluidics device versus standard sperm selection.

DESIGN: Single academic IVF center retrospective cohort study.

MATERIALS AND METHODS: The IVF/ICSI cycles of 45 patients aged 18-46 years between 2014-20 utilizing a microfluidics chamber (ZyMot^{TM}) with ICSI for sperm selection were compared to the same patients' previous ICSI cycles in which standard sperm selection was used. Use of microfluidics was based on physician discretion and/or the IVF lab recommendation based on previous low fertilization rate or blastulation rate. For standard selection, after centrifugation and washing by swim-up method sperm was chosen manually based on motility and morphology. In study cycles, motile sperm were manually selected after traversing through a microfluidics chamber. Primary outcome was high-quality blastulation rate ($\geq$3BB by Gardner scoring). Secondary outcomes included fertilization rate, number of high-quality blastocysts frozen, and euploidy rate among IVF cycles using preimplantation genetic testing for aneuploidy (PGT-A). For paired data, McNemar's test was used for categorical and paired T-test for continuous data. A two-sided p-value of <0.05 was considered statistically significant.

RESULTS: Mean patient age, partner age, BMI, and AMH level at the time of standard selection cycle were 37.3 years, 37.7 years, 25.5 kg/m^2, and 2.5 ng/mL, respectively. The majority of patients' primary infertility diagnosis was male factor (42.2%), followed by unexplained (22.2%). 35.6% of patients used the same stimulation protocol for both cycles. The use of PGT-A, mean numbers of oocytes retrieved, and pre- and post-processing sperm parameters were similar. Although the high quality blastulation rate was higher in microfluidics cycles, the difference was not significant. The fertilization rate, euploidy rate and mean number of embryos frozen did not differ significantly (Table 1).

CONCLUSIONS: Microfluidics sperm selection did appear to improve blastulation rate although this was not statistically significant due to the sample size. Further large prospective randomized studies are needed.

SEQUENTIAL VERSUS SINGLE STEP CULTURE MEDIA IN RELATION TO EUPLOIDY RATES IN PGTAI PROGRAM: PRELIMINARY DATA.

Manar Hozyen, MSc, Amr Elshimy, BSc, Nawal Mohamed, Ashrakat Abdeltawab, Hana Elkhader, Hosam Zaki. Ganin Fertility Center, Cairo, Egypt.

OBJECTIVE: To evaluate PGTai results for embryos cultured in sequential versus single step media.

TABLE 1. Embryologic Outcomes

	Standard Selection Cycles	Microfluidics Cycles	p-value
No. of oocytes retrieved (n ± SEM)	10.1 ± 8.8	11.7 ± 8.6	0.08
Fertilization rate (% ± SEM)	54.1 ± 4.6	57.8 ± 3.5	0.49
High-quality blastulation rate (% ± SEM)	25.2 ± 7.3	38.1 ± 4.7	0.15
Number of high-quality blastocysts frozen (n ± SEM)	1.9 ± 0.3	2.8 ± 0.6	0.11
Euploidy rate (% ± SEM)	16.7 ± 8.9	20.1 ± 6.4	0.78

DESIGN: A prospective cohort study including 122 couples that underwent ICSI at a private fertility center in Egypt from December 2019 till April 2020, patient recruitment is still ongoing. Female age $\leq$37 years with $\geq$ 8 mature oocytes. Male partner had normal semen parameters according to WHO 2010. PGT-A was done at the blastocyst stage.

MATERIALS AND METHODS: Injected oocytes from 72 patients were cultured in Continuous Single Culture-NX media (CSC-NX) with 10% SSS (Irvine, USA) while those from 50 patients were cultured in sequential cleavage and blastocyst media with 10% SPS (SAGE, Denmark). All blastocytes with 4BB quality and better according to Gardner's criteria 1999 were eligible for PGT-A using next generation sequencing (NGS) (Miseq illumina, USA). Results were confirmed with PGTai platform (Cooper Surgical, USA). Data were collected, analyzed using SPSS (version 23) and considered significant if p value $\leq$ 0.05.

RESULTS: There were no significant differences in female age, number of mature oocytes nor semen parameters between the two groups.

	Single step media %	Sequential media %	p values
Fertilization rate	75.34	73.59	0.57
Cleavage rate	90.20	90.40	0.64
High quality day 3 embryos	72.94	75.85	0.45
Blastulation rate	64.27	67.07	0.89
High quality day 5/6 embryos	69.53	68.63	0.82
Euploidy rate on day 5	48.62	55.06	0.31
Euploidy rate on day 6	47.12	66.99	0.08
Total euploidy rate	51.76	62.29	0.06
Aneuploidy rate on day 5	31.87	34.32	0.73
Aneuploidy rate on day 6	34.70	26.06	0.31
Total aneuploidy rate	30.53	27.86	0.60
High mosaicism rate on day 5	11.13	2.06	0.01*
High mosaicism rate on day 6	10.63	2.50	0.12
Total high mosaicism rate	10.17	4.09	0.04*
Low mosaicism rate on day 5	5.55	3.84	0.57
Low mosaicism rate on day 6	0.87	4.43	0.21
Total low mosaicism rate	3.09	4.91	0.39

* is a significant value

CONCLUSIONS: Embryos have the same preimplantation developmental competence in both single step or sequential media. However, a significantly high mosaic rate in single step media as well as a non-significant tendency toward higher euploidy rate in sequential media. Hence, our results showed that blastocysts from young patients cultured in sequential media have had a lower high mosaic rate in favor of euploid rate, which may increase the euploid embryos available for transfer.

LASER ASSISTED HATCHING OF HUMAN EMBRYOS AT FERTILIZATION CHECK, ON DAY 1 OF CULTURE, ALLOWS FOR CONTINUOUS UNINTERRUPTED TIME-LAPSE INCUBATION OF 5+ DAYS, WHILE PRODUCING HATCHING BLASTOCYSTS AS EXPECTED.

Hannah Virginia Aycock, BS,[1] Nasario E. Ramos, BS,[1] Deborah E. Johnson, MA,[1] Zachary Haimowitz, BS,[1] Alin Lina Akopians, MD, PhD,[2] Jason A. Barritt, PhD[1] [1]ART Reproductive Center, Beverly Hills, CA; [2]Southern California Reproductive Center, Beverly Hills, CA.

OBJECTIVE: Human embryos must fully hatch from the Zona Pellucida (ZP) for implantation. Furthermore, studies show that implantation rates increase when the embryo has low energy expenditure. Extended culture of embryos to the blastocyst stage does not allow the natural process of hatching to occur, thus necessitating assisted hatching (AH) to breach the ZP for optimal embryo development. This AH is generally performed on day 3 of culture, however this necessitates interrupting any continuous culture of embryos during incubation from day 1 to 7, especially during Time-Lapse. We set out to determine if human blastocysts possess the ability to reach the hatching stage during 5+ days of continuous culture after laser AH is performed two days earlier than standard; at the Day 1 fertilization check.

DESIGN: A retrospective data analysis at a single large private fertility center to analyze blastocyst laser hatching performed on Day 1 when embryos undergo 5+ days of continuous culture in a Time-Lapse incubator.

MATERIALS AND METHODS: Oocytes were retrieved and inseminated using standard clinical practice protocols. 16 -18 hours post insemination, the day 1 fertilization check was performed. Embryos with abnormal fertilization (3PN and MPN) were donated for research and underwent AH using a Hamilton Thorne Lykos Laser at a Pulse setting of 290μs. The laser hatched embryos were placed into a Time-Lapse Embryoscope in order to monitor their ability to form blastocysts and to undergo hatching.

RESULTS: A total of 41 abnormally fertilized embryos were cultured for 5+ days, with only 12 embryos undergoing blastulation, which is an expected rate for abnormal embryo development. All 12 embryos that formed blastocysts, hatched successfully (100%). Initial hatching was observed as early as 95 hours post insemination (3.96 days of culture) and the latest observed at 140 hours (5.83 days) with a mean time to start hatching of 112.31 hours (4.68 days).

CONCLUSIONS: This study demonstrates that laser AH performed on day 1 at the fertilization check can produce hatching blastocysts at the expected rate. This allows practices to place embryos into Time-Lapse incubation with completely uninterrupted continuous culture for 5+ days, until the desired hatching blastocyst stage has been achieved.

P-99 4:30 PM Saturday, October 17, 2020

EMBRYO AUTOMATIC DIAGNOSTIC TEST; BLASTULATION, ANEUPLOIDY AND IMPLANTATION RATE PREDICTION.

Sonia Perez-Albala, PhD,[1] Belén Aparicio-Ruiz, PhD,[2] Lorena Bori, MSc,[3] Jose Alejandro Remohi, MD, PhD,[1] Thamara Viloria, PhD,[2] Marcos Meseguer, PhD[4] [1]IVIRMA Valencia, Valencia, Spain; [2]IVIRMA, Valencia, Spain; [3]IVIRMA Global, Valencia, Spain; [4]IVIRMA Global, Valencia, Spain, Valencia, Spain.

OBJECTIVE: To analyze the relationship of the automatic classification test provided on Day 3 by the EevaXtend algorithm (Early embryo viability assessment) system with blastocyst and implantation rate, blastocysts available for biopsy and aneuploidy rates.

DESIGN: Observational, retrospective cohort study.

MATERIALS AND METHODS: The study included 400 patients from our egg donation (193 cycles) and PGT program (207 cycles) from which 5135 embryos generated by ICSI were incubated in a GERI Time-Lapse Incubator (Genea, Australia) with an automatic cell-tracking software (Eeva, Xtend) that classifies embryos from 1 to 5 using: P2 (t3-t2), P3 (t4-t3), egg age, number of cells on day 3 and a texture image analysis (correlated with fragmentation). Blastocyst were classified by morphology using ASEBIR criteria (Asociación para el Estudio de la Biologa de la Reproducción). We analyzed for implantation those cases in which the number of gestational sacs matched with the number of embryos transfer (KID).

RESULTS: The distribution of the embryos classified according to the automatic algorithm was: 1: 25.4%, 2: 20.4%, 3: 15.8%, 4: 17.5%, 5: 20.9%. The percentage of viable embryos (transferred or vitrified) or non viable in each category was: 1: 66% vs 34%, 2: 56.9% vs 43.1%, 3: 49.4% vs 50.6%, 4: 34.6% vs 65.4%, 5: 12.5% vs 87.5% ($p<0.0001$). Of the 5135 embryos categorized, 3551 reached blastocyst stage. Blastocyst rate in each category was: 1: 88.9%, 2: 84%, 3: 76%, 4: 61.9%, 5: 35.4% ($p<0.0001$). We also explored the relationship with blastocysts morphology (ASEBIR) in each Xtend category. 1: A: 11.3%, B: 52.5%, C: 28.2%, D: 8.1; 2: A: 6.6%, B: 50.9%, C: 31.8%, D: 10.7%; 3: A: 5.5%, B: 44.5%, C: 38.1%, D: 11.8%; 4: A: 2.8%, B: 41.2%, C: 34.9%, D: 21.1%; 5: A: 3.6%, B: 25.1%, C: 40.7%, D: 30.5%. ($p<0.0001$). The distribution of the KID embryos (n=777) was: 1: 39.7%, 2: 28.4%, 3: 16.4%, 4: 10%, 5: 5.5%. Implantation rate was: 1: 54.9%, 2: 55.5%, 3: 46.9%, 4: 43.6%, 5: 27.9% ($p<0.005$). The percentage of blastocysts available for biopsy (n=927): 1: 74.3%, 2: 67.8%, 3: 62.4%, 4: 40.1%, 5: 17.6% ($p<0.0001$). We didnt́ find significant differences between the percentage of euploid blastocysts in each category. We also performed a logistic regression model for implantation, in which BMI, type of cycle and standard morphology were included. The model

revealed an OR 2,402 (CI95% 1,161-4,970) (p=0.003) comparing Xtend 1 vs 5.

CONCLUSIONS: There is a direct correlation between Xtend categories, percentage of viable embryos, blastocyst rate and blastocysts available for biopsy. Moreover, the best Xtend categories corresponded to the embryos with better morphology. Regarding the implantation rate, we observed significant differences between categories. Retrospective nature of this study may be a reason for caution; nevertheless, it is the largest sample size reported with this test, based in blastocyst transfer with>90% of single-embryo-transfer. Additionally a multivariable-analysis confirmed the magnitude of the results. It confirms that morphology and automatic time-lapse classifications can be used together to increase success rate in the laboratory.

IDENTIFYING INHERENT POOR QUALITY EMBRYO DATA USING ARTIFICIAL INTELLIGENCE TO IMPROVE AI PERFORMANCE AND CLINICAL REPORTING.

Milad A. Dakka, PhD,[1] Matthew David VerMilyea, PhD,[2] Tuc Van Nguyen, PhD,[1] Don Perugini, PhD,[1] Sonya M. Diakiw, PhD,[1] Kaylen Silverberg, MD,[3] Jonathan MM. Hall, PhD,[4] Michelle Perugini, PhD[1] [1]Presagen and Life Whisperer, Adelaide, SA, Australia; [2]Ovation Fertility, San Antonio, TX; [3]Texas Fertility Center, Austin, TX; [4]Australian Research Council Centre of Excellence for Nanoscale Biophotonics, Adelaide, SA, Australia.

OBJECTIVE: Analysis of clinical data suggests inherent errors in the classification of Day 5 blastocyst images, where viable embryos are wrongly classified non-viable based on a negative pregnancy outcome. A novel AI technique (UDC) was used to identify and remove mis-classified data to obtain a cleaned dataset which improves AI performance and reduces misleading reporting of AI accuracy.

DESIGN: Retrospective analysis in private reproductive technology programs.

MATERIALS AND METHODS: We assessed ~5,500 static 2D images of Day 5 blastocysts with known clinical pregnancy outcomes. Clinical analysis considered patients under 35 years because they are likely to contain more mis-classified non-viable embryos with patient factors preventing a pregnancy. A novel AI technique (UDC) which identifies incorrectly classified (labeled) data, was used to identify viable embryos incorrectly classified as non-viable. We compared the performance of AI trained using the original embryo dataset and a new cleaned dataset, by assessing accuracy on both an uncleaned and cleaned blind test dataset.

RESULTS: Patients <35 that did not achieve a pregnancy had a higher rate (63.6%) of patient factors (e.g. endometriosis) compared with patients ≥35 (49.1%). For patients <35, 49.2% of embryos transferred did not lead to a pregnancy, despite only 17% of these being deemed non-viable by traditional morphological grading. This indicates that there are many examples of embryos deemed non-viable that are likely viable, but did not result in a pregnancy. These mis-classified cases are deemed poor quality data.

Applying the UDC to the images identified a significant proportion of embryos suspected to be viable but labeled as non-viable. We removed mis-classified nonviable data to create a clean AI training dataset, and a clean test dataset which is used to report the performance of the AI.

Cleaning the training data improved overall AI performance from 59.7% to 61.1%, as measured on an unclean test dataset. There was a large accuracy increase in the (correct) viable class from 76.8% to 80.6%, and a drop in the (misclassified) non-viable class from 37.3% to 35.4%.

When measuring the AI performance of the same model on the cleaned test dataset with mis-classified data removed, we found that the original AI accuracy was under-reported, and the true performance overall was 77.1%. For the non-viable class of embryos the under-reported accuracy was even more pronounced, consistent with a larger amount of poor quality data in this class, and the true performance was actually 58.8%.

CONCLUSIONS: These data suggest that in the class of embryos deemed non-viable due to a negative pregnancy outcome, there are many embryos that are viable and just wrongly classified. The UDC is a unique technique that is effective at identifying these mis-classified cases, which when removed from the AI training datasets results in improved AI performance and enables the true reporting of AI performance. This also calls into question whether it is even possible to achieve the high accuracy (above 90%) reported by others in the literature when embryo viability data is inherently poor quality.

A STRATEGY TO VALIDATE THE INTRODUCTION OF TIME-LAPSE INCUBATOR IN THE LABORATORY.

Ricardo Azambuja, DVM, PhD, Bibiana Cunegatto, Msc, Marta Ribeiro Hentschke, MD, PhD, Alice Tagliani Ribeiro, Msc, Fabiana Mariani Wingert, DVM, Victória Campos Dornelles, MD, Vanessa Devens Trindade, MD, Msc, Alvaro Petracco, MD, PhD, Mariangela Badalotti, MD, PhD Fertilitat-Centro de Medicina Reprodutiva, PORTO ALEGRE, Brazil.

OBJECTIVE: To present a strategy to validate the introduction of time-lapse technology in the laboratory for clinical use.

DESIGN: Retrospective case-control study performed at an assisted reproduction clinic in southern Brazil.

MATERIALS AND METHODS: The data refers to a period from January to February 2020 and was collected from electronic records. Inclusion criteria: patients undergoing in vitro fertilization (IVF), with at least two fertilized oocytes. A total of 39 patients were included in the analysis. Embryos from the same patient were then divided into two groups: Group 1, embryos cultured in the Time-lapse technology, and Group 2: embryos cultured in a conventional incubator. A total of 417 inseminated oocytes (G1=210; G2: 207) and 188 blastocysts (G1=111; G2=77) were included. Fertilization rate, embryo development and blastocyst rate were analyzed between groups. Mann–Whitney U-test test was applied. Variables was expressed in median [25th-75th], and statistical significance was defined as p<0.05.

RESULTS: The mean maternal age was 34.6 ± 4.4. When compared Group 1 with Group 2 the following results were observed: inseminated oocytes (5 [4-6] *vs.* 5 [4-7], p=0.800); fertilized oocytes (5 [3-6] *vs.* 4 [3-5], p=0.334); fertilized oocytes rate (fertilized/inseminated) (83.3% [71.4-100.0] *vs* 83.3 % [66.7-100], p=0.657); D3 embryos with more than 6 cells (4 [2-5] *vs.* 2 [1-5] (p=0.028); number of blastocysts (D5 plus D6) (3 [1-4] *vs.* 1.5 [1-3], p=0.039) and blastocysts rate (60.0% [33.3-75.0] *vs* 45% [18,6-61.7], p=0.038).

CONCLUSIONS: In this study, data from 39 patients and 188 blastocysts was sufficient for demonstrating statistical difference regarding to embryo development in different incubators. Hence, the applied methodology in this study may be a strategy to validate the introduction of time-lapse technology in the laboratory for clinical use.

GERMLINE TRANSMISSION OF DONOR MTDNA IN TRANS-MITOCHONDRIAL MONKEYS.

Crystal Van Dyken, BS,[1] Hong Ma, PhD,[1] Hayley Darby, MS,[1] Aleksei Mikhalchenko, PhD,[1] Nuria Marti-Gutierrez, PhD,[1] Amy Koski, BS,[2] Ying Li, MS,[1] Dan Liang, PhD,[1] Rebecca Tippner-Hedges, MS,[1] Travis Hodge, HT,[3] Heather M. Sidener, DVM, DACLAM,[3] Cathy Ramsey, BS,[3] Paula Amato, MD,[1] Shoukhrat Mitalipov, PhD[1] [1]Oregon Health & Science University, Portland, OR; [2]5204 SE 36th PL, Portland, OR; [3]Oregon Health & Science University, Beaverton, OR.

OBJECTIVE: To examine efficacy and long-term safety of mitochondrial replacement therapy (MRT) in rhesus macaques.

DESIGN: Five MRT rhesus macaques were produced in 2009-2012 via MRT. This is a form of germline gene therapy developed to prevent transmission of mtDNA mutations from mother to child. We produced MRT monkeys by reciprocal replacement of cytoplasm and mtDNA complement in oocytes from the two different rhesus macaque subpopulations. Their health, development, reproductive fitness and mitochondrial DNA (mtDNA) inheritance was studied for over a decade.

MATERIALS AND METHODS: The study followed approved IACUC protocols at the Oregon National Primate Research Center. The TMB (time-mated breading) and ART (Assisted Reproductive Technologies) cores assisted in sperm and oocyte collections and breeding.

RESULTS: Sperm morphology, count, and motility in MRT adult male monkeys were within normal range and matched to controls. Moreover, when naturally mated with females they produced healthy offspring. The only female MRT monkey was also bred and produced a healthy infant demonstrating a germline transmission of original donor mtDNA to the second generation. During the MRT procedure a small amount of residual maternal mtDNA inevitably persists in oocytes resulting in 1-3% heteroplasmy in MRT monkeys. Dynamics of maternal mtDNA heteroplasmy levels in skin, blood, and urine remained stable in all MRT monkeys. Maternal mtDNA heteroplasmy was also measured in most major internal organs and tissues of post-necropsied animals. Two MRT animals showed a noticeable increase of maternal mtDNA in internal organs reaching 10% in kidney, 12% in stomach and liver and 17% in small intestine.

CONCLUSIONS: These results provide critical long-term safety and efficacy data for clinical applications of MRT. While heteroplasmy levels in peripheral tissues were maintained into adulthood, other internal organs showed an increase. While it is re-assuring that complete reversion was not observed, patients would need to be informed of the risk of potential reversion.

AUTOMATED OOCYTE AND ZYGOTE DENUDATION USING A NOVEL MICROFLUIDIC DEVICE.

Javier Guerrero Sánchez, Embryologist,[1] Joana Sales Fidalgo, PhD,[1] Yolanda Cabello, PhD, Sr., Embryologist,[1] Ignacio Hernández Montilla, Engineer,[1] Pablo Carasa, Engineer,[1] David Cancio-Villalonga, Engineer,[1] Daniel Garcia, Engineer,[1] Susana Cortes, Sr., Embryologist,[2] Laura García De Miguel, Gynecologist,[2] Lionel Matthys, Engineer,[1] Santiago Munne, PhD,[1] Jose A. Horcajadas, PhD[1] [1]Overture Life, Madrid, Spain; [2]Tambre, Madrid, Spain.

OBJECTIVE: The aim of the study was to develop an automated denudation device, supervised by a computer vision algorithm, that could reduce shear stress while efficiently removing cumulus cells to allow vitrification and ICSI and for subsequent NI-PGT or metabolomics analysis.

DESIGN: Experimental comparative study using bovine and human cumulus-oocyte complexes in a novel microfluidic device.

MATERIALS AND METHODS: We developed a microfluidic biochip that exerts a particular fluid motion while avoiding egg entrapment within microfluidic channels. Firstly, cow cumulus oocyte complex (COCs) were used due to their size similarity with human COCs. Later human COCs were used. These were either denuded 16-20 hours post insemination for 15 min or were denuded in a second denudation run on day 3 for NI-PGT or metabolomics analysis. Alternatively, COCs were denuded for 15 min pre-insemination. COCs were classified as partially denuded if fertilization assessment, ICSI or vitrification was possible, and completely denuded if no cumulus cells remained (necessary for NI-PGT and metabolomics). Cow COCs controls were manually denuded (Stripper® pipette 145μm ID) to compare shear stress between procedures. Experiments were repeated with the use of human COCs. A Computer Vision model was developed using human COCs in order to optically assess denudation efficiency. In order to obtain meaningful performance metrics, half of the entire dataset was defined as a test set of images, with a balanced ratio of denuded and non-denuded images. The model used was a Pytorch implementation of Resnet18 with ImageNet pretrained weights.

RESULTS: 50 bovine COCs were microfluidically handled post insemination achieving complete (12/50) or partial (38/50) removal of the cumulus cells on day 1, while for day 3 double denudation group, 46 (92%) were completely denuded while the rest remained partially denuded. In comparison, 50/50 (100%) of manually denuded cow COC, achieved complete denudation (post insemination group). In addition, 60% (N=10) cow COCs treated pre-insemination were partially denuded after 15 min of treatment while 100% were partially denuded after one hour of treatment.

Of 20 donated human COCs, 12 were denuded manually and 8 automatically. Those in the automatic group, were all partially denuded enough to see PNs and PBs.

The shear stress of our design was calculated to be smaller than 4.4 Pa, about ten times lower than the one applied by the manual process (~44Pa).

The deep learning algorithm was tested on 20 unseen human oocytes on day 1, with 10 true positives 9 true negatives, and 1 false negative (95% accuracy).

CONCLUSIONS: Complete denudation is key to avoid DNA contamination for non-invasive PGT or metabolomics analysis, while avoiding damage to the oocyte by excessive shear force. Our automated system efficiently denude cow and human COCs with x10 less shear force without human intervention. Using a computer vision algorithm, the device could recognize degrees of denudation to subsequently treat each oocyte individually.

DOES A LOW SERUM ESTRADIOL CONCENTRATION PRIOR TO START OF PROGESTERONE HAVE AN ADVERSE EFFECT ON LIVE BIRTH IN FROZEN EMBRYO TRANSFER CYCLES, EVEN WHEN ENDOMETRIAL THICKNESS IS ADEQUATE?

Karrie A. B. Walker, D.O.,[1] Kiley Hunkler, M.D.,[2] Amalia Namath, M.D.,[3] Samad Jahandideh, PhD,[3] Saioa Torrealday, MD,[2] John M. Csokmay, MD,[2] Eric A. Widra, M.D.,[4] Mae W. Healy, DO,[2] Kate Devine, MD,[3] Micah J. Hill, DO[2] [1]National Institutes of Health, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]Shady Grove Fertility Center, Rockville, MD; [4]SG Fertility, Washington, DC.

OBJECTIVE: To investigate whether a low serum estradiol concentration (E2) during frozen embryo transfer (FET) has an adverse effect on pregnancy outcomes in the setting of an adequate endometrial thickness.

DESIGN: A retrospective cohort study utilizing 2018 data at a private REI practice.

MATERIALS AND METHODS: We evaluated 4 thresholds for serum estradiol (150, 200, 250 and 300 pg/ml) collected at the endometrial measurement prior to starting progesterone. The primary outcome was live birth (LB); secondary outcomes were clinical pregnancy (CP) and spontaneous abortion (SAB). All FET cycles utilized only oral estradiol and when the

Outcome	Threshold Comparisons											
E2 concentration (pg/mL)	<150	>150	p	<200	>200	p	<250	>250	p	<300	>300	p
N (transfers)	235	1981	-	579	1637	-	991	1225	-	1347	869	-
LB	106 (45.1)	957 (48.3)	0.354	274 (47.3)	789 (48.2)	0.718	493 (49.7)	570 (46.5)	0.132	665 (49.4)	398 (45.8)	0.100
CP	132 (56.2)	1200 (60.6)	0.192	337 (58.2)	995 (60.8)	0.275	602 (60.7)	730 (59.6)	0.584	825 (61.2)	507 (58.3)	0.173
SAB	26 (11.1)	233 (11.8)	0.752	61 (10.5)	198 (12.1)	0.315	106 (10.7)	153 (12.5)	0.191	156 (11.6)	103 (11.9)	0.920

endometrium achieved at least 7 mm, double thickness, progesterone in oil was initiated with or without vaginal progesterone. Vitrified-warmed single blastocyst transfer occurred on the 6th day of progesterone. Generalized estimating equations (GEEs) were used to account for repeated cycles and adjusted for age.

RESULTS: 2,216 frozen embryo transfer (FET) cycles from 1920 patients in 2018 were included. The mean endometrial thickness of included cycles on day of progesterone start was 10.1mm. The average E2 concentration on the day that progesterone was initiated was 416 pg/mL. No differences in any outcomes were observed (table 1). Furthermore, estradiol as a linear variable was not associated with live birth (OR 0.99, 95%CI 0.99-1.00)

CONCLUSIONS: In programed FET cycles with an endometrial thickness of 7mm or greater, there was no association between serum estradiol concentration and live birth, clinical pregnancy, or miscarriage. These data suggest that measuring serum estradiol may not be necessary in programmed FET. Further, prolonging estradiol preparation and/or changing estrogen formulation in order to achieve a minimum serum estradiol concentration is likely unnecessary, if endometrial lining is adequate.

AN APPLICATION OF THE ASRM EMBRYO TRANSFER SIMULATOR: CORRELATION OF EJECTION VELOCITY WITH CLINICAL OUTCOMES.

Angela Q. Leung, MD,[1] Katherine M. Baker, MD,[2] Denny Sakkas, PhD,[1] Thomas L. Toth, MD,[1] Alan S. Penzias, M.D.[3] [1]Boston IVF, Waltham, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.

OBJECTIVE: Embryo transfer (ET) is a crucial last step of IVF. Studies of fluid dynamics during embryo transfer have shown that pressure changes due to ejection speed can lead to increased sheer stress and velocity differences on an embryo during ET (1). However, these parameters are difficult to measure in vivo. The ASRM Embryo Transfer Simulator has the unique ability to record many parameters of a simulated ET. The goal of this study was to examine the ejection velocity during ET using the simulator and determine if there is any correlation with clinical outcomes.

DESIGN: A retrospective cohort study at a large university-affiliated IVF clinic.

MATERIALS AND METHODS: The ASRM simulator was used for training purposes during January 2018. At this institution, the ejection of the embryo during ET is typically performed by the embryologist. Twenty-four embryologists participated in the training and their ET parameters were recorded and de-identified. Each participant performed the simulated ET multiple times and ejection velocities were recorded, as well as their experience in performing live ETs in years. Clinical outcomes from live ETs from January – December 2018 were obtained for each participant, including pregnancy (defined as positive pregnancy test, PR), live birth (LBR), and ectopic rates (EPR). Those who did fewer than 20 live ETs in 2018 were excluded from the analysis. Data were assessed using linear regression.

RESULTS: Twenty embryologists were included in the analysis. They performed the simulated ET a mean of 5 times each (range 2-10). The mean ejection velocity across all participants was 0.21 ml/s (range 0.036-0.63 ml/s). While the measured velocities varied widely between participants, the variability within each participant's repetitions was relatively low. The mean experience for performing ETs was 10 years (range 0-29 years).

The mean PR and LBR per transfer for all ETs during 2018 were 61.8% and 41.1%, respectively. The mean PR among the study participants was 61.9% (range 51.1 to 67.9), and LBR was 40.4% (range 31.9 to 47.3). For both PR and LBR, all except one participant were within 2 standard deviations (SD) of the institution mean. The mean EPR among participants was 0.8% per transfer, compared to 0.7% clinic wide.

The ejection velocity was not associated with PR, LBR, or EPR (p=0.79, 0.31, 0.47). Similarly, participant's years of experience with live ET was not associated with clinical outcomes (p=0.14, 0.82, 0.12).

CONCLUSIONS: Data on whether ejection velocity affects the success of ET is limited by the ability to measure this parameter in vivo. Using the ASRM Embryo Transfer Simulator as a proxy for live ETs, this study found no correlation between embryo ejection velocity and clinical outcomes. Even though no correlation was found, this important step of the ET has not been well studied and may benefit from the use of simulation for standardization.

ASSOCIATIONS BETWEEN EMBRYO BIOPSY AND OBSTETRICAL AND NEONATAL OUTCOMES FOLLOWING FROZEN-THAWED SINGLE EMBRYO TRANSFER.

Cynthia K. Sites, MD,[1] Sophia Bachilova, MD,[1] Daksha Gopal, MPH,[2] Howard J. Cabral, PhD, MPH,[2] Charles C. Coddington, MD,[3] Judy E. Stern, PhD[4] [1]University of Massachusetts Medical School–Baystate, Springfield, MA; [2]Boston University, Boston, MA; [3]University of North Carolina, Charlotte, NC; [4]Dartmouth-Hitchcock, Lebanon, NH.

OBJECTIVE: Trophectoderm biopsy involves removing several syncytiotrophoblast cells that would become the placenta. Our objective was to determine if removal of trophoblast cells is associated with obstetrical and neonatal outcomes following frozen-thawed embryo transfer.

DESIGN: We linked ART surveillance data (SART-CORS) to birth certificates and maternal and neonatal hospitalization discharge diagnoses in Massachusetts from 2014-2017, considering only singleton births following autologous frozen-thawed single embryo transfers.

MATERIALS AND METHODS: We compared outcomes of those having embryo biopsy (n=585) to those having no biopsy (n=2192), using Chi-square test for categorical and binary variables. We ran logistic regression to calculate adjusted odds ratios (AORs) and 95% confidence intervals (CI) for embryo biopsy vs. no biopsy (reference), adjusting for mother's age, race, education, parity, and BMI.

RESULTS: There were no differences between groups with respect to: pre-eclampsia (AOR=0.72, p=0.20) or eclampsia (AOR=0.74, p=0.22), placental disorders (AOR=0.87, p=0.56), method of delivery (AOR = 0.93, p=0.46), preterm birth (AOR=1.06, p=0.74), low birthweight (AOR=1.01, p=0.98), gestational diabetes (AOR=1.00, p= 0.99), or non-gestational diabetes mellitus (AOR=0.9, p=0.87). However, women having embryo biopsy had a prolonged length of hospital stay compared to those who did not (>3 days for vaginal delivery, >5 days for cesarean section), (AOR= 1.47, p=0.02). Significant diagnoses associated with prolonged maternal hospital stay included hemorrhage (intrapartum and postpartum, 44.8% biopsy vs. 26.1% no biopsy, p=0.005). There was no prolonged stay for neonates following cycles with embryo biopsy (AOR=1.44, p=0.08).

CONCLUSIONS: Considering cryopreserved thawed single embryo transfers, embryo biopsy does not increase the odds for diagnoses of conditions related to placentation (preeclampsia, eclampsia, placental disorders, preterm delivery, or low birthweight). Embryo biopsy is related to increased lengths of maternal hospitalization following delivery due to maternal hemorrhage.

SUPPORT: None.

PERINATAL OUTCOME FROM THE TRANSFER OF FROZEN, EUPLOID, BLASTOCYSTS BIOPSIED ON DAY 7.

Margeaux Oliva, MD,[1] Devora Aharon, MD,[1] Joseph A. Lee, BA,[2] Carlos Hernandez-Nieto, MD,[2] Eric Flisser, MD,[2] Alan B. Copperman, MD,[1] Lucky Sekhon, MD[2] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: The current study aimed to evaluate perinatal outcomes from transfers of euploid embryos that required trophectoderm (TE) biopsy on day 7 due to delayed cavitation.

DESIGN: Retrospective study

MATERIALS AND METHODS: This study included euploid embryos that underwent IVF and preimplantation genetic testing for aneuploidy (PGT-A) from 2011 to 2019. Embryos with morphology ≥4CC (modified Gardner scoring system) were biopsied on day 5. Embryos not ready for biopsy were re-evaluated on days 6 and 7. Euploid blastocysts were grouped by day of TE biopsy. Donor oocyte cycles were excluded. Patient age at IVF and embryo transfer (ET), BMI, AMH, basal antral follicle count (BAFC), endometrial thickness at ET, and morphology grade were covariates. Outcomes included neonatal birth weight, gestational age (GA) at delivery, low birth weight rate (<2500 g), fetal macrosomia rate (>4500g) and preterm delivery rate. ANOVA, chi-squared tests and multivariate linear regression were used for the analysis.

RESULTS: 1,795 blastocysts biopsied on day 5, 950 on day 6, and 32 on day 7 were identified. Blastocysts biopsied on day 7 were more likely to come

GA at delivery	39.1 ± 2	39.1 ± 1.7	39 ± 1.7	0.85
Preterm delivery (%)	159 (8.9)	88 (9.2)	4 (12.5)	0.69

from women of advanced age at IVF, lower BAFC, and AMH. Day 7 biopsied embryos were more likely to be hatched, have a grade C ICM and grade C TE. Extended culture was not associated with neonatal birth weight, low birth weight rate, rate of fetal macrosomia, GA at delivery, or preterm delivery rate. In the multivariate model, slow-growing embryos were not associated with birth weight (ß= .015, p= .66) or GA at delivery (ß=-.018, p= .65).

CONCLUSIONS: Patients who underwent transfer with embryos biopsied on day 7 had comparable perinatal outcomes to transfers with embryos biopsied on days 5 or 6. These results support the continued utilization of extended embryo culture with PGT-A, as pregnancies from transfers with embryos biopsied on day 7 did not show evidence of impaired placentation.

VITAMIN D3 (25 OH D) LEVELS IN FOLLICULAR FLUID STRONGLY CORRELATE WITH DEVELOPMENTAL POTENTIAL AND GRADES OF EMBRYO IN IVF CYCLES.

Natchandra Manoharrao Chimote, M.Sc., Ph.D,[1] Bindu N. Chimote, M.Sc., M.Phil, Ph.D.(Biochemistry); M.Sc. Clinical Embryology (Leeds-UK)[2] [1]Scientific Director, Vaunshdhara Fertility Centre, Nagpur, India; [2]Consultant Clinical Embryologist, Nagpur, India.

OBJECTIVE: To evaluate if follicular-fluid (FF) levels of Vitamin D3 correlate with the oocyte and embryo developmental competence.

DESIGN: Prospective study of reproductive age women (n=300, 22-42 years) undergoing IVF without any previous history of vitamin D3 supplementation. On day of oocyte pickup (OPU), fluid from first aspirate of each follicle was pooled for each patient and centrifuged to obtain clear follicular fluid. Vitamin D3 levels were measured in FF using RIA diagnostic kits. Sequential culture to blastocyst stage was done and blastocysts were graded as top, good and poor quality as per standard evaluation criteria. All blastocysts were vitrified for transfer in next natural cycle.

MATERIALS AND METHODS: All women underwent controlled ovarian hyper-stimulation (COH) with recombinant FSH. Women with endometriosis, tuberculosis, hydrosalpynx, poor ovarian response ($\leq$ 3 retrieved oocytes) to COH and male partners with severe or moderate male factor were excluded from the study. Cycles were classified into Low (< 41 ng/ml; n=152) and High (> 41 ng/ml; n=148) FF Vitamin D3 groups on the basis of their median values. Rates of fertilization, cleavage, blastocyst formation and grades of blastocysts formed were recorded in both the study groups.

RESULTS: There was no significant difference in age, number of eggs retrieved and mean MII oocytes (p>0.05) between the two study groups. However, rates of fertilization (93.3 $\pm$ 22.6 vs. 86.1 $\pm$ 29.5% P: 0.0205) and cleavage (87.0$\pm$18.5 vs. 79.3$\pm$24.6% p:0.02) were significantly higher in low group than in high FF Vitamin D3 group. Interestingly, although overall Blastocyst formation rate remained comparable (50.3 $\pm$37.9 vs. 54.1 $\pm$ 35.4% : P value 0.3740); the percentage of top (34.4 $\pm$0.4 vs 24.2 $\pm$0.8%, P= 0.0183) and good 37.8 $\pm$ 0.69 vs 21.4 $\pm$ 0.72%, p= 0.0002) grade blastocysts were significantly higher in low FF Vitamin D3 group than in high FF Vitamin D3 group. Importantly, poor quality blastocysts were significantly high in high FF Vitamin. D3 compared to Low FF Vit. D3 group (45.0 $\pm$ 38.5 vs 26.3 $\pm$ 33.0 %, P value: < 0.0001). FF Vit. D3 correlated with top grade blastocysts (Pearson r= 0.56). There have been contradictory results of correlation between serum levels of Vitamin D3 and embryo quality. However, since follicular-fluid is the microenvironment which reflects the fate of follicle and oocyte development, study of this correlationship in FF, as done in our study, seems more logical. Also, with changes in weather conditions and carbon emission affecting the ozone layer all over the world, the natural synthesis of Vitamin D3 seems to be disturbed. Therefore, it is extremely prudent to evaluate this hormone to improve embryo development and pregnancy rates in IVF cycles.

CONCLUSIONS: FF level of Vitamin D3 is potentially predictive of embryo quality and facilitates non-invasive selection of best blastocyst for transfer.

A PROMISING LIGAND AND MICROFLUIDICS SPERM SEX SELECTION METHOD.

Stephanie Cheung, B.S., Philip Xie, B.S., Alessandra Parrella, M.Sc., Derek Keating, B.A., Zev Rosenwaks, M.D., Gianpiero D. Palermo, M.D., Ph.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To test the reliability of selecting sex-specific spermatozoa through ATP content modulation in a microfluidics (MF) system.

DESIGN: In 5 years, we processed ejaculates from 98 consenting couples undergoing treatment at our center with a lengthy, custom multilayer density gradient (MDG) system. The proportion of X- and Y-bearing spermatozoa before and after selection was assessed by a targeted karyotype using fluorescent in situ hybridization (FISH). Cycle pregnancy outcomes and offspring sex were recorded. To expedite our selection process while maintaining sperm sex enrichment, we tested a new method utilizing TLR7/8 ligand activation together with an MF system.

MATERIALS AND METHODS: A total of 98 couples were treated at our center (IRB 1306014043) in 120 ICSI cycles. A proprietary MDG method was used to select spermatozoa according to sex. We assessed $\geq$1,000 cells/specimen by FISH to confirm successful selection. Pregnancy outcomes and offspring sex were assessed and compared between the sex-enriched groups. We tested a new selection technique by initially selecting spermatozoa with MF, followed by a 45-minute incubation in HTF medium containing 0.3μM of the TLR7/8 ligand, and then a second round of MF.

RESULTS: Of the couples (maternal age 36.8$\pm$4yrs; paternal age 39.6$\pm$5yrs) included, 53.1% wanted a female child, while 46.9% desired a male child. The initial sperm concentration was 65.4$\pm$26x10^6/ml, with 47.7$\pm$5% motility, normal morphology, and average sperm aneuploidy of 3.3$\pm$4%. After MDG selection, sperm concentration decreased to 24.3$\pm$14x10^6/ml, while motility rose to 94.5$\pm$3% (P<0.0001).

Of the 52 couples who wanted a female child, FISH assessment confirmed a sex-specific enrichment at 80%, which translated to >80% of couples obtaining a female embryo confirmed by PGT-A. The clinical pregnancy rate for these couples was 25.7% (18/70), with a delivery rate of 78.6% (11/14) of the desired sex; the remaining 4 pregnancies are ongoing.

For 46 couples who desired male offspring, FISH analysis confirmed an 80% enrichment for Y-bearing spermatozoa that translated to an equivalent proportion of male embryos confirmed by PGT-A. The clinical pregnancy rate for these couples was 28.0% (14/50), and the delivery rate was 88.9% (8/9) of the desired sex, with 5 ongoing pregnancies.

In a separate non-clinical investigation, we tested our new method on five additional sperm specimens. The proposed ligand activation/MF method yielded >80% spermatozoa enrichment for each sex, confirmed by a karyotype. Moreover, this process was able to maintain spermatozoa sex enrichment within a significantly expedited processing time of 105 minutes, compared to the 180 minutes required for MDG (P<0.0001).

CONCLUSIONS: While we were able to consistently achieve an enrichment of X- and Y-bearing spermatozoa that resulted in an equivalent proportion of embryos and delivery of children of the desired sex, this process is lengthy and tedious. Although this new proposed ligand/MF mechanism requires clinical testing, it demonstrated comparable results in much less time and could therefore be applied to more couples within the same day.

Statistical analysis	n.a.	n.s.	n.s.	n.s.	P<0.01	P <0.05	n.s.	n.s.	n.s.

PPN: poly pronuclei; Blast.: Blastocysts; BXed: Biopsied, the quality of blastocyst should be =>3BB ; Eup: Euploid; Cryoed: Cryopreserved, both biopsied and non-biopsied blastocysts. Blastocyst quality below 2CC not preserved.

OBJECTIVE: In a *in vivo* situation, the pH within the female reproductive tract is not constant. From literature, the pH is high in the fallopian tube at 7.5-7.9 (Ng et al, 2018), while the intra-oocyte pH is about 7.4 (Dale et al, 1998) and gradually decreases to 7.2 in the uterus. In the *in vitro* system, the majority of IVF labs will usually set the percentage of CO_2 in the incubator constant at one point, i.e. 5-7%, with the pH between 7.2 -7.4 (Swain, 2012). The question is why use a higher pH in the initial phase of fertilization since these physiologic pH levels are different. Does it have an affect on fertilization or embryo development?

DESIGN: Prospective study

MATERIALS AND METHODS: During 11/15/2019 – 3/20/2020, all ICSI cycles are included in the study. The age range is 27- 42 with a mean age of 35.8. The study is a paired- t design. For each cycle, half of the number of mature oocytes are assigned to the control group and the other half of mature oocytes are assigned to the experimental group. The control group follows a routine protocol, i.e. culture mature oocytes, fertilization, and embryo development at the same pH at 7.27. The experimental group follows the same protocol except the initial pH is at 7.40 following ICSI. For the experimental group, the culture pH is switched back to the regular pH of 7.27 after verification of presence of pronuclei (about 18 hours after ICSI). Chi-square tests were used for

RESULTS:

CONCLUSIONS: Increasing the pH on day 0 does not result in a significant difference upon fertilization or abnormal fertilization rates. While there is no significant difference upon blastocyst formation rate, the quality of formed blastocyst showed a significant difference for trophectoderm biopsy. It is also interesting to observe that the experimental group showed better quality blastocyst for trophectoderm biopsy while also showing a significantly lower euploid rate by biopsy. There is no significant difference of euploid rate by # Fert or # blast. The results indicate increasing pH at day 0 may enhance developmental morphology but has no effect on total euploid rate of tested blastocysts.

FEMALE EMBRYOS ARE MORE SUSCEPTIBLE TO PERTURBATIONS IN DNA METHYLATION IN FROZEN-THAW EMBRYO TRANSFER CYCLES.

Suneeta Senapati, MD MSCE,[1] Jayashri Ghosh, PhD,[2] Sneha Mani, PhD,[1] Charikleia Kalliora, MD, MSc,[1] Elizabeth Ruiz, BA, MHS,[1] Christos Coutifaris, MD, PhD,[1] Carmen Sapienza, PhD,[2] Monica Mainigi, MD[1] [1]University of Pennsylavia, Philadelphia, PA; [2]Temple University, Philadelphia, PA.

OBJECTIVE: To examine the effect of embryo vitrification and fetal sex on placental DNA methylation following assisted reproductive technologies.

DESIGN: Prospective cohort study

MATERIALS AND METHODS: Placentas were obtained from singleton pregnancies after: 82 fresh IVF cycles, 64 programmed frozen embryo transfer cycles without PGT (FETs), and 26 full-term unassisted conceptions. Bisulfite treated DNA was analyzed using the 850K MethylationEPIC BeadChip array. CpGs with an adjusted *p*-value less than 0.05 in a two–tailed unpaired t test, and a mean difference in methylation of greater than 0.05 were considered differentially methylated between fresh and frozen samples. ANOVA was used to identify differences in methylation patterns amongst multiple groups with Tukeys adjustments for multiple comparisons.

RESULTS: We found 4847 CpG sites differentially methylated between placentas from fresh and frozen embryo transfers, with 4578 CpGs hypomethylated and 269 hypermethylated in fresh cycles compared to FETs. We found 428 genes with at least 2 CpG sites differentially methylated between groups, including the imprinted genes *DLGAP2*, *SNRPN*, *KCNQ1* and *ATP10A*. For example, we found 9 CpG sites differentially methylated between fresh and frozen embryo transfer cycles in the imprinted gene *DLGAP2* (adjusted p <0.05 for all sites). At these sites, DNA methylation in placentas from FET cycles closely resembled methylation from control, non-IVF unassisted pregnancies, with both FETs and controls differing significantly from fresh embryo transfer cycles. Sex specific analysis uncovered that this overall finding held true only for male fetuses (i.e. cg22763586 p=0.002 fresh vs. frozen). Placentas of female fetuses from FET cycles had similar perturbations in DNA methylation as the placentas of females from fresh embryo transfer cycles. (cg22763586 p=0.13 fresh vs. frozen).

CONCLUSIONS: Embryo transfer following a fresh IVF cycle leads to more perturbations in placental DNA methylation compared to frozen embryo transfer. Nevertheless, female fetuses appear to be more susceptible to perturbations in placental DNA methylation following vitrification and transfer in programmed frozen embryo transfer cycles. Animal studies are necessary to assess whether the changes noted are secondary to the vitrification process and/or the maternal hormonal environment.

DNA METHYLATION DIFFERENCES IN LIVER OF MICE CONCEIVED BY IN VITRO FERTILIZATION.

Saúl Lira-Albarrán, M.D., D. Sc.,[1] Xiaowei Liu, Ph.D,[2] Paolo Rinaudo, MD, PhD[3] [1]University of California San Francisco, San Francisco, CA; [2]UCSF REI fellow, San Francisco, CA; [3]UCSF, San Francisco, CA.

OBJECTIVE: IVF generated offspring are believed to be healthy, but display a host of short term (low birth weight, preterm birth) and possibly long-term health problems, including predisposition to hypertension and glucose intolerance. Epigenetic changes are believed to underlie such changes. This study aimed at describing global DNA methylation changes in the liver of adult mice generated by natural mating (control group; flushed blastocysts, FB) or by IVF.

DESIGN: Experimental animal study.

MATERIALS AND METHODS: Mice were generated by IVF (and cultured with KSOM medium with amino acids in 5% oxygen) or by natural mating. Resulting blastocysts were transferred to recipient and offspring growth and phenotype was assessed to 30 weeks of age, at which points animals were sacrificed. Liver was removed and global DNA methylation was assessed in 3 IVF and 3 FB male mice, using whole-genome bisulfite sequencing (WGBS). GREAT was used to associate genes to differentially methylated regions (DMRs; mouse genome build, mm9). G:Profiler (p-adjusted value < 0.05) was used for functional enrichment analysis. Overrepresented gene ontology terms were summarized with REVIGO while canonical pathways were identified with Ingenuity Pathway Analysis (IPA).

RESULTS: Overall, 2,692 DMRs (4.91%) were different between the groups. The majority of DMRs (n=2,286, 84.92%) were hypomethylated in the IVF group and more frequently located 50-500 kb distal to the transcription start sites, particularly in intronic and intergenic regions. Surprisingly, only 0.16% of CpG islands were differentially methylated between IVF and FB liver samples, and only a few DMR were located on known gene promoters (n=283) or enhancers (n=190). The key canonical pathways modified by IVF were the hepatic fibrosis and insulin receptor signaling pathways, while non-redundant biological processes included the developmental and cellular

metabolic processes and transcription from RNA polymerase type II promoter. The main molecular functions enriched were the protein, enhancer, chromatin, and transcription factor binding. In particular, the transcription factors ZF5, E2F, and Kaiso showed the highest statistical significance.

CONCLUSIONS: IVF modifies the DNA methylation signature in the adult liver, resulting in the hypomethylation of genes involved in metabolism and regulation of gene transcription. These findings may shed light into the mechanisms underlying the developmental origin of health and disease.

PREDICTING NUMBER OF MATURE OOCYTES AT RETRIEVAL: A MACHINE-LEARNING MODEL FOR PATIENT COUNSELING.

Baruch Abittan, M.D.,[1] Jill Karten, M.D.,[2] Alixandra Domney, M.D., M.P.H.,[2] Weiwei Shan, MS PhD,[3] Randi H. Goldman, M.D.[1] [1]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [3]Northwell Health Department of Biostatistics, New Hyde PArk, NY.

OBJECTIVE: To develop a prediction algorithm utilizing both clinical baseline characteristics and cycle-specific parameters to accurately predict (on the day of trigger shot administration) the number of mature oocytes (MII) that will be obtained at oocyte retrieval.

DESIGN: This was a model-prediction study based on a retrospective cohort of patients who underwent their first fresh autologous in vitro fertilization (IVF) cycle between the years 2016-2019. Only cycles that resulted in oocyte retrieval were included.

MATERIALS AND METHODS: A dataset consisting of 1009 first IVF cycles was randomly partitioned into a training group (60% of cycles, N= 606) and a testing group (N= 403). Patient- and cycle-specific characteristics (ex: patient age, anti-Mullerian hormone level, FSH dosage, etc.) were evaluated as model inputs. Three different prediction models were used for cross-validation training with a K-fold of 10, repeated 20 times. The best-performing model (random forest) was validated on the test dataset. Root mean square error (RMSE) was calculated to ascertain model accuracy. RStudio® was used for all statistical analyses.

RESULTS: Baseline and cycle characteristics of the study population are shown in the table. The final model used patient age, day 3 FSH, AMH, FSH dosage, number of follicles >14mm on the day of trigger, and peak serum estradiol level. RMSE of the model was 5.0 oocytes, indicating that the model is able to predict the number of mature oocytes at retrieval ± 2.5 oocytes. The model was most accurate for patients with <14 follicles 14mm or more in diameter on day of trigger (RMSE of 3.8; prediction accuracy: ± 1.9 oocytes). These models are more accurate than our current method of estimation, which uses *only* the number of follicles >14mm on the day of trigger to predict number of MIIs (RMSE 6.0 for the entire cohort and 4.3 for patients with fewer than 14 follicles).

CONCLUSIONS: We have developed a machine-learning model to predict the number of MIIs at oocyte retrieval on the day of trigger shot. The model has an accuracy of ± 1.9 oocytes when used for patients with fewer than 14 visible follicles >14mm on transvaginal ultrasound. Validation will be carried out on a prospective cohort of patients undergoing IVF.

BETTER LATE THAN NEVER?: IMMATURE OOCYTES THAT MATURE IN-VITRO LATER ON THE DAY OF RETRIEVAL AND UNDERGO INTRACYTOPLASMIC SPERM INJECTION ARE A VALUABLE SOURCE OF USABLE EMBRYOS.

Rachel S. Mandelbaum, MD, Meghan Brooke Smith, MD, Michael S. Awadalla, MD, Brittany L. Klooster, MD, Rachel Blair Danis, MD, Lynda K. McGinnis, PhD, Jacqueline Ho, MD MS, Kristen Bendikson, MD, Richard J. Paulson, MD, MS, Ali Ahmady, PhD University of Southern California, Los Angeles, CA.

OBJECTIVE: Important questions exist regarding the utility of immature oocytes that subsequently mature in-vitro for assisted reproduction. This study sought to examine outcomes of immature oocytes and the impact of female age, oocyte stage of meiosis at retrieval and timing of progression to metaphase II (MII), and percentage of mature oocytes in the cycle on fertilization, cleavage, and blastulation rates.

DESIGN: Retrospective analysis at a single institution of all consecutive oocyte retrievals for ICSI that included immature oocytes from 2015 to 2019

MATERIALS AND METHODS: Initial maturity stage was assessed at oocyte denudation. Immature oocytes were reassessed later on day 0 and again on day 1 for progression to MII. Intracytoplasmic sperm injection (ICSI) was performed on all MII oocytes on either day 0 or day 1. Fertilization, cleavage, and blastulation rates were compared between 4 groups: 1) initially mature MII oocytes, 2) immature oocytes that reached MII and underwent ICSI later on day 0, 3) metaphase I (MI) to MII on day 1, and 4) germinal vesicle (GV) to MII on day 1.

RESULTS: 10,817 oocytes from 879 women were included. 3,137 (29.0%) were immature; 418 (13.3%) matured later on day 0, and 1,911 (60.9%) matured on day 1. Embryos derived from immature oocytes had lower cleavage and blastulation rates (Table 1). However, late day 0 MII oocytes had significantly improved outcomes compared to those that reached MII on day 1 (cleavage: 74.5% vs. 54.9% OR 2.40 [1.77-3.27]; blastulation: 40.9% vs. 11.3% OR 5.43 [3.65-8.08], P<0.001 both). Ultimately, 12.9% of all transferred or frozen embryos were derived from immature oocytes. Cleavage and blastulation rates, as well as the percent of immature oocytes that contributed to usable embryos, were higher in cycles with lower percentages of mature oocytes at time of retrieval and in women >40 years of age (P<0.001, both).

CONCLUSIONS: Immature oocytes can be a valuable source of usable embryos, however those that mature later on day 0 are five times more likely to undergo blastulation than those that mature on day 1. Routine reassessment of immature oocytes prior to ICSI on day 0 may be worthwhile, and additional assessment on day 1 may also be of use in older patients or those with low percentages of mature oocytes given higher clinical yield in these subgroups.

P-116 4:30 PM Saturday, October 17, 2020

TRIGGER DAY FSH SUPPLEMENTATION AND EUPLOIDY. Isaac J. Chamani, M.D.,[1] David H. McCulloh, Ph.D.,[2] Frederick L. Licciardi, M.D.[2] [1]NYU School of Medicine, New York, NY; [2]NYU Langone Fertility Center, New York, NY.

OBJECTIVE: Administering additional FSH on trigger-day may improve IVF outcomes by enhancing folliculogenesis and oocyte maturation. Recent reports have demonstrated an increase in oocyte maturation, but not in clinical pregnancy rates, with FSH supplementation. We therefore examined patients undergoing IVF with recombinant human chorionic gonadotropin (rHCG) ovulation triggers, in order to assess the effect of supplementation on ploidy, a valuable predictor of pregnancy, and the cost associated with providing FSH supplementation.

DESIGN: Retrospective cohort

MATERIALS AND METHODS: Patients undergoing GnRH-antagonist IVF cycles, with rHCG ovulation triggers, from 1/2015 through 12/2018, were separated into two groups for comparison: those receiving only trigger injections on trigger day (No Sup), and those also receiving FSH supplementation (Sup). Demographics, days of gonadotropin, #oocytes retrieved, #mature, #blastocysts, and #euploid embryos, were compared (Student's t-test or X^2).

RESULTS: Initial comparisons between the groups revealed a selection bias. No Sup patients had more robust responses, with higher trigger-day estradiol levels ($E2_{trig}$) and more eggs. In order to examine the effect of supplementation in each age group, we created No Sup comparison groups with $E2_{trig}$values indistinguishable from the Sup's. This was done by randomly selecting No Sup patients from the same SART age group and $E2_{trig}$stratum as the Sup patients.

962 patients were included in this matched comparison. 481 received supplementation, and 481 did not. Sup patients had significantly more IUs of gonadotropin administration over more days than No Sup patients. Sup patients also had more oocytes retrieved, oocytes matured, and euploid embryos formed, than No Sup patients (see table). There was, however, no difference in the number of patients who experienced a drop in their estrogen levels on the day after trigger (14.3% and 11.6% respectively, X^2= 1.5539, p > .05).

The overall cost associated with FSH supplementation was $446. However, the cost associated per unit increase of different outcomes varied, and amounted to $1,487 for each euploid embryo.

CONCLUSIONS: Among cycles matched for similar estradiol levels, trigger day FSH supplementation is associated with modest improvements in #oocytes, #mature oocytes, #blastocysts, and #euploid embryos. The increase in cost is significant but small in comparison to total cycle costs.

CLINICALLY IRRELEVANT EFFECT OF NON-APOPTOTIC SPERM SELECTION BY MAGNETIC ACTIVATED CELL SORTING BEFORE INTRACYTOPLASMIC SPERM INJECTION IN DONATED OOCYTES, AS MEASURED BY CUMULATIVE LIVE BIRTH RATES. Maria Gil Julia, MSc, MRes,[1] Fernando Quintana, Sr., PhD,[2] David Amoros, PhD,[3] Alberto Pacheco, PhD,[4] Cristina Gonzalez-Ravina, PhD,[5] Rocio Rivera-Egea, PhD,[6] Irene Hervas, MSc,[1] Nicolas Garrido, PhD[1] [1]IVI Foundation - IIS La Fe Biomedical Research Institute, Valencia, Spain; [2]IVIRMA Bilbao, Bilbao, Spain; [3]IVIRMA Barcelona, Barcelona, Spain; [4]IVIRMA Madrid, Madrid, Spain; [5]IVIRMA Sevilla, Sevilla, Spain; [6]IVIRMA Valencia, Valencia, Spain.

OBJECTIVE: There is no consensus on the true clinical contribution of annexin V negative, non-apoptotic sperm selection via magnetic activated cell sorting (MACS) in the reproductive outcomes of assisted reproduction techniques due to limited sample size in the literature and expression of success as pregnancy rates per embryo transfer, biasing to the negative, since only the best embryo in the cohort is selected for transfer, neglecting the contribution of the remaining embryos and the sperm selection technique. Measuring cumulative live birth rates (CLBR) per embryos transferred and oocytes used until the achievement of a live birth suppress these biases, offering a more realistic approach. This study aims to assess the effect of MACS on classical reproductive parameters and cumulative rates per embryo replaced and oocyte consumed until achieving the first live birth in patients that underwent intracytoplasmic sperm injection (ICSI) cycles using donated oocytes.

DESIGN: Multi-center retrospective observational cohort study.

MATERIALS AND METHODS: Data from ICSI cycles with donated oocytes (Jan 2008-Feb 2020) in which semen samples underwent standard preparation (control group), or included an added MACS step. T-test and Fisher's exact test were used to compare descriptives and the gestational outcomes per embryo transfer (ET) and, in the case of the live birth rate (LBR), also per completed cycle (CC). Kaplan-Meier curves were plotted to show the CLBR per ET, per number of transferred embryos and per metaphase II oocytes (MII) used. Mantel-Cox tests were performed to compare the obtained curves for each group. The threshold for statistical significance was set at p-value<0.05.

	IU Gndtpn	Days of Gndtpn	#Oocytes	#Mature Oocytes	Fertilization Rate	#Blastocysts	#Euploid
Sup	5078.7+/-1562.9*	11.3+/-2.0*	8.8+/-6.5*	7.0+/-5.5*	73.0%	2.7+/-3.0	1.2+/-1.7*
NoSup	4609.1+/-1530.5*	9.9+/-2.0*	7.9+/-5.0*	7.4+/-4.3*	75.6%	2.4+/-2.2	0.9+/-1.2*

*indicates p < 0.05

RESULTS: Overall characteristics of both groups were similar.

When analysed per ET, controls (n=68151) had a 59.6% biochemical pregnancy rate, whereas MACS (n=1996) showed 60.3%, none were statistical differences, neither were clinical pregnancy, for which the MACS showed a 0.4% (0.92, 1.10) increase or the ongoing gestation rates, for which the MACS had a 3.6% lower rate.

Groups had comparable 41.3% LBR per ET, and a 67.6% per CC (n=967), MACS, vs control showing 42.2% LBR per ET and 66.8% per CC (n=36302).

CLBR in the controls was 58.7% (58.2, 59.2) for two embryos replaced, 65.1% (64.5, 65.6) for three and 78.5% (78.0, 79.1) for four. MACS showed 63.7% (60.3, 66.8), 71.4% (68.0, 74.4) and 81.6% (78.2, 84.4). Kaplan-Meier curves showed a statistically significant difference between both groups in the CLBR per embryo transferred.

Computed per MII used, the control group showed a CLBR 43.2% (42.7, 43.7) for 10 MII and 78.3% (77.7, 78.8) for 15 MII, MACS 35.8% (32.6, 38.8) and 75.6% (71.8, 78.7) respectively, being statistically different.

CONCLUSIONS: In the largest sample size ever reported, our findings suggest that the use of annexin V negative, non-apoptotic sperm by MACS prior to ICSI in oocyte donation, result in less embryos needed to reach the first live birth but no less oocytes, although clinical relevance of this intervention seems very low.

P-118 4:30 PM Saturday, October 17, 2020

OOCYTE STIMULATION/TRIGGER PROTOCOL CORRELATES WITH THE PROPORTION OF IMMATURE OOCYTES RETRIEVED IN ASSISTED REPRODUCTIVE TECHNOLOGY CYCLES. Damla C. Gonullu, MD,[1] David H. McCulloh, PhD,[2] Cheongeun Oh, PhD,[2] LeRoy G. Robinson, Jr., PhD,[2] Sana Salih, MD,[1] David L. Keefe, MD[2] [1]Wayne State University School of Medicine, Detroit, MI; [2]NYU Grossman School of Medicine, New York, NY.

OBJECTIVE: The goal of oocyte retrieval in cycles of oocyte cyropreservation and intracytoplasmic sperm injection (ICSI) is to obtain meiosis II (MII) mature oocytes that can be immediately fertilized or frozen without the need for in vitro maturation. The fraction of oocytes that are immature following controlled ovarian hyperstimulation (COH), in other words, arrested in germinal vesicle (GV) or meiosis I (MI) phases of the cell cycle, varies from patient to patient. In this study, we identify parameters that are associated with the proportion of immaturity (P_{im} = number of immature oocytes [GV and MI] / total number of oocytes retrieved [GV, MI, and MII]).

DESIGN: A retrospective chart review of de-identified patient information to investigate the association between COH parameters and the fraction of immature oocytes retrieved per patient undergoing oocyte cryopreservation or ICSI.

MATERIALS AND METHODS: Records for a total of 2771 NYU Langone Fertility Center patients undergoing either ICSI or egg freeze cycles were included. Parameters examined included age, basal cycle day 2/3 follicle-stimulating hormone (FSH) and estradiol (E2) levels, total dose of gonadotropins administered (including FSH and human menopausal gonadotropin [hMG]), fraction of hMG administered, number of days of treatment with gonadotropins, as well as the dose of gonadotropin administered per day, and the trigger method used (human chorionic gonadotropin (hCG) vs. Leuprolide vs. combination of the two). Stepwise multivariable logistic regression was used to identify predictors of immaturity.

RESULTS: The strongest predictor of P_{im} was the trigger method. After adjusting for other parameters, hCG trigger showed 24% immaturity, followed by hCG + Leuprolide trigger showing 22%, followed by Leuprolide trigger alone obtaining only 20% ($p<0.025$). Additionally, more P_{im} was associated with fewer days of gonadotropin administration (4% more immaturity for 3.75 less days of stimulation), and with a higher gonadotropin dose per day (4% more P_{im} for 247 IU/day more gonadotropin). P_{im} was not associated with patient age, total number of oocytes retrieved per patient, total gonadotropin dose administered, fraction of gonadotropin provided by hMG, baseline FSH or E2 levels, or the number of retrievals performed on the same day.

CONCLUSIONS: Leuprolide trigger when combined with a smaller amount of gonadotropins administered per day and a higher number of days of gonadotropin administration yielded the highest proportion of mature oocytes retrieved in this data set. This was independent of the patient's age, baseline FSH and E2 levels, total amount and type of gonadotropins used, number of retrievals performed per day, and the total number of oocytes retrieved per patient.

P-119 4:30 PM Saturday, October 17, 2020

ULTRASONOGRAPHIC CHARACTERISTICS OF DEEP INFILTRATING ENDOMETRIOSIS FOLLOWING REPEATED OVARIAN HYPERSTIMULATION: AN OBSERVATIONAL PILOT STUDY. Fabio Barra, MD,[1] Matteo Tantari, MD,[1] Gloria D'Alessandro, MD,[1] Carolina Scala, MD,[2] Simone Ferrero, MD PhD[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Istituto G. Gaslini, Genova, Italy.

OBJECTIVE: Ovarian hyperstimulation for in-vitro fertilization (IVF) causes a significant rise in serum estrogens, which may have detrimental effects on endometriosis. The aim of this study is to investigate the impact of repeated ovarian hyperstimulation on the characteristics of deep endometriotic (DIE) nodules at ultrasound.

DESIGN: This was a prospective observational pilot study.

MATERIALS AND METHODS: Women with endometriosis who underwent at least three ovarian stimulation for IVF within 12 months were enrolled. The diagnosis of DIE and ovarian endometriomas (OMA) was performed by transvaginal ultrasound. The following locations of DIE were evaluated: uterosacral ligament, bladder, recto-vaginal, recto-vaginal infiltrating the rectum. The size of DIE nodules and OMA and the intensity of pain symptoms were systematically evaluated one month before each ovarian stimulation within 2 months after ovarian hyperstimulation or the failed transfer. Changes in the volume of DE nodules were ultrasonographically evaluated by the virtual organ computer-aided analysis (VOCAL).

RESULTS: A total of 69 DIE lesions and 19 OMA were diagnosed in 42 women included in the study; the mean (±SD) age of the study population was 38.3 (±2.3). The total number of ovarian hyperstimulations was 182 with a median (range) of 3 (3-5) stimulation for each patient. After the last hyperstimulation, the mean volume of DE nodules significantly increased (4.01 ± 3.07 mm^3 vs. 4.68 ± 3.55 mm^3; $p=0.041$). The volume of DE lesions increased in 59.4% (n=40/69), was stable in 34.7% (n=24/69) and decreased in 8.7% (n=6/69) of cases. A new DIE lesion was diagnosed in 9.5% (n=4/42) of patients. Similarly, the mean volume of OMA significantly increased (3.42 ± 2.45 mm^3 vs. 4.28 ± 3.04 mm^3; $p=0.032$). The mean intensity of dysmenorrhea ($p=0.025$), chronic pelvic pain ($p=0.039$), dyspareunia ($p=0.046$), chronic pelvic pain ($p=0.034$) and dyschezia ($p=0.036$) worsen. One case of bowel sub occlusion in a patient with rectal endometriosis occurred.

CONCLUSIONS: Women with DIE undergoing repeated ovarian hyperstimulation within a short period have a higher risk of lesion size growth and worsening of pain.

P-120 4:30 PM Saturday, October 17, 2020

NIPT RESULTS IN PREGNANCIES RESULTING FROM EUPLOID EMBRYO TRANSFERS. Rahana Harjee, MD,[1] Gary S. Nakhuda, MD,[2] Chen Jing, MSc[3] [1]University of, BC, Canada; [2]Olive Fertility Centre, Vancouver, BC, Canada; [3]Biostatistic, Olive Fertility Centre, Vancouver, BC, Canada.

OBJECTIVE: Preimplantation Genetic Testing for Aneuploidy (PGT-A) helps to optimize IVF outcomes by identifying euploid embryos for transfer. The typical approach involves trophoectoderm biopsy at the blastocyst stage, and chromosome copy number analysis with next generation sequencing (NGS). Depending on the technique, error rates of PGT-A are estimated to be 1-4 %; therefore, patients are typically counselled to also undergo routine prenatal screening. Non-invasive prenatal testing (NIPT), which uses maternal and placental circulating cell-free DNA (ccfDNA) to identify chromosomally abnormal pregnancies, can be performed as early as 9 weeks gestation and has shown to have greater diagnostic accuracy than precedent non-invasive prenatal screening. While the benefit of NIPT seems evident as first line aneuploidy screening, it is unknown if NIPT provides additional or discrepant diagnostic information for patients with PGT-A screen embryos.

Our aim was to examine NIPT results for patients who conceived following euploid embryo transfer after PGT-A to determine the frequency of discrepant findings.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: A chart review was completed at an independent fertility centre between April 2015 - January 2020 for patients who underwent single, euploid, frozen embryo transfer as determined by NGS- PGT-A, then chose to have NIPT.

RESULTS: A total of 1723 euploid transfers were performed during these dates. 369 patients elected to have NIPT through the clinic following assisted

reproduction (in vitro fertilization (IVF), in vitro fertilization – intracytoplasmic sperm injection (IVF-ICSI), and frozen embryo transfer), 52 of whom had undergone PGT-A prior to transfer. Patients' ages ranged from 25 to 44 (mean 36.8 years). NIPT results were normal for 48 patients (92.3%), 1 patient (1.9%) had inconclusive results for the sex chromosomes (euploid for numerical chromosomes). 6 patients required an additional test (11.5%) and 3 patients (5.8%) had non-diagnostic results following 2 failed attempts secondary to low fetal ccfDNA fraction. In patients who had NIPT (without PGT-A), 15 patients required a second NIPT test (4.7%), all of which received results following a second sample.

Of the 48 patients with normal NIPT findings, 37 delivered healthy neonates, 1 had a spontaneous loss at 24 weeks secondary to severe preeclampsia, and 10 currently have ongoing pregnancies. One patient elected to terminate after fetal anomalies were detected on anatomic ultrasound, although fetal karyotype was found to be normal.

CONCLUSIONS: Almost all patients who underwent PGT-A with transfer of a euploid embryo, and subsequently obtained diagnostic NIPT results had normal findings (98.0%). The remaining inconclusive or non-diagnostic results may represent limitations of current NIPT technology. While sample size is limited, these results suggest that subsequent to euploid embryo transfer following PGT-A, NIPT may be of questionable additional value. However, given the possibility of malformations without a chromosomal etiology, anatomical ultrasound screening is still indicated.

SUPPORT: None

THE SAFETY AND EFFECTIVENESS OF MILD GONADOTROPIN STIMULATION/INTRAUTERINE INSEMINATION IN IDIOPATHIC INFERTILITY. DO SHOTS WORK BETTER THAN PILLS? Karissa C. Hammer, MD, Stylianos Vagios, MD, Caitlin Sacha, MD, Irene Dimitriadis, MD, Charles L. Bormann, PhD, Kaitlyn E. James, PhD, Irene Souter, MD Massachusetts General Hospital, Harvard Medical School, Boston, MA.

OBJECTIVE: Ovulation induction (OI) with gonadotropins (Gn) has been associated with higher overall success than oral medication (oral med), albeit higher rate of multiples. Our objective was to compare the success and safety of a mild Gn stimulation/IUI regimen to oral med [clomiphene citrate (CC) or letrozole]/IUI regimen among patients with idiopathic infertility (IdI).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS:

Setting: Academic fertility center.

Patients: Women with IdI undergoing OI/IUI from 12/2003 - 09/2019.

Interventions: Retrospectively reviewed data from 3,155 OI/IUI cycles (1,193 patients). Gn/IUI cycles (n=2,113) were compared to oral med/IUI ones (n =1,042).

Outcomes:

Primary: Clinical pregnancy rate (CPR)/cycle.

Secondary: Spontaneous abortion, non-viable pregnancy (ectopic, biochemical, unknown location), and multiple pregnancy rates (SABR, NVPR, and MPR, respectively), and cycle characteristics: length of stimulation (days), pre-ovulatory follicle number ($\geq$ 13 mm), endometrial thickness (ET), and cycle cancellation due to over-response.

Statistics: Wilcoxon rank sum, x^2-tests, and logistic regression were used. Odds ratios (OR) were calculated utilizing generalized linear mixed effects models, adjusted for age and multiple cycles per patient.

RESULTS: Gn/IUI patients compared to oral med/IUI patients were older, had higher FSH and lower AMH levels [mean (SD): 35.2 (3.6) vs. 33.5 (3.3) years, p<0.001; 7.1 (2.1) vs. 6.9 (1.8) IU/mL, p: 0.005; 3.0 (2.1) vs. 3.5 (2.4) ng/mL, p<0.001; respectively]. Mean (SD) daily FSH dose was 58.9 (45) IU producing a mean (SD): 2.2 (1.4) follicles in the Gn/IUI group.

When comparing Gn/IUI to oral med/IUI cycles, CPR was significantly higher in the former group (CPR: 14.5% vs 11.7%, p: 0.03, respectively), which had higher odds of clinical pregnancy [OR (95%CI): 1.28 (1.0, 1.6), p: 0.03; aOR (95%CI): 1.32 (1.0, 1.7), p: 0.036]. Results did not change when restricting the comparison of Gn/IUI to CC/IUI cycles only [14.5% vs 11.6%, p: 0.026; aOR (95%CI): 1.29 (1.0, 1.6), p: 0.03, respectively].

Gn/IUI compared to oral med/IUI cycles, had significantly shorter stimulation duration, lower cancellation risk, and thicker endometrium [mean (SD): 10.6 (2.2) vs 12.0 (1.8) days, p<0.001; 3.6% vs 6.0%, p: 0.003; 8.6 (2.1) vs 7.2 (2.1) mm, p<0.001; respectively). Mean number of follicles differed between groups but not in a clinically meaningful way [mean (SD): 2.2 (1.4) vs. 2.0 (1.5), p: 0.001, Gn/IUI vs oral med/IUI).

Age-adjusted MPR and SAB rate did not differ between groups [MPR: 12.5% vs 11.5%, p: 0.82, aOR (95%CI): 0.8 (0.4, 1.9, p: 0.63; SAB: 20.8% vs 10.7%, p: 0.013, aOR (95%CI): 1.7 (0.9, 3.4), p: 0.11, Gn/IUI vs oral med/IUI]. NVPR was lower for Gn/IUI cycles [8.8% vs 15.1%, p: 0.042, aOR (95%CI): 0.47 (0.3, 0.9), p: 0.02, respectively].

CONCLUSIONS: Our data suggests that among IdI patients, mild stimulation with Gn is associated with a significantly higher CPR and a lower NVPR, without an increased risk of a multiple pregnancy. Mild stimulation with gonadotropins coupled with IUI is a safe and effective treatment of IdI.

P-122 4:30 PM Saturday, October 17, 2020

APPLICATION OF DROTAVERINE IN FROZEN-THAWED CYCLE: A SINGLE COHORT STUDY USING PROPENSITY SCORE ANALYSIS. Tingting Li, Doctor,[1] Panyu Chen, Master,[2] Cong Fang, PHD, MD[2] [1]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the clinical value of drotaverine in vitro fertilization-embryo transfer (IVF-ET) in frozen-thawed cycle.

DESIGN: A retrospective study

MATERIALS AND METHODS: A retrospective study was conducted with clinic-based data in the Reproductive Medicine Research Centre of the Sixth Affiliated Hospital of Sun Yat-sen University from Jan 2014 to May 2019. Patients aged below 40 years old underwent their first or second IVF-ET cycle and transferred 1-2 good embryos, Intervention measures were

	Group A (n=422)	Group B (n=422)	*F/X2*	*P*
Age(y)	31.930±3.749	32.76±3.765	0.023	0.881
BMI	21.840±3.075	21.912±2.851	0.796	0.372
Basal FSH(U/L)	7.526±3.423	7.565±3.429	0.002	0.963
Basal LH(U/L)	5.707±5.547	5.791±4.999	0.120	0.729
Basal E2(pg/ml)	45.495±36.017	43.711±23.957	0.812	0.214
Basal PRL	18.868±12.669	18.572±11.992	0.184	0.668
Basal T	0.366±1.560	0.309±1.219	0.571	0.450
AMH (ng/ml)	3.340±3.205	3.350±3.258	0.086	0.969
AFC	11.980±8.244	11.770±8.368	0.064	0.800
Endometrial thickness	10.231±2.143	10.523±2.211	0.078	0.971
Chemical pregnancy rate	48.815% (206/422)	28.436% (120/422)	36.965	0.000
Clinical pregnancy rate	44.313% (187/422)	24.408% (103/422)	37.068	0.000
Implantation rate	29.193% (235/805)	15.273% (126/825)	45.786	0.000
Miscarriage rate	17.112% (32/187)	16.505% (17/103)	0.018	0.895
Multiple pregnancy rate	26.203% (49/187)	22.330 (23/103)	0.534	0.465
Ectopic pregnancy rate	2.674% (5/187)	1.942 (2/103)	0.151	0.647
Live birth rate	35.545% (150/422)	19.905% (84/422)	25.756	0.000

Chemical pregnancy rate=number of biochemical pregnant cycle/number of embryo transfer cycle; Clinical pregnancy rate=number of clinical pregnant cycle/number of embryo transfer cycle; Embryo implantation rate=number of gestational sac/number of embryo transferred;

oral administration of 80mg of drotaverine twice a day for 5 consecutive days from 1 day before embryo transfer. According to the plan of embryo transfer and whether or not to use drotaverine, the patients were divided into 2 groups. The day before D3 embryo transfer, drotaverine was used (group A: 422 cases); The propensity score analysis of SPSS statistical software was used to match the selection of control group (group B: 422 cases).

RESULTS: There were no significantly differences with regard to age, BMI, AMH, and number of antral follicle between 2 groups. The positive rate of HCG (48.815% vs 28.436%), clinical pregnancy rate (44.313% vs 24.408%) and embryo implantation rate (29.193% vs 15.273%) were statistically significant ($p < 0.05$) between 2 groups.

CONCLUSIONS: Drotaverine can significantly improve embryo implantation and pregnancy rate for D3 embryo transfer in frozen-thawed cycle.

P-123 4:30 PM Saturday, October 17, 2020

FOLLICULAR ACTIVATION BY INTRAOVARIAN INJECTION OF AUTOLOGOUS PLATELET RICH PLASMA (PRP) IN WOMEN WITH PRIMARY OVARIAN INSUFFICIENCY (POI): IMPACT ON OVARIAN RESERVE AND IVF OUTCOME.

Yigit Cakiroglu, M.D.,[1] Ayse Saltik, M.D.,[1] Aysen Yuceturk, M.D.,[1] Ozge Karaosmanoglu, M.D.,[1] Sule Yildirim Kopuk, M.D.,[1] Richard Thomas Scott, Jr., MD,[2] Bulent Tiras, M.D.,[1] Emre Seli, MD[2] [1]M.D., Istanbul, Turkey; [2]IVI RMA New Jersey, Basking Ridge, NJ.

OBJECTIVE: Primary ovarian insufficiency (POI) affects 1% of reproductive age women, and is characterized by a severe decrease in ovarian reserve prior to 40 years of age. Currently, oocyte donation is the only established treatment modality for women with POI. In this study, we aimed to determine whether intraovarian injection of autologous platelet rich plasma (PRP) improves follicle development, response to ovarian stimulation and in vitro fertilization (IVF) outcome in women with primary ovarian insufficiency (POI).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Women (N=311; age range 24-40) diagnosed with POI based on European Society of Human Reproduction and Embryology (ESHRE) criteria ((i) oligo/amenorrhea for at least 4 months, (ii) an elevated serum FSH >25 IU/l on two occasions 4 weeks apart (iii) onset before the age of 40 years) were included in the study. PRP was prepared from patient's own peripheral blood by centrifugation and injected transvaginally under ultrasound guidance into at least one ovary using a 35 cm 17 G single lumen needle. On the 2-4th days of the second menstrual cycle after the PRP procedure, AFC and serum AMH and FSH levels were re-assessed, and followed up to 6 consecutive months. Women who were found to have at least one antral follicle were started on ovarian stimulation for IVF-ICSI.

RESULTS: PRP treatment resulted in increased AFC (1.7 ± 1.4 vs 0.5 ± 0.5; $p<0.01$) and serum AMH (0.18 ± 0.18 vs 0.13 ± 0.16; $p<0.01$), while serum FSH did not change significantly (41.6 ± 24.7 vs 41.9 ± 24.7; $p=0.87$). After the PRP injection, 23 women (7.4%) conceived spontaneously, 201 (64.8%) developed antral follicle(s) and attempted IVF, and 87 (27.8%) had no antral follicles and therefore did not receive additional treatment. Among the 201 women who attempted IVF, 71 (22.8% of total) could not undergo oocyte retrieval due to stimulation failure or premature ovulation, and 48 (15.4% of total) did not develop embryos due to lack of oocytes at retrieval or failed fertilization. Of the 82 women (26.4% of total) who developed embryos with IVF, 25 preferred to cryopreserve embryos for transfer at a later stage, while 57 underwent embryo transfer resulting in 13 pregnancies (22.8% per transfer, 4% of total). In total, of the 311 women treated with PRP, 25 (8.0%) achieved livebirth/sustained implantation (either spontaneously or after IVF), while another 25 (8.0%) stored cryopreserved embryos.

CONCLUSIONS: Our findings suggest intraovarian injection of autologous PRP might be considered as an experimental treatment option for follicular activation in women with POI. Additional studies with randomized prospective study design are necessary to determine whether this intervention truly results in improved clinical outcomes, through spontaneous conception and/or assisted reproduction.

P-124 4:30 PM Saturday, October 17, 2020

PREDICTORS AND CLINICAL SIGNIFICANCE OF RETAINED SINGLE EUPLOID EMBRYOS.

Devora Aharon, MD,[1] Dmitry Gounko, MA,[2] Rose Marie Roth, MSc, TS(ABB), CLT (NYS),[2] Richard Slifkin, BA, TS(ABB), CLT(NYS),[2] Christine Briton-Jones, PhD, HCLD,[2] Joseph A. Lee, BA,[2] Alan B. Copperman, MD[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: In approximately 1-4% of embryo transfers, upon flushing the catheter to verify expulsion, a retained embryo is noted.[1-3] Limited data exist regarding the characteristics of euploid embryos that increase the likelihood of retention in the catheter, and on the impact of repeat transfer of retained embryos on pregnancy outcomes.[1-3] The objective of this study is to determine the characteristics of euploid single blastocyst transfer that are associated with retention in the catheter, and to determine the prognosis of repeat ET of retained euploid blastocysts.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Patients who underwent a euploid FET from 2016-2018 were included in the study. Preimplantation genetic testing for aneuploidy (PGT-A) was performed using Next Generation Sequencing. Euploid FET cycles were separated into groups: Group 1 consisted of cases in which embryo retention was noted upon catheter inspection, and Group 2 consisted of controls in which the embryo was successfully expelled in a single attempt. Baseline demographics, cycle characteristics, and pregnancy outcomes were assessed using comparative statistics and adjusted logistic regression.

RESULTS: A total of 6,703 single euploid FET were identified and included in the analysis, including 76 cycles in Group 1 (1.1%) and 6,627 in Group 2. The groups were similar in terms of age, oocyte age, AMH, BMI, and endometrial thickness. Embryo expansion, inner cell mass grade, trophectoderm grade, and day of trophectoderm biopsy were not associated with the probability of retention within the catheter. Embryo retention was significantly associated with presence of mucus ($p=0.044$) or a mucus plug ($p=0.002$) noted upon inspection of the catheter following embryo transfer. Mucus aspiration, type of catheter used, difficult transfer, cervical dilation, and the quality of the fluid squirt were not associated with embryo retention. Implantation and ongoing pregnancy rates were significantly decreased in Group 1 compared to Group 2 (44.02% vs. 61.3%, OR 0.49, 95% CI 0.31-0.78, $p=0.002$; 37.3% vs. 51.6%, OR 0.56, 95% CI 0.35-0.90, $p=0.014$). A decrease in odds of live birth was seen but this was not statistically significant (37.0% vs. 49.7%, OR 0.59, 95% CI 0.34-1.04, $p=0.06$). Embryo retention was not associated with pregnancy loss or with monozygotic splitting. When controlling for age, oocyte age, AMH, BMI, endometrial thickness, presence of mucus in the catheter and mucus plug, embryo retention was still significantly associated with a decline in implantation rate (OR=0.54, 95% CI=0.32-0.91, $p=0.02$) and ongoing pregnancy rate (OR=0.56, 95% CI=0.33-0.96, $p=0.035$). Live birth rate did not differ significantly between the groups (OR=0.61, 95% CI=0.32-1.14, $p=0.12$).

CONCLUSIONS: Retention was associated with mechanisms indicating difficulty of the transfer rather than embryo characteristics such as expansion or grade. Our data indicates that while a retained euploid frozen-thawed embryo may have a decreased ability to implant, once ongoing pregnancy is established, live birth outcomes are similar.

IS MOCK EMBRYO TRANSFER AN ADD-ON? A REVIEW OF CURRENT CLINICAL PRACTICE AND A SYSTEMATIC REVIEW OF PUBLISHED EVIDENCE.

Yusuf Beebeejaun, MRCOG MHDL MBBS BSc(Hons),[1] Ippokratis Sarris, MRCOG DM,[2] James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons)[3] [1]King's College London, London, United Kingdom; [2]King's Fertility, London, United Kingdom; [3]Institute for Women's Health, University College London, Greater London, United Kingdom.

OBJECTIVE: A systematic review and meta-analysis to assess the assess the effectiveness of mock embryo transfer. We also identified the number of fertility clinics offering mock embryo transfer, the stated justification for offering the procedure, and the associated additional cost.

DESIGN: Systematic examination of fertility clinic websites and systematic review of published randomized trials evaluating the effectiveness of mock embryo transfer.

MATERIALS AND METHODS: We identified fertility clinic websites using google.com. Information was extracted from individual clinic websites related to the provision of embryo transfer and associated costs. The systematic review of published randomized trials was prepared by following Cochrane Collaboration guidelines. Selection of studies, assessment of trial quality, and extraction of relevant data were performed independently by two researchers. Summary estimates and 95% confidence intervals were calculated using random-effects methods.

RESULTS: Worldwide 1,200 clinics and fertility networks, have been identified to offer mock embryo transfer at an average cost of $350 (range $240 to $500). 40 % of identified clinic websites stated that mock embryo transfer was associated with improved success rates.

The systematic search of published literature identified two randomized trials, reporting data from 499 women. Live birth was not reported. Mock embryo transfer increased pregnancy confirmed by ultrasound (OR 1.80, 95% CI 1.07-3.05) when compared to routine care. Mock embryo transfer did not increase biochemical pregnancy (OR 0.91, 95% CI 0.28-2.99) when compared to routine care. There was poor reporting of other secondary outcomes, including ectopic pregnancy, miscarriage, and other adverse events.

CONCLUSIONS: There is insufficient evidence to support the routine use of mock embryo transfer. The uncertainty regarding the procedure's effectiveness should be presented alongside online information pertaining to mock embryo transfer, discussed openly during consultations, and summarised within accessible patient information leaflets and websites. Regulators, including the Human Embryology and Fertility Authority, should consider treating mock embryo transfer as an add on. Using their established system, it would currently be classified as amber: do not offer routinely. Mock embryo transfer may have a role in selected cases.

DOES THE INTERVAL TIME BETWEEN OVULATION TRIGGERING AND OOCYTE PICK UP AFFECT BIOLOGICAL RESULTS IN LOW, NORMAL AND HIGH OVARIAN STIMULATION RESPONDERS ?

Marouen Braham, Associate Professor, Khadija Kacem, Associate Professor, Basma Jardak, Medical Doctor, Zeineb Zemni, Medical Doctor, Sarah Amari, Medical Doctor, Manel Hamdoun, Associate Professor, Olfa Bahri, Professor, Nozha Chakroun, Professor, Fethi Zhioua, Professor, Anis Fadhlaoui, Associate Professor Aziza Othmana University hospital, Tunis, Tunisia.

OBJECTIVE: To assess the effect of time interval between ovulation triggering (OT) and oocyte pick up (OP) on biological results in low, normal and high responders

DESIGN: A prospective observational study performed in the department of Reproductive Medicine in Aziza Othmana Hospital between January and December 2019.

MATERIALS AND METHODS: Inclusion criteria : age between 18 and 42 years old. Controlled ovarian stimulation with antagonist protocol for ICSI.

Exclusion criteria: Mild ovarian stimulation / ovulation triggering by GnRH agonist (OHSS prevention)

We divided patient into poor, normal and high ovarian responders (based on AMH and AFC)

The ovarian stimulation was performed with an antagonist protocol for all patient with recombinant FSH (Gonal F, Merck) and cetrorelix acetate (Cetrotide, Merck). The ovulation triggering was performed when 2 or more follicles reached 17 mm with recombinant HCG (Ovitrelle 250, Merck). The interval time between OT and OP was divided into 4 groups: 35 h (group 1), 36 h (group 2) , 37 h (group 3) and $\geq$ 38 h (group 4).

$\chi 2$ test was used to compare qualitative variables. Student's t-test was used to compare quantitative variables. P-value < 0.05 was considered as statistically significant.

RESULTS: Five hundred and eighty four patients were included: 204 poor responders, 310 normal responders and 70 high responders group. For poor ovarian responders, we did not find a statistical difference for the number of oocyte retrieved (5.8 ; 3.3 ; 3.7 ; 3.6 ; p=0,2) the number of MII (3.8 ; 2.1; 2.4 ; 2.6 ; p=0,2) and the ratio MII/CCO: (0.65 ; 0.63 ; 0.66 ; 0.7é ; p=0,06) in the group 1, 2, 3 and 4 respectively.

For normal ovarian responders, we did not find a statistical difference for the number of oocyte retrieved: (7.7 ; 8.8 ; 8.1 ; 8.5 ; p=0,8) ; the number of MII: (5.2 ; 5.9 ; 5.6 ; 5.5 ; p=0,9) and the ratio MII/CCO (0.67 ; 0,67 ; 0.69 ; 0.64 ;p=0,3) in the group 1, 2, 3 and 4 respectively.

For high ovarian responders, we did not find a statistical difference for the number of oocyte retrieved (22 ; 18 ; 17 ; 23 ; p=0,3); the number of MII (16 ; 11,9 ; 12,1 ; 14 ; p=0,8) and the ratio MII/CCO (0.72 ; 0.66 ; 0,71 ; 0.6 ; p= 0,1) in the group 1, 2, 3 and 4 respectively.

CONCLUSIONS: It is not certain that adjustment of the interval time between OT and OP is necessary according to different ovarian responders in order to improve the IVF output. Moreover; studies are needed to determine if these results are applicable when using a GnRH agonist ovarian stimulation protocol.

INTRAUTERINE INJECTION OF HUMAN CHORIONIC GONADOTROPIN BEFORE EMBRYO TRANSFER: A RANDOMIZED CONTROLLED TRIAL.

Karim S. Abdallah, MSc,[1] Esraa Badran, MD,[1] Ahmed M. Abdelmagied, MD,[1] Ihab M. El-Nashar, MD,[1] Tarek K. Al-Hussaini, MD, FRCOG,[1] Tarek Farghaly, MD,[1] Hazem Saadeldine, MD,[1] Rui Wang, MD, PhD,[2] , MD, PhDBen W. Mol, Prof,[2] Ahmad Makhlouf, MD[1] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Department of Obstetrics and Gynaecology, Monash University, Melbourne, VIC, Australia.

OBJECTIVE: Human chorionic gonadotropin (hCG) is produced by the syncytiotrophoblast and plays a key role in implantation. However, quality evidence on intrauterine administration of hCG prior to embryo transfer (ET) is lacking. Our study aimed at evaluating whether intrauterine administration of hCG before ET improves in vitro fertilization (IVF) outcomes.

DESIGN: A double-blinded randomized controlled trial (RCT) (NCT03238807) in an University-affiliated IVF center in Assiut, Egypt. The study protocol was approved by the University's Institutional Review Board (IRB) (approval number: 17200094).

MATERIALS AND METHODS: We included infertile women scheduled for intra-cytoplasmic sperm injection (ICSI). After informed consent, women were randomized using a simple computer-generated random allocation in a 1:1 ratio to receive either 500 IU hCG intrauterine (hCG group), or culture media intrauterine (control group) prior to ET. Women in the hCG group received 500 IU of hCG in 0.1 mL of tissue culture media via intrauterine injection 4 minutes before ET, while women in the control group received 0.1 mL of tissue culture media. In both groups, an intra-uterine insemination (IUI) catheter was used for intrauterine administration. The patients and the clinician who conducted the procedure were blinded to the allocated intervention.

Our primary outcome was live birth, while ongoing pregnancy and clinical pregnancy were secondary outcomes. According to the intention-to-treat principle, analyses of outcomes were done and were represented as risk ratios (RRs) with 95% confidence intervals (CIs). We needed a sample size of 204 to show an increase of live birth from 28% to 48% at 80% power with an alpha error of 0.05. Accounting for 8% of drop-outs, we planned to recruit 220 participants.

Due to the COVID-19 pandemic, all IVF procedures have been suspended in our center since March 2020. As a consequence, recruitment was halted on 27 February 2020 at 181 participants. At the time of abstract submission, data on ongoing pregnancy are available. At the congress, we will be able to present data on live birth.

RESULTS: From July 2018 to February 2020, 181 women were randomized into the hCG group (n=90) and the control group (n=91). Baseline and cycle characteristics were comparable between the two groups. In the control group, one woman was lost to follow-up after confirmation of clinical pregnancy. Ongoing pregnancy was 23% (21/90) in the hCG group versus 19% (17/90) in the control group (RR 1.24, 95% CI 0.70 – 2.19), while clinical

pregnancy was 34% (31/90) in the hCG group versus 26% (24/91) in the control group (RR 1.31, 95% CI 0.84 – 2.04).

CONCLUSIONS: From the available data in this RCT, we did not find evidence that intrauterine hCG administration before ET improves ongoing pregnancy rates.

PROLONGED FOLLICULAR PHASE LENGTH COMPARED TO BASELINE CYCLE NEGATIVELY AFFECTS OUTCOMES IN NATURAL FROZEN EMBRYO TRANSFER CYCLES.

Phillip A. Romanski, MD,[1] Pietro Bortoletto, MD,[1] Nirali J. Shah, MD,[2] Yung-Liang Liu, MD PHD,[2] Pak Chung, M.D.,[1] Zev Rosenwaks, M.D.[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine whether a prolonged follicular phase in a natural frozen embryo transfer cycle as compared to the baseline follicular phase length affects pregnancy outcomes.

DESIGN: Retrospective cohort study performed in an academic hospital setting.

MATERIALS AND METHODS: Patients who utilized natural cycles for their first frozen embryo transfer using autologous day 5 PGT euploid embryos in our IVF clinic between 01/01/2013 and 12/31/2018 were included. Patients were stratified by variance of LH surge day in their natural frozen embryo transfer cycles as compared to their LH surge day in their baseline menstrual cycles (0-6 days longer than baseline and >6 days longer than baseline). Patients with an LH surge earlier than their baseline day of LH surge were excluded. The primary outcomes were pregnancy and live birth rates. Logistic regression adjusted *a priori* for patient age and number of embryos transferred was used to estimate the odds ratio with a 95% confidence interval (CI) for pregnancy outcomes.

RESULTS: A total of 524 natural frozen embryo transfer cycles met inclusion criteria, including 451 cycles in the 0-6 day group and 73 cycles in the >6 day group. The mean age was 37.2 ± 3.9 days in the 0-6 day group and 36.6 ± 4.0 days in the >6 day group. The mean number of embryos transferred was 1.1 in both groups. The pregnancy rate was significantly higher for women with an LH surge day within 6 days of their LH surge at baseline (75.4%) compared to women with an LH surge day >6 days from their baseline (60.3%; OR 0.50; 95% CI 0.30-0.84). Among patients who achieved pregnancy, however, there were no significant differences between the 0-6 day group and the >6 day group for biochemical pregnancies (8.2% versus 6.8%, OR 0.80; 95% CI 0.23-2.79), miscarriage rate (6.2% versus 6.8%, OR 1.12; 95% CI 0.32-3.95), or live birth rate (82.9% versus 86.4%, OR 1.30; 95% CI 0.52-3.22).

CONCLUSIONS: Many frozen embryo transfer cycles using PGT normal embryos take place quickly after fresh stimulated cycles. We have observed that patients often ovulate later than their usual ovulation cycle day at baseline. In cycles with an LH surge >6 days from baseline, the pregnancy rate was significantly reduced compared to those with an LH surge within 6 days from baseline. These observations indicate that a prolonged follicular phase compared to a patient's baseline cycle may alter endometrial proliferation and development, leading to a negative impact on endometrial receptivity. Interestingly, once pregnancy was achieved, pregnancy outcomes were similar between the two groups. However, due to the significantly lower chances of achieving a pregnancy in the first place, we conclude that women undergoing a natural frozen embryo transfer cycle who ovulate beyond 6 days from their baseline LH surge day should consider postponing their frozen embryo transfer to another cycle.

THE RELATIONSHIP BETWEEN NUMBER OF FOLLICLES 14MM OR GREATER AT TIME OF TRIGGER OF PREGNANCY RATES IN IUI CYCLES IN WOMEN 38 YEARS AND OLDER.

Maryam Al Shatti, MD,[1] Namaa Steiner, MD,[1] Russell Frank, M.D.,[1] Jacob Ruiter-Ligeti, MD,[2] Michael H. Dahan, M.D.[2] [1]McGill University Health Centre, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada.

OBJECTIVE: To determine the pregnancy rate at IUI in women 38-42 years of age based on number of mature follicles stimulated.

DESIGN: A Retrospective Cohort Study

MATERIALS AND METHODS: A database was created of all women aged 38-42 years old who underwent IUI with stimulation at the McGill University Reproductive Centre between 2009-2018. The database contains 1597 IUIs from 944 women, 1574 has data of follicle size at hCG-trigger. All subjects were stimulated with either clomiphene (n=240), letrozole (n=176) or FSH (n=1158). ANOVA, chi square tests, and stepwise multivariate logistic regression were performed. The primary outcome was clinical pregnancy rate per cycle (intrauterine fetal pole and heartbeat), and 2nd outcomes were rate of pregnancy & amp; multiple pregnancy. Data presented are X±SD or %. Power analysis requires 785 cycles for an effect size of 0.1, alpha 0.05 and β=0.80.

RESULTS: Clinical pregnancy rates per stimulation agent were similar (p=0.87). Based on serum (chemical) pregnancy rates (p=0.93), clinical pregnancy rates (p=0.21) and multiple pregnancy rates per clinical pregnancy were similar (p=0.33) (see table). Baseline demographics were compared in the follicle groups. Female age (p=0.03), previous deliveries (p=0.04), maximum endometrial thickness (p=0.02), and serum basal FSH level (p=0.03) differed. However male age (p=0.64,) and basal serum estradiol levels (0.20), FSH (p=0.27) levels, AFC (p=0.17), and Total Motility Sperm (TMS) count (0.06) did not differ.

When stepwise multivariate logistic regression with 1 mature follicle stimulated is taken as the bench mark and controlling for age, total motility sperm count (TMS), number of previous deliveries, antral follicular count, and endometrial thickness, in no cases did having more mature follicles improve clinical pregnancy rates (table).

CONCLUSIONS: Surprisingly, number of stimulated value mature follicles did not relate to outcomes at IUI in women 38-42 years of age. Interestingly in subjects requiring triggering prior to development of any mature follicles, pregnancy rates remained robust (9%). Overall pregnancy rates in this older group were acceptable at 7% per IUI cycle.

SUPPORT: I accept complete responsibility for the data at the time of submission. I verify that I am in compliance with HIPPA standards to protect the privacy of the patients discussed in my presentation. I either have received written authorization from the patients, have removed any identifiable images or patients records from my presentation, or my presentation does not pertain to any patient treatment.

# of mature follicles at hCG	Chemical Pregnancy	Clinical Pregnancy	Multiple Pregnancy	95% CI for clinical pregnancy rate compared to 1 follicle as benchmark (MV regression)	P value MV logistic Regression for predictor of clinical pregnancy
0	8/86	8/86	0/8	0.33-37.6	0.30
1	87/983	67/983	1/67	N/A	N/A
2	35/385	28/385	2/28	0.53-6.5	0.34
3	12/94	6/94	2/6	0.43-13.9	0.31

5	0/4	0/4	0/4	N/A	0.996

P-130 4:30 PM Saturday, October 17, 2020

AFFORDABLE IVF: DETERMINANTS OF LIVE BIRTH OR ONGOING PREGNANCY AFTER FIRST CYCLE OF LETROZOLE (LTZ) – GONADOTROPIN (GN) MILD STIMULATION, IMMEDIATE ICSI, AND INTRAVAGINAL EMBRYO CULTURE. Nicholas A. Cataldo, MD, MPH,[1] Karen R. Hammond, DNP, CRNP,[1] Lisa J. Ray, MS, HCLD,[2] Cecil A. Long, MD[1] [1]America Institute for Reproductive Medicine, Birmingham, AL; [2]ART Labs Unlimited, Streamwood, IL.

OBJECTIVE: To determine what patient and cycle factors are associated with a favorable outcome when mild ovarian stimulation and immediate ICSI are combined with intravaginal embryo culture.

DESIGN: Observational cohort of all 252 women with their first cycle start on this protocol in our practice from 6/2018 to 12/2019 who planned fresh transfer, comprising nearly all our first ART cycles. Later patient cycles were censored for lack of 24-week follow-up. Ongoing pregnancy (24+ weeks' gestation) or live birth (OP/LB) was modeled by logistic regression.

MATERIALS AND METHODS: Women were non-tobacco users with BMI <40 kg/m^2. LTZ x5 days was started 4 d after oral contraceptives were stopped, then overlapped on its 5th day with customized dose gonadotropins. No GnRH analogs were used. Cycle monitoring was repeated if necessary before hCG trigger; retrieval was 35 hr later under mild sedation in a hospital office. Metaphase (M) oocytes were immediately treated by ICSI and placed with media into an INVOcell (INVO Biosciences, Sarasota, FL), which was secured in the upper vagina by a diaphragm. Typically after 5 days, if available 1-2 blastocysts (blasts) were transferred. We modeled OP/LB according to patient and stimulation factors and oocyte and embryo outcomes using JMP Pro 12.0.1 (SAS Institute, NC).

RESULTS: Mean female age was 34.2 ($\pm$4.6) yr; 25% had AMH <1.0 ng/mL, 67% were nulliparous, and 42% had prior pregnancy loss(es). Stimulations used 5–10 mg/day LTZ (5 mg in 69%) plus 1000 ± 500 units FSH over a median of 4 days (range 1-9). Only one follicle scan was done in 79%. Cancellation rate was 15%. Retrievals successfully obtained M-stage oocytes in 93% (M-2 in 78%), with a mean of 1.9 M-2's and 1.3 M-1's. Transfer [of blast(s)] followed 82% [60%] of 202 successful retrievals, with 93% of transfers on Day 5. There were 47 pregnancies ongoing or resulting in live birth.

By univariable regression, factors associated ($p<0.05$) with OP/LB included age (odds ratio [OR] 0.92/yr; 95% confidence interval [CI] 0.85–0.98); total number of metaphase (M) oocytes (OR 1.24; 95% CI 1.08–1.42) and M-2 oocytes (OR 1.50; 95% CI 1.24–1.84) retrieved; and number of blasts obtained (OR 2.47; 95% CI 1.67–3.81). LTZ at 10 mg/d and higher daily GN dose were each negatively associated with OP/LB.

No association of OP/LB was found with serum AMH, (nulli)parity, prior pregnancy loss, M-1 oocytes retrieved, or transfer of 2 *vs.* 1 blast. A non-significant negative trend was found for association of OP/LB with cycle-day-3 E_2 ($p=0.08$) and total GN dose ($p=0.09$), and a positive trend with number of embryos transferred ($p=0.07$).

After adjustment for M-2 oocyte number, LTZ dose ($p<0.01$) and total GN dose ($p<0.015$) were each negatively associated with OP/LB; age retained borderline significance ($p=0.07$).

CONCLUSIONS: Our lower-cost ART protocol, with LTZ-based mild stimulation, few monitoring visits, and intravaginal embryo culture, is more successful in younger women. M-2 oocyte yield and blast formation are predictive for successful pregnancy, but transfer of a second blast did not improve outcome. Higher LTZ and GN doses as employed were not associated with greater success.

P-131 4:30 PM Saturday, October 17, 2020

CLINICAL VALIDATION SUPPORTS THE CONCEPT OF UNIVERSAL WARMING PROTOCOLS FOR VITRIFIED HUMAN OOCYTES. Cristina Labrado, B.Sc., José Manuel Navarro, M.D. Instituto para el Estudio de la Biología de la Reproducción Humana, Sevilla, Spain.

OBJECTIVE: Human oocytes are commonly cryopreserved using a combination of vitrification and warming solutions under specific instruction for use. However, the respective warming solutions might not always be available. Vitrified oocytes may be stored for long periods or shipped to other centres. Such circumstances could result in the use of warming kits of alternative brands with different formulations and protocols, i.e. not related to the kits used for vitrification. Although many warming kits show certain similarities, they have not been comprehensively cross validated and could potentially impact survival and development rates. It is therefore of general interest to know the compatibility of a new warming protocol with already cryopreserved oocytes. It has previously been reported that vitrification and warming solutions of different brands can be successfully combined. The aim of this study was to validate if oocytes previously vitrified with a DMSO-based (dimethyl sulfoxide) kit at room temperature can be successfully warmed in a kit from another manufacturer with a different composition and used at a different temperature (37^{o}C).

DESIGN: Single centre, prospective data collection during a transition period (August 2017 to December 2019) from one oocyte vitrification and warming procedure/protocol to another.

MATERIALS AND METHODS: Oocytes from both IVF patients and donors were collected 36 hrs post HCG administration, denuded after 2.5 hrs and vitrified after a further 0.5 hrs. Vitrification was performed with a DMSO-containing kit at room temperature using an open device (VT801/Cryotop, Kitazato, Japan). Oocytes were warmed at 37°C (RapidWarm Omni, Vitrolife, Sweden). All procedures were performed according to manufacturer's recommendations. Oocytes were fertilised and cultured until day 3 or day 5/6, followed by embryo transfer or re-vitrification for later use. Survival, fertilisation and implantation rates were measured.

RESULTS: Totally, 592 oocytes from 52 patients and donors were vitrified and warmed. The survival rate was 92.3% (108/117) for patient oocytes and 92.2% (438/475) for donated oocytes. Fertilisation rate was 74.1% (80/108) and 76.5% (335/438) for patient and donor oocytes, respectively. A mean number of 2.2 and 1.8 embryos were transferred per recipient for patients and acceptors, respectively. Implantation rates were 52.9% (9/17) for patients and 50.0% (28/56) for acceptors.

CONCLUSIONS: The results show that oocytes vitrified with VT801 can be warmed with RapidWarm Omni. Here we used solutions designed for warming of oocytes at physiological temperature, which has the advantage of minimising temperature changes which can potentially result in improved performance of vitrification outcome. This information is important in view of potential stock-out situations and reassuring to provide continuity in laboratory activities and patient treatment. It will also help clinics to avoid the concomitant use of two different products and methods during the transition from one manufacturer to another.

P-132 4:30 PM Saturday, October 17, 2020

DEVELOPING A MINIMUM DATA SET, KNOWN AS A CORE OUTCOME SET, FOR IVF RESEARCH. James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Yusuf Beebeejaun, MRCOG MBBS,[2] Cindy Farquhar, FRANZCOG FRCOG MD MPH[3] COMMIT: Core Outcomes Outcome Measures for Infertility Trials [1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]King's College London, London, United Kingdom; [3]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop a minimum data set, known as a core outcome set, for IVF research.

DESIGN: Consensus development study. Core outcomes were identified using an eDelphi survey (372 participants from 41 countries) and consensus development meeting (27 participants from 11 countries).

MATERIALS AND METHODS: Potential core outcomes were identified by extracting outcomes previously reported in infertility trials. These outcomes were entered into a three-round eDelphi survey. Professionals, researchers, and people with fertility problems were asked to score the importance of each outcome. Based on their feedback, potential core outcomes were prioritised, and subsequently discussed in a consensus development meeting. Using the modified Nominal Group Technique, a minimum data set for future IVF research was agreed.

RESULTS: A longlist of 101 potential core outcomes was developed. When considering the Delphi survey, 261 healthcare professionals, 57 researchers, 54 people with fertility problems, from 41 countries, participated. Twenty-eight consensus outcomes were identified and discussed during the consensus development meeting. 14 healthcare professionals, seven researchers, and six people with fertility problems, from 11 countries, participated in the consensus development meeting. A minimum data set for IVF research was agreed (Table 1).

TABLE 1. A minimum data set for IVF research.

1 Number of embryos available for transfer or freezing
2 Biochemical pregnancy
3 Viable intrauterine pregnancy confirmed by ultrasound accounting for singleton pregnancy, twin pregnancy and higher multiple pregnancy
4 Pregnancy loss accounting for ectopic pregnancy, miscarriage, stillbirth and termination of pregnancy
5 Live birth
6 Number of embryo transfer procedures leading to a live birth
7 When applicable → time to pregnancy leading to live birth
8 Gestational age at delivery
9 Birth weight
10 Neonatal mortality
11 Major congenital anomaly
12 Serious adverse events including:
12.1 Ovarian hyperstimulation syndrome
12.2 Pelvic infection
12.3 Life threatening bleeding
12.4 Emergency surgery
12.5 Admission to level two or three care
12.6 Serious medication reaction
12.7 Death

CONCLUSIONS: Embedding the core outcome set within IVF research should ensure the comprehensive selection, collection, and reporting of core outcomes, including live birth, pregnancy confirmed by ultrasound, and pregnancy losses. Research funding bodies, the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) statement, and over 80 speciality journals, including *Fertility and Sterility*, have committed to implementing this core outcome set.

AUTOMATED VITRIFICATION AND WARMING OF OOCYTES MEDIATED BY A NOVEL MICROFLUIDICS DEVICE.

Tamara Martin, Embryologist,[1] Cristina Dosdá Munuera, Jr., Embryologist,[1] Joana Sales Fidalgo, PhD,[1] Daniel Garcia, Engineer,[1] David Cancio-Villalonga, Biomedical Engineer,[1] Pablo Carasa, Engineer,[1] Sara Álvarez-Argüelles, Engineer,[1] Susana Cortes, Sr., Embryologist,[2] Laura garcia De Miguel, PhD,[2] Enrique Criado, Sr., Embryologist,[3] Lionel Matthys, Engineer,[1] Jose A. Horcajadas, PhD,[1] Santiago Munne, PhD[1] [1]Overture Life, Madrid, Spain; [2]Tambre, Madrid, Spain; [3]OVOBANK, marbella, Spain.

OBJECTIVE: The purpose of this study is to develop a microfluidic device to automate the critical process of vitrification and thawing procedures, providing standardization, minimizing inter and intra-center variability, and reducing hands on time.

DESIGN: Experimental comparative study of both vitrification and warming of bovine and human oocytes using an automated microfluidics device (Davitri, Overture Life).

MATERIALS AND METHODS: a microfluidics system has been developed that infuses the solutions required in a central well, where the oocytes are placed, and withdraws the spent solutions. The system and the protocols were first tried in bovine oocytes, which are of similar size as human, and later on human donated oocytes. After 24 hours of maturation the cumulus oocyte complex (COCs) were denuded manually and vitrified using the palm-size Davitri device. The scripts controlling the process are based on the Kitazato protocol. Once the procedure was validated with bovine, frozen human oocytes from donors were warmed and vitrified automatically and fresh human oocytes were vitrified and warmed automatically.

RESULTS: 100 fresh bovine oocytes were vitrified automatically and warmed manually, 5 of them were lost during the procedure and 84 oocytes survive after culture (88%), compared to 80% for a control group. Also 50 fresh bovine oocytes were vitrified manually and warmed with the microfluidics device, and 48 of them survived (96%).

Donated frozen human oocytes (N=19) were warmed automatically, and 12 survived (63.15%) compared to 80% expected (1,2). Those 12 were re-vitrified automatically and 71% survived thawing compared to 70% expected after re-vitrification (3).

After these promising results 4 fresh human mature oocytes from an egg donor were automatically vitrified and manually warmed of which 100% survived. Also, 13 fresh immature oocytes were automatically vitrified and manually warmed of which 11/13 (86.6%) survived.

CONCLUSIONS: The automation of vitrification and thawing of eggs is an improvement in assisted reproduction by allowing constant high survival rates with reduced hands-on time. Here we provide proof of concept that the Davitri microfluidics device is able to vitrify and warm both bovine and human oocytes with high survival rates.

TRANSFER OF CHROMOSOMAL-ABNORMAL EMBRYOS, PREVIOUSLY REFUSED SUCH TRANSFERS.

David H. Barad, MD, MS,[1] David F. Albertini, PhD, MS,[1] Emanuela Molinari, PhD,[1] Pasquale Patrizio, M.D.,[2] Norbert Gleicher, MD[3] [1]Center for Human Reproduction, New York, NY; [2]Yale Fertility Center, New Haven, CT; [3]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY.

OBJECTIVE: To determine IVF cycle outcomes after transfer of embryos previously by preimplantation genetic testing for aneuploidy (PGT-A) diagnosed as chromosomal abnormal and previously refused such transfers.

DESIGN: Cohort study.

MATERIALS AND METHODS: Since April of 2016, 50 patients moved 249 embryos to our center that by PGT-a were characterized as chromosomal-abnormal (mosaic-aneuploid or aneuploid) and their original IVF centres were not willing to transfer. Two additional patients convinced their local centers to transfer the embryos after consulting with our center, while 2 of our own patients insisted on PGT-A against our advice. Their embryos were, therefore, included. This study, thus, reports on 54 patients, 40 (74.1%) of which have since undergone at least one selective embryo transfer (total cycles, n=45), involving 112 embryos and excluding survivable trisomies and sex chromosome abnormalities.

RESULTS: Patient age was 42.4 ± 3.7 years; 63% were Caucasian, 20% Asian and 17% of African descent; 30 (75.0%) had at least one prior pregnancy but only 11 (27.5%) achieved live birth; 25/40 (62.5%) had at least one miscarriage. Further evidence for poor IVF prognosis was that over half of embryos were day-6/7 blastocysts, with poorer pregnancy chances than day-5 blasts; 50/112 (44.6%) transferred embryos had 1 chromosomal abnormality (10 mosaic, 40 aneuploid), 54 (48.2%) had 2 or more (complex) and 8 (7.1%) were undiagnosed (degraded DNA). Pregnancy-, likely miscarriage- and likely live birth rates were per patient and per cycle, respectively, 15/40 (37.5%), 8/15 (53.3%) and 7/40 (17.5%) and 15/45 (33.3%), 8/15 (53.3%) and 7/45 (15.6%). Among pregnancy losses, 7/8 occurred before fetal heart and one was consequence of a septic amniocentesis at 18 weeks. All deliveries and ongoing pregnancies were sex-concordant with a transferred mosaic embryo; 6/8 (75%) transfers with a single mosaic abnormality resulted in live birth or ongoing pregnancy; 4/7 (57%) miscarriages were

chromosomal-concordant between PGT-A and products of conception (POCs) and, therefore, likely caused by chromosomal-abnormal embryos; 2 patients declined testing of POCs; 1 chromosomal-normal 46, XX miscarriage (with maternal contamination ruled out), was discordant, likely, miscarried because of an autoimmune disease.

CONCLUSIONS: Even in very poor prognosis patients of advanced age, transferring selected embryos, by PGT-A labelled as chromosomal-abnormal, therefore, creates significant pregnancy and live birth chances and, therefore, in conjunction with genetic counselling, should not be refused by their IVF centers.

ALTERNATIVE BLASTOCYST VITRIFICATION WARMING-DILUTION APPROACHES: DO VIRTUES OF THE KISS PRINCIPLE APPLY?

Mitchel C. Schiewe, Ph.D., H.C.L.D. (ABB),[1] Tannia Ochoa, BA,[1] Casey Zeffiro, B.A., B.S., M.S.,[1] Shane Zozula, B.S., T.S. (ABB),[1] James Stachecki, PhD[2] [1]Ovation Fertility, Newport Beach, CA; [2]Innovative Cryo Enterprises LLC, Linden, NJ.

OBJECTIVE: The global shipment of embryos has become commonplace, yet universal warming protocols for various vitrification systems (devices and solutions) are not widely used. The aim of our study is to validate effective protocols that can ease concerns regarding the warming of vitrified blastocysts sent to outside laboratories, including international shipments, when alternatives to their typical commercial products are needed.

DESIGN: Prospective, randomized study. An apriori arrangement of 4 sugar solution treatments was applied post-warming: A) fresh I.C.E. solutions; B) frozen-thawed I.C.E. solutions (i.e., stored in LN_2); C) sucrose; and D) honey (commercial grade, multi-floral).

MATERIALS AND METHODS: Research consented, discard blastocysts (>2BB quality) vitrified by the microSecure method in I.C.E. non-DMSO solutions (>7.9M glycerol/EG) were rapidly warmed in 1 of 4 solution treatment groups. The initial pilot study included 20 blastocysts per group accounting evenly for quality and batch effects before randomly assigning the treatment. Solutions A and B were a commercial I.C.E. product (T1-T4), whereas C and D were lab-made, filtered stock H-HTF+additive solutions (1M sucrose w/v and 10% honey v/v, respectively). The latter solutions both required heating and agitation over a 30 min period to completely mix into suspension before 0.22μm filtration. All treatments involved a 4-step dilution (3 min/step, 50% reduction/step, 21°C) prior to isotonic equilibration (LG-H+additives; 5 min at 37°C), followed by 18-24 hr in vitro group culture/microdroplet (5 embryos/drop). Survival, based on osmotic responsiveness and cellular integrity/fullness was visually assessed at 0 and +2 hr, followed by overnight blastocyst expansion and continued development. Potential differences were assessed using Chi-squared statistics.

RESULTS: There was no differences ($p>0.05$) in blastocyst survival (95-100%) or in-vitro development (85-95%) was observed between treatments.

CONCLUSIONS: This study proves that a variety of non-permeating sugar-based dilution solutions can be effectively used to elute concentrated cryoprotective agents from blastomeres independent of source. We, and others, have previously advocated for the use of 1M sucrose as a universal diluent. Furthermore, we have now proven that a natural product, honey, composed predominantly of fructose and glucose, is also an efficient low-cost, readily available option for any lab around the world to safely extract potentially toxic cryoprotectants from cells. Finally, we have validated that thaw solutions stored in cryovials can be frozen in LN_2 and maintain functionality, thus facilitating the potential transcontinental shipment of vitrified material with procedurally compliant thaw solutions transported in the same LN_2 dry-shipper. Additional validation replicates are planned with an open device/DMSO-EG system, but we do not anticipate a dilution treatment effect.

SUPRISING RATE OF REBOUND IN FOLLICLE GROWTH AFTER CESSATION OF OVAIAN STIMULATION IN INITIAL NON-RESPONDERS.

Norbert Gleicher, MD,[1] Andrea Weghofer, MD, PhD, MBA,[2] Sarah K. Darmon, PhD,[3] David F. Albertini, PhD, MS,[3] Emanuela Molinari, PhD,[3] David H. Barad, MD, MS[3] [1]Center for Human Reproduction, Foundation for Reproductive Medicine, Rockefeller University, Medical University Vienna, New York, NY; [2]Medical University Vienna, Vienna, Austria; [3]Center for Human Reproduction, New York, NY.

OBJECTIVE: To follow-up on the prior anecdotal observation that non-responders to ovarian stimulation, at times, spontaneously demonstrate follicle growth after sudden withdrawal of gonadotropin stimulation ("rebound"), and to prospectively quantitate such rebound rates.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: We investigated 49 consecutive patients, absolutely unresponsive to maximal exogenous gonadotropin stimulation, for a so-called rebound response to ovarian stimulation. Such a response was defined as rebound in follicle growth after complete failure to respond to maximal gonadotropin stimulation (600IU daily) over up to 5-7 days. A patient was considered to have a successful rebound if, following complete withdrawal of exogenous gonadotropin stimulation for 3-5 days, at least 1 growing follicle became visible on vaginal ultrasound and peripheral estradiol levels increased. At that point gonadotropin stimulation was reinstated in form human menopausal gonadotropin (hMG) at 225IU/day until ovulation was induced with human chorionic gonadotropin (hCG, 10,000IU). Oocyte retrieval was performed in routine fashion.

RESULTS: Median age of study patients was 40.5 ± 5.1 years (range 23-52). Women with and without rebound did not differ significantly in age (40.0± 6.0 vs. 41.0 ± 7.0 years, P=0.405). FSH levels trended lower in women with positive rebound (20.9 ±20.8 vs. 40.0 ± 58.7 mIU/mL; P=0.071); AMH levels, through extremely low in both groups, were even significantly lower in women with no rebound (0.0 ±0.1 vs. 0.1 ±0.2 ng/mL, P=0.003). Initial baseline estradiol (E2) levels did not differ (P=0.769) but last E2 levels before hCG did (45.2 ±19.4 vs. 162.0 ±70.1 (P<0.01). Among 49 patients, 24 (49.0%) demonstrated a rebound and 25 (51.0%) did not. Among the former, 21 (87.5%) reached retrieval of 1-3 oocytes and 15 (30.6%) reached embryo transfer.

CONCLUSIONS: A successful rebound in almost half of prior completely non-responsive patients was an unsuspected response rate, as was retrieval of 1-3 oocytes in over half of rebounding patients. Attempting rebounds may, thus, represent another incremental step in very poor prognosis patients before giving up on utilization of autologous oocytes. Here presented findings, furthermore, create a rational for investigating the underlying physiology leading to such an unexpectedly high rebound rate.

SUPPORT: Intramural funds from The Center for Human Reproduction and Foundation for Reproductive Medicine.

THE NEW STANDARD FOR OVULATION TRIGGERING SHOULD BE GNRH AGONIST OVER HCG DURING CONTROLLED OVARIAN STIMULATION FOR IVF/ICSI: A SYSTEMATIC REVIEW AND META-ANALYSIS.

Mathilde Bourdon, MD,[1] Maeliss Peigné, MD,[2] Celine Solignac, PharmD,[3] Bernadette M. Darné, MD,[4] Solene Languille, PHD,[4] Khaled Pocate-Cheriet, MD,[1] Pietro Santulli, MD - PHD[1] [1]Université Paris Descartes, Sorbonne Paris Cité, Faculté de Médecine, Assistance Publique–Hôpitaux de Paris (AP–HP), Hôpital Universitaire Paris Centre, Centre Hospitalier Universitaire (CHU) Cochin, Paris, France; [2]AP-HP– Université Sorbonne Paris Nord, Hôpital Jean Verdier, Bondy, France; [3]Gedeon Richter France, Paris, France; [4]Monitoring Force, Maisons Laffitte, France.

OBJECTIVE: Gonadotropin-releasing hormone agonists (GnRHa) represent an alternative way for ovulation triggering after controlled ovarian stimulation compared to the use ofhuman chorionic gonadotropin (hCG)before *in vitro* fertilisation (IVF) or intracytoplasmic sperm injection (ICSI) treatment. GnRH triggering isconsidered more physiologicaldue to the endogenous LH and FSH surges. However, the benefit of GnRHa over hCG triggering on oocyte maturation remains controversial. The objectives of this study were to evaluate whether GnRHa triggering improves oocyte maturation, clinical outcomes and safety compared to hCG triggering during controlled ovarian stimulation for IVF/ICSI.

DESIGN: Systematic review and meta-analysis of randomized controlled clinical trials.

MATERIALS AND METHODS: Searches were conducted on MEDLINE, EMBASE, the Cochrane Library, ClinicalTrials.gov and

EudraCTfrom January 1990 to June 2019, using the following keywords:'GnRH agonist', 'hCG', 'triggering'. Two independent reviewers carried out study selection, bias assessment using RoB2 tool and data extraction according to Cochrane methods. Random-effect meta-analysis was performed followed by pre-specified sensitivity and subgroup analyses.The primary outcomes were the total number of retrieved oocytes and the number of mature oocytes.

RESULTS: A total of 32studies were included in the meta-analysis. Mean-numbers of retrieved oocytes [difference in means (95% CI) 0.96 (0.25, 1.67); p< .01; n=28] and mature oocytes [0.69 (0.04, 1.33); p< .05; n=12] were statistically significantly higherafterGnRHa than after hCG triggering. After dual triggering (hCG and GnRHa), the differences in means were 1.21 (0.34, 2.08) [p< .01; N=9] for number of retrieved oocytes and 0.53 (0.02, 1.04) [p<0.05; N=8] for number of mature oocytes. No difference in clinical pregnancy [Risk ratio 1.02 (0.90, 1.15); p= .79; n=24], ongoing pregnancy [0.98 (0.84, 1.15); p= .84; n=15] and live birth [1.01 (0.71, 1.42); p=0.97; n=5] were shown. GnRHa was associated with lower global incidence of OHSS [Odds ratio 0.25 (0.08, 0.74); p= .01; n=20] and of severe OHSS [0.21 (0.05, 0.96); p< .05; n=20].

CONCLUSIONS: Evidence suggests that final triggering should be performed using GnRHa, which allows to achieve a potential higher number of retrieved and mature oocytes with comparable clinical outcomes and lower OHSS risk.

P-138 4:30 PM Saturday, October 17, 2020

PROSPECTIVE RANDOMIZED COMPARATIVE TRIAL BETWEEN ESTRADIOL HEMIHYDRATE AND ESTRADIOL VALERATE FOR ENDOMETRIAL PREPARATION IN FROZEN-THAWED EMBRYO TRANSFER CYCLES. Kundan Vasant Ingale, Sr., MBBS, DGO, DNB, FICOG, Kalyani Kundan Ingale, MBBS, DGO, DNB, Anjum Asif Shaikh, BAMS Nirmiti Clinic. Center for Assisted Reproduction, Pune, India.

OBJECTIVE:

• To compare Implantation rate, Clinical Pregnancy rate, Ongoing pregnancy rate after FET cycles between two study groups

• To compare endometrial thickness and Pulsatility index in arterioles in sub endometrial region achieved during FET cycles between two study groups

DESIGN: Prospective Randomized Comparative trial

MATERIALS AND METHODS: Total 103 patients undergoing frozen embryo transfer cycles were randomly selected who underwent in vitro fertilization with ovarian stimulation by rFSH with GnRh Antagonist protocol followed by intracytoplasmic sperm injection (ICSI) to produce at least minimum 1-2 blastocyst. During FET Cycles, endometrial preparation was done by exogenously administered estrogen for 30 days in Downregulated cycles by GnRHa Depot preparation. Group A included those patients who received Estradiol Hemihydrate for endometrial preparation during FET cycles (n=53) and Group B included those patients who received Estradiol Valerate (n-50) for endometrial preparation during FET cycles

RESULTS: Out of 103 patients, 75 patients got pregnant (72.81%). There was no statistically significant difference in endometrial growth in both groups (10.9 ± 2.5mm vs 10.9mm±2.2mm; P=1.0000). There was no significant difference in Pulsatility index (PI) in arterioles in sub endometrial region between both groups (1.26±0.14 vs 1.23±0.17, P = 0.3297).

There was significant difference in implantation rate (87.7% vs 71.1%; P = 0.0444) and ongoing pregnancy rate (75.5% vs 53.33%, P =0.0244) between Estradiol Hemihydrate and Estradiol Valerate group respectively. Though the clinical pregnancy rate was higher in Estradiol Hemihydrate group (75.5% vs 60%), it was not statistically significant (P=0.1074). There was no significant difference between biochemical pregnancy & miscarriage rate (10.2% vs 11.11%; P=0.8886, 12.24% vs 14.2%; P=0.7641) in both groups.

CONCLUSIONS: Our study demonstrated that Estradiol Hemihydrate is better estrogen compound than Estradiol Valerate not only for optimum endometrial growth but also to improve reproductive outcome in FET cycles.

P-139 4:30 PM Saturday, October 17, 2020

SIMPLE NATURAL ALTERNATIVE PROCEDURE (SNAP) METHOD FOR BLASTOCYST BIOPSY. Anthony R. Anderson, D.HSc, Darleen Taylor, B.Sc., Elizabeth Williams, B.Sc., Donna Covington, B.Sc., Ursula Balthazar, M.D. Aspire Fertility San Antonio, San Antonio, TX.

OBJECTIVE: To evaluate different lasers to the SNAP method for blastocyst biopsy

DESIGN: Retrospective cohort study evaluating PGT-A success with an alternative biopsy method.

MATERIALS AND METHODS: A total of 857 day 5 and 6 embryos were biopsied for PGT-A using Octax laser, Hamilton Thorne Zilos laser and mechanical SNAP procedure for embryo sampling. Embryos were evaluated on day 3 and assisted hatched for via laser ablation. Embryos on day 5 and day 6 with a distinct inner cell mass and multiple cells herniating form the zona pellucida were biopsied for PGT aneuploidy testing. Embryo biopsy consisted of laser removal of 5 to 7 cells from the trophectoderm juxtaposed to the inner cell mass. The biopsied cells were treated according to the reference laboratory protocol for off site aneuploidy screening. Embryos available for testing were vitrified and stored under liquid nitrogen until results were obtained from the reference laboratory.

RESULTS: There was no significant difference between any of the biopsy methods evaluated. A total of 232 (60%) from 384 embryos were euploid and 2% no amplification using the Octax Laser. The Hamilton Thorne Zilos laser resulted in 151 (59%) euploid from 256 embryos biopsied and 2.3% no amplification. The SNAP method resulted in 122 (56%) euploid of 217 embryos biopsied and 0.9% no amplification.

Additionally, there was not significant difference in ongoing pregnancy and implantation with the various biopsy methods. The Octax, HT Zilos, and SNAP methods resulted in an implantation of 74% (53/72), 76% (48/63) and 80% (34/42) respectively. Ongoing pregnancy outcome for the three groups were 53/71 (74%) for the Octax laser, 45/62 (73%) for the HT Zilos, and 33/41 (80%) for the SNAP method (not significant)

CONCLUSIONS: This study evaluates the efficacy of differing lasers and biopsy methods. Although there was no significant difference with the various methods, the SNAP method did trend toward a higher implantation per embryo transferred and lower no amplification per embryo biopsied. This study also shows that if the even of a laser failure the SNAP method is a very good alternative for evaluating aneuploidy in embryos.

LIVE BIRTH RATES AND OVARIAN HYPERSTIMULATION SYNDROME (OHSS) RISK WITH RECOMBINANT FOLLITROPIN ALFA BIOSIMILAR PREPARATIONS VERSUS ORIGINATOR PREPARATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS. Su Jen Chua, Bachelor of Medicine,[1] Salvatore Longobardi, MD,[2] Ben W. Mol, MD, PhD Prof,[3] Rui Wang, MD PhD,[4] Christos Venetis, MD, MSc, PhD,[5] Ashleigh Storr, PhD,[6] Thomas M D'Hooghe, MD, PhD[7] [1]Barwon Health, Victoria, Australia; [2]Merck Healthcare KGaA, Darmstadt, KS, Germany; [3]Monash University, School of Medicine, Melbourne, VIC, Australia; [4]Monash University, Melbourne, VIC, Australia; [5]University of New South Wales, Sydney, NSW, Australia; [6]Flinders Fertility, Adelaide, SA, Australia; [7]Merck Healthcare KGaA, Darmstadt, Germany.

OBJECTIVE: Follitropin alfa is used for ovulation induction or stimulation of multifollicular development in women undergoing assisted reproductive technologies (ART). Published randomized controlled trials (RCTs) comparing originator follitropin alfa and biosimilar preparations were not powered to assess clinically relevant outcomes. We performed a systematic review and meta-analysis to compare clinically relevant outcomes between the originator and biosimilar preparations across head-to-head RCTs.

DESIGN: Systematic review and meta-analysis

MATERIALS AND METHODS: Medline, Embase, Cochrane, Web of Science and clinical trial registries were searched for RCTs comparing biosimilars with originator follitropin alfa. Search results were screened for eligibility by two reviewers. The main endpoint was live birth. Secondary endpoints included clinical and ongoing pregnancy, ectopic pregnancy and ovarian hyperstimulation syndrome OHSS (moderate or severe), as well as cumulative live birth, ongoing pregnancy and clinical pregnancy. A fixed-effect model for meta-analysis was used to analyze the data and relative risks (RRs) with 95% confidence intervals (CIs) were calculated for each outcome. The I^2 statistic was used to evaluate heterogeneity.

RESULTS: From the 273 records identified, four RCTs were eligible for analysis. Live birth rate was significantly lower with biosimilar (Bemfola®/Afolia®, Ovaleap® and Primapur®) versus (vs) originator (GONAL-f®/GONAL-f RFF®) preparations (RR 0.83, 95% CI 0.71–0.97; n=1881). Clinical and ongoing pregnancy rates were also lower with biosimilar vs originator

preparations and there were no differences observed in risk of OHSS or ectopic pregnancy (Table). Evidence level was moderate to low.

TABLE. Relative risks for outcomes with biosimilar versus originator preparations of follitropin alfa

Outcomes	RR (95%CI)
Live birth (4 RCTs, n=1881, I^2=0%)	0.83 (0.71–0.97)
Clinical pregnancy (3 RCTs, n=1771, I^2=0%)	0.82 (0.70–0.95)
Ongoing pregnancy (3 RCTs, n=781, I^2=0%)	0.81 (0.67–0.99)
OHSS (4 RCTs, n=1881, I^2=5%)	1.33 (0.75–2.36)
Ectopic pregnancy (3 RCTs, n=1509, I^2=0%)	1.16 (0.39–3.43)
Cumulative live birth (4 RCTs*, n=1881, I^2=0%)	0.85 (0.73–0.97)
Cumulative clinical pregnancy (3 RCTs, n=1771, I^2=0%)	0.84 (0.73–0.96)
Cumulative ongoing pregnancy (3 RCTs, n=781, I^2=0%)	0.91 (0.77 – 1.07)

*Only data from the 1st cycle of Ovaleap® study are included, only Ovaleap® used in subsequent cycles. CI, confidence interval; OHSS, ovarian hyperstimulation syndrome; RCT, randomized controlled trial; RR, relative risk.

CONCLUSIONS: This meta-analysis suggests that there is a risk for inferior live birth and clinical and ongoing pregnancy rates with biosimilars vs originator preparations.

P-141 4:30 PM Saturday, October 17, 2020

HUMAN UTERINE LAVAGE: EMBRYO SAFETY AND FIRST LIVE BIRTHS FROM IN VIVO CONCEIVED GENETICALLY SCREENED BLASTOCYSTS.

Sam Najmabadi, MD,[1] José L. Rivas, MD,[2] Marlane Angle, PhD, HCLD,[3] Jacques Cohen, PhD, HCLD,[4] Alex Nadal, BA,[5] Ercan Bastu, MD,[6] Santiago Munné, PhD,[7] Sandra Ann Carson, MD,[8] John E. Buster, MD,[9] Steven T. Nakajima, MD[10] [1]Center for Reproductive Health & Gynecology, Beverly Hills, CA; [2]Punta Mita Hospital, Punta Mita Fertility Center/ Center for Reproductive Health & Gynecology, Punta de Mita, NA, Mexico; [3]Laurel Fertility Care, San Francisco, CA; [4]Althea Science Inc., Hudson, NY; [5]Previvo Genetics Inc., Parker, CO; [6]Acibadem University School of Medicine, Istanbul, Turkey; [7]Overture Life, Madrid, Spain; [8]Yale University, New Haven, CT; [9]Brown University, Providence, RI; [10]Stanford University School of Medicine, Sunnyvale, CA.

OBJECTIVE: To determine the impact of the uterine lavage procedure on human embryos. To determine the implantation and live birth rate of in vivo conceived blastocysts obtained by uterine lavage.

DESIGN: Two separate protocols. Protocol #1, Human Blastocyst Safety Study: Uterine lavage of a known number of human in vitro fertilization (IVF) blastocysts from silicon uterus model then cultured for 24 hours in an embryology laboratory. Protocol #2, Lavage Feasibility Study: Observational case series of 9 embryo transfer procedures performed at an outpatient fertility center. Human Blastocyst Safety Study performed before Lavage Feasibility Study.

MATERIALS AND METHODS: Human Blastocyst Safety Study:

Five uterine lavage procedures performed after 4-6 human IVF blastocysts per uterine lavage were placed into a silicon uterus model. Human IVF blastocysts had been previously donated for research purposes. Three uterine lavages performed with standard intrauterine suction and two performed with increased intrauterine suction. Recovered embryos were cultured for 24 hours.

Lavage Feasibility Study:

In vivo conceived embryos recovered by uterine lavage five days after intrauterine insemination were available for embryo donation. In vivo embryos were the result of prior controlled ovarian stimulation cycles in oocyte donors and intrauterine insemination with donor sperm. Nine embryo transfer procedures performed with in vivo conceived embryos recovered by uterine lavage. One to two embryos were transferred to eight infertile women.

RESULTS: Human Blastocyst Safety Study:

92% (23/25) of IVF blastocysts placed into uterine model were recovered after uterine lavage. 95% (20/21) of IVF blastocysts recovered with standard intrauterine suction were viable after 24 hours of culture. 75% (6/8) of IVF blastocysts recovered with increased intrauterine suction were viable after 24 hours of culture.

Lavage Feasibility Study:

Nine ETs were performed with 14 blastocysts in eight women resulting in a blastocyst implantation rate of 36% (5/14), clinical pregnancy rate of 44% (4/9) and live birth rate of 44% (4/9). There has been the birth of five infants from the four delivered pregnancies with one set of twins.

CONCLUSIONS: This is the first report of live births and ongoing pregnancies from genetically screened human euploid blastocysts obtained by uterine lavage. The nonsurgical uterine lavage office procedure represents the only current approach to obtain in vivo conceived embryos and provides a benchmark for comparison to standard in vitro cultured blastocysts. Live births of in vivo conceived blastocysts represents the validation that the nonsurgical uterine lavage procedure allows simplified access to naturally conceived embryos. Due to its simplicity, uterine lavage may be useful in screening embryos for preimplantation genetic testing for aneuploidy and/or for known genetic diseases in fertile and infertile couples.

EQUIVALENT BIOCHEMICAL PREGNANCY RATE BETWEEN FRESH AND FROZEN EMBRYO TRANSFERS.

Caitlin Boylan, BS,[1] Jessica R. Kanter, MD,[2] Nathanael C. Koelper, MPH,[3] Jennifer Mersereau, MD,[4] Dara S. Berger, PhD[5] [1]University of North Carolina, Raleigh, NC; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylavia, Philadelphia, PA; [4]UNC Fertility, Raleigh, NC; [5]University of Pennsylvania, Division of Reproductive Endocrinology and Infertility, Philadelphia, PA.

OBJECTIVE: To determine if there is a difference in biochemical pregnancy rates as a marker of early pregnancy loss between fresh and frozen embryo transfer cycles with fair or high quality embryos.

DESIGN: Single center retrospective cohort.

MATERIALS AND METHODS: All cycles completed between the years 2015-2019 at a single academic institution were reviewed. Fresh embryo transfers included in analysis were limited to autologous, day 5 embryo transfer of fair or good quality embryos only (3BC/3CB or higher according to Gardner's grading scale). Cycles with transfer of poor-quality embryos were excluded (any embryo with a lower grade of 3CB/3BC). Frozen embryo transfers included all autologous blastocyst transfers of fair or good quality embryos. A total of 1,890 cycles were evaluated which included 1,419 frozen embryo transfers and 471 fresh embryo transfers. Chi-square tests and multivariable logistic regression were used to assess associations and account for potential confounding.

RESULTS: Overall pregnancy rates did not differ between frozen and fresh embryo transfers (69.1% vs 71.1%, p=0.40). Live birth rates were also consistent between groups at 41.23% for frozen embryo transfer and 44.37% for fresh transfer (p=0.23). Biochemical pregnancy rates as a percentage of total transfers were 9.6%. There was no difference in biochemical pregnancy rate for frozen or fresh embryo transfer (9.6% vs 10.6%, p=0.52) When adjusted for BMI and age at cycle start, the OR of biochemical pregnancy for fresh embryo transfer is 1.13 [95% CI 0.80-1.59].

CONCLUSIONS: There is no significant difference in biochemical rates between fresh and frozen embryo transfers. This suggests the early pregnancy loss rate may not be affected by the changes involved in fresh embryo transfer cycles including the supraphysiologic hormonal milieu.

P-143 4:30 PM Saturday, October 17, 2020

AUTOLOGOUS PLATELET-RICH PLASMA INJECTION INTO THE ENDOMETRIUM IN PATIENTS WITH UTERINE FACTOR INFERTILITY. Zulfiia Nurudinovna Efendieva, Dr,[1] Inna Anatolyevna Apolikhina, Professor,[2] Elena Anatolyevna Kalinina, Professor,[2] Tatiyana Anatolyevna Fyodorova, Professor,[2] Dmitriy Mikhailovich Belousov, Dr,[2] Timur Khaisamudinovich Fathudinov, Professor[2] [1]I.M. Sechenov First Moscow State Medical University, Ministry of Healthcare of Russian Federation, Moscow, Russian Federation; [2]National Medical Research Center for Obstetrics, Gynecology and Perinatology named after Academician V.I.Kulakov of Ministry of Healthcare of Russian Federation, Moscow, Russian Federation.

OBJECTIVE: The study aims to evaluate the effectiveness of autologous platelet-rich plasma (PRP) injection during histeroscopy in infertile patients with thin endometrium which is refractory to conventional treatment.

DESIGN: Prospective interventional study.

MATERIALS AND METHODS: All patients signed informed consent for medical intervention and participation in the study. The study included 42 patients aged 18-38 years (34.9 (3.6) years) with an endometrial thickness (EMT) of $\leq$7 mm during the mid-luteal phase of menstrual cycle, who had a history of implantation failures or canceled embryo transfer (ET) cycles due to a thin endometrium. During the mid-luteal phase transvaginal ultrasound was performed to all patients to assess the EMT, as well as Doppler examination, and endometrial aspiration biopsy to further assess its receptivity. PRP was prepared from 400 (50) ml of autologous blood by two-stage centrifugation and reinfusion of the patient's autoerythrocytes. All patients were injected 40 (5) ml of autologous PRP into the most altered areas of endometrium with an endoscopic needle with a diameter of 0.6/1.16 mm through the operating channel of the hysteroscope to a depth of 0.2-0.3 mm on the 6th - 8th day of the proliferative phase of the menstrual cycle preceding the ET. The duration of the intervention was on average 15 minutes. In the new menstrual cycle, patients took orally administered estradiol valerate, starting from the 3rd-4th day with initial dose of 4 mg per day with subsequent correction according to the endometrial response. The daily maximum dose was 10 mg. In the mid-luteal phase patients underwent a control ultrasound examination by the same specialist to assess the EMT. Patients who reached the optimal EMT were transferred one good quality embryo. Posttransfer support was performed by 600 mg of micronized progesterone intravaginally per day until the results of serum β-chorionic gonadotropin were obtained. Numerical parameters were presented as M (SD) and Me (Q1; Q3). Statistical significance was determined at $p<0.05$.

RESULTS: In study population 71.4% of patients (30/42) had a history of cancellation of ET cycles due to inadequate endometrial growth. The mean EMT on the previous-cycle mid-luteal phase was 5.4 (4; 6) mm. After PRP treatment, EMT was 7.5 (7; 9), which was significantly thicker than initial values ($P<0.001$). The clinical pregnancy rate was 33.3% (14/42) after ET. Three patients had a livebirth after ET, 3 patients had a miscarriage at 7-8 weeks, and 8 pregnancies develope normally in accordance with the gestation period. There were no cases of transmission/allergic reactions or infectious complications in any patient. The study is ongoing, and Doppler parameters and endometrial receptivity are being evaluated.

CONCLUSIONS: The study has demonstrated for the first time a new approach to the treatment of women with infertility caused by thin endometrium which is refractory to conventional hormonal and "vascular" treatment methods. Further research is needed to provide the opportunity for the women with refractory thin endometrium to conceive without surrogacy.

TOP TEN RESEARCH PRIORITIES FOR MEDICALLY ASSISTED REPRODUCTION. James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Cindy Farquhar, FRANZCOG FRCOG MD MPH,[2] Priority Setting Partnership for Infertility[1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop the top 10 research priorities for medically assisted reproduction.

DESIGN: International consensus development study including healthcare professionals, researchers and people with fertility problems.

MATERIALS AND METHODS: Potential research questions were collated from an initial international survey, a systematic review of national and international fertility guidelines, and Cochrane systematic reviews. A rationalized list of confirmed research uncertainties were prioritized in an international survey. Prioritized research uncertainties were discussed during a consensus development meeting.

RESULTS: The initial survey was completed by 388 participants, from 40 countries, and 111 potential research questions were submitted. By reviewing 14 clinical practice guidelines and 162 Cochrane systematic reviews, a further 50 potential research questions were identified. A rationalized list of 101 confirmed research uncertainties were entered into an interim prioritization survey completed by 317 respondents from 43 countries. The top 10 research priorities for female and unexplained infertility were identified during a consensus development meeting involving 41 participants from 11 countries (Table 1).

CONCLUSIONS: We anticipate these research priorities will help research funding organizations and researchers to develop their future research agenda. Healthcare professionals, professional organisations, and patient advocacy groups should champion the research priorities to highlight the many unanswered questions which need to be addressed in order to improve the outcomes of people with fertility problems.

FIGURE 1. Top ten research priorities for medically assisted reproduction.

1	What are the causes of implantation failure?
2	What is the optimal treatment for women who are poor responders undergoing IVF to increase live birth rates?
3	What is the optimal method of sperm selection in IVF cycles?
4	In couples with unexplained infertility does intrauterine insemination increase live birth rates when compared with other assisted reproductive techniques, including IVF?
5	In couples with unexplained infertility what is the optimal number of intrauterine insemination cycles before moving to IVF?
6	What is the optimal method of embryo selection in IVF cycles?
7	What are the factors which affect cycle to cycle variability in the number and quality of oocytes produced in an IVF cycle?
8	What is the optimal time interval between ovulation and intrauterine insemination?
9	What is the emotional and psychological impact on children born using donor gametes?
10	What is the emotional and psychological impact of repeated fertility treatment failure?

SIGNIFICANT IMPROVEMENT IN SPERM MOTILITY IN SEMEN SAMPLES FROM ASTHENOZOOSPERMIC MEN BY USING CONTROLLED INCUBATION PROTOCOLS WITH SINGLE CONTINUOUS CULTURE MEDIUM (CSCM®). Juliana Risso Pariz, PhD, Caroline Ranéa, BSc, Jorge Hallak, PhD Universidade de Sao Paulo, Sao Paulo, Brazil.

OBJECTIVE: To test different incubation periods and to assess an appropriate commercially available medium to improve the performance of semen samples from asthenozoospermic men.

DESIGN: Prospective study

MATERIALS AND METHODS: Semen samples (progressive motility <32%) from 54 asthenozoospermic patients (men aged 21-45 years) were used in the study after signed the informed consent form. Fresh semen samples separated by a discontinuous density gradient or by simple washing, were incubated in different culture media and then analyzed. Four different culture media were studied: a) Single Continuous Culture Medium (CSCM®) containing 10% Human Serum Albumin (HSA®); b) Sperm Rinse medium (SR®) supplemented with fructose and carnitine; c) *In Vitro* Fertilization Medium (G-IVF®) with fructose and 15% Synthetic Serum Substitute (SSS®) and; d) a control group in which Human Tubal Fluid (HTF®) supplemented with 15% SSS® was used. The last one represents the most commonly used medium by labs worldwide. Samples were then

incubated at 37°C in a 5% CO_2 atmosphere for 2-hour (defined as the optimal incubation time in previous study). Sperm parameters were then analyzed both in fresh samples and after incubation in different media: manual sperm analysis; motility via Sperm Computer Analysis (SCA®); sperm chromatin integrity via Sperm Chromatin Structural Assay (SCSA®); Reactive Oxygen Species level (ROS) by chemiluminescent detection and mitochondrial activity by staining with 3.3′-diaminobenzidine (DAB). Data were analyzed using the IBM SPSS software. Analysis of variance (ANOVA) and independent student *t*-tests were used to evaluating statistical significance ($P<0.05$).

RESULTS: CSCM® medium demonstrated a significant increase in post-incubation motility (progressive motility = 24.55±13.97%; total motility = 41.17±19.06%) compared to pre-incubation parameters (progressive motility = 8.33±6.82; total motility = 26.61±18.10%; $P<0.025$). For all other culture media, no significant differences were observed in seminal parameters.

CONCLUSIONS: Asthenozoospermic men may have significant improvement in their semen samples in the andrology lab after a 2-hours incubation in CSCM®+HSA® medium. This technique has proven to be very attractive because of its efficiency, low cost and ease of reproduction.

SUPPORT: Miss Ranéa was a recipient of a Master scholarship from the São Paulo Research Foundation (FAPESP, process number 2017/03599-1). Dr. Pariz received research grant from the FAPESP (process number 2019/24800-2). Prof. Dr. Hallak received research grant from the FAPESP (process number 2018/26171-0).

P-146 4:30 PM Saturday, October 17, 2020

CLINICAL PREGNANCY IN FROZEN EMBRYO TRANSFER WITH FRESH VERSUS VITRIFIED METAPHASE II OOCYTES IN AN EGG DONATION PROGRAM: A RETROSPECTIVE STUDY.

Carlos Manuel Duarte, Sr., Bachelor,[1] Victor Hernán Nuñez, Bachelor,[2] Mayra Alessandra Guzman, Bachelor,[1] Paola Stephanie Olavegoya, Bachelor in biology,[1] Carlos Alberto Vivar, Bachelor,[1] Elder Omar Benites, Bachelor,[3] Urso Victor Rodriguez, MSC,[3] Carlos Alfredo Vergara, Bachelor[3] [1]Biologist, Lima, Peru; [2]Clinical Embryologist, Lima, Peru; [3]Medical director, Lima, Peru.

OBJECTIVE: Determine the impact of vitrification process on the embryo development and clinical pregnancy rate in assisted reproduction treatments with frozen embryo transfer (FET) in an egg donation program.

STUDY DESIGN: Retrospective study was performed at Niu Vida in Lima, Peru during 2018-2019. A total of 77 cycles were included. We used oocytes from donors which fertility was proved and blastocyst transfer was performed in a delayed artificial cycle.

Cases with at least one optimum quality blastocyst were included. An exclusion criteria was Oligoasthenozoospermia. We assigned two groups, Group A: FET cycles with fresh oocytes and Group B: FET cycles with frozen-thawed oocytes.This study was declared exempt by the clinic's ethics committee.

MATERIALS AND METHODS: Oocytes were obtained applying FSH / LH, antagonists (one follicle of 14 mm) and triptorelin®.

We injected oocytes with seminal samples at a minimal concentration of 10 x 106 spz / ml separated by density gradients. Only metaphase II oocytes maturation stages were considered. Cryotech® protocol was used for vitrification and the thawing process. For endometrial preparation progesterone and progynova were used. Embryo transfers were performed minutes after thawed, post evaluation of embryo survival.

Variables analyzed: receptor age, fertilization rate, blastocyst rate per fertilized oocyte, ongoing clinical pregnancy rate, number of oocytes assigned per receptor, fertilized and blastocysts.

Stata 12.1 software was used for statistical analyses. We use T Student's test for continuous variables normally distributed and chi-square test for categorical variables. Statistical significance was set at $p < 0.05$.

RESULTS: Receptor's ages were not significantly different among groups evaluated (Group A: 42.71 ± 4.13 and Group B: 42.7 ± 4.90, p 0.49). Nevertheless, the number of oocytes assigned per receptor was higher in patients who received FET coming from fresh oocytes cycles (Group A: 13.33 ± 3.87, Group B: 10.75 ± 3.58, $p <0.004$).

The fertilization rate (Group A: 11.93 ± 3.79, Group B: 8.78 ± 3.33, $p <0.001$) and the number of blastocysts developed (Group A: 6.95 ± 3.44 and Group B: 5.15 ± 2.56, $p <0.014$) were higher for Group A compared to Group B.

Our results suggest that there is no significant difference ($p <0.05$) neither in the blastocyst formation rate (Group A: 58.29% and Group B: 58.72%, $p <0.90$) or the clinical pregnancy rate (Group A: 60% and Group B: 62%, $p <0.61$).

CONCLUSIONS: We conclude that in our egg donation program there is no impact of the vitrification process neither in the blastocyst formation rate nor on the clinical pregnancy rate.

In addition, patients undergoing assisted reproduction procedures with FET and donated oocytes have the same possibility to become pregnant regardless of whether fresh or frozen-thawed oocytes were used for their procedures.

NORMAL FERTILIZATION AND BLASTOCYST DEVELOPMENT RATES OF IN-VITRO FERTILIZATION INSEMINATION VS INTRA CYTOPLASMIC SPERM INJECTION.

Seyedeh Nahaleh Salvatian, MS,[1] Deborah E. Johnson, MA,[1] Zachary Haimowitz, B.S.,[1] Alin Lina Akopians, MD, PhD,[2] Mark Surrey, MD,[2] Jason A. Barritt, PhD[1] [1]ART Reproductive Center, Beverly Hills, CA; [2]Southern California Reproductive Center, Beverly Hills, CA.

OBJECTIVE: In-vitro fertilization has been highly successful using both conventional insemination (IVF) and intracytoplasmic sperm injection (ICSI) methods for fertilization. Despite many studies comparing IVF versus ICSI outcomes, there is insufficient evidence that supports one method is superior to the other. We set out to determine if results differ for fertilization and blastocyst development when comparing IVF vs ICSI.

DESIGN: Retrospective data analysis of laboratory outcomes of IVF vs ICSI cycles at a large, private fertility center.

MATERIALS AND METHODS: All 2018 IVF and ICSI cycles underwent ovulation induction per standard clinical protocols. Oocyte retrievals were performed, and oocytes for ICSI were denuded one-hour post retrieval; and incubated for one additional hour until ICSI was performed. By comparison, IVF of oocytes was performed two hours post retrieval. Spermatozoa used in both procedures were isolated following a single gradient centrifugation processing. A total of 11,861 oocytes were exposed to sperm; with 1,115 by IVF and 10,489 by ICSI. Normal and abnormal fertilizations and blastocyst developmental rates were analyzed for both procedures. Data was analyzed using Chi-square analysis with $p<0.05$ set for significance.

RESULTS: Normal fertilization, the presence of 2 pronuclei (2PN), was significantly lower in the IVF group (59.5% vs 67.0%; $p<0.0001$). Abnormal fertilization, the presence of $\geq$ 3 pronuclei, was significantly higher in the IVF group (4.6% vs 1.2%; $p <0.0001$). However, overall blastocyst formation rates were not statistically different between the two groups (52.1% in the IVF group and 49.5% in the ICSI group).

CONCLUSIONS: According to our findings, ICSI results in a significantly higher normal fertilization rate, as well as a significantly lower abnormal fertilization rate compared to conventional IVF. These differences alone account for an approximately 10% decrease in the overall number of developing embryos when using IVF. This data demonstrates that ICSI produces more useable embryos, which may be substantially beneficial for patient's long-term outcomes using ART technologies.

P-148 4:30 PM Saturday, October 17, 2020

INTRAOVARIAN INJECTION OF AUTOLOGOUS PLATELET RICH PLASMA (PRP) ENHANCES OVARIAN FOLLICULOGENESIS.

Janelle M. Jackman, MBBS,[1] Shelena Ali-Bynom, M.D., M.P.H,[2] John Zhang, MD, PhD,[1] Alex Amberg, M.D.,[2] Lana Lipkin, M.D.,[1] Meir Olcha, M.D.,[1] Zaher Merhi, MD, HCLD[3] [1]New Hope Fertility Center, New York, NY; [2]The Brooklyn Hospital Center, Brooklyn, NY; [3]SUNY Downstate University and New Hope Fertility Center, New York, NY.

OBJECTIVE: To determine the efficacy of PRP on ovarian folliculogenesis in women with severe diminished ovarian reserve (DOR).

DESIGN: Retrospective data analysis at a fertility center with university-based affiliation.

MATERIALS AND METHODS: 140 patients (mean age 43.9 ± 0.5) with severe DOR at a single fertility clinic had their antral follicle count (AFC) measured by transvaginal ultrasound before (baseline, week 0) and after (once weekly for a total of 6 weeks) bilateral intraovarian PRP injection. The PRP was prepared from the patient's own peripheral blood

TABLE. AFC at baseline before PRP and after PRP on weeks 1 through 6 following the procedure.

Week	AFC before PRP	AFC after PRP	p-value (comparison against baseline week 0)
0 (baseline)	Both ovaries 1.24 ± 0.16 Right ovary 1.04 ± 0.20 Left ovary 1.44 ± 0.25	—	
1	—	Both ovaries 1.78 ± 0.22 Right ovary 1.55 ± 0.28 Left ovary 2.10 ± 0.34	0.0007
2	—	Both ovaries 1.53 ± 0.17 Right ovary 1.42 ± 0.23 Left ovary 1.64 ± 0.24	0.0014
3	—	Both ovaries 1.57 ± 0.16 Right ovary 1.48 ± 0.22 Left ovary 1.67 ± 0.28	0.0012
4	—	Both ovaries 1.5 ± 0.18 Right ovary 1.41 ± 0.22 Left ovary 1.59 ± 0.29	0.0016
5	—	Both ovaries 1.58 ± 0.26 Right ovary 1.58 ± 0.26 Left ovary 2.14 ± 0.33	0.0012
6	—	Both ovaries 1.77 ± 0.33 Right ovary 1.77 ± 0.33 Left ovary 1.91 ± 0.30	0.0008

and injected in the cortex of each ovary under transvaginal ultrasound guidance under intravenous sedation. Data are expressed as mean ± SEM. Repeated measures ANOVA was performed to compare the AFC changes over the period of the study in both ovaries as well as in the right and the left ovary separately.

RESULTS: Compared to baseline (week 0), the total AFC in both ovaries, the AFC in the right ovary (p-value <0.05 for all), and the AFC in the left ovary (p-value <0.05 for all) were significantly increased following PRP on weeks 1, 2, 3, 4, 5 and 6 (Table).

CONCLUSIONS: These preliminary data show that PRP can stimulate follicular development for at least 6 weeks following the intraovarian injection. Whether these findings reflect better hormonal milieu or better pregnancy rates in infertile women with severe DOR will be determined in our future continuing studies.

P-149 4:30 PM Saturday, October 17, 2020

ON THE UTILITY OF THE ENDOMETRIAL RECEPTIVITY ASSAY (ERA) TO CORRECT RECURRENT IMPLANTATION FAILURE (RIF): NOT AS SIMPLE AS IT SEEMS. Bruce I. Rose, MD, PhD,[1] Lauren Cover, RN,[1] S. E. Brown, MD[2] [1]Brown Fertility LLC, Jacksonville, FL; [2]Mayo Clinic College of Medicine and Science, Jacksonville, FL.

OBJECTIVE: To use information from ERA testing to improve ongoing/delivered pregnancy rates of patients with RIF

DESIGN: A prospective non-experimental series

MATERIALS AND METHODS: The ERA test (Igenomix, Miami, FL) measures mRNA from endometrial tissue produced from 228 genes during a mock frozen embryo transfer (FET) cycle. Using a determination of up and down regulation of transcripts, an optimal time for embryo transfer is recommended. The test is standardized to evaluate endometrial tissue obtained after approximately 120 hours of progesterone exposure to an estrogen treated endometrium.

Brown Fertility routinely performs embryo transfers of vitrified/warmed embryos after approximately 144 ± 3 hours of progesterone exposure to estrogen treated endometrium. This protocol results in an overall pregnancy rate of 59.1% (164 transfers).

Patients with two or more failed transfers of at least 3 high quality (or 2 known euploid) embryos (with at least 1 FET) were offered the opportunity to have ERA testing done during a mock FET cycle. Patients were informed of the cost of this test, that it was unlikely to be covered by their insurance, and that we had no experience as to whether or not it would be helpful for them.

RESULTS: Twenty-four patients elected to have this testing done from 2016-2019. The average age of these patients was 36.6 ± 5.7 years. They had had a total of 174 embryos transferred during 94 transfers resulting in 5 clinical pregnancies and one live birth. Of these 174 embryos, 75 were created using donor oocytes from young women.

Biopsies were adequate to obtain ERA results on 21 patients (87.5%). Of the 21 patients with results, 81% (17) had results suggesting the need to modify the transfer time interval of their next FET cycle from our normal protocol (144 ± 3 hours).

The results of the subsequent FET cycles using the modification suggested by the ERA results were as follows:

Clinical pregnancy rate per transfer- 76.5% (13/17)

Implantation rate- 50% (16/32)

Ongoing or delivered pregnancy rate per transfer- 58.8% (11/17)

CONCLUSIONS: Results from ERA testing were highly effective in enabling 58.8% of our patients with severe RIF to achieve ongoing pregnancies.

The interpretation of the significance of this series is less straightforward. Most of this practice's patients were able to achieve a live birth after FET at 144 ± 3 hours of progesterone exposure. However, those that repetitively fail to do so can be identified by ERA testing and a modification of their transfer timing can effectively result in a viable pregnancy.

These observations suggest that the ERA is unlikely to define the "universal/true" implantation window for all patients. The implantation window likely occurs at a range (120-144 hours) of times. However, there is a subset of women (those with RIF at 144 hours) for whom the ERA test is effective in identifying their narrow window of implantation at approximately 120 hours.

P-150 4:30 PM Saturday, October 17, 2020

DIFFERENCES IN MORPHOKINETICS PARAMETERS BETWEEN EUPLOID MALE AND FEMALE BLASTOCYSTS AND ITS POTENTIAL IMPLICATION ON CLINICAL PREGNANCY RATES. Aline R. Lorenzon, PhD,[1] Catherine Jacobs, BSc,[2] Mariana Nicolielo, BSc,[2] Fabiana Mendez, BSc,[2] Mauricio B. Chehin, MD, PhD,[3] Eduardo LA. Motta, MD, PhD,[2] Jose Roberto Alegretti, MSc[4] [1]Scientific Coordinator, Huntington Medicina Reprodutiva, Sao Paulo, Brazil; [2]Huntington Medicina Reprodutiva, Sao Paulo, Brazil; [3]Huntington Medicina Reprodutiva, São Paulo, Brazil; [4]Huntington Medicina Reprodutiva, Embryology Department, Sao Paulo, Brazil.

OBJECTIVE: Differences on male and female metabolism and kinetics have been reported in early embryo development. However, there is still no consensus regarding the influence of sex on embryo's morphokinetics parameters, although recent studies pointed differences in morphokinetics markers for reproductive outcomes. We aimed to investigate if the embryo sex affects morphokinetics and implantation rates in euploid transfers and if those parameters are related to clinical pregnancy rates.

DESIGN: Retrospective cohort study (December 2017 to December 2019), analyzing morphokinetic parameters collected from a time-lapse

system from 482 euploid embryos. Embryo transfers and clinical pregnancies were followed up.

MATERIALS AND METHODS: Patients with clinical indication to IVF treatment and blastocyst biopsy (NGS platform) were included (n=257). All oocytes retrieved were fertilized by ICSI and cultured in a time-lapse system (Embryoscope Plus, Vitrolife). Euploid embryos were morphologically graded according to Gardner's system and also followed morphokinetic parameters on time of pronucleous fading (tPNf), time to 2-cell(t2), time to 3-cell (t3), time to 4-cell (t4), time to 5-cell (t5), time to 8-cell (t8) and time to blastulation (tB). Chi-square or t-test were used for statistical analysis.

RESULTS: From 482 reported euploid blastocysts, 240 were male (49,8%) and 242 females (50,2%). Maternal age was similar between male and female groups (38,13±3,62 versus 38,40±3,78, p=0.3009). Analysis of morphokinetics parameters revealed that at t8, male embryos were faster than females (58,61±9,93 versus 59,85±8,89, p=0.0349). Other morphokinetic parameters analyzed were similar between genders. Two-hundred twenty-seven embryos were transferred and had known implantation outcomes. Clinical pregnancy rates were similar between male and female (48,8% versus 56,8%, p=0.2329). Maternal age in positive and negative clinical pregnancy were similar between genders (male: 38,30±2,90 versus 38,47±2,95, p=0.8705 and female: 38,55±3,38 versus 38,19±4,72, p=0.7078, respectively). Morphokinetics parameters in positive and negative clinical pregnancy in male embryos were not statistically different. However, in female blastocysts, clinical pregnancy was correlated with faster t5 and t8 (t5: 48,84±6,30 versus 50,95±6,95, p=0.0416 and t8: 57,01±7,20 versus 62,22±10,15, p=0.0029, respectively). Morphology grades between male and female embryos were not different between good quality embryos (grades A and B – 80% versus 76%) and poor quality embryos (at least one grade C – 20% versus 24%, p=0.2736).

CONCLUSIONS: Our results showed that euploid male blastocysts are faster at t8, however the clinical pregnancy rate is correlated to t5 and t8 only for female euploid embryos. The morphokinetic parameters, as a tool for embryo selection, is an increasing demand in IVF routine mainly after the time-lapse technology's implementation. The differences in morphokinetics between male and female blastocysts must be taken into consideration at the time of selection of the embryo with best potential of clinical pregnancy.

P-151 4:30 PM Saturday, October 17, 2020

STUDY OF LET 7 MIRNAS IN CUMULUS CELLS OF WOMEN UNDERGOING IVF. Sofoklis Stavros, MD, PhD,[1] Despoina Mavrogianni Dr, PhD,[2] Elmina Papatheodorou, Biologist,[1] Maria Poulimenea, Biologist,[1] Rami Raouasnte, MSc,[2] Dimitris Loutradis, Professor,[1] Peter Drakakis, Professor[2] [1]Molecular Biology of Reproduction Unit and Recurrent Abortions Unit, Assisted Reproduction Division, Athens, Greece; [2]Molecular Biology of Reproduction Unit and Recurrent Abortions Unit, Assisted Reproduction Division, Athens, Greece, Greece.

OBJECTIVE: To investigate the expression of let7b and let 7c genes in women undergoing IVF

DESIGN: This is a single-centre study carried out in the molecular biology laboratory of the IVF unit of a gynecological and obstetrics department spanning the period September 2018 to September 2019. We studied the expression of let 7b and c genes in cumulus cells of 25 women undergoing IVF treatment

MATERIALS AND METHODS: RNA was extracted from cumulus cells of 25 women using Monarch total RNA kit. Subsequently cDNA was synthesized by using Takara primescipt cDNA synthesis kit and Real time PCR (LightCycler480II) using SYBR Green and specific primers for let 7b and c genes was applied.

RESULTS: The expression of let 7b was higher (mean value of Cp 28.7) than the expression of let7c (mean value of Cp 36.2), indicating that the let 7b gene may be a biomarker, associated with the maturation and function of cumulus cells. High expression levels of various let-7 family members have been reported in cumulus cells. Additionally, let-7 miRNAs are negatively associated with pluripotency although they are highly expressed in oocytes indicating a high degree of tissue specificity of miRNA expression. Our findings are in accordance with previous results and underline the likelihood that they are involved in regulating different processes at specific time points.

CONCLUSIONS: Our findings show that the let7b gene has a higher expression than the let7c gene in cumulus cells indicating a possible mechanism involving miRNAs in female infertility. The limitations of our study include our small group size. Larger sample would be valuable and potentially helpful in critically evaluating our findings. Detecting candidate genes associated with overexpressed or downregulated miRNAs such as let 7b appears essential, for the better understanding of the mechanism underlying the oocyte-cumulus cells complex

P-152 4:30 PM Saturday, October 17, 2020

OUTCOMES AND CHARACTERISTICS OF PATIENTS WHO UNDERGO INTRAUTERINE INSEMINATION IMMEDIATELY FOLLOWING FAILED OOCYTE RETRIEVAL. Pietro Bortoletto, MD, Stephanie Willson, MD, Phillip A. Romanski, MD, Owen Davis, M.D., Zev Rosenwaks, M.D. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To describe the patient and cycle characteristics of women who undergo intrauterine insemination (IUI) immediately following an oocyte retrieval in which no oocytes are retrieved.

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: We identified women at our center who underwent controlled ovarian stimulation or natural cycles that culminated in an oocyte retrieval procedure. Of these women, we then identified those who had no oocytes retrieved and were advised to undergo an IUI on the same morning. All women undergoing IUI had at least one patent fallopian tube and access to sperm with adequate semen parameters. We report the mean (standard deviation) for each patient and cycle level variable.

RESULTS: Between 2009 and 2020, a total of 157 unique cycles were identified in which women had no oocytes retrieved. Of these, 49 women (27.7%) then underwent IUI on the same day. The mean (SD) age for this group was 40.3 (3.8), parity was 0.5 (0.6), BMI (kg/m^2) was 25.1 (6.9), and AMH (ng/ml) was 0.3 (0.3). Ninety percent had been diagnosed with diminished ovarian reserve, with a mean of 3.6 (3.1) previous IVF attempts. Thirteen (26.5%) were on natural cycle protocols, 31 (63.3%) were on GnRH antagonist protocols, and 5 (10.2%) were on GnRH agonist protocols. One in three women (31.3%) had a leading follicle (>10mm) on cycle day 2/3 with a mean size (mm) of 13.3 (3.7). The mean follicular size (mm) on the day of trigger was 19.9 (2.8), with a mean of 1.9 (1.4) total follicles greater than 14mm in size. Over ninety percent underwent a pure 10,000 IU HCG trigger, while 8.2% (n=4) received a combined trigger. The mean LH (IU/L) was 8.2 (6.0) on the day of trigger and 40.0 (47.7) post-trigger. Twenty-two percent experienced a post-trigger fall in their estradiol levels (pg/mL), with a mean drop of 17.9% (13.8). None of the 49 women became pregnant as a result of the IUI. Fourteen percent (n=7) went on to deliver a live-born child with subsequent ART treatment at our center.

CONCLUSIONS: The practice of offering IUI for patients who have no oocytes retrieved is not supported by our data. However, patients can be counseled that even though they failed to have oocytes retrieved in one cycle, we have shown that 1 in 7 such patients go on to deliver a live-born baby.

P-153 4:30 PM Saturday, October 17, 2020

TOWARDS AUTOMATED SELECTION OF EMBRYOS FOR IVF BY THE INVESTIGATION OF CHANGES IN RELATIVE ENTROPY OVER TIME. Shunping Wang, PhD,[1] Dhananjay Bhaskar, MSc,[2] Shiyun Zou, MS,[2] Denny Sakkas, PhD[3] [1]Women & Infants' Fertility Center, Providence, RI; [2]Brown University, Providence, RI; [3]Boston IVF, Waltham, MA.

OBJECTIVE: We propose a novel image recognition framework, based on machine learning, to assess embryo quality and viability for in-vitro fertilization (IVF) treatment using time-lapse images obtained from a morphokinetic system (EmbryoScope).

DESIGN: We quantified morphometric changes in time-lapse images obtained from the EmbryoScope using relative entropy, which measures changes in the distribution of pixel intensities over time. We processed the time-series data using dynamic time warping (DTW) to automatically assess the pace of development of embryos relative to each other. Lastly, we employed machine learning to predict embryo quality and interpreted results by computing the marginal effect of input features on the predicted outcome.

MATERIALS AND METHODS: Our data consisted of time-lapse images for 395 embryos obtained from frozen donor eggs at a university affiliated IVF clinic. Images were taken at an interval of 20 mins at 7 different focal planes over 1-6 days by the EmbryoScope. In addition, each embryo was associated with an outcome (cryo-preserved, transferred or discarded) and ground-truth assessment of embryo quality by embryologists at different time points. We preprocessed the images (segmentation and registration) prior to relative

entropy calculation. For each patient, the RE data was normalized to a reference embryo, using the DTW algorithm to identify lag/lead during development. Embryo quality prediction was performed using a multi-layer perceptron and results were interpreted using partial dependence plots and the Local Interpretable Model-Agnostic Explanations (LIME) algorithm.

RESULTS: Our investigation revealed that early milestones in embryo development (disappearance of pronuclei, stages of cleavage, compaction, etc.) correspond to spikes in relative entropy that can be easily detected. Embryos that stall in development exhibit persistently low entropy which indicates lack of cell division and rearrangement. The pace of development of an embryo, relative to a reference embryo was quantified using DTW and interesting cases where an embryo that lags in development early but is able to catch up later could be readily identified. Our preliminary findings from supervised classification suggest that the time taken to reach developmental milestones can be used to identify promising candidates for implantation as soon as day 3. We achieved classification accuracy of approx. 70% (excl. embryos that failed to develop) with limited observation up to advanced cleavage stage (9+ cells). Accuracy increased by 10-15% upon including time taken to form morula and blastocyst.

CONCLUSIONS: We have successfully developed a novel methodology to assess embryo development in a clinical setting. Compared to traditional assessment by embryologists, our approach provides unbiased, quantifiable determination of changes in embryo morphology. Combined with our novel framework of DTW and machine learning, this approach provides an excellent tool for automated selection of quality embryos, which is transparent and easily interpretable.

P-154 4:30 PM Saturday, October 17, 2020

TO CURETTE OR NOT TO CURETTE; EFFICIENCY OF OOCYTE RETRIEVAL TECHNIQUE. Seifeldin Sadek, MD,[1] Hadi Ramadan, M.D.,[2] Tamar Matitashvili, MD,[1] Laurel Stadtmauer, MD, PhD[1] [1]Jones Institute, Norfolk, VA; [2]Eastern Virginia Medical School, Norfolk, VA.

OBJECTIVE: To assess the effect of follicular curetting on oocyte yield during retrieval

DESIGN: This is a retrospective review on all patients that underwent oocyte retrieval from January 1st, 2016 until August 31st, 2019 35 hours after trigger with 10,000 units hCG.

MATERIALS AND METHODS: The main outcomes measured were oocytes retrieved and clinical pregnancies. Oocyte yield was defined as the total number of oocytes retrieved / the number of follicles >12 mm in diameter (measured in 2 dimensions) on the day of the hCG trigger

RESULTS: A total of 818 patients were included in this study, 671 underwent curetting while 147 did not. There were no differences in patient demographics, Anti-Mullerian hormone, average follicular size, peak estradiol levels and quantity of follicles on day of trigger. Retrievals that were performed using a curetting technique had a significantly increased number of oocytes retrieved 12.4 ± 8.1 versus 10.7 ±7.5 (p=0.011), mature (M2) oocytes retrieved 8.1 ± 6.4 versus 6.9 ± 6.0 (p=0.03), number of 2PNs 6.75 ± 5.3 versus 5.6 ± 4.9 (p=0.013), number of embryo's frozen 3.1 ±3.4 versus 2.5 ± 3.2 (p=0.036), and a significantly shorter duration of retrieval 25.4 minutes ±8.2 versus 27.5 minutes ± 10.6 (p=0.02). Curetting was also associated with an increased clinical pregnancy rate of 45% versus 36% (p=0.035) and an increased rate of OHSS 8% versus 3% (p=0.041). However, curreting resulted in a non-significant increase in oocyte yield 98.0% ± 4.8 versus 92.7% ± 4.9 (p=0.2) and M2 yield 61.6% ± 4.0 versus 60.7 ± 4.2 (p=0.8)

CONCLUSIONS: The technique of oocyte retrieval with curetting significantly increased the number oocyte and M2 oocyte retrieved, but it did not result in a significant increase of yield in either one. This was still associated with improved cycle outcomes, such as the number of embryo's frozen and clinical pregnancies. However, curetting seemed to be associated with an increased rate of OHSS, which could be due to the increased release of estradiol with associated with granulosa cell mechanical damage.

DOSE ADJUSTMENT OF FOLLICLE-STIMULATING HORMONE (FSH) DURING OVARIAN STIMULATION AS PART OF MEDICALLY-ASSISTED REPRODUCTION IN CLINICAL STUDIES: A SYSTEMATIC REVIEW COVERING 10 YEARS (2007–2017). Human M. Fatemi, MD, PhD,[1] Wilma Bilger, PhD,[2] Deborah Denis, PhD,[3] Georg Griesinger, MD, PhD,[4] Antonio La Marca, MD, PhD,[5] Salvatore Longobardi, MD,[6] Mary C. Mahony, PhD, HCLD,[3] Xiaoyan Yin, PhD,[3] Thomas M D'Hooghe, MD, PhD[6] [1]IVIRMA Middle East Fertility Clinic, Abu Dhabi, United Arab Emirates; [2]Merck Serono GmbH, Darmstadt, Germany; [3]EMD Serono, Inc., Rockland, MA; [4]University Hospital Schleswig-Holstein, Lübeck, Germany; [5]University of Modena and Reggio Emilia and Clinica Eugin Modena, Modena, Italy; [6]Merck Healthcare KGaA, Darmstadt, Germany.

OBJECTIVE: Individualization of FSH starting dose is standard clinical practice during ovarian stimulation. Furthermore, gonadotropin dose is regularly adjusted during ovarian stimulation to avoid hyper- or hypo-ovarian response and possibly to improve endometrium and oocyte quality. This study evaluated the frequency and direction (increase/decrease) of recombinant-human FSH (r-hFSH) dose adjustments in clinical trials.

DESIGN: Systematic review

MATERIALS AND METHODS: PubMed was searched for articles (published 6 Sept 2007 to 6 Sept 2017) that allowed dose adjustment within the study protocol and reported ≥1 dose adjustment of r-hFSH in women receiving ART treatment. Data on study design, dose adjustment and patient characteristics were extracted. Point-incidence estimates were calculated per study and overall. The Clopper–Pearson method was used to calculate 95% confidence intervals for incidence where adjustments occurred in <10% of patients; otherwise a normal approximation method was used.

RESULTS: 1409 publications were identified; 18 (6630 cycles) reported r-hFSH dose adjustment. Five studies (1359 cycles) reported data for an unspecified dose increase or decrease, 10 (3952 cycles) reported dose increases and 11 (5123 cycles) reported dose decreases. The studies were performed in women with poor, normal and high responses, with one study reporting in oocyte donors and one in obese women. The median day for dose adjustment was Day 6. The dose adjustments for individual studies are shown in the Table.

CONCLUSIONS: This review highlights that dose adjustment during treatment does occur during clinical trials of patients undergoing ART treatment if allowed by the study design and protocol, with dose increases occurring more commonly than dose decreases. The allowance and the use of dose adjustments in clinical trials suggest that healthcare providers consider adjusting the dose during treatment a worthwhile approach for improving treatment outcomes and/or reducing risks. The incidence of this dose adjustment in routine clinical practice and its impact on clinical outcomes requires further evaluation.

SUPPORT: Â Funding: Merck KGaA, Darmstadt, Germany

TABLE. Reported dose adjustments

	Unspecified dose increase or decrease	Dose increase	Dose decrease
Overall, point estimate, % (95% CI)	45.3 (42.7, 48.0)	19.2 (18.0, 20.5)	9.5 (8.7, 10.3)
Point estimate in individual studies, range, % (95% CI)	26.8 (13.3, 40.4) to 72.7 (64.0, 81.5)	3.0 (0.8, 5.3) to 58.5 (45.2, 71.8)	1.9 (−1.8, 5.5) to 53.4 (47.0, 59.8)

DEVELOPMENT OF AN ARTIFICIAL INTELLIGENCE-BASED ASSESSMENT MODEL FOR PREDICTION OF PREGNANCY SUCCESS USING STATIC IMAGES CAPTURED BY OPTICAL LIGHT MICROSCOPY DURING IVF. Jared Geller, NA (Undergraduate Student),[1] Ineabelle Collazo, BS,[2] Raghav Pai, BS,[1] Nicholas Hendon, BS,[2] Soum D. Lokeshwar, BS, MD, MBA,[1] Himanshu Arora, PhD,[1] Sabrina A. Gerkowicz, MD,[2] Katherine L. Palmerola, BS, MD,[2] Ranjith Ramasamy, M.D[1] [1]University of Miami Miller School of Medicine, Miami, FL; [2]IVFMD, South Florida Institute for Reproductive Medicine, Miami, FL.

OBJECTIVE: Conventional embryo evaluation for in-vitro-fertilization (IVF) involves manually grading human embryos using various microscopic observations in different planes. However, this process has been shown to be subjective, time consuming, and costly. Our primary objective was to create and assess a model using artificial intelligence, namely convolutional neural networks and transfer learning, to aid in the selection of high-quality embryos for transfer following IVF.

DESIGN: A recent study has utilized deep learning models and public datasets, mainly the Inception V1 network and ImageNet weights, to predict chance of pregnancy given a day 5 embryo image. We hypothesized that we can improve this existing model by using deep convolutional neural networks and transfer learning on a moderately sized novel dataset.

MATERIALS AND METHODS: A total of 361 static images from four IVF laboratories across South Florida were initially netted. This allowed for the development of a Softmax layer with three target classes as the final layer of the network. Given an embryo image, the model would predict: pregnancy, no pregnancy, or live birth. Next, new data augmentation techniques were used to reduce variance in our model and increase our training set 10-fold.

RESULTS: The algorithm achieved 59% accuracy for the 2-class model (pregnancy vs. non-pregnancy); however, there was not any casual signal linked to the three-class model. This limited dataset achieved slightly lower accuracy than conventional embryo selection, and continuous improvements in accuracy are ongoing with the addition of more images. This is currently the first and only algorithm incorporating static images, rather than the less generalizable previous time-lapse imaging.

CONCLUSIONS: For individuals undergoing IVF, embryo transfer is the culmination of an extensive emotional, physical, and financial journey. The goal of every fertility center is to optimize chance of pregnancy in order to best help the patient. Traditional embryo quality assessment leads to discrepancies among embryologists, thus, the use of our artificial intelligence algorithm in embryo selection has the potential to reduce subjectivity, shorten time to pregnancy, and improve patient outcomes by identifying embryos with the highest potential for successful pregnancy.

THE BENEFICIAL EFFECT FOR LBR OF SERUM LH (5-10IU/L) ON TRIGGER DAY WITH GNRH ANTAGONIST PROTOCOL. Yanru Hou, MD., Li Tian, MD Peking University People's Hospital, Beijing, China.

OBJECTIVE: To investigate the effect of various serum LH on trigger day with GnRH antagonist protocol in patients receiving in-vitro fertilization (IVF) /Intracytoplasmic sperm injection (ICSI) for pregnancy outcomes.

DESIGN: A retrospective, single-center cohort study.

MATERIALS AND METHODS: **Setting:** We retrospectively reviewed the medical documents of patients receiving IVF/ICSI with fresh embryo transfers in the Reproductive Medicine Center of Peking University People's Hospital between January 2016 and December 2018.

Patients: 894 patients were included and divided into three groups by various serum LH on trigger day.

Interventions: Group A ,Group B and Group C were defined as LH concentration <1.0 IU/l, ≥ 1.0 IU/l and ≤ 5.0 IU/l, >5.0 IU/l and ≤ 10.0 IU/l on trigger day during the cycle, respectively.

Main Outcome Measures: implantation rate, clinical pregnancy rate, early pregnancy loss rate and live-birth rate (LBR).

RESULTS: Pregnancy results were compared among these three groups. There was significant difference in implantation rates between Group A and Group C (20.57%versus 35.90%, respectively). The clinical pregnancy rates (35.42% versus 48.65%) and LBR (29.17% versus 41.89%) appeared higher in Group C, though the differences were not significant. According to Multivariate logistic regression analysis, compared with Group A, the LBR of Group B(OR=4.160, $P = 0.039$) and Group C(OR=5.037, $P = 0.034$) increase and the differences were significant.

CONCLUSIONS: Our study has proposed Chinese patients in 5-10 IU/l of the serum LH on trigger day with GnRH antagonist protocol may have better clinical outcomes than 1-5IU/l of LH. So the serum LH on trigger day with GnRH antagonist protocol should not be very low. The level of LH should be beneficial for outcomes in our suggested LH range. Whereas, we still need more adequate sample size and multi-center research to make RCTs and in-depth study on the mechanism.

P-158 4:30 PM Saturday, October 17, 2020

INTRAUTERINE ADMINISTRATION OF A PHENOL-POLOXAMER GEL DISRUPTS EPITHELIAL INTEGRITY SUPPORTING DEVELOPMENT AS A PERMANENT CONTRACEPTIVE. Tanner J. Grenz, B.S.,[1] Lauren Drew Martin, DVM,[2] Shan Yao, MD,[1] Jeffrey T. Jensen, MD, MPH,[3] Ov D. Slayden, PhD,[4] Carol B. Hanna, Ph.D.[5] [1]Senior Research Assistant, Beaverton, OR; [2]Assistant Chief/Associate Surgical Veterinarian, Beaverton, OR; [3]Oregon Health & Science University, Portland, OR; [4]Professor, Beaverton, OR; [5]Oregon National Primate Research Center, Beaverton, OR.

OBJECTIVE: Transcervical administration of 30% phenol in a mucilage or paste will induce fallopian tube occlusion and provide permanent contraception for women but administration of these materials is difficult and inconsistent. We evaluated delivery of phenol in a thermally responsive poloxamer-based gel that is liquid at room temperature and a gel at 37°C. We hypothesized this gel would be easy to administer and provide controlled delivery and release of the phenol sufficient to induce permanent epithelial damage to the fallopian tubes and uterine horn.

DESIGN: In vivo guinea pig study.

MATERIALS AND METHODS: Phenol release rates from gels containing 16.5% P407 poloxamer, 0.46% sodium alginate, and 0% (control gel), 5%, 7.5% or 10% phenol were determined by LC-MS/MS following incubation in saline at 37°C up to 24 hours. Based on these results, we evaluated 10% phenol gel in guinea pigs (*cavia porcellus*). Estrous cycles were synchronized with 0.22 mg Altrenogest for fifteen days followed by 5 days of withdrawal. Up to 4 mL of gel supplemented with 16% contrast reagent and either 10% or 0% (control) phenol was administered transcervically in n=18 animals and bilateral uterine horn fill was visualized by fluoroscopy with minimal syringe pressure reported during delivery. Reproductive tracts were collected at 1, 7 and 30 days post treatment, segmented, and embedded in paraffin. Epithelial integrity of the uterine horns and fallopian tubes were evaluated by hematoxylin/eosin staining. Masson's Trichrome was used to quantify changes in collagen deposition and data was analyzed by One-way ANOVA ($P < 0.05$).

RESULTS: Phenol release from the 5% and 7.5% gels declined to baseline by 4 and 24 hours, respectively. In contrast, the 10% gel displayed sustained release, >80% for 24 h. Tracts exposed to control gel (n=9) showed no change in histology relative to naive animals across all time points. In contrast, the 10% gel disrupted the uterine mucosa at day 1 in all animals and 1/3 displayed fragmented epithelium and cellular debris in the fallopian tubes. On day 7, the uterine horns appeared to be inflamed with 2/3 showing evidence of re-epithelialization and 1/3 animals had complete tubal epithelial damage. By day 30 the endometrium in all animals had mostly recovered but focal tubal occlusion with collagen deposition was present in 1/3 animals. There was no difference in the proportion of collagen present in the tracts across all treatments, however animals that received the 10% gel tended to have increased collagen content in the uterine horn and fallopian tubes compared to controls at 7 and 30 day time points.

CONCLUSIONS: Poloxamer-based gels are tissue inert and provides controlled delivery of phenol to target regions of the reproductive tract. The guinea pig reproductive tract anatomy differs from primates in that rodents lack a muscular intramural fallopian tube, the site most susceptible to sclerosant-based occlusion. However, our observation that phenol containing gel initiated tissue occlusion events supports our broad goals to develop tubal sclerosants for permanent contraception.

P-159 4:30 PM Saturday, October 17, 2020

HORMONAL CONTRACEPTIVE USE IS ASSOCIATED WITH SIGNIFICANTLY LOWER AMH LEVELS IN WOMEN OF REPRODUCTIVE AGE. Sharon Briggs, PhD,[1] Eduardo Hariton, MD, MBA,[2] Talia Shirazi, MA,[1] Avner Hershlag, MD.[1] [1]Modern Fertility, San Francisco, CA; [2]University of California, San Francisco School of Medicine, San Francisco, CA.

OBJECTIVE: To evaluate the effects of contraceptive methods on anti-Mullerian hormone (AMH) levels in women of reproductive age.

DESIGN: Prospective cross-sectional analysis of serum AMH levels and survey data.

MATERIALS AND METHODS: 9,014 participants between ages 21 and 46 who used at-home fertility hormone testing between June 2018 and April 2020 and had consented to research were included in the study. Participants with prior diagnoses of polycystic ovary syndrome (PCOS) or primary ovarian insufficiency (POI) were excluded. Mean (SD) age, BMI, and AMH were 31.4 years (4.3), 25.9 kg/m2 (6.2), and 3.46 ng/ml (2.87), respectively. Five contraceptive methods had a large enough sample size (n > 100) to be included in the final analysis: combined oral contraceptives (COC) (n=1,301), levonorgestrel IUD (LNG-IUD) (n=1,012), implant (n=141), ring (n=209), and copper IUD (n=317).

Linear regression models were used to estimate relevant covariates that predicted AMH levels. Of the potential covariates investigated (contraceptive type, age, BMI category, number of cigarettes smoked per month, age of menarche, race/ethnicity, household income, and years of education), only current age, contraceptive type, and age at menarche significantly predicted AMH levels. A linear regression model was fitted to estimate the variance in AMH that can be predicted by contraceptive use after adjustment for current age and age of menarche, the significant covariates we identified.

RESULTS: Mean AMH levels were significantly lower in women using each hormonal contraceptive, but not the copper IUD, compared to women not on contraception after controlling for age and age of menarche. COCs (-26.36%) and the ring (-28.72%) were associated with the largest percent declines in mean AMH levels. Progestin-only methods, the implant (-17.29%) and LNG-IUD (-6.55%), were associated with smaller, but still significant, percent declines. Mean AMH levels were not significantly different in women using the copper IUD (-1.26%) compared to those not on contraception.

CONCLUSIONS: AMH levels may be lower due to contraceptives, but AMH is still a useful predictor of ovarian reserve. The use of combined contraception is associated with larger differences in AMH levels while progestin-only methods are associated with smaller differences that, while statistically significant, may not be of clinical significance.

Having more precise estimates of the impact of contraceptive methods on AMH makes it easier to interpret these values in women on contraceptives. In many cases, whether a woman is on or off contraceptives, the followup would be similar: a normal AMH indicates normal ovarian reserve, while low AMH, unlikely to represent more than a 28% decline in contraceptive users, requires followup. Among users with an intermediate AMH level (roughly between 0.8 and 1.3 ng/ml), followup is more nuanced.

These data should eliminate the common practice of stopping COCs before measuring AMH, which could result, at times, in unwanted pregnancies. Clinicians should incorporate these findings when counseling women who tested AMH while on hormonal contraceptives.

P-160 4:30 PM Saturday, October 17, 2020

CHARACTERIZATION OF WOMEN ACCORDING TO THEIR SEXUAL SATISFACTION AFTER TREATMENT WITH THE NOVEL VAGINAL PH REGULATOR (VPR™) DURING THE AMPOWER STUDY. Michael A. Thomas, MD,[1] Kelly R. Culwell, MD, MPH,[2] Clint Dart, MS,[3] Brandon Howard, PhD.[2] [1]University of Cincinnati, Cincinnati, OH; [2]Evofem Biosciences, Inc., San Diego, CA; [3]Health Decisions, Inc., Durham, NC.

OBJECTIVE: The novel vaginal pH regulator (VPR™) is a non-hormonal, woman-controlled contraceptive vaginal gel. This analysis describes the characteristics of women in the phase 3 AMPOWER trial who reported better sex satisfaction after 1 cycle of VPR use vs those who did not.

DESIGN: AMPOWER was a single-arm, open-label, multi-center trial based in the United States (NCT03243305).

MATERIALS AND METHODS: Women aged 18-35 years administered one prefilled applicator of VPR intravaginally ≤1 hour before intercourse. The primary study objective was contraceptive efficacy over 7 cycles. Sexual satisfaction was an exploratory endpoint, assessed via questionnaires administered at baseline and after 1, 5, and 7 cycles of VPR use. Women reported a score assessing how VPR use impacted their sex lives: "lot better than before"=1, "little better"=2, "no different"=3, "little worse"=4, "lot worse"=5. Sensitivity analyses for sexual satisfaction were conducted with respect to women's demographic, obstetric, and contraceptive histories.

RESULTS: Sexual satisfaction data were available for 1118 women enrolled in AMPOWER. After 1 cycle of VPR use, 497 (44.5%) women reported sex life as a lot better or a little better than before ("satisfied"), 570 (51.0%) reported no difference, and 51 (4.6%) reported that their sex lives were a little or a lot worse (together, "no difference/worse"). A mean sexual satisfaction score improvement of 0.5 was observed ($p<0.0001$). Mean (±SD) age (27.5±4.6 satisfied; 28.0±4.3 no difference/worse), mean BMI

(28.3±7.6 satisfied; 29.1±8.0 no difference/worse), and race (70.2% white satisfied; 71.8% white no difference/worse) were similar between groups. The most common recently used (last 6 months) contraceptive methods were male condom, oral contraceptive, and withdrawal. Among women reporting satisfaction, 19.1% had recently used male condoms, 7.0% used oral contraceptives, and 3.0% used withdrawal method. Among women reporting no difference/worse satisfaction, 16.1% had recently used male condoms, 9.3% used oral contraceptives, and 3.5% used withdrawal method. Among women recently using male condoms, 48.7% reported satisfaction, 51.3% reported no difference/worse. Among women recently using oral contraceptives, 37.6% were satisfied, 51.3% were no difference/worse; and among women recently using withdrawal method, 40.1% experienced improvement, 59.6% reported no difference/worse. Mean (±SD) number of past pregnancies was similar between groups (1.4±1.9 satisfied; 1.5±1.5 no difference/worse). 40.4% of women reporting sexual satisfaction had no past pregnancies, 54.12% had 1-4, and 5.4% had ≥5. Among women reporting no difference/worse satisfaction, 38.3% had no past pregnancies, 54.3% had 1-4, and 7.4% had ≥5. Mean (±SD) number of full-term deliveries was also similar between groups (0.9±1.3 satisfied; 0.9±1.2 no difference/worse).

CONCLUSIONS: Demographic characteristics, recent contraceptive methods, and obstetric history were comparable between women who reported better sex satisfaction with VPR and those who did not.

USE OF CONTRACEPTION AMONG ULTRA-ORTHODOX JEWS: A MATCHED CASE-CONTROL STUDY.

Yehuda Sabiner, MD,[1] Misgav Rottenstreich, MD,[2] Sorina Grisaru-Granovsky, MD PhD,[3] Daniel S. Seidman, MD[4] [1]The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel; [2]Shaare Zedek Medical Center, Jerusalem, Israel; [3]Shaare Zedek Medical Center, The Hebrew University, Jerusalem, Israel; [4]Assuta Medical Center, Tel, Israel.

OBJECTIVE: The fertility of the ultra-Orthodox Jewish population is known to be exceptionally high. Our aim was to study the little-known family planning practices of this religious conservative population.

DESIGN: In a prospective case-control study, we assessed the frequency and type of contraceptive use among ultra-Orthodox compared to secular Jewish women. We also studied the awareness to various forms of birth-control and the sources of information regarding contraceptives in this unique population.

MATERIALS AND METHODS: The study was based on comprehensive interviews with ultra-Orthodox women (N=160), compared with a control group of secular Jewish women (N=80). The size of the group of non-ultra-Orthodox participants was determined based on statistical analysis of a pilot study.

RESULTS: The mean±SD age was 29.1±6.4 and 31.3±8.2 years for ultra-Orthodox and secular women. Of the ultra-Orthodox women, 57.5% reported ever using birth control compared to 86.0% of the secular women ($p<0.001$). The majority, 83.1%, of ultra-Orthodox women reported requesting religious guidance before using contraception. Among ultra-Orthodox women, reporting previous contraceptive use, the most common birth control methods were oral contraceptive pills by 81.5%, IUDs by 27.1% and spermicides by 36.9% versus 78.2%, 15.9% and 2.8%, respectively, among matched secular women.

CONCLUSIONS: Contraceptive use among ultra-Orthodox Jewish women is indeed less prevalent than in the secular population. However, it is more widespread and common than stereotypes might portray. IUDs and spermicides were more frequently used by ultra-Orthodox women. A significant majority of ultra-Orthodox women interviewed consult a Halachic or religious authority prior to using contraception.

P-162 4:30 PM Saturday, October 17, 2020

THE EFFECTS OF ORAL CONTRACEPTIVES IN HUMAN ENDOMETRIAL STEM CELLS DERIVED FROM MENSTRUAL BLOOD.

Gabrielle Ferrante Alves de Moraes, Ms,[1] Doris Ferreira Moriyama, M.Med.Sci,[2] Marcela de Oliveira Pinheiro, Bs,[1] Edson G. Lo Turco, PhD[3] [1]São Paulo Federal University, São Paulo, Brazil; [2]Sao Paulo Federal University, School of Medicine, Department of Surgery, Division of Urology, Human Reproduction Section, Sao Paulo, Brazil; [3]IonMedicine - Precision Medicine, Sao Paulo, Brazil.

OBJECTIVE: This study aimed to evaluate whether the use of oral hormonal contraceptives alters the characterization of endometrial mesenchymal stem cells of women in reproductive age.

DESIGN: controlled prospective study.

MATERIALS AND METHODS: Study groups were established according to the use or not of oral hormonal contraceptives (OHC group and control group), 20 women were recruited to participate in this study, being 10 users of the oral contraceptives and 10 non-users. Isolation of endometrial mesenchymal stem cells from menstrual blood from each individual woman were analyzed in duplicates. The menstrual blood was collected from healthy volunteers aged between 20 and 35 years. Collection was performed with a menstrual collector in saline solution supplemented with antibiotic/antimycotic and subsequent isolation of endometrial mesenchymal stem cells. Cells were kept in a humidified environment at 37°C and 6% CO_2 and cultivate in culture medium with 10% FBS and 1% antibiotic/antimycotic for cellular expansion until confluence. Alterations in the endometrial mesenchymal stem cells characterization were determined by Flow Cytometry with mesenchymal markers CD105 and CD90 and hematopoietic markers CD45 and CD31. Statistical analysis of the data was performed using the software SPSS 18.0. The data were tested for normality and if it didn't have a normal distribution, it was standardized by z-score. Student's t-test was applied and an alpha error of 5% was adopted.

RESULTS: Isolation in cell culture proposed proved to be effective. The standardization tests for menstrual blood collection showed visual variation in endometrial mesenchymal stem cells amount obtained by isolation in cell culture, regardless of the group studied. There was no statistical differences between groups regarding by Flow Cytometry characterization: in OHC group, cells showed 91,4% and 98% of labeling for CD105 and CD90 mesenchymal cell markers, respectively and 0,42% and 13,5% for CD45 and CD31 hematopoietic markers, respectively. In control group, cells showed 98,9% and 99,2% of labeling for CD105 and CD90 mesenchymal cell markers, respectively and 0,24% and 5,52% for CD45 and CD31 hematopoietic markers, respectively. The experiments were validated by reading 10,000 cells per tag.

CONCLUSIONS: With this preliminary data, we concluded that the use of oral contraceptives does not affect the characterization and consequent development of human endometrial mesenchymal stem cells derived from menstrual blood.

SUPPORT: The present work was performed with support from CNPq, Conselho Nacional de Desenvolvimento CientíficoÂ e Tecnológico - Brasil.

CONTRACEPTIVE CHOICES BY WEIGHT STATUS AMONG WOMEN IN THE UNITED STATES: AN ANALYSIS OF THE 2015-2017 NATIONAL SURVEY OF FAMILY GROWTH.

Omosalewa Itauma, MD, MPH,[1] Chidinma Abara, MD,[2] Damla C. Gonullu, MD,[1] Megan Fee, BS,[1] Itauma Itauma, PhD,[3] Awoniyi Olumide Awonuga, MD[1] [1]Wayne State University School of Medicine, Detroit, MI; [2]Windsor University School Of Medicine, Cayon, MI; [3]Wayne State University, Detroit, MI.

OBJECTIVE: Over 40% of adult women in the United States have obesity. Exploring the differences in contraceptive use among women with normal weight, overweight, and obesity will improve understanding of fertility and unintended pregnancies in reproductive-aged women. Our objective was to examine contraceptive choices by weight among women in the United States.

DESIGN: This was a retrospective, cross-sectional study utilizing data from the 2015-2017 National Survey of Family Growth (NSFG).

MATERIALS AND METHODS: The 2015-2017 NSFG is a population-based survey conducted by the National Center for Health Statistics division of the Centers for Disease Control and Prevention that is nationally representative of the United States household population between ages 15-49 years. The NSFG includes information on participants' general and reproductive health, pregnancy, infertility, and use of contraception. Analyses of data were from 5,554 women, aged 15-49 years. Body mass index (BMI) was calculated based on self-reported height and weight and was divided into four categories. Those with a BMI <18.5 kg/m2, 18.5–24.9 kg/m2, 25.0–29.9 kg/m2, and ≥30.0 kg/m2 were classified as being underweight, normal, overweight and having obesity respectively. We excluded from analyses women < 20 years and those > 44 years old, those that were pregnant or recently delivered and those trying to get pregnant but included those with a history of previous tubal ligation. We used Chi-squared test to determine the relationship between the different contraceptive choices and weight

variables. We performed multinomial logistic regression analysis to determine the relationship between each contraceptive choice and each weight category. Statistical analyses were performed using R version 3.6.1.

RESULTS: Compared to women of normal weight, those that are overweight were more likely [1.56 (1.09-2.21), p=0.01] to use female sterilization and less likely [0.69 (0.49-0.98), p=0.04] to use oral contraceptive pills. Similarly, women with obesity were [2.09 (1.50-2.91), p <0.001] more likely to use female sterilization and were [1.9 (1.15-3.16), p=0.01] more likely to use Depo Provera than women of normal weight. In addition, women with obesity were less likely [0.68 (0.49-0.95), p=0.02] to use the pill and less likely [0.59 (0.36-0.94), p=0.03] to use male sterilization compared to women of normal weight.

CONCLUSIONS: Female sterilization use was the method of choice for contraception in women who are overweight and women with obesity compared to their normal weight counterparts. Women with obesity are also less likely to use contraceptive pills and instead more likely to use Depo Provera for contraception.

P-164 4:30 PM Saturday, October 17, 2020

EXPLORING TECHNOLOGY-BASED INTERVENTIONS TO IMPROVE ORAL CONTRACEPTIVE PILL ADHERENCE: A CROSS-SECTIONAL SURVEY. Anne Nichols Flynn, MD,[1] Rachel Galvao, BA,[2] Arden McAllister, MPH,[1] Sarita Sonalkar, MD, MPH[1] [1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

OBJECTIVE: 1) To describe the resources that oral contraceptive pill (OCP) users access for information about missed pills, and 2) to assess OCP users' desire for technology-based (text messaging, application, web-based) resources to manage missed pills.

DESIGN: A cross-sectional online and telephone survey of OCP users.

MATERIALS AND METHODS: We enrolled women aged 18-44 receiving a prescription for OCPs between October-December 2017 at 3 clinical locations at the University of Pennsylvania, and excluded those receiving OCPs for non-contraceptive indications. Our electronic survey primarily assessed how participants obtain information at the time of a missed pill, what information they would prefer to access, and whether they would use additional information if it was available. We collected demographics, duration of OCP use, number of missed pills in the past month, reasons for missed pills, use of reminder systems, patient's recall of provider counseling, discussion of missed pills by a provider, and knowledge of what to do after a missed pill. We distributed the surveys by email with a telephone contact for non-responses. We performed all analyses in Stata 15.1. The University of Pennsylvania Institutional Review Board approved this study.

RESULTS: We sent surveys to 666 patients with responses from 211 (32%). Of these, 21% (n=45) were ineligible due to discontinuation of OCPs, leaving a remaining sample of 166. Nearly half of participants (47%, n=76, 95% CI 39.0-54.4%) did not seek any additional information about how to manage their subsequent pills after missing a pill. When missing a pill, patients slightly preferred non-technology-based information (57%, n=93, 95% CI 49.3-64.5%) over technology-based information (43%, n=70, 95% CI 35.5-50.7%). Most reported they would use information at the time of missed pills if they had access to it (76%, n=124, 95% CI 68.9-82.0%). The majority of respondents were white (57%, n=94) and had a median age of 29 (IQR 26-33). Approximately half (47%, n=78) reported OCP use of 5 or more years in duration. About half (52%, n=86) missed one or more pill in their last pill pack, with an overall median of one pill missed (IQR 0-1), usually due to forgetting (61%, n=97) or being away from home (23%, n=37). Of participants who used a reminder system (n=112), the majority of users either set an alarm (46%, n=61) and/or put the pill in the same place every day (42%, n=55). The majority of participants reported receiving counseling on what to do after missing a pill (68%, n=112), as well as side effects (70%, n=116) and risks (54%, n=89) of taking OCPs. Most were not asked about missed pills at their follow up visit (49%, n=81), or had no follow up visit (28%, n=46). The vast majority (89%, n=147) knew what to do after missing a single pill.

CONCLUSIONS: This study indicates that OCP users desire more accessible information at the time of missed pills. User-friendly technology and non-technology-based solutions may facilitate OCP adherence and improved management of missed pills.

P-165 4:30 PM Saturday, October 17, 2020

REPRODUCTIVE AUTONOMY AND CHOICE OF CONTRACEPTIVE METHOD. Deena Elwan, MD, Shandhini Raidoo, MD, MPH. University of Hawaii, Honolulu, HI.

OBJECTIVE: Reproductive autonomy, defined as having control over whether and when to use contraception, become pregnant, or continue a pregnancy, is important for young adults since parents and partners may have significant influence in their contraceptive decision-making. The primary outcome of this study was to assess if reproductive autonomy correlates with young women's choice of contraceptive method.

DESIGN: Cross-sectional survey.

MATERIALS AND METHODS: We electronically distributed a nationwide survey to sexually active women ages 18-25 years via the Mechanical Turk (MTurk) crowdsourcing marketplace. The survey included questions from the *Reproductive Autonomy Scale,* a previously validated questionnaire by Advancing New Standards in Reproductive Health (ANSIRH), demographic questions, and questions about birth control use. Descriptive statistics were performed and logistic regression models were constructed to determine if the reproductive autonomy subscales were associated with birth control use overall and long acting reversible contraception (LARC) use specifically.

RESULTS: Of the 250 respondents that completed our survey, 48 were excluded from analysis because they were currently pregnant, attempting to conceive, or not sexually active within the past six months. The average age was 23.7 years old and 78% of participants were White. Ninety-one percent of participants reported completing at least some college or greater. Eighty-three percent of women reported using birth control. Among birth control users, oral contraceptive pills (49.7%) were the most commonly used contraceptive method followed by intrauterine devices (16%) and male condoms (13%). Twenty-six percent of participants reported using either an intrauterine device or contraceptive implant as their contraceptive method. Most participants scored high on the reproductive autonomy scales, with mean scores for decision-making, freedom from coercion and communication of 2.59 (range 0-3), 3.74 (range 0-4) and 3.61 (range 0-4) respectively. Current birth control users (n=167) scored significantly higher on the decision-making subscale than those not currently using birth control (n=35, 2.63 vs 2.44, p= .01). Among women who reported current contraceptive use, those using a LARC (n=44) scored significantly higher on the freedom from coercion (3.91 vs 3.71, p= .01), and communication (3.75 vs 3.57, p = .02) scales than those using less effective methods (n=123). A logistic regression model to predict birth control use revealed that, when controlling for age, race, marital status and education, women who scored higher on the freedom from coercion subscale were significantly more likely to use birth control (AOR 2.89, 95% CI 1.03-8.09, p= .04). A similar model predicting LARC use demonstrated that women who scored higher on the decision-making subscale were more likely to use a LARC method (AOR 4.35, 95% CI 1.10-17.30, p= .04).

CONCLUSIONS: Reproductive autonomy correlates with a young woman's choice to use birth control, and those with higher autonomy were more likely to choose the most effective methods.

P-166 4:30 PM Saturday, October 17, 2020

REPRODUCTIVE HEALTH AMONG FEMALE RESIDENT PHYSICIANS. Cristina Adelia Zottola, MD,[1] Adi Katz, MD, FACOG, FACS,[1] Tung Ming Leung, PhD,[2] Moti Gulersen, MD, MSc[3] [1]Northwell Health-Lenox Hill Hospital, New York, NY; [2]Feinstein Institute for Medical Research, Great Neck, NY; [3]Northwell Health-North Shore University Hospital/Long Island Jewish Medical Center, Manhasset, NY.

OBJECTIVE: This study aimed to explore reproductive health practices among current female resident physicians in ACGME accredited programs in the United States.

DESIGN: This was an exploratory cross-sectional study utilizing a survey distributed through RedCap. A recruitment email was sent to ACGME accredited residency programs in the United States for distribution to female trainees across all years of training. The survey included 17 questions addressing demographics and various reproductive health practices such as contraception, pregnancy, and egg freezing.

MATERIALS AND METHODS: Respondents were classified according to medical specialty and average number of hours worked per week. Descriptive statistics, including frequency distribution, were used for categorical variables, while mean, median, standard deviation, interquartile range, minimum, and maximum values were used for continuous variables. Chi square or Fisher's Exact test was performed to determine differences in the distribution of reproductive health practices among specialty and work hour groups.

RESULTS: A total of 229 respondents were included in the study (26% Obstetrics and Gynecology (OBGYN), 22% Internal Medicine, 10% Pediatrics, 10% Emergency Medicine, 8% General Surgery, 24% Other). The distribution by age and marital status was similar across the specialty groups. Most respondents had an OBGYN visit within the past year (44.3%), while 22.6% had an OBGYN visit more than 3 years prior. Most respondents (88%) experienced a barrier in visiting an OBGYN provider during residency, and lack of time was the most common reason reported. Ninety-two percent of respondents were using contraception (39% long acting reversible contraception and 32% ring or oral contraceptive pills). Most respondents (87%) were not pregnant at the time of the survey or trying to conceive during residency, and this was not significantly different across the specialty groups (p=0.2663). Forty-five percent of respondents felt that if they got pregnant during residency, it would negatively affect the way their peers viewed them as physicians. Over half (54%) of the respondents felt that their medical profession negatively impacted their plans for fertility, and this was not significantly different across specialty groups (p=0.3716).

CONCLUSIONS: Our data demonstrate that most female residents experienced a barrier in seeing an OBGYN provider and nearly half of the respondents felt that pregnancy during their training would negatively affect their image as a physician. Additionally, our data shows that over half of the respondents felt that their medical profession negatively impacted their plans for fertility. Based on our analysis, we recommend placing additional emphasis on reproductive health needs when addressing the wellness of medical residents. Identifying opportunities for improvement in this area could help diminish the escalating problem of physician stress and ultimately improve residents' reproductive health needs.

POSTER SESSION: COVID-19

P-167 4:30 PM Saturday, October 17, 2020

TO TREAT OR NOT TO TREAT: PERCEPTIONS OF THE INITIAL AMERICAN SOCIETY FOR REPRODUCTIVE MEDICINE COVID-19 RECOMMENDATIONS AMONG WOMEN'S HEALTH PROVIDERS.

Ashley M. Wiltshire, MD,[1] Tia Jackson-Bey, MD MPH,[2] Zachary Walker, MD,[1] Jasmine L. Chiang, MD,[1] Deidre Gunn, MD,[1] William W. Hurd, MD, MPH[1] [1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Illinois at Chicago, College of Medicine, Chicago, IL.

OBJECTIVE: On March 17, 2020 ASRM published "Patient Management and Clinical Recommendations During the Coronavirus (COVID-19) Pandemic" a statement for clinical management of infertility care based on the anticipated burden of COVID-19 at that time. Receptivity of these initial recommendations has varied across the media, patients, and women's health providers. Our objective is to evaluate the perception of the initial ASRM COVID-19 associated recommendations held by women's health providers.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: After IRB exemption was obtained, an electronic survey was sent to all women's health providers, including physicians, mid-level providers and nurses, in all subspecialties of obstetrics and gynecology at a single large academic center. All data is being collected anonymously and stored in a REDCap database. Preliminary analysis was done with REDCap to be followed by further statistical analysis once data collection is complete.

RESULTS:Of the 278 eligible providers, the survey response rate is 40% (n=112), representing 8 OB/GYN sub-specialties and all categories of providers. The majority of respondents are female (81%) and $\leq$40 years of age (67%). Most providers view infertility treatment as elective, specifically defined as not a medical necessity (44%). Of the 29% of providers who reported provision of infertility care, 69% reported practice changes between March 16- 31and another 19% initiated practice changes after March 31st. Six percent of the surveyed providers continued all fertility treatment in the same manner as before the pandemic; 15% cancelled all fertility treatment immediately, 33% completed treatment for patients currently in cycle but cancelled new cycle starts and 30% continued some treatment on case-by case basis. Safety concerns for the practice (94%), shared decision making with patients (84%), and ASRM guidance (69%) were amongst the most important factors to impact continuation of fertility treatment.

After reviewing a summary of initial ASRM recommendations provided within the survey, 67% of all participants viewed the recommendations as fair, and 71% as reasonable. Most (43%) agreed that ASRM recommendations should be enforced for all patients despite patient opinion. Sixty-six percent agreed that some degree of infertility treatment should be allowed currently, however the least supported treatment type was in vitro fertilization (32%). Regardless of infertility diagnosis, 70% did not feel that women should refrain from planned conception during the pandemic.

CONCLUSIONS: Considering the immediate and long term impact of the COVID-19 pandemic on fertility care delivery, a better understanding of perceptions regarding infertility management during this time is important. In doing so, we must consider the full spectrum of women's health providers. Our study shows overall support for the initial ASRM recommendations from women's health providers within our institution. We intend to use the methods used for this study to conduct a larger assessment of women's health providers nationwide.

SUPPORT: none

P-168 4:30 PM Saturday, October 17, 2020

PERCEIVED STRESS, INSOMNIA SEVERITY, AND THE IMPACT OF EVENTS AMONG IN VITRO FERTILIZATION (IVF) PATIENTS DURING THE CORONAVIRUS DISEASE 2019 (COVID-19) PANDEMIC.

Ariana Kam, BA,[1] Jennifer Gottfried, BS,[2] Julia E. Mieleszko, BA,[2] You J. Kim, BS,[2] Edward J. Nejat, MD, FACOG,[2] Janelle Luk, MD, FACOG[2] [1]Generation Next Fertility, New York, NY; [2]■■■.

OBJECTIVE: The objective of this study was to evaluate the Perceived Stress Scale, Insomnia Severity Index, and Impact of Events Scale-Revised scores of patients at a fertility clinic in Manhattan during the coronavirus disease 2019 (COVID-19) pandemic.

DESIGN: Surveys were administered to 220 patients at a fertility clinic in Manhattan during the COVID-19 pandemic. The surveys included a 7-item questionnaire on patient demographics, the Perceived Stress Scale (10-item questionnaire), the Insomnia Severity Index (7-item questionnaire), and the Impact of Events Scale-Revised (IES-R, 21-item questionnaire).

MATERIALS AND METHODS: Online surveys were administered to 220 patients at Generation Next Fertility (GNF), located in Manhattan. Percentages of patients who met different thresholds along the Perceived Stress Scale, Insomnia Severity Index, and the IES-R questionnaires were calculated. We excluded one question from the standard 22-item IES-R questionnaire: "During the past seven days with respect to (insert event) have you felt yourself acting or feeling like you were back at that time?" All patients who did not respond to the Perceived Stress Scale, Insomnia Severity Index, and/or IES-R questionnaires were excluded from the respective analyses. Multiple linear regression was run to determine if surpassing a high school education and being unemployed were correlated with higher Perceived Stress Scale scores. A p-value of less than 0.05 was considered as statistically significant.

RESULTS: According to the results of the Perceived Stress Scale, 66.9% of patients at the Manhattan-based fertility clinic self-reported experiencing moderate stress during the COVID-19 pandemic. 21.9% and 11.2% of patients perceived low and high stress, respectively. There was no statistically significant relationship between the demographic variables of not surpassing a high school education and being unemployed and the perceived stress levels of IVF patients during the COVID-19 pandemic. Additionally, the results of the Insomnia Severity Index survey demonstrated that 43.7% of patients self-reported no clinically significant insomnia, 39.5% self-reported subthreshold insomnia, 15.6% self-reported clinical insomnia of moderate severity, and 1.2% self-reported severe clinical insomnia. Furthermore, the results of the IES-R survey showed that 52.1% of patients self-reported scores high enough to indicate that post-traumatic stress disorder (PSTD) is of clinical concern, 27.1% of patients self-reported scores at the cut-off level or higher for a probable diagnosis of PTSD, and 18.8% of patients self-reported scores that are high enough to suppress immune system functioning (for even 10 years after the COVID-19 pandemic).

CONCLUSIONS: According to surveys administered at an IVF clinic in Manhattan, the majority of the patients self-reported moderate stress, no clinically significant levels of insomnia, and PTSD levels of clinical concern during the COVID-19 pandemic. Not surpassing a high school education and

being unemployed did not influence patients' perceived stress levels during the COVID-19 pandemic.

P-169 4:30 PM Saturday, October 17, 2020

MATURE HUMAN OOCYTES AND PRE-IMPLANTATION EMBRYOS ARE SUSCEPTIBLE TO SARS-COV-2 INFECTION BASED ON THE PRESENCE OF ACE2 AND TMPRSS2 PROTEINS.

Sandeep K. Rajput, PhD,[1] Deirdre Logsdon, MS,[1] Shaihla A. Khan, PhD,[2] Rebecca Kile, MS,[1] Heidi J. Engelhorn, MS,[3] Ye Yuan, PhD,[1] Sue McCormick, BS,[1] William B. Schoolcraft, MD,[3] Rebecca L. Krisher, PhD[3] [1]Colorado Center for Reproductive Medicine, Lone Tree, CO; [2]Post-Doctoral Research Associate, Lone Tree, CO; [3]CCRM Colorado, Lone Tree, CO.

OBJECTIVE: SARS-CoV-2 entry in host cells requires the presence of angiotensin-converting enzyme 2 (ACE2) as the extracellular receptor, and the serine protease TMPRSS2 to cleave the viral spike protein for incorporation into the host cell. Basigin (BSG/CD147) may also act as an ACE2 independent receptor mechanism. The cysteine protease cathepsin-L (CTSL) may also cleave the viral spike proteins and facilitate cell entry. The objective of this study was to characterize the mRNA and protein expression of these cellular entry receptors and proteases in female reproductive cells to determine their susceptibility to SARS-CoV-2 infection.

DESIGN: Prospective Research Study.

MATERIALS AND METHODS: Materials and Methods: Oocytes (GV, MII), follicular cells (cumulus, CC; granulosa, GC) and embryos (1 cell, 1C; blastocyst, BL) were collected from a minimum of three different patients per sample type, with consent. Samples were analyzed for mRNA expression of *ACE2, CD147, TMPRSS2,* and *CTSL* genes relative to GAPDH using RT-qPCR. Primers were validated using human mixed tissue cDNA. Protein quantification was performed by immunoblotting using the Jess system (ProteinSimple) optimized to detect over 10 proteins/5-10 oocytes or embryos. Antibodies for ACE2, CD147, TMPRSS2, and CTSL proteins were validated and then used to determine protein abundance relative to total protein. Data were obtained from three independent biological replicates and analyzed using one-way ANOVA.

RESULTS: Results from q-PCR analysis revealed high ($p<0.05$) abundance of *ACE2* transcripts in GV and MII oocytes compared to CC, GC, and BL. ACE2 protein was present in all the samples, but was relatively higher ($p<0.17$) in M2 oocytes, 1C, BL, and CC compared to GV oocytes and GC. TMPRSS2 protein was abundant in MII oocytes, 1C, and BL, and was present but at low levels in GV oocytes and follicular cells. Protein abundance of CD147 was five-fold higher ($p<0.05$) in GV and ~1.5 fold higher in GC compared to all other samples analyzed. No CTSL protein was observed with the expected molecular weight (38 kD), although a 55 kD band (a possible isoform) was detected in GV oocytes and CC.

CONCLUSIONS: Cumulus and granulosa cells are least susceptible to SARS-CoV-2 infection due to the lack of required receptors and proteases. Co-expression of the protein for ACE2 and TMPRSS2 in MII oocytes, zygotes, and blastocysts suggests that these reproductive cells are susceptible to SARS-CoV-2 infection. In conclusion, using a combined approach of mRNA and protein analysis from the same samples suggests that mature human oocytes and preimplantation embryos have the cellular machinery required for SARS-Cov2 entry, although we do not know if this occurs in vivo. The potential for viral infection in oocytes and embryos has important ramifications for ART. Care must be taken to avoid introduction of the virus to the embryo while in the ART laboratory, as well as potentially introducing the virus from an infected embryo to laboratory workspaces.

P-170 4:30 PM Saturday, October 17, 2020

WE ARE HERE FOR YOU: INFERTILITY CLINIC WEBSITE COMMUNICATION DURING THE ESCALATING STAGES OF THE COVID-19 PANDEMIC.

Holly Mehr, MD MSEd,[1] Tia Jackson-Bey, MD MPH,[2] Michelle Vu, MD,[2] Victoria Lee, BS,[1] Christopher Herndon, MD,[3] Jacqueline Ho, MD MS,[4] Lusine Aghajanova, MD PhD,[5] Molly M. Quinn, MD[1] [1]University of California, Los Angeles, Los Angeles, CA; [2]University of Illinois at Chicago, College of Medicine, Chicago, IL; [3]University of Washington, Seattle, WA; [4]University of Southern California, Los Angeles, CA; [5]Stanford University, Stanford, CA.

OBJECTIVE: On March 17th, ASRM published guidance for REI clinics regarding infertility treatment during the COVID-19 pandemic. The recommendations advised against initiation of new fertility treatment cycles outside of emergent fertility preservation. Our objective was to evaluate what SART-member fertility clinics communicated to the public and their patients via clinic websites during this time period.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: Between 4/20/20 and 4/24/20, SART-member fertility clinic websites were reviewed for REI-specific COVID-19 messages (REI-CM). The REI-CM was evaluated for: type of treatment offered, and to whom; adherence to updated ASRM guidance; and citation of ASRM (or other) guidance. Each website was evaluated by two reviewers and arbitrated by a third in the case of discrepancies. Practice size, type, and location were abstracted from SART. Clinics were classified by whether they were under a shelter in place (SIP) order and the duration of that order. Chi squared analyses were performed to determine associations between clinic demographics and patterns in messaging.

RESULTS: 381 SART-member clinics maintained active websites. Of those, 249 (65.3%) had REI-CM. The presence of REI-CM was more common in private than academic practices (73% vs 38%, $p<0.001$) and with increasing practice volume: 38% of clinics with <200 annual cycles vs 91% of clinics with >1000 cycles ($p<0.001$). There was a trend toward increased REI-CM use in states with a SIP order for ≥30 days (70% of 212, $p=0.064$).

ASRM guidance was cited in 61% (n=152) of REI-CM; however, only 33% (n=82) outlined treatment practices that reflected ASRM guidance published at the time of the data extraction. Adherence to ASRM guidelines was more common in academic than private practices (54% vs 31%, $p=0.02$) but was not correlated with size of practice or geographic region.

Conversely, 18% (n=44) of practices announced treating patients on a "case-by-case basis" with definitions ranging from specific ("women with AMH <0.7") to vague ("as determined by our providers alongside our patients"). Additionally, 9% of REI-CM (n=23) announced continued treatment regardless of a patient's clinical urgency. This messaging was more common in groups doing >1000 cycles a year (18%, $p=0.009$), with a trend toward practices in the northeast (16%, $p=0.113$) and in states with SIP orders lasting <30 days (14%, $p=0.09$). Clinics treating all-comers were less likely to cite ASRM than other clinics (41% vs 62%, $p=0.045$). However, 75% (n=14) cited COVID-19 guidance from WHO, CDC and state and local governments.

CONCLUSIONS: While public messaging may not reflect the actual practices of a clinic, this study reveals heterogeneity in how clinics incorporated ASRM recommendations and responded to the early stages of the COVID-19 pandemic. Academic practices were more likely to indicate their adherence to ASRM recommendations. High volume groups were more likely to communicate with their patients about what treatments they offered and to treat patients outside ASRM guidance. Lessons learned may inform optimal response in future waves of COVID-19.

P-171 4:30 PM Saturday, October 17, 2020

THE IMPACT OF CORONAVIRUS DISEASE 2019 (COVID-19) ON THE RELATIONSHIP BETWEEN THE STRESS LEVELS OF IN VITRO FERTILIZATION (IVF) PATIENTS AND THE AMOUNT OF TIME SPENT TRYING TO GET PREGNANT.

Ariana Kam, BA,[1] Jennifer Gottfried, BS,[2] Julia E. Mieleszko, BA,[2] You J. Kim, BS,[2] Mehriniso Khaydarova, BS,[2] Edward J. Nejat, MD, FACOG,[2] Janelle Luk, MD, FACOG[2] [1]Generation Next Fertility, New York, NY; [2]■ ■ ■.

OBJECTIVE: The objective of this study was to determine the impact of coronavirus disease 2019 (COVID-19) on in vitro fertilization (IVF) patients' stress levels, insomnia, and risk of post-traumatic stress disorder (PSTD) relative to the amount of time each patient spent trying to get pregnant.

DESIGN: Surveys were administered to 220 patients at a fertility clinic in Manhattan during the COVID-19 pandemic. The surveys included a 13-item questionnaire regarding fertility plans in relation to the COVID-19 pandemic, a 10-item Perceived Stress Scale questionnaire, a 7-item Insomnia Severity Index questionnaire, and a 21-item Impact of Events Scale-Revised (IES-R) questionnaire.

MATERIALS AND METHODS: Surveys were administered online to 220 patients at Generation Next Fertility in Manhattan. IVF patients were categorized according to the amount of time they spent trying to get pregnant (less than 6 months, between 6 months-1 year, between 1-2 years, between 2-3 years, between 3-4 years, and greater than 4 years). Multiple linear regression was run to determine if the amount of time patients spent trying to get pregnant was related to their Perceived Stress Scale scores, Insomnia Severity Index scores, and IES-R total scores. We excluded individuals who did not answer the Perceived Stress Scale, Insomnia Severity Index, and IES-R questionnaires. A p-value of less than 0.05 was considered as statistically significant.

RESULTS: There was a statistically significant relationship between Perceived Stress Scale scores during the COVID-19 pandemic and attempting to get pregnant for less than 6 months (p=0.00837), between 1 year and 2 years (p=1.96e-08), between 2 and 3 years (p=7.93e-07), between 3 and 4 years (p=1.24e-06), and greater than 4 years (p=1.93e-05). The relationships between Insomnia Severity Index scores during the COVID-19 pandemic and attempting to get pregnant for between 6 months and 1 year (p=0.0462), between 1 year and 2 years (p=1.26e-05), between 2 and 3 years (p=0.00465), between 3 and 4 years (p=0.000685), and greater than 4 years (p=0.0114) were statistically significant. There was a statistically significant relationship between IES-R scores during the COVID-19 pandemic and attempting to get pregnant for less than 6 months (p=0.003322), between 1 year and 2 years (p=9.22e-06), between 2 and 3 years (p=0.000671), between 3 and 4 years (p=0.000175), and greater than 4 years (p=0.008695). Spending between 3 and 4 years trying to get pregnant had the largest impact on the Perceived Stress Scale, Insomnia Severity Index, and IES-R scores.

CONCLUSIONS: Spending between 3 and 4 years attempting to get pregnant had the largest impact upon IVF patients' perceived stress, insomnia severity, and risk of PTSD during the COVID-19 pandemic.

TELEMEDICINE AND AT-HOME IVF KIT: NOVEL APPLICATION DURING THE COVID-19 PANDEMIC. Zaher Merhi, MD, HCLD, John Zhang, MD, PhD. SUNY Downstate University and New Hope Fertility Center, New York, NY.

OBJECTIVE: During the COVID-19 pandemic, access to fertility has been difficult due to fear of contracting the virus. Many patients, especially those with diminished ovarian reserve (DOR), strongly desire to pursue their fertility treatments that include oocyte and/or embryo freezing for fertility preservation because it is a time-sensitive matter fearing the loss of all their ovarian reserve. Given this challenging situation and in order to minimize the repeated office visits for monitoring during an IVF cycle, we aimed to test the efficacy of a new modality for IVF treatment using telemedicine and a patented kit called At-HOME IVF kit.

DESIGN: Large fertility clinic with university affiliation.

MATERIALS AND METHODS: A retrospective study assessed the outcome of using telemedicine with At-HOME IVF kit in patients who have DOR (n=22) based on previous history of poor ovarian response, previously documented low serum anti-Mullerian hormone (<1 ng/mL), elevated day 3 follicle-stimulating hormone (>10 mIU/mL), or low antral follicle count (<8). Patients desired either embryo (n=17) or oocyte (n=5) freezing. Telemedicine was used for consultation in order to reduce the total waiting time for seeking fertility treatment and to minimize office visits. The kit was mailed to the patient's home, contained no injectable medications and contained all the necessary medications needed for ovarian stimulation, ovulation suppression, and oocyte maturation trigger. The oral pills were clomid 100 mg taken from cycle day 3 until cycle day 11 and letrozole 5 mg taken from cycle day 3 until cycle day 7, the vaginal pill was the GnRH antagonist (Elagolix) 50 mg taken on cycle days 9 and 11, and nasal spray (lupron 30 IU) taken on cycle days 12 and 13. Oocyte retrieval was then performed on cycle day 14. Each patient took the medications included in the kit without office visits for monitoring and presented only on the day of the oocyte retrieval. The main outcome included the number of oocytes and embryos (cleavage-stage or blastocyst-stage) cryopreserved. Because of the COVID-19 pandemic, embryo transfer was not currently recommended or performed. Data are presented as mean ± sem.

RESULTS: The mean age of the participants was 39.9 ± 0.9 years. Upon presentation on the day of oocyte retrieval, blood hormonal testing and transvaginal ultrasound showed that none of the patients had ovulated and that all patients had appropriate ovarian stimulation response with the number of mature follicles (>18mm) up to 8 (3.3 ± 0.4). All patients underwent oocyte retrieval with 21 out of 22 patients having up to 8 mature oocytes collected (2.4 ± 0.4). Ten out of 17 patients who underwent IVF had up to 4 embryos cryopreserved at either the cleavage-stage or blastocyst stage.

CONCLUSIONS: During the global health emergency and current/future pandemics due to a highly transmissible infectious organism, oocyte and embryo cryopreservation can be performed without frequent monitoring and without the injectable medications using At-HOME IVF kit. This will allow patients with DOR the possibility of proceeding with fertility treatments with minimum exposure to office visits.

RELATIONSHIPS BETWEEN SPECIFIC INFERTILITY DIAGNOSES AND FERTILITY QUALITY OF LIFE (FERTIQOL), INSOMNIA, AND PERCEIVED STRESS DURING COVID-19 PANDEMIC. Jennifer Gottfried, BS, Ariana Kam, BA, You J. Kim, BS, Julia E. Mieleszko, BA, Edward J. Nejat, MD, FACOG, Janelle Luk, MD, FACOG. Generation Next Fertility, New York, NY.

OBJECTIVE: The objective of this study was to determine if different infertility diagnoses impacted patients' scores on the FertiQol questionnaire, Insomnia Severity Index (ISI), and Perceived Stress Scale (PSS) during the COVID-19 pandemic. The study also investigated if patients who were forced to discontinue their fertility treatment during the COVID-19 pandemic had different FertiQol scores than patients who were able to continue.

DESIGN: Surveys were administered to 220 patients at a fertility clinic in Manhattan during the COVID-19 pandemic. The surveys included a 36-item FertiQol questionnaire assessing Fertility Quality of Life in men and women experiencing fertility problems. The surveys also asked patients to specify their infertility diagnoses (polycystic ovary syndrome, diminished ovarian reserve, uterine factor, endometriosis, or male infertility). Patients were further given a 7-item ISI questionnaire and a 10-item PSS questionnaire. Finally, the surveys asked whether patients were forced to disrupt their fertility treatment plans due to the COVID-19 pandemic.

MATERIALS AND METHODS: Using multiple linear regression, we looked for statistically significant relationships between different infertility diagnoses and FertiQol scores. For this regression, we excluded all individuals who did not know their infertility diagnosis, had unexplained infertility issues, answered that they were fertile, or did not answer the FertiQol questionnaire. We also used multiple linear regression to look for statistically significant relationships between different infertility diagnoses and levels of insomnia and between different infertility diagnoses and perceived stress. Next, using Welch's t-test, we investigated if patients who discontinued their fertility treatments during the COVID-19 pandemic had a different mean FertiQol score from patients who continued treatment. We excluded all individuals who were not currently undergoing treatment and who did not answer the FertiQol questionnaire. A p-value less than 0.05 was considered statistically significant.

RESULTS: The majority of the IVF patients sampled self-reported moderate stress (66.9%). There was no statistically significant relationship between the exact etiology of an IVF patient's infertility diagnosis and the patient's FertiQol score. There was also no statistically significant relationship between the exact etiology of an IVF patient's infertility diagnosis and the patient's ISI nor PSS scores. Patients who discontinued their fertility treatments during COVID-19 did not have different FertiQol scores from patients who were able to continue.

CONCLUSIONS: The majority of the IVF patients sampled self-reported moderate stress during the COVID-19 pandemic. Interestingly, the exact etiology of an IVF patient's infertility diagnosis did not have

a statistically significant impact upon his or her Fertility Quality of Life, ISI, and PSS scores during this time period. Patients who were forced to discontinue their fertility treatments due to COVID-19 did not have different FertiQol scores from patients who were able to continue.

P-174 4:30 PM Saturday, October 17, 2020

IMPACT OF COVID-19 ON QUALITY OF LIFE AND PATIENT SATISFACTION AMONGST PATIENTS SEEKING FERTILITY EVALUATION AND TREATMENT. Hillary Pearson, M.D.,[1] Rachel P. Gerber, MD,[1] Stephanie R. Brownridge, M.D.,[2] Randi H. Goldman, M.D.,[2] Christine Mullin, M.D.[2] [1]Department of OBGYN, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; [2]Northwell Health Fertility, North Shore University Hospital/Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: The purpose of this study was to assess the effect of the pause on fertility treatments, due to the COVID-19 pandemic, on patients' fertility quality of life (FQoL).

DESIGN: Web-based survey.

MATERIALS AND METHODS: Patients seeking fertility care at a single academic fertility center from 1/2020 - 3/2020 with valid email addresses were surveyed. Patient demographics, evaluation or treatment type, history, satisfaction with newly instituted TeleHealth, viewpoint on ASRM guidance, and an adapted version of the validated Fertility Quality of Life Questionnaire (FQoL) were assessed. FQoL score was the primary outcome and was used to quantitatively assess the impact of COVID-19 on patients' FQoL. Student's T-tests were used to compare FQoL scores between patients who experienced a delay in evaluation or treatment vs. those who did not.

RESULTS: Four hundred fifty-six patients received a survey link and 38.8% (177/456) responded. The most common delayed treatments were intrauterine inseminations (36.0%), frozen embryo transfers (35.2%), and oocyte retrievals (26.4%). 37.3% (66/177) of patients had a TeleHealth appointment with a provider. The majority (90.9%) were dissatisfied with their encounter; however, 42.4% would consider utilizing TeleHealth in the future. Of 125 patients who experienced delays, 12.8% agreed with the decision to pause treatments and 41.6% disagreed. The remaining 45.6% patients neither agreed nor disagreed.

Of the 54.2% (96/177) of patients that completed the adapted FQoL survey in its entirety, those with delayed fertility evaluation or treatment (n=77) had significantly lower mean FQoL scores than those who did not experience a delay (76.6 vs 86.5, p=0.01). 52% of patients who completed FQoL questions agreed with the pause of fertility treatments; they had significantly higher FQoL scores than those who disagreed (82.0 vs. 71.8, p<0.005).

	No Delay (n=52)	Delay (n=125)	P value
Average FQoL average*	86.5	76.6	0.01
% Utilized TeleHealth	23.1	43.2	0.01
% Desires future TeleHealth	32.7	50.4	<0.01
% Impartial or agreed with treatment pause	30.8	48.0	<0.01

*Data from 96 patients who completed FQOL questions.

CONCLUSIONS: Patients who experienced delays in fertility care due to COVID-19 reported lower FQoL compared to those who did not. Less than half of patients agreed with guidance suggesting a delay in treatments, despite continued access to care via TeleHealth. Although efforts were made to maintain open lines of communication and patient access to care during the pandemic via TeleHealth, the majority of patients were dissatisfied with their experience, regardless of delays. In spite of their experience, nearly half of participants expressed interest in using TeleHealth for future fertility care.

SUPPORT: None.

P-175 4:30 PM Saturday, October 17, 2020

PATIENTS UNDERGOING ASSISTED REPRODUCTIVE CYCLES ARE MORE LIKELY TO FOLLOW UP AFTER ATTEMPTED OUTREACH COMPARED WITH INTRAUTERINE INSEMINATION CYCLES DURING THE COVID-19 PANDEMIC. Chelsea Boltja, PA-C,[1] John J. Zhang, MD, PhD,[2] Meir Olcha, MD[3] [1]Physician Assistant, New York, NY; [2]New Hope Fertility Center, New York City, NY; [3]New Hope Fertility Center, New York, NY.

OBJECTIVE: As COVID-19 has been spreading rapidly both globally and throughout the US, public fear of contracting and spreading the virus has greatly hindered access to medical care including fertility clinics. Given the time-sensitive nature of fertility treatment, especially in older women, the American Society of Reproductive Medicine published updated guidelines for clinics to safely resume fertility services on April 24, 2020. The purpose of this study was to assess whether contacting established patients who missed or cancelled follow-up appointments via phone calls improved patient retention in the midst of the COVID-19 global pandemic.

DESIGN: Practice management analysis.

MATERIALS AND METHODS: Patients undergoing fertility treatment during the COVID-19 pandemic and who missed scheduled follow-up appointments were contacted by designated clinical staff members. Patients who desired to continue their treatment were offered either physical appointments or telehealth consultations. The contacting staff member documented patient responses and demographics in a master spreadsheet. Approximately 1-4 weeks after the patients were initially contacted, their charts were revisited to determine if the follow-up prompted patients to pursue future treatment. A Chi-square test was used to compare outcomes between Assisted Reproductive Technology (ART) cycles and Intrauterine Insemination (IUI) cycles.

RESULTS: There were 700 patients identified who underwent 215 IUI cycles and 709 ART cycles in the form of Egg Retrieval (ER) or Embryo Transfer (ET) between January 2020 - April 2020. The average age of all patients undergoing IUI and ART was 37.9 and 39.6, respectively (p=0.001). The clinical team contacted 88 IUI and 213 ART patients who missed a follow-up appointment scheduled 2 weeks after undergoing their procedure. Of those contacted, 13 (15%) IUI patients and 72 (34%) ART patients scheduled appointments with their physicians (p=0.001). Fear about COVID-19 was cited as the most common reason for missing their follow-up appointment (p=0.001).

CONCLUSIONS: These data support contacting patients lost to follow-up in order to improve patient retention rates. Patients who had undergone ART treatment were more likely to resume care compared to those who had IUI treatment. One explanation is that IUI patients may be more comfortable delaying active treated while attempting unmonitored timed intercourse cycles at home. There also may be differences in the population of patients undergoing ART vs IUI cycles, such as fertility prognosis or financial implications. Tracking patients during the pandemic also identified those who became pregnant post-procedure and helped ensure early monitoring when appropriate, but this data is not presented here. Lastly, the follow-up initiative provided clinical teams with a unique opportunity to assess patient satisfaction, as well as employee productivity during these difficult times.

P-176 4:30 PM Saturday, October 17, 2020

COVID-19 PANDEMIC: A SURVEY ASSESSING CLINICAL PRACTICE CHANGES IN REPRODUCTIVE MEDICINE ACROSS THE NATION. Andrea Starostanko, M.D.,[1] Sophia D. Halassy, M.D., M.S.,[2] Abhinav Hasija, BS, MS,[3] Brady Gelvin, M.D.,[4] Michael A. Thomas, MD,[5] Julie Sroga Rios, MD,[6] Suruchi Thakore, MD[7] [1]University of Cincinnati Center for Reproductive Health, West Chester Township, OH; [2]Ascension Providence Hospital, Southfield, MI; [3]The Ohio State University- Fisher College of Business, Columbus, OH; [4]University of Cincinnati College of Medicine, Cincinnati, OH; [5]University of Cincinnati, Cincinnati, OH; [6]University of Cincinnati, West Chester, OH; [7]University of Cincinnati Medical Center, West Chester, OH.

OBJECTIVE: Currently, there is limited data regarding the implications of infection with COVID-19 on reproductive or pregnancy outcomes. Given the lack of knowledge, the American Society for Reproductive Medicine (ASRM) released recommendations on March 17th, 2020 for reproductive

health providers to guide clinical practice during this global pandemic. The primary objective of this study was to determine practice preparedness, clinical changes, compliance with ASRM recommendations, and patient/reproductive health provider reactions in response to the COVID-19 pandemic. The secondary objective was to assess whether these changes will alter the practice patterns of reproductive health providers in the future.

DESIGN: Survey study distributed nationally to American reproductive health providers and practice staff between April 13th to May 19th, 2020.

MATERIALS AND METHODS: The survey was distributed using social media platforms and subspecialty specific list-servs utilized by reproductive health providers. To ensure survey question face validity, expert review and interim analysis of the responses was conducted. Statistical analysis was performed with Chi squared tests using R software.

RESULTS: A total of 134 responses were received of 612 surveys distributed. There was a significant difference in the method by which reproductive health practices received the ASRM recommendations, with e-mail being the most common for private practice, and word-of-mouth for academic practice ($p=0.02$). Once distributed, the academic providers were significantly more likely to follow guidelines compared to those in private practice ($p=0.006$). Most practices implemented guidelines, regardless of specialty and location, within one week of publication (March 16-20th), however academic providers implemented them earlier (March 9-13th) ($p=0.002$). The majority of practices completed their last embryo transfer within one to two weeks (March 16-27th). Continued unmonitored ovulation induction was more commonly offered to the Midwest population compared to the rest of America ($p=0.03$), regardless of practice type ($p=0.07$). Overall, the patients' responses to practice changes were well received. Nonetheless, specialists at academic practices were significantly more likely to offer their patients mental health resources ($p=0.001$). Provision of telehealth, whether before, during, or planning for after the COVID-19 pandemic, did not yield any statistically significant results.

CONCLUSIONS: The guidelines proposed by ASRM have had an obvious impact on reproductive care during the COVID-19 pandemic. Reproductive health practice changes were quickly implemented once received. Although the patient population was undoubtedly affected, patients were understanding regarding the need for delay in care.

P-177 4:30 PM Saturday, October 17, 2020

UNIVERSAL SCREENING OF COVID-19 IN ASYMPTOMATIC PATIENTS STARTING FERTILITY TREATMENT IN NEW YORK CITY. Alex Robles, MD,[1] Brittany Noel Robles, MD, MPH,[2] Laura C. Gemmell, MD,[1] Paula C. Brady, MD,[1] Eric J. Forman, M.D.,[3] Zev Williams, M.D., PhD.[3] [1]Columbia University Medical Center, New York, NY; [2]Wyckoff Heights Medical Center, Brooklyn, NY; [3]Columbia University Fertility Center, New York, NY.

OBJECTIVE: To evaluate a protocol of universal symptom and viral screening prior to initiation of controlled ovarian hyperstimulation among patients receiving care in New York City.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: Prior to initiation of controlled ovarian hyperstimulation for oocyte cryopreservation or in vitro fertilization cycles, patients were screened by phone for symptoms of fever, cough, sore throat, recent travel or contact with confirmed COVID cases. If negative, patients were scheduled for nasopharyngeal swabs at our center the following day, with visits spaced at 15 minute intervals to avoid crowding. Upon presentation for swab testing, patients were again screened for symptoms and fever. Nasopharyngeal swabs were collected in accordance with the Center for Disease Control (CDC) guidelines, and delivered to the university's clinical microbiology laboratory. The swabs were tested using the Roche Cobas 6800 SARS-CoV-2 test, a qualitative assay, using real-time reverse transcriptase polymerase chain reaction (RT-PCR) test (Roche Diagnostics, USA), with results delivered in the same day. A negative test result was required prior to patients' baseline ultrasound and bloodwork the following morning. This study was conducted from April 21- May 21, 2020,

RESULTS: The study sample included 151 asymptomatic patients who were tested for SARS-CoV-2 via nasopharyngeal swab. Overall, 149 (98.68%) tested negative for COVID-19, 1 (0.66%) tested indeterminate, 2 (1.32%) tested invalid, and 0 (0%) tested positive for COVID-19. Of the 149 patients who have tested negative, 81 have successfully undergone oocyte retrieval without complications. One patient screened positive for symptoms at the time of swab presentation and was instructed to return for testing in 2 weeks.

CONCLUSIONS: The incidence of COVID-19 infection among asymptomatic patients seeking fertility treatment in NYC is low. We have demonstrated that fertility care can safely resume in a way to limit risk to our patients, staff, and our physicians working in the epicenter of infection.

P-178 4:30 PM Saturday, October 17, 2020

THE IMPACT OF COVID-19 ON FERTILITY CARE: AN EVALUATION OF SOCIETY FOR ASSISTED REPRODUCTION TECHNOLOGY (SART) MEMBER CLINICS' WEBSITES. Seth J. Barishansky, M.D., M.S.,[1] Miriam A. Andrusier, M.P.H.,[2] Elizabeth A. Dilday, M.D.,[3] Angela K. Lawson, Ph.D.,[4] Luis R. Hoyos, M.D.[5] [1]The George Washington University School of Medicine and Health Sciences, Washington, DC; [2]SUNY Downstate Health Sciences University, Brooklyn, NY; [3]Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, University of California, Los Angeles, Los Angeles, CA; [4]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL; [5]UCLA, Los Angeles, CA.

OBJECTIVE: To evaluate the available COVID-19 content in regard to fertility care on the websites of Society for Assisted Reproductive Technology (SART) member clinics.

DESIGN: Cross-sectional study.

MATERIALS AND METHODS: From March 17 to March 30, 2020, following the release of the first American Society for Reproductive Medicine (ASRM) COVID-19 recommendations, SART member clinics' websites were examined. The presence of information on COVID-19 and pregnancy implications, acknowledgement of and compliance with ASRM recommendations, description of Centers for Disease Control and Prevention (CDC) risk mitigation strategies and local health department guidelines, as well as advertisement of telehealth and available mental health resources were queried. Websites were categorized by practice size (small: <500 vs. large: ≥ 500 cycles/year), type (academic vs. private) and degree of statewide COVID-19 burden based on CDC data (low: 0-1000; high: ≥ 1000 diagnosed cases). Group differences were evaluated using χ^2.

RESULTS: Larger clinics, compared to smaller, were more likely to report COVID-19 information, acknowledge and comply with ASRM recommendations, mention CDC risk mitigation strategies and local health department guidelines, discuss pregnancy implications and advertise telehealth [88% (130/148) vs. 64% (146/227); 49% (72/148) vs. 32% (72/227); 52% (77/148) vs. 34% (75/227); 76% (112/148) vs. 53% (120/227); 50% (74/148) vs. 31% (71/227); 36% (53/148) vs. 21% (48/227) and 38% (101/148) vs. 29% (119/227), respectively, $P<0.05$, all values]. Academic clinics, compared to private, were more likely to report COVID-19 information and report CDC risk mitigation strategies [87% (77/89) vs. 70% (199/286); 76% (68/89) vs. 57% (164/286), respectively, $P<0.05$, all values]. Private clinics were more likely to acknowledge and quote $\geq 3/5$ ASRM key recommendations but tended to devise individualized guidelines [44% (126/286) vs. 20% (18/89); 28% (80/286) vs. 12% (11/89) and 34% (97/286) vs. 4% (4/89), respectively, $P<0.05$, all values]. Private clinics were also more likely to advertise telehealth and discuss pregnancy implications [63% (179/286) vs. 46% (41/89) and 37% (106/286) vs. 20% (18/89), respectively, $P<0.05$, all values]. Only 35/375 websites offered mental health resources. Degree of statewide COVID-19 burden did not appear to impact the information available on clinic websites.

CONCLUSIONS: Clinic size and type of practice, rather than COVID-19 burden, influenced websites use for patient education and care during the pandemic. Telehealth advertisement as well as adherence to regulatory agencies' and societal recommendations were more common in larger clinics. Private clinics more frequently devised individualized patient care guidelines, addressed common concerns about the effect of COVID-19 on pregnancy, and made telehealth more readily accessible. The exclusion of such information on clinic websites may be a missed opportunity to support and educate patients about fertility treatment during a uniquely vulnerable time.

P-179 4:30 PM Saturday, October 17, 2020

PATIENT PERCEPTIONS AND IMPACT OF FERTILITY TREATMENT CANCELLATION RELATED TO COVID-19. Hanna Kim, MD, Josette C. Dawkins, MD, David M. Owen, MD/Ph.D, Bruce R. Carr, MD, Ellen Wilson, MD. UT Southwestern Medical Center, Dallas, TX.

OBJECTIVE: To assess the knowledge, attitudes, and perception of burdens on patients after fertility treatment cancellations in response to the COVID-19 pandemic.

DESIGN: A web-based survey involving people who experienced cancellations to fertility treatment due to COVID-19 precautions.

MATERIALS AND METHODS: A survey link was disseminated though online infertility forums and groups in the USA. Survey data was collected and stored via REDCap and then analyzed with descriptive statistics and Chi square test.

RESULTS: A preliminary data set of 208 respondents was used. 99% of respondents were female and either married or in a relationship. The median age was 33 years (range 23-44 years) with 1-12 years of infertility (mode 2 years). Respondents included a wide range of infertility diagnoses and all common modes of treatment. In this population, 78.8% reported that they were in the middle of their treatment when cycles were cancelled while 21.1% were cancelled prior to starting. Most reported anxiety and stress (79.6%) but also understanding of the situation (68.9%). The major factors contributing to anxiety and stress were lost treatment time (50.7%), younger age (< 35 years 90.5% vs 78.8% in >35 years, p value 0.024), and desire for increased communication and emotional support. The data showed that only 20.2% of patients perceived the support from their clinics as adequate. These patients who felt supported generally reported personal phone calls from their doctors and continued outlets of communication to ask questions and receive updates. People reporting perceptions of less support were more likely to have reported getting a recorded message or email with some even stating that the lack of communication caused them to seek out other fertility clinics to feel more supported. Additionally, 36% of patients desired more emotional support, and only 3.1% reported being provided additional resources such as mental health counseling. 57.7% of patients had positive perceptions of telemedicine as a resource for the future even though most (75%) had not tried it in the past. Finally, data showed that the type of cycle affected stress levels: ovulation induction reported most stress 89% followed by in vitro fertilization 80% then frozen embryo transfer 62.9%. Patients even suggested a system to help prioritize more urgent patients over others.

CONCLUSIONS: Infertility patients suffered significant stress related to their cycle cancellation from COVID-19. Despite being most worried about lost treatment time, patients advocated for a triage system to prioritize those with poorer prognosis when planning for safe return of fertility treatment. Additionally, consensus showed that personal and ongoing communication is key in patients' perception of support. Virtual support platforms and telemedicine may provide a valuable and supplemental outlet to improve patient communication, emotional support, and access to providers. Moving forward, incorporating this technology into standard practice will likely enhance patient satisfaction and help decrease anxiety and stress particularly when patients need to delay fertility treatment.

IVF TREATMENT PRE- AND POST- THE ASRM COVID-19 PAUSE.

Joseph A. Lee, BA,[1] Christine Briton-Jones, PhD, HCLD,[1] Carlos Hernandez-Nieto, MD,[1] Margaret Daneyko, RN,[1] Beth McAvey, MD,[2] Eric Flisser, MD,[1] Daniel E. Stein, MD,[2] Tanmoy Mukherjee, MD,[2] Benjamin Sandler, MD,[2] Alan B. Copperman, MD[2] [1]Reproductive Medicine Associates of New York, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.

OBJECTIVE: The coronavirus (COVID-19) pandemic has forever reshaped the United States health care system. However, assisted reproductive technology (ART) treatment remains an essential form of medicine. Reproductive practices have since incorporated vigilant practices regarding social distancing, ample use of Personal Protective Equipment (PPE), and consistent decontamination protocols in order to mitigate risk of COVID-19 infection. Altogether, changes to standard operating procedures within ART treatment centers are anticipated to support patient safety without compromising quality of reproductive care. Finally, there is ample evidence of the mental health burden stemming from this pandemic with regard to anxiety and depression in both healthcare workers and patients. Given the current uncertainty, our study evaluates IVF cycle outcome in a New York City patient cohort prior to and subsequent to the ASRM COVID-19 task force's recommended treatment pause.

DESIGN: Retrospective cohort analysis.

MATERIALS AND METHODS: The study includes patients who underwent a single, euploid frozen-thawed embryo transfer (FET) from January 1st, 2020 to May 18th, 2020. Cohorts were separated into two groups based on period of IVF treatment (Group 1: Treatment prior to the COVID-19 pandemic pause; Group 2: Treatment subsequent to the COVID-19 pause). Primary outcome included early pregnancy rates. Chi squared test was used and statistically significance was considered at p= <0.05.

RESULTS: A total of 601 single, euploid FET cycles in which pregnancy outcomes coming prior to the COVID-19 pandemic pause (n=526) were compared to outcomes subsequent to COVID-19 (n=75). No differences were found in early pregnancy rates among cohorts (Table 1).

TABLE 1. IVF Treatment Cycle Outcomes During COVID-19

Groups	Positive Pregnancy Count
Group 1: Prior to Covid-19 Pause (n=526 FET Cycles)	396 (75.2%)
Group 2: Era of Covid-19 (n=75 FET Cycles)	59 (76.2%)

* p-value = 0.75.

CONCLUSIONS: The COVID-19 pandemic has placed an unprecedented burden on patients, physicians, and the entire healthcare system. Urgent treatments, including reproductive care, were postponed, as scarce resources needed to be re-directed. Resumption of treatment required modification in workflow, staffing, decontamination protocols, and utilization of PPE. Although the patient experience has changed, our study is first to demonstrate implantation rates were not compromised in an era of COVID-19. Importantly, our preliminary data suggests that the stress and anxiety that pervade modern COVID-era reproductive care do not alter outcomes. With an abundance of caution, a modern fertility clinic can work to "flatten the curve," abide by guidelines, and deliver safe and effective patient care.

FERTILITY PRESERVATION DURING THE COVID-19 PANDEMIC: MODIFIED BUT UNCOMPROMISED.

Kara N. Goldman, M.D., Jennifer Elvikis, MSN, RN, Elnur Babayev, MD, MSc, Kristin Smith, B.S. Northwestern University, Chicago, IL.

OBJECTIVE: During the peak of the COVID-19 pandemic, our clinic remained operational for patients with cancer and other fertility-compromising medical conditions requiring urgent fertility preservation (FP). As patients with cancer are at a higher risk of death or serious illness from COVID-19, our FP approach was modified for patient safety. We sought to characterize FP care during the peak of our city's COVID-19 shelter-in-place order and compare outcomes to historical controls.

DESIGN: Retrospective cohort study with historical controls.

MATERIALS AND METHODS: We analyzed all medically-indicated FP cycles completed from March 17, 2020 (ASRM COVID-19 Task Force initial recommendation to suspend fertility treatments) until May 11, 2020 (ASRM update no. 4). Cycles performed during the same time period in 2019 were compared as historical controls. Data were analyzed using student's T-test, Mann-Whitney-U, or Fisher's Exact test where indicated ($p<0.05$).

RESULTS: Despite suspension of routine fertility care, our center managed 27 urgent FP cycles for 24 patients. 3 cycles were cancelled for acutely decompensating lymphoma, no response to gonadotropins (prior chemotherapy), and symptomatic COVID-19, respectively. 24 cycles from 21 patients were analyzed. Of 11 embryo cryopreservation cycles, 6 underwent FDA screening for future gestational carrier. More cycles were initiated in 2020 vs. 2019 (27 vs. 19), including significantly more embryo cryopreservation cycles (45.8% vs. 5.2%, $p<0.005$). Diagnoses were equally divided between breast cancer (29% vs 37%), leukemia/lymphoma (37.5% vs. 26.3%), and other (33.3% vs. 36.8%) ($p>0.05$). There was no difference in mean age (30 ±7 vs 28 ±7), AMH (2.9±2.0 vs. 4.2±3.1), or days of ovarian stimulation (11±1 vs. 11±2) ($p>0.05$) but patients retrieved in 2020 utilized significantly more gonadotropin (4770±1480 vs. 3846±1438, $p=0.04$). Notably, patients managed during COVID-19 had significantly fewer monitoring visits (5±1 vs. 6±1, $p=0.02$), and 37.5% of cycles utilized a blind trigger injection (without monitoring). Despite modifications, there was no difference in no. of oocytes retrieved (19±14 vs. 22±12) ($p>0.05$). All cycles (majority random-start) were timed to ensure anesthesiology availability for retrieval given COVID coverage responsibilities. Extensive safety precautions were employed including appropriate personal protective

equipment, telemedicine when possible, and office-wide social distancing. One patient who recovered from COVID-19 successfully and safely completed FP.

CONCLUSIONS: At our center FP care remained uninterrupted but appropriately modified during COVID-19. We completed more cycles compared to 2019, absorbing patients from centers facing COVID-related closures. Despite significantly fewer monitoring visits and more than one-third of trigger shots administered blindly, outcomes were optimal and equivalent to historical controls. Our center's experience illustrates that FP care can be adapted without compromising outcomes; long-term modifications should be considered given the continued vulnerability of this population.

PATIENT REACTIONS ON SOCIAL MEDIA TO THE ASRM COVID TREATMENTS SUSPENSIONS.

Isaac J. Chamani, M.D.,[1] David H. McCulloh, Ph.D.,[2] Frederick L. Licciardi, M.D.[3] [1]NYU School of Medicine, New York, NY; [2]NYU Langone Fertility Center, New York, NY; [3]NYU Langone Health, New York, NY.

OBJECTIVE: On March 17, 2020, the American Society for Reproductive Medicine (ASRM) issued its initial recommendations regarding patient management and infertility treatment during the ongoing COVID-19 outbreak. Included were recommendations to suspend initiation of new treatment cycles, including those of patients of advanced age or diminished ovarian reserve. The purpose of this study was to survey patient opinions and reactions, as expressed on social media, to these recommendations and the three subsequent updates.

DESIGN: Cross sectional study.

MATERIALS AND METHODS: We surveyed "r/Infertility," a group with 17,800 members on the social medial site Reddit, for reactions following each of the initial four ASRM recommendations. Comments were made in individual "COVID/Coronavirus Mega Threads" on the days surrounding the March 17th, March 30th, April 13th, and April 24thannouncements. We categorized posts based on their content, and quantified the number of posts per category. Categories included emotional reaction, resulting concerns, shared empathy, exchanges of advice and information.

RESULTS: 344 posts made by 148 users were categorized. The largest number of posts (n=90, 26.2%) expressed empathy to difficult news that was shared by another user. 82 posts (23.8%) discussed the future uncertainty, and 13 posts (3.8%) expressed an uncertainty in their clinics present policy. The most common emotional reaction was of disappointment (n=38, 11.1%), but others also expressed anger, anxiety, and frustration (5.2%, 6.4%, and 7.3% respectively). A total of 23 posts (6.7%) expressed frustration specifically at treatment being cancelled mid-cycle.

A small number of comments questioned aspects of the guidelines, and expressed frustration with ASRM (7, 2.0%), but more users expressed concerns regarding the risk of becoming pregnant ((17, 4.9%), and none questioned the validity of the guidelines. A significant portion of users questioned whether patients with diminished ovarian reserve should be restricted as well, or whether they should be given priority when treatments resume (21, 6.1%). Several users questioned why the general population was not being cautioned about becoming pregnant (9, 2.6%), and also expressed annoyance regarding comments made in the general population of an upcoming COVID "baby boom" as a result of the self-quarantining taking place (13, 3.8%). 38 posts exchanged advice (11.1%) and 83 posts offered information (24.1%).

CONCLUSIONS: We surveyed a popular social media site for patient responses to the recent ASRM COVID guidelines, and demonstrate that while users overwhelmingly endorsed the treatment suspension, they struggled with the disappointment, frustration and anxiety that came with the delay in their care, the backlog that will result when treatments resume, and the uncertainty surrounding present and future ASRM/clinic policies. In particular, patients with diminished ovarian reserve, and those whose treatment was canceled mid-cycle, were distraught by the lack of differentiation in the COVID guidelines.

P-183 4:30 PM Saturday, October 17, 2020

MOTHERHOOD PLAN: HAS IT CHANGED IN FACE OF THE COVID-19 PANDEMICS?

Daniela Paes de Almeida Ferreira Braga, PhD, Amanda Souza Setti, MSc, Assumpto Iaconelli, Jr., MD, Edson Borges, Jr., PhD. Fertility Medical Group / Sapientiae Institute, Sao Paulo, Brazil.

OBJECTIVE: The novel coronavirus (Covid-19) outbreak led to a public health emergency of international concern, putting health organizations on alert. World authorities implemented suppression plans to control community spread, including restrictions to non-urgent medical care. Assisted reproduction centers had to adapt to these restrictions. The infertility diagnosis and reproductive treatments possess an inherent psychological burden. This associated with the uncertainty of the consequences of the passage of time in the prognosis of treatments may impact on patient's psychological health. The goal for the present study was to investigate whether women seeking fertility care have different perception concerning the impact of Covid-19 on the motherhood plan than a target population?

DESIGN: Prospective randomized study.

MATERIALS AND METHODS: From 22/April/2020 to 25/may/2020, a survey through an online-platform was conducted. Participants were randomized by age in one of the two groups: ART-GROUP (n=92), including patients seeking for fertility treatment, but still didn't start their cycles or INTERESTED-GROUP (n=92), including participants interested in the subject, who accessed the website of a university-affiliated IVF-center. Participants in the ART-GROUP were invited via e-mail, with a cover-letter outlining the survey and a link to access it. Participants in the INTERESTED-GROUP accessed the questionnaire via website. Information on demographic data and their perceptions in face of the COVID-19 pandemics and the motherhood plan was collected. Women were asked: (i) How do you see the possibility of becoming pregnant after the beginning of the COVID-19 pandemic? (ii) How long do you think that suppression strategies will last? and (iii) Did you postpone your plans to become pregnant? If yes, why?

RESULTS: Most patients in the ART-GROUP were married or in a common-law relationship (83.6%), while a half of women in the INTERESTED-GROUP were in the same situation (50.0% $p<0.001$). When asked about the possibility of becoming pregnant, after the beginning of the pandemic, 47.8% of the ART-GROUP stated to believe the pandemic could affect their plans, while only 28.2% of the INTERESTED-GROUP stated the same ($p=0.035$). Concerning the duration of the suppression strategies, 64.1% of patients in ART-GROUP stated to believe the suppression strategies will be over by July, while only 18.5% of women in the INTERESTED-GROUP believed the same ($p<0.001$). The plan to become pregnant was postponed by 41.3% of the ART-GROUP and by 57.6.1% of the INTERESTED-GROUP ($p=0.341$). The main reasons that led people to this decision were fear of getting sick (52.6% vs. 73.6%, $p=0.083$, for ART-GROUP and INTERESTED-GROUP, respectively) and economic reasons (47.3% vs. 24.5%, $p=0.085$ FOR ART-GROUP and INTERESTED-GROUP, respectively).

CONCLUSIONS: Besides the fear of becoming sick, the economic burdens are the main reason for the delay in the motherhood plain, especially among women seeking for fertility care. This may be due to the fear of future economic instabilities and the fact that, in Brazil, ART do not qualify for reimbursement.

SUPPORT: None.

P-184 4:30 PM Saturday, October 17, 2020

USING VIDEO VISITS FOR NEW PATIENT EVALUATIONS DURING COVID-19.

Juan J. Andino, MD, MBA,[1] Alex Zhu, DO,[1] Chad Ellimoottil, MD, MS,[1] James M. Dupree, M.D., M.P.H.[2] [1]Michigan Medicine, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.

OBJECTIVE: With the rapid expansion of telehealth use during COVID-19, it remains unknown how video visits are being used to evaluate male infertility particularly when patients are not able to undergo a physical exam. We sought to assess what diagnoses were seen and which tests were pursued as part of the new patient evaluation. Herein we summarize a single institution's experience with video visits for male infertility during COVID-19.

DESIGN: Retrospective case series of patients with male infertility managed via video visits.

MATERIALS AND METHODS: We identified video visits completed at our institution between March 23, 2020 and April 29, 2020 for male infertility. We included new patients visits and return visits for men 18 years of age or older completed by two andrology-trained urologists. We collected and categorized scheduled visit type; visit completion rate; patient demographic and referral information; primary diagnoses; and laboratory and imaging tests ordered for new patient evaluations.

RESULTS: There were 51 scheduled video visits with 21 (41.2%) new patient and 30 (58.8%) established patient encounters. Eight (15.7%) video

visits were cancelled—7 re-scheduled and 1 converted to a telephone encounter due to technical issues—and 6 (11.8%) were no-shows. The median age was 32 years (range 22 – 48) and most patients were referred by their primary care provider or their partner's reproductive endocrinologist (53% and 18%, respectively).

For the 38 completed video visits, primary diagnoses included 11 (29%) idiopathic cases, 11 (29%) endocrinologic derangements, and 9 (24%) cases had anatomic contributors to infertility such as varicocele, previous vasectomy or ejaculatory duct obstruction. Additional diagnoses included genetic abnormalities (5%), concurrent partner evaluation (3%), sperm DNA integrity concerns (3%), active infection with pyospermia (3%), and post-operative hematoma (3%).

Of the 17 completed new patient visits, most were diagnosed with idiopathic 6 (35%) or anatomic (24%) conditions. Only 4 new patients (24%) had previously undergone an examination by a urologist. Eleven new patients (65%) required additional hormonal testing, 5 (29%) required another semen analysis, and 5 (29%) had scrotal ultrasound ordered due to inability to perform a physical exam due to limited use of outpatient clinics during COVID-19. Three (18%) required genetic testing, 2 (12%) a pituitary MRI, and 1 (6%) required DNA fragmentation testing.

CONCLUSIONS: Due to COVID-19, use of video visit has expanded to include new patient, male infertility evaluations. The most commonly ordered tests for these men included additional hormonal testing, additional semen analyses, and scrotal ultrasounds. While the physical exam is a crucial aspect of the infertility work-up, this series suggests that video visits could help ensure that a complete evaluation takes place even before a man undergoes a physical exam in clinic.

P-185 4:30 PM Saturday, October 17, 2020

COVID 19 PANDEMIC: ANXIETY AMONG PATIENTS WITH INFERTILITY IN IRAN. Elham Neisani Samani, MD,[1] Farzaneh Nemati, MD[2] [1]University of Massachusetts, Amherst, MA; [2]Qazvin University of Medical Sciences, Qazvin, MA, Iran (Islamic Republic of).

OBJECTIVE: A unprecedented spread of novel coronavirus disease (COVID-19) has influenced all over the world. However, the psychological effects of the pandemic on the general population, particularly patient with infertility, is lacking. The present study investigated the anxiety and worries in infertile patients during the COVID-19 outbreak.

DESIGN: Case-Control.

MATERIALS AND METHODS: Study was conducted using an online survey to assess anxiety and worries of patients with infertility who were being treated in a private Artificial Reproductive Technology (ART) center from 1th Jan to 15th March 2020. Two researchers followed up with the respondents, among whom 130 returned their questionnaires.

RESULTS: Among the responders, 92.30% (n=120, case group) obtained scores higher than 5 on the Beck Anxiety Inventory (BAI). Patients with infertility have shown statistically significant effects of COVID 19 on psychology, worries, and mean scores in the Beck Anxiety Inventory (BAI). Statistical analysis was performed using SPSS version 25. Chi-Square and Spearman correlation tests were applied to control confounders and assess the relation of the patient's response concerning age and educational level.

CONCLUSIONS: This study revealed the effects of the Covid-19 pandemic on the anxiety level and worries of the patients with infertility. Our results illustrated effective strategies are needed to provide psychosocial support to these individuals during the crisis.

POSTER SESSION: CRYOPRESERVATION

P-186 4:30 PM Saturday, October 17, 2020

DISTURBANCE IN OOCYTE MEMBRANE LIPIDS DURING EQUILIBRATION STEP OF THE VITRIFICATION PROTOCOL. Thalita S. Berteli, MSc,[1] Eduardo D. Borges, MSc,[1] Caroline M. Luz, MSc,[1] Christina R. Ferreira, PhD,[2] Paula A. Navarro, MD, PhD,[1] Alessandra A. Vireque, PhD[3] [1]Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo - Departamento de Ginecologia e Obstetrícia, Ribeirão Preto-SP, Brazil; [2]Purdue University - Metabolite Profiling Facility, Bindley Bioscience Center, IN; [3]Invitra – Assisted Reproductive Technologies LTD, Supera Innovation and Technology Park, Ribeirão Preto-SP, Brazil.

OBJECTIVE: In order to obtain a stable glassy state in the vitrification process, it is necessary to combine high cooling rates, small volumes of highly concentrated cryoprotectant solutions and short exposure times. During equilibration phase of oocyte vitrification, the exposure time varies from 10 to 15 minutes according to manufacturers' recommendations and a dynamic flow of water and solutes occurs through plasma membrane, a step closely related to oocyte quality maintenance after warming. Studies investigating oocyte lipid profile, especially lipids related to membrane lipid bilayer, may be useful to evaluate the impact of the equilibration protocol of vitrification on oocyte cryotolerance. Here we report the feasibility of the targeted lipidomics using multiple reaction monitor profiling (MRM-profiling) to investigate and monitor the impact of the exposure times to equilibration solution (ES) during vitrification on lipid profile of mice oocytes.

DESIGN: Experimental study.

MATERIALS AND METHODS: C57BL/6J mice oocytes (3 replicates; n=20 oocytes/group) were collected after superovulation with eCG and hCG and exposed to ES (Irvine Scientific) for distinct durations. The two groups were vitrified following the manufacturer recommended protocol: 10-minute total duration (oocytes stay for 6 minutes in third drop - ES10) or a shorter, 7-minute total protocol (oocytes stay for 3 minutes in the third drop - ES7). At the final step of equilibration, oocytes were washed 3 times in methanol: H_2O solution (1:3 v/v) and kept at -80^{o}C until lipid extraction. Lipids, equivalent to a pool of 5-7 oocytes per group/replicate were extracted using *One Step Methanol* protocol and flow injected into the triple quadrupole spectrometer equipped with an electrospray ion source (ESI-MS). Lipid classes were analyzed by MRM-profiling. The relative ion intensities values were evaluated using univariate (change fold, t-test, volcano plot), and multivariate analysis (PCA, PLS-DA, cluster analysis). Most informative lipid species in each group were sorted out using the partial least square discriminant analysis (PLS-DA) variables of importance (VIP) scores >1.

RESULTS: A relative ion intensity overrepresentations for saturated free fatty acids C19:0, C20:0 and C22:0 was observed in ES10 (change fold>2; $p< 0.05$) when compared to ES7 group. In the PCA scores, ES7 and ES10-CTR oocytes showed a tendency of discrimination at PC1 (68,8% of variability explained) and 4 membrane phospholipids (phosphatidylcholines and sphingomyelins) classified by PLS-DA were downregulated in ES10, indicating the presence of lipid composition changes in mice oocyte membrane due to amount of equilibration time used for the vitrification protocol.

CONCLUSIONS: Even slight changes in vitrification protocol such as the duration of the equilibration phase impacted the lipid profile of mice oocytes and could be monitored by MRM-profiling. Our results indicate that shorter time exposure in ES compared to long equilibration recommended by the manufacturer (7 min versus 10 min, respectively) is related to less disturbance of the plasma membrane of mice oocytes.

P-187 4:30 PM Saturday, October 17, 2020

IMPACT OF OOCYTE VITRIFICATION AND SUPPLEMENTATION OF THE VITRIFICATION MEDIA WITH ANTIOXIDANTS AND FATTY ACIDS ON LIPID PROFILE OF MICE BLASTOCYSTS. Thalita S. Berteli, MSc,[1] Eduardo D. Borges, MSc,[1] Caroline M. Luz, MSc,[1] Christina R. Ferreira, PhD,[2] Alessandra A. Vireque, PhD,[3] Paula A. Navarro, MD, PhD[1] [1]Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo - Departamento de Ginecologia e Obstetrícia, Ribeirão Preto-SP, Brazil; [2]Purdue University - Metabolite Profiling Facility, Bindley Bioscience Center, IN; [3]Invitra – Assisted Reproductive Technologies LTD, Supera Innovation and Technology Park, Ribeirão Preto-SP, Brazil.

OBJECTIVE: To investigate the impact of oocyte vitrification on lipid profile of mice blastocysts by comparing blastocysts originated from fresh and from vitrified oocytes subjected to in vitro fertilization. Also, to assess the effects of supplementing the vitrification media with antioxidants and unsaturated fatty acids by comparing blastocysts vitrified with Irvine Scientific, a

commercial standard vitrification media; Tvitri-4, produced in small scale for research by INVITRA®, based on the standard composition with four modifications including carbohydrate trehalose instead sucrose, reduced non-permeant cryoprotectant concentration, and addition of two aminoacids; and Tvitri-4 supplemented with L-carnitine (LC) and oleic and linoleic fatty acids (FA).

DESIGN: Experimental study.

MATERIALS AND METHODS: 23 C57BL/6J females were superovulated with 5UI eCG followed by 5UI hCG and oocytes (n=562; 4 replicates) were randomly divided in 4 groups: fresh control group (FC), vitrified using Irvine (IRV), Tvitri-4 (T4), or supplemented Tvitri-4 (T4-LC/FA) media. Fresh or vitrified-thawed oocytes were inseminated with $1x10^6$ sptz/ml and cultivated for 96 or 120 hours in *KSOM (Cosmo bio co., LTD)* incubated at 37°C with 5% CO_2. Blastocysts of each group were individually fixed in methanol/water. Lipids were extracted using *One Step Methanol* protocol (9 blastocysts/group) and flow injected into the triple quadrupole spectrometer equipped with an electrospray ion source. Lipids were analyzed using the multiple reaction monitoring profiling (*MRM*-profiling) method and values of relative intensities of ions detected in each group were compared using univariate (one-way ANOVA, volcano plot) and multivariate analysis (PLS-DA).

RESULTS: One-way ANOVA (p-value ≤ 0.05) showed that 90 out of the 125 lipids were differently expressed among the four groups, while a comparison between the vitrified groups showed no difference. Two by two comparisons between the control and vitrified groups using volcano plot (p-value ≤ 0.05, fold-change ≥ 1.5) detected 55, 17, and 11 significant features between FC vs. IRV, FC vs. T4, and FC vs. T4-LC/FA, respectively; all of them more abundant in the FC group. Partial least square discriminant analysis (PLS-DA) variables of importance (VIP scores) higher than 1.3 followed the same pattern and identified the phosphatidylinositol containing 36 carbon and one unsaturation in the fatty acyl residues - PI(36:1), and phosphatidylcholines PC(38:4), PCo(36:5), PC(34:1), and PC(30:0) among the top features; the exception being the free stearic acid (C18:0), which was the top feature in the FC x T4-LC/FA comparison, being more abundant in the latter.

CONCLUSIONS: Vitrification changed the lipid profile of mice blastocysts causing an overall reduction on lipid abundances that affected PC lipids the most. This effect was more apparent in IRV, followed by T4, and T4-LC/FA suggesting that supplementation of media with L-carnitine and unsaturated fatty acids may have protective effects on lipid content of blastocysts from vitrified oocytes, whose impacts needs further investigation.

P-188 4:30 PM Saturday, October 17, 2020

OPTIMAL STORAGE TEMPERATURE FROM THAWING OF CRYOPRESERVED OVARIAN TISSUE TO TRANSPLANTATION: XENOTRANSPLANTATION INTO NUDE MICE.

Nobuya Aono, Ph.D.,[1] Ena Nakatsukasa, Ph.D.,[2] Noriyuki Okuyama, M.Sc.,[1] Yusuke Nakamura, BS,[1] Sena Shibasaki, BS,[1] Miho Mori, BS,[1] Tomoko Hashimoto, M.D., Ph.D.,[1] Toshikuni Sasaoka, M.D., Ph.D.,[2] Koichi Kyono, M.D., Ph.D.[1]
[1]Kyono ART Clinic, Human Ovarian-tissue Preservation Enterprise (HOPE), Tokyo, Japan; [2]Niigata University, Brain Research Institute, Niigata, Japan.

OBJECTIVE: Human ovarian tissue cryopreservation, an essential method of fertility preservation, has led to the birth of more than 180 healthy babies around the world. Although there are many reports on cryopreservation and transplantation of ovarian tissues, the optimum storage conditions after thawing are still unclear. In this study, we performed xenotransplantation of ovarian tissue into nude mice to determine what kind of storage conditions are appropriate.

DESIGN: Prospective controlled animal study.

MATERIALS AND METHODS: We used ovaries derived from four SD rats at 10 weeks of age. Each ovary was cut in half, then 16 slices were cryopreserved by the slow freezing method (using 1.5M DMSO as cryoprotectant). Then, the tissues were thawed and stored at 4°C, RT (24°C), or 37°C for 2.5 hours in DPBS buffer. They were grafted under the kidney capsule of an ovariectomized nude mice (8-20 weeks old). Five IU PMSG and 5 IU hCG was injected once into mice at about 4 weeks after transplantation. Engraftment and follicle development in each group was compared with that in the control group (immediately grafted after being thawed).

RESULTS: The engraftment rates of frozen-thawed ovarian tissues were assessed in the control group (100%), 4°C group (87.5%), RT group (84.6%), and 37°C group (50.0%). The engraftment rate was significantly decreased when the tissues were stored at 37°C compared with those of the other groups ($P < 0.05$). The rates of engrafted ovarian tissues with macroscopically confirmed follicles were assessed in the control group (61.5%), 4°C group (71.4%), RT group (45.5%), and 37°C group (33.3%). Those rates in the RT and 37°C groups decreased compared with the control and 4°C groups although there was no significant difference. The follicles were aspirated and oocytes were collected in the control group (9), 4°C group (12), RT group (3), and 37°C group (1).

CONCLUSIONS: Storing the frozen-thawed tissues at 4°C led to a successful engraftment and follicle development. Although the tissues were well engrafted, there was little follicular growth in the RT group compared with the 4°C group. The storage at 37°C resulted in poor engraftment and follicle development. This study showed that the storage temperature of frozen-thawed ovarian tissues affects the engraftment and/or follicle development. Frozen-thawed ovarian tissues should be transplanted immediately after being thawed. In case they need to be kept a while before transplantation, storage at lower temperatures is recommended.

P-189 4:30 PM Saturday, October 17, 2020

HIGH SECURITY CLOSED DEVICES ARE EFFICIENT AND SAFE FOR VITRIFICATION TO PROTECT HUMAN OOCYTES FROM THE RISK OF VIRAL CONTAMINATION ESPECIALLY DURING THE COVID-19 PANDEMIC.

Eleonora Porcu, MD, Maria Lucrezia Tranquillo, BSc, Leonardo Notarangelo, BSc, Patrizia Maria Ciotti, BSc, Nilla Calza, BSc, Silvia Zuffa, Lab Technician, Lisa Mori, BSc, Elena Nardi, PhD, Maria Dirodi, MD, Linda Cipriani, MD, Giuseppe Damiano, MD, Francesca Sonia Labriola, Data Manager. Infertility and IVF Center, S.Orsola University Hospital, Medical and Surgical Sciences Department (DIMEC) University of Bologna, Bologna, Italy.

OBJECTIVE: To compare the efficacy of high security versus open devices for human oocytes vitrification.

DESIGN: Prospective study. Between October 2015 and April 2020, 737 patients (775 oocytes cryopreservation cycles) were randomly assigned to two Groups:

Group 1: 368 patients (389 vitrification cycles) by High Security Vitrification™ (HSV)

Group 2: 369 patients (386 vitrification cycles) by Cryotop® open system.

Vitrification was performed in case of Ovarian Hyper Stimulation Syndrome, failure semen production and supernumerary oocytes.

MATERIALS AND METHODS: All patients attending IVF and Infertility Center, University Hospital S.Orsola (Italy), were stimulated with recombinant-follicle stimulating hormone and gonadotropin releasing hormone analogues. Oocyte retrieval by transvaginal needle aspiration was performed 36 hours after ovulation triggering with recombinant Human chorionic gonadotropin injection. Metafase II oocytes were vitrified by Kuwayama's protocol (2005) and microinjected after warming.

RESULTS: Results are shown in Table 1.

CONCLUSIONS: The efficacy of vitrification was assessed in vitro using survival, fertilization and cleavage rates and in vivo after embryo transfer by pregnancy, implantation and miscarriage rates.

Results shows no statistically significant differences using HSV or Cryotop® for oocytes vitrification. Therefore, in order to ensure safety, especially during the current COVID-19 pandemic, the use of the closed device eliminates the potential sample contamination during vitrification and storage without compromising its in vitro and in vivo survival and development.

TABLE 1.

	TOTAL	GROUP 1: HSV	GROUP 2: Cryotop	P
Patients	737	368	369	
Vitrification cycles	775	389	386	
Age (m ± ds)	36.03 ± 3.90	36.18 ± 3.92	35.88 ± 3.88	.285
Age (range)	25-46	25-46	26-44	
Oocytes frozen (m±ds)	4389 (6,67 ± 3,55)	1980 (5,09 ± 3,09)	2409 (6,24 ± 4,0)	
Warming cycles	624	354	270	
Oocytes thawed (m±ds)	2564 (4,12 ± 1,53)	1469 (4,15 ± 1,65)	1095 (4,06 ± 1,41)	
Oocytes survived (%)	1835 (71,6)	1032 (70,3)	803 (73,3)	.096
Oocytes microinjected (m±ds)	1386 (2,23 ± 0,89)	792 (2,25 ± 0,95)	594 (2,20 ± 0,82)	.320
Normal Fertilization (%)	1006 (72,6)	561 (70,8)	445 (74,9)	.104
Cleaved Embryos (%)	910 (90,5)	508 (90,6)	402 (90,3)	.994
N° Transfer	545	297	248	
Transferred Embryos (m±ds)	917 (1,69 ± 0,74)	512 (1,66 ± 0,79)	405 (1,71 ± 0,69)	.127
Pregnancy/Transfer (%)	174/545 (32.0)	79/248 (31.8)	95/297 (32.0)	.953
Implantation rate	180/917 (19.6)	80/405 (19.7)	100/512 (19.5)	1.000
Miscarriage rate	38/174 (21.8)	17/79 (21.5)	21/95 (22.1)	.927

No statistically significant differences was observed between the two groups in biological and clinical outcomes.

P-190 4:30 PM Saturday, October 17, 2020

STATUS QUO – OR IS IT TIME TO RECONSIDER THE VITRIFICATION METHOD RELATIVE TO THE RISK OF EMBRYO DISEASE TRANSMISSION IN CRYOSTORAGE?

Mitchel C. Schiewe, Ph.D., H.C.L.D. (ABB),[1] Shane Zozula, B.S., T.S. (ABB),[1] Nancy L. Nugent, MS,[1] James Stachecki, PhD,[2] Robert E. Anderson, MD[3] [1]Ovation Fertility, Newport Beach, CA; [2]Innovative Cryo Enterprises LLC, Linden, NJ; [3]SCCRM, Newport Beach, CA.

OBJECTIVE: The current global pandemic has triggered concerns regarding the potential infectivity of the SARS-CoV-2 virus to blastomeres known to possess ACE-2 receptors. In 2010, Pomeroy and coauthors reviewed the negligible risks associated with the potential cross contamination of human reproductive tissues, gametes and embryos in cryostorage. The purpose of this investigation is to explore changes in ART lab practices over the last decade that could warrant a reassessment of the latter AAB/CRB embryo cryopreservation guidelines relative to disease transmission potential.

DESIGN: Retrospective analysis of clinical practices that may alter the way we look at acceptable risks in embryo vitrification (VTF) and cryostorage methods. Specifically, we will investigate the effectiveness of a validated closed VTF system relative to zona pellucida (ZP)-intact and non-intact blastocyst cryopreservation. Additionally, we will discuss the merits and need for safer cryostorage systems.

MATERIALS AND METHODS: Human blastocysts were vitrified in a closed, aseptic device system and rapidly-warmed and sucrose diluted using standard procedures. From 2009 to 2012, 90% of all vitrified blastocysts had an intact ZP without the need for pre-VTF collapsing due to the use of I.C.E. non-DMSO solutions (>7.9M glycerol/EG). Between 2012-2014 we transitioned into 100% of all embryos experiencing laser ZP ablation and or blastocyst biopsying procedures by 2015. The latter trophectoderm exposed blastocysts were effectively contained in flexipettes which were weld-sealed into CBS straws without risk to possible pathogen exposure in liquid nitrogen cryostorage. Chi-squared analysis was used to assess differences ($p<0.05$) in survival and pregnancy outcome data.

RESULTS: The routine application of ZP-exposed trophectoderm and blastocyst biopsying improved ($p<0.05$) our survival rates from 95% (1066 of 1126 BL) to 99.4% (3352 of 3373 BL) with increased ($p<0.05$) embryo implantation efficiency (46% vs 69% implantation using 1.91 vs 1.07 blastocysts/FET, respectively).

CONCLUSIONS: The protective barrier of an intact ZP to potential pathogen exposures is no longer a clinical reality for cryopreserved blastocysts. Although we agree that the relative risks of embryo disease transmission in cryostorage remain negligible, why take any risks when highly effective closed VTF systems (ICE straw, HSV, μS-VF, VitriSafe) have been established over the last decade? Alternatively, we question whether the use of LN_2-vapor storage tanks for open-VTF systems alleviates potential airborne viral cross-contamination, while they most certainly create a greater risk for potential embryo wastage as discussed by Pomeroy et al. (2010) and overtly realized by recent tank failure experiments and known catastrophic events. Finally, it is worth noting that embryos vitrified in an insulated straw environment are more resistant to detrimental additive temperature fluxes that can occur under sub-optimal cryostorage handling procedures. So, we ask, is it time to reconsider the status quo of embryo good tissue practices when viral pandemics are a reality?

RESEARCH ON THE RELATIONSHIP BETWEEN THE CAPACITY OF EMBRYO STORAGE TANKS AND THE ESTIMATED EMBRYO SALVAGE PERIOD WHEN TANKS ARE DAMAGED.

Manami Irie, B.S.,[1] Akari Obashi, B.S.,[1] Hiroshi Matsumoto, B.S.,[1] Satoshi Mizuno, Ph.D.,[1] Ippei Akezumi, B.S.,[2] Isao Tsuji, M.D., Ph.D.,[1] Aisaku Fukuda, M.D., Ph.D.,[1] Yoshiharu Morimoto, M.D., Ph.D.[3] [1]IVF Osaka Clinic, Osaka, Japan; [2]astec, Osaka, Japan; [3]HORAC Grand Front Osaka clinic, Osaka, Japan.

OBJECTIVE: Keeping liquid nitrogen (LN_2) tank properly is extremely important for an ART clinic. As the accident in the U.S. in 2018 showed, a tank failure causes serious damage for embryos and patients. However, there's no detailed information as to what to do when tanks are damaged. In our previous study, we indicated that a damaged 10L tank can keep freezing for 7-8 hours if it retains a certain level of LN_2. In this study, we analyzed the influence of tank capacity on the estimated embryo salvage period in a simulated tank failure.

DESIGN: Prospective experimental trial.

MATERIALS AND METHODS: We prepared 3 tanks of different capacity (XT10, HC20, HC35, Taylor-Wharton, USA). All tanks were filled up to full with LN_2. To simulate tank failure, we drilled a 2mm diameter hole in the vacuum valve of each tank. A temperature prove was set in a plastic sleeve of cane in the tanks. We measured the temperature and LN_2 levels every 15 min for the first hour. Then, they were measured every hour to until the rise in temperature began. After the temperature initiated to rise, they were measured every 15 min to until the temperature reached -80 °C, which is the temperature at which embryos start to get damaged. Before tank failure simulation, temperatures and LN_2 level of each tank were measured every 24 hours for 7 days to see the temperature and LN_2 volume shift without tank damage.

RESULTS: Speed of LN_2 level decrease of the 10, 20 and 35L tank was 4.6, 4.5, and 2.8 cm/h, respectively. The temperature at the start of measurement for all tanks was -196 °C. In the 10L tank, the rise in temperature began when the remaining LN_2 level was 1cm. In the 20 and 35L tanks, it began

when the LN_2 was gone. The time at which the rise in temperature began was 6h45min for the 10L tank, 8h00min for the 20L tank, and 11h45min for the 35L tank, respectively. The time it took for the temperature to reach -80 °C for the 10, 20, and 35L tanks were 7h54min, 8h41min, and 14h14min, respectively. The decrease in LN_2 levels of the 10, 20, and 35L tanks for 7days without a drilled hole were 2cm, 4cm, and 4cm, respectively. The temperature remained at -196 °C in all tanks without tank damage.

CONCLUSIONS: In this study, the speed of LN_2 decrease of the 35L tank was slower than that of the 10 and 20L tanks when damaged. The larger the capacity of the tank, the longer it took for the temperature rise to begin and for the temperature to reach -80 °C. There was a difference of 6h20min between the 10L and 35L tanks to reach -80 °C. Therefore, it should be kept in mind that the rescue duration of embryos over the tank failure vary depending on each tank capacity.

P-192 4:30 PM Saturday, October 17, 2020

AN UPDATE IN SPERM CRYOPRESERVATION: DETERMINATION OF MELATONIN CONCENTRATION USED AS ANTIOXIDANT AGENT IN PRE-FREEZING SAMPLES. Larissa Namie Chiba, Bsc, Ana Clara Monteiro Barduchi, Bsc, Mayara Rodrigues, Bsc, Heloisa Faquineti, Bsc, Juliana Risso Pariz, PhD, Jorge Hallak, PhD. Androscience, Science and Innovation Center in Andrology and High-Complex Clinical and Andrology Laboratory, Sao Paulo, Brazil.

OBJECTIVE: To determine the melatonin concentration used as antioxidant agent in pre-freezing semen samples.

DESIGN: Prospective study.

MATERIALS AND METHODS: Fifteen semen samples from male volunteers (21-45 years of age) in Androscience – Science and Innovation Center and High-Complexity Clinical and Research Andrology Laboratory, Sao Paulo, Brazil, were included in this study, from August 2019 to April 2020. As inclusion criteria, were adopted fresh samples (FS) with seminal volume $\geq$1.5 ml, sperm concentration $\geq$15 millions/ml and leukocytes $<$1.0 million/ml. After initial seminal and functional analysis, each sample was divided to evaluate different melatonin final concentrations: 0.01mM, 2.0mM and 3.0 mM of melatonin, added in cryoprotectant solution Test Yolk Buffer®. One samplem was cryopreserved with melatonin (control sample). Sperm viability, DNA fragmentation (SCSA®), and reactive oxygen species (ROS, luminol) levels were analyzed before and after cryopreservation.

RESULTS: Significant reduction was identified in sperm concentration, total and progressive motility and increase of ROS in postthaw samples compared to fresh samples ($p<0.05$). Motility parameters and reactive species of oxygen have improved in samples supplemented with 3mM and 0,01mM respectively ($p<0.05$). No differences were observed in DNA fragmentation.

CONCLUSIONS: The present results demonstrated slight positive effect on sperm motility and cryosurvival rate in samples with 3mM of melatonin. In a previous study carried out by our research group, 2 mM melatonin pre-cryopreservation and 2 mM caffeine in postthaw samples with progressive motility> 32% had beneficial effects on seminal quality. Therefore, we can suggest that the positive effect of melatonin depends on the initial quality of the cryopreserved samples.

VITRIFICATION WITH CUMULUS CELLS: IMPACT ON FERTILIZATION AND SUBSEQUENT EMBRYO DEVELOPMENT. Rocío Soledad Iaizzo, BSc, María Lovaglio Diez, BSc, Noelia Jorgelina Hechenleitner, BSc, Ariel Octavio Ahumada, PhD. Procrearte, Buenos Aires, Argentina.

OBJECTIVE: Assess the impact of leaving cumulus cells in fresh and thawed oocytes, and its consequences on fertilization and embryo development. Moreover, investigate whether the corona radiata has a protective effect on the oocyte during vitrification.

DESIGN: 718 oocytes were divided into 4 groups: fresh with cumulus ("group A"; n = 359), fresh denuded ("group B"; n = 123), thawed with cumulus ("group C"; n = 92) and thawed denuded ("group D"; n = 144).

IVF results were measured by fertilization, cleavage and blastulation rates, and top quality blastocysts percentage. These results were compared between groups A and B, and between groups A and C, while survival rate was compared between groups C and D.

MATERIALS AND METHODS: For total denudation, oocytes were exposed to a 30 U hyaluronidase solution during 30 seconds. The remaining cells were removed by using capillaries. Partial denudation was done by exposing oocytes to the same solution but only during 10 seconds, and washed with larger-gauge capillaries. For vitrification, the Kitazato protocol was used. Oocytes were inseminated with approximately 30,000 sperm cells in 20μl drops of Global Total for Fertilization under mineral oil. Embryos were cultured in groups of up to three, at 37°C, 6.5 CO_2 (pH 7.28) and 5% O_2, in 20μl drops of Global Total under mineral oil.

For statistical analysis, contingency tables with chi-square test were done. P-values <0.05 were considered significant.

RESULTS: Statistically significant differences were found in fertilization rate between group A (76,6%) and group B (41,4%), appreciating better results in group A (p=0,0009). Regarding other parameters, no differences were found between these groups. Regarding survival rates, no significant differences were found between groups C and D. Among the groups A and C, there were no differences in IVF results.

CONCLUSIONS: Presence of granulosa cells is vital for normal fertilization rates, in both fresh and thawed oocytes. However, it did not affect survival or blastulation rates.

The survival rate in thawed oocytes did not change according to the presence or absence of cumulus cells. This indicates that the corona radiata does not accomplish a protective function, as described by some authors. However, their presence does not impact negatively either. Therefore, it is not necessary to denude the oocytes before vitrification, which would benefit maturation, and the possibility of performing conventional IVF instead of ICSI.

The ICSI technique is used on thawed oocytes to solve the potential low fertilization rate through conventional IVF in fully denuded oocytes. However, the fact that the cumulus cells maintain the oocyte's fertilizing ability even after vitrification corroborates that it would be possible to perform conventional IVF instead of ICSI in thawed oocytes with their cumulus cells. This would decrease the workload in laboratories, and improve the results, since IVF is a less invasive and more physiological technique.

P-194 4:30 PM Saturday, October 17, 2020

RETROSPECTIVE STUDY TO COMPARE BETWEEN HYALURONAN ENRICHED MEDIUM AND BLASTOCYST TRANSFER MEDIUM FOR FROZEN EMBRYO TRANSFER(FET) AND ITS IMPACT ON CLINICAL PREGNANCY RATE (CPR) IN PATIENTS WITH 2 OR MORE IVF-ICSI CYCLE FAILURES. Fiyazur Rahman, M.Sc,[1] , P.hDAnkita Gupta, scholar,[2] Dr. Rashmi Sharma, MD, DNB, FICOG,[3] Rohan Sharma, B.Sc,[4] Dr. Navkiran k Kaur, Ph.D.[5] [1]chief embryologist, New delhi, India; [2]Senior embryologist, Noida, India; [3]head of department, New Delhi, India; [4]Jr. Embryologist, New Delhi, India; [5]Assistant professor, Noida, India.

OBJECTIVE: To study the impact of use of hyaluronan enriched medium on CPR in frozen embryo cycles as compare to blastocyst culture medium in 2 or more IVF-ICSI failure.

DESIGN: This was a retrospective observational study.

MATERIALS AND METHODS: Record of all FET patients were analyzed in past one year and those patient who went FET with prior history of 2 or more IVF failure were included in this study, irrespective of the three stage of embryo transferred (D-3, D-4 and D-5). The transfer cycles where age of women was more than 40 yrs were excluded along with cycle where donor gametes were used. 195 patient fulfill the inclusion criteria out of which in 114 patients hyaluronan enriched medium was used. these patients were categorized as Group A while in 81 patients blastocyst culture media was used and categorized as Group B.

RESULTS: The two groups found to be comparable in baseline characteristics. The CPR was found to be 42.1 % (48/114) in group A verses 35.8%(

29/81)in group B . No statistically significant difference was observed between these two groups (p =0.375).

CONCLUSIONS: Use of Hylarunon enriched medium for frozen embryo transfer in patients with 2 or more IVF failures is not associated with statistically significant improvements in clinical pregnancy rate as compared to blastocyst transfer medium

THE DEVIL IS IN THE DETAILS: DISTRIBUTION OF CRYOPRESERVED OOCYTE MATURATION STAGE FOR PATIENTS UNDERGOING ONCOLOGY-INDICATED FERTILITY PRESERVATION.

Elnur Babayev, MD, MSc,[1] Danielle E. Strom, MD,[1] Emma C. Trawick, M.D.,[2] Kara N. Goldman, M.D.[3] [1]Northwestern University, Chicago, IL; [2]Northwestern University, Feinberg School of Medicine, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, Chicago, IL.

OBJECTIVE: For patients with cancer undergoing fertility preservation, a careful balance exists between cryopreserving all oocytes, including immature oocytes, and providing realistic expectations regarding future reproductive potential of cryopreserved gametes. The objective of this study was to characterize oocyte maturity and success with in vitro maturation (IVM) prior to oocyte cryopreservation by age and medical diagnosis.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Oncology-indicated fertility preservation cycles completed between Jun/2011 and Dec/2018 were reviewed. Maturation stage of oocytes retrieved and cryopreserved were recorded. 149 stimulation cycles were available for analysis. Data are presented as mean±SD ($p<0.05$). One-way ANOVA or Kruskal-Wallis test were used for statistical analysis.

RESULTS: The mean age was 29±6, BMI 27±8, AMH 3.0±2.6 ng/ml, with a mean 11±2 days of ovarian stimulation, 3685±1751 units of total gonadotropin used, and peak estradiol level 1959±1237 pg/ml. As expected, the number of retrieved and cryopreserved oocytes per cycle decreased with age. All GV oocytes were cryopreserved on the day of retrieval and comprised 8-15% of all cryopreserved oocytes. Metaphase I (MI) oocytes were either frozen on the day of retrieval (3-6% of all cryopreserved oocytes) or in vitro matured overnight. The proportion of cryopreserved oocytes at metaphase II stage (MII) on the day of retrieval (Day 0, range 71-82% of all oocytes) or following IVM (Day 1, 1-5% of all oocytes), as well as the proportion of MI and GV oocytes were not different across age groups. The proportion of frozen eggs at different maturation stages also did not differ by diagnosis.

CONCLUSIONS: Our data did not demonstrate a difference in maturation stage of cryopreserved oocytes by age or clinical diagnosis. Notably, in a large fertility preservation program approximately 20% of oocytes are cryopreserved at the GV or MI stage or following IVM. Studies suggest that patients undergoing medically indicated fertility preservation may overestimate their likelihood of success with cryopreserved gametes; this may be of particular consequence among patients freezing immature or in vitro matured oocytes with lower pregnancy potential. Patients must be carefully counseled to ensure realistic expectations of success with cryopreserved gametes.

Mohamed Ali Bedaiwy, M.D., Ph.D.[3] [1]The University Of British Columbia, Vancouver, BC, Canada; [2]BC Children's Hospital Research Institute, an agency of the Provincial Health Services Authority, Vancouver, BC, Canada; [3]University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE: Unexplained recurrent pregnancy loss (uRPL) includes non-visualized pregnancy loss (NVPL, i.e. preclinical), visualized pregnancy loss (VPL, i.e. clinical), and Mixed (combination of VPL and NVPL) types of pregnancy losses. Our objective was to evaluate the association between the types of prior pregnancy losses and the outcome of the subsequent pregnancy in a cohort of uRPL women.

DESIGN: A retrospective cohort study approved by ethics board (Approval number: H13-03306).

MATERIALS AND METHODS: Women with uRPL who were referred to the RPL centre at British Columbia Women's Hospital (BCWH), between from January 1, 2011 to August 31, 2017 (n=806) were included. Their clinical evaluations were completed according to the American Society of Reproductive Medicine (ASRM) guidelines. Data were collected using Research Electronic Data Capture (REDCap) data management platform. We compared women who had only non-visualized pregnancy losses (NVPL) with women who had only visualized pregnancy losses (VPL) and those with both types of uRPL with respect to demographic and clinical characteristics. We also compared pregnancy outcomes (successful pregnancy $\geq$10 weeks gestation vs. miscarriage at $<$ 10 weeks gestation) among women with NVPL vs VPL groups. Logistic regression was used to adjust for potential confounders.

RESULTS: There were 142 (18%) women with only NVPL, while 152 (19%) women had only VPL. The remaining 512 (63%) women had a mixture of both. In this cohort of 806 women, 679 had a subsequent pregnancy within 12 months, among these, 397 (58.4%) pregnancy reached $\geq$10 weeks' gestation, and 282 (41.5%) of pregnancies were miscarried ($<$10 week's gestation). Successful pregnancy reaching $\geq$10 weeks occurred in 45.4% (69/152) women with VPL, in 35.2% (50/142) women with NVPL, and in 54.3% (278/512) of women with both types (mixed group).

Compared to women with VPL, women with NVPL were more likely to have prior primary pregnancy losses (AOR = 2.26, 95% CI = 1.32 – 3.86), and prior history of therapeutic abortions (AOR =4.26 and 95% CI = 1.65 – 11.02). Among those who became pregnant, women with VPL were more likely to remain pregnant at or beyond 10 weeks' gestation (AOR = 1.94, 95% CI = 1.03 – 3.66).

CONCLUSIONS: Our study suggests that exclusive NVPLs are prevalent in women with uRPL. Women who had only NVPL were more likely to experience miscarriage at $<$ 10 weeks' gestation compared with women with VPL in their subsequent pregnancy.

P-198 4:30 PM Saturday, October 17, 2020

MATERNAL SERUM B-HCG LEVELS IN THE PERI-IMPLANTATION PERIOD ARE PREDICTIVE OF RISK FOR 3RD TRIMESTER HYPERTENSIVE DISORDERS IN IVF PREGNANCIES. Samantha Simpson, MD,[1] Seth Guller, PhD,[2] Lubna Pal, MBBS[1] [1]Yale University, Orange, CT; [2]Yale School of Medicine, Orange, CT.

OBJECTIVE: In patients conceiving with in vitro fertilization and embryo transfer (IVF-ET), β-chorionic gonadotropin (β-hCG) levels are measurable in the maternal serum as early as 10 days after ET. The progressive rise in serum β-hCG levels that occurs in the first few weeks of pregnancy are indicative of the degree to which the invading trophoblast is successfully implanting. Because inadequacy of trophoblastic invasion of maternal decidua is a recognized mechanism underlying development of hypertensive disorders of pregnancy, we aimed to examine the predictive potential of peri-implantation levels of β-hCG for subsequent development of hypertensive disorders of pregnancy.

DESIGN: Prospective longitudinal cohort study at an academic fertility center.

MATERIALS AND METHODS: Infertile patients attaining a positive pregnancy test following blastocyst ET (between 10/ 2017 and 03/ 2019) were eligible. Serial estimates of β-hCG levels were performed at 48-hour intervals, as per standard clinical care, until level of $>$2,500 IU/mL, when intrauterine gestation/s were confirmed by transvaginal ultrasound. For the purpose of this work, singleton pregnancies were followed until delivery. The course of pregnancy and occurrence of pre-eclampsia or gestational hypertension (two systolic blood pressures $\geq$140 or diastolic $\geq$90 more than 6 hours apart prior to delivery) were monitored. Relationship between peri-implantation maternal serum β-hCG levels (log-transformed) with incident hypertensive disorders in the third trimester was examined using student's t-test; multivariable logistic regression analysis was used to examine relationship between β-hCG levels and pregnancy related hypertensive disorder after controlling for body mass index (BMI), age and race.

RESULTS: In singleton pregnancies conceived with IVF-ET, as early as between days 12-15 after blastocyst ET, β-hCG levels were significantly lower in those pregnancies that were eventually complicated by hypertensive disorder in the 3rd trimester (n=9) compared to those with an uneventful course (n=71), (days 12/13, 496.5mIU/mL (range 199-846) vs. 717mIU/mL (194-2920), p=0.03; days 14-15, 1225mIU/mL (339-1960) vs. 1690mIU/mL (400-4110) , p=0.03]. Multivariable logistic regression analysis adjusting for age, BMI and race using a propensity score approach identified serum β-hCG thresholds of less than 530mIU/mL on days 12/13 and less than 1230mIU/mL on days 14/15 following ET as predictive of incident pregnancy related hypertensive disorder in the 3rd trimester (26.6% v 5.9%, OR 6.6, 95% CI 1.01 – 43.4, p=0.049).

CONCLUSIONS: Precisely timed β-hCG serum levels after IVF-ET may be the earliest marker of risk for hypertensive disorders in the current pregnancy.

P-199 4:30 PM Saturday, October 17, 2020

RISK FACTORS FOR SUBCHORIONIC HEMATOMA AFFECTED PREGNANCIES IN THE INFERTILE POPULATION. Erin Inman, MD,[1] Daniel Miranian, MD,[2] Micaela J. Stevenson, BS,[3] Molly B. Moravek, MD, MPH,[1] Samantha B. Schon, MD, MTR[4] [1]University of Michigan, Ann Arbor, MI; [2]Obstetrics and Gynecology, University of Michigan, Ann Arbor, MI; [3]University of Michigan Medical School, Ann Arbor, MI; [4]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI.

OBJECTIVE: Subchorionic hematoma (SCH) is common, however, is of unknown significance among the infertile population as most studies evaluate women without a history of infertility or with naturally conceived pregnancies. The objective of this study was to identify risk factors for SCH affected pregnancies in the infertile population.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: CPT codes were used to identify all obstetric (OB) scans performed at a single infertility clinic from 1/2015-3/2018. All viable intrauterine pregnancies on initial OB scan were included for analysis (n=1210). Chart review was performed to identify the presence of SCH. Data on patient demographics, fertility treatments, and pregnancy outcomes were collected. Bivariate analysis was performed to compare pregnancies with and without SCH, and multivariable logistic regression was used to identify independent risk factors for SCH.

RESULTS: The prevalence of SCH was 12.5% (n = 151). Prevalence of SCH did not vary significantly by age, race, or fertility treatment groups. Male-factor infertility was more prevalent among patients with SCH compared to those without SCH (34.4% versus 24.6%, p = 0.009). There were no other differences in SCH across other infertility diagnoses. In donor egg, in vitro fertilization, and frozen embryo transfer pregnancies, trophectoderm grade (good, fair, and poor) and stage of transfer (blastocyst or cleavage) did not vary significantly between pregnancies with and without SCH. However, use of 81-162mg aspirin was more common among patients with SCH compared to those without (49.7% versus 38.6%, p = 0.01) as well as the use of IM progesterone supplementation (16.6% versus 9.6%, p = 0.009).

After adjusting for age, factors significantly associated with SCH were the number of prenatal ultrasounds (aOR 1.72 [95% CI: 1.32-2.24], p$<$.0001) and vaginal bleeding (aOR 3.31 [2.20-5.50], p$<$.0001). Gynecologic complications (including fibroids, endometrial polyps, endometriosis, adenomyosis, and polycystic ovarian syndrome) were associated with decreased odds of SCH (aOR 0.61 [0.41-0.89], p=0.01).

CONCLUSIONS: Male-factor infertility and aspirin use are more common among infertile patients with SCH. While vaginal bleeding and number of prenatal ultrasounds were risk factors for SCH, a significant gynecologic history was protective for SCH.

P-200 4:30 PM Saturday, October 17, 2020

PREDICTIVE VALUE OF EARLY SERUM HCG LEVELS IN PROGRAMMED FROZEN EMBRYO TRANSFER CYCLES. Brady I. Magaoay, BA,[1] Pietro Bortoletto, MD,[2] Adamantios Athanasiou, MD,[2] Antonia Iliana Athanasiou, MD,[2] Phillip A. Romanski, MD,[2]

Daylon James, PhD,[2] Steven Spandorfer, MD[2] [1]Weill Medical College of Cornell University, New York, NY; [2]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine if early serum hCG assessment (2-8 days post-blastocyst transfer) in patients achieving a pregnancy following a programmed frozen embryo transfer (FET) cycle can predict subsequent miscarriage.

DESIGN: Retrospective cohort study conducted at a university-affiliated center.

MATERIALS AND METHODS: Women with a positive hCG (>0.2 mIU/mL, Roche Cobas e801 assay) ≥ 10 days after a programmed FET cycle were categorized into two groups: early positive versus early negative hCG (between 2-8 days post-ET). Women with a vanishing twin or non-singleton live births were excluded. Only single blastocyst transfers were analyzed. Miscarriage, defined as demise of a clinical intrauterine gestation, was the primary outcome. Live birth rate was the secondary outcome. A multivariable logistic regression was performed to examine the association between both early hCG groups and miscarriage while controlling for the use of donor oocytes and the day of early hCG assessment. Odds ratios (OR) with 95% confidence intervals (CI) were estimated.

RESULTS: In total, 337 pregnant patients met inclusion criteria, of which 123 (36.5%) had a negative early hCG and 214 (63.5%) had a positive early hCG. Maternal age (35.7 vs. 36.4, p=0.20), BMI (24.0 versus 23.9 kg/m^2, p=0.51), and the use of donor oocytes (12.8 vs. 15%, p=0.59) were similar between the two groups. The median number of days post-ET of early hCG assessment was statistically different between the early negative versus early positive hCG groups (3 vs. 5 days post-ET, p<0.001), respectively. The mean (SD) early positive hCG level was 18.7 (25.2) mIU/mL. In the univariate analysis, a positive early hCG was associated with a 55% reduction in the odds of subsequent miscarriage compared to a negative early hCG (10.0 vs. 19.7%, OR: 0.45, CI: 0.24-0.86). After controlling for the use of donor oocytes and days of early hCG assessment, the model estimate did not change (OR: 0.44, CI: 0.19-0.99). There was no difference in live birth rates between the two groups (36.8 vs. 37.7, p=0.860).

CONCLUSIONS: In patients who become pregnant after a programmed FET cycle, an early positive hCG 2-8 days after transfer is associated with a significant reduction in the odds of a subsequent miscarriage. A strategy of early hCG assessment may allow for more individualized counseling and expectations setting regarding cycle success for patients and providers alike.

P-201 4:30 PM Saturday, October 17, 2020

LUTEAL PHASE PROGESTERONE SUPPORT DOES NOT IMPROVE ONGOING PREGNANCIES IN TRUE NATURAL CYCLE CRYOPRESERVED BLASTOCYST EMBRYO TRANSFERS. Ian Waldman, MD,[1] Catherine Racowsky, PhD,[1] Emily Disler, BS,[1] Ann M. Thomas, PhD,[2] Andrea Lanes, PhD,[1] Mark D. Hornstein, MD[1] [1]Brigham and Women's Hospital, Boston, MA; [2]Brigham & Women's Hospital, Boston, MA.

OBJECTIVE: To study the addition of progesterone luteal phase support for cryopreserved blastocyst transfers in natural cycles not using an ovulatory trigger (i.e. "true" natural cycles).

DESIGN: Retrospective cohort study in a single academic medical center.

MATERIALS AND METHODS: All patients who underwent day 5 or day 6 true natural cycle cryopreserved transfer between July 30, 2012 and June 30, 2018 were screened for inclusion. Evaluation of outcomes following progesterone supplementation was compared to those who did not receive luteal phase progesterone support. The primary outcome was ongoing pregnancy rate at discharge of care to the patient's obstetrician, typically around 8-12 weeks gestational age. Secondary outcomes were positive serum human chorionic gonadotropin (HCG) level, implantation rate, clinical pregnancy rate, miscarriage/abortion rate, ectopic pregnancy rate, and multifetal gestations.

RESULTS: 229 patients were included in the analysis with 149 receiving luteal phase progesterone supplementation and 80 receiving no luteal phase support. Patient demographic and cycle characteristics and embryo quality were similar between the two groups. No difference was seen in ongoing pregnancy rate (49.5% vs. 47.5%, p=0.8738), clinical pregnancy rate (50.3% vs. 47.5%, p= 0.7483), positive HCG rate (62.4% vs. 57.5%, p=0.5965), miscarriage/abortion rate (5.4% vs. 2.5%, p=0.2622), ectopic pregnancy rate (0% vs. 1.3%, p=0.3493), or multifetal gestations (7.4% vs. 3.8%, p=0.3166).

CONCLUSIONS: The addition of progesterone luteal phase support in true natural cycle cryopreserved blastocyst transfers does not improve cycle outcomes.

P-202 4:30 PM Saturday, October 17, 2020

RETAINED PRODUCTS OF CONCEPTION AFTER EARLY PREGNANCY LOSS: A CLOSER LOOK. Vaishnavi Purusothaman, MD, MA,[1] Emma M. Rosen, MSPH,[2] Linnea R. Goodman, MD[1] [1]University of North Carolina, Chapel Hill, NC; [2]UNC Gillings School of Public Health, Chapel Hill, NC.

OBJECTIVE: Missed abortion is an unfortunate, yet common outcome following fertility treatment. The rate of retained products of conception (RPOC) after early pregnancy loss has been reported to be 0.4% - 3.8%. The primary purpose of this study was to assess and compare the incidence of RPOC after manual vacuum aspiration (MVA) or medical management of early pregnancy loss.

DESIGN: Retrospective cohort of patients seen at a university fertility program who underwent treatment for early pregnancy loss between January 2014 and January 2020.

MATERIALS AND METHODS: Patients were categorized into two groups: MVA group, and medical management group (vaginal misoprostol with or without oral mifepristone). Clinical information and laboratory results were collected from chart abstraction. RPOC and intrauterine adhesions were defined as presence of such findings on follow-up Saline Infusion Sonography (SIS) and/or Hysteroscopy. Statistical analysis was performed using SAS. T-tests and Fisher's exact tests were used where appropriate; unadjusted and adjusted risk ratios were calculated. Models were adjusted for history of RPOC and history of miscarriage.

RESULTS: A total of 110 patients with a mean age of 34.8+/- 4.3 years were identified as having a missed abortion requiring intervention with MVA (n = 56) and medical management (n =54). The mean gestational age at diagnosis was 7.6 +/-1.0 weeks, and 89.1% of patients conceived after IVF. There was no difference in age, race, BMI, parity, gestational age at time of diagnosis, or history of previous intrauterine surgery between groups. 80% of patients underwent follow up ultrasound (62.5% in the MVA group vs. 98.2% in the medical management group; p <0.01). In total, 57.2% of patients underwent uterine cavity evaluation, of which 93.7% were uterine cavity evaluation utilizing saline for improved cavity evaluation (SIS) and 6.3% were cavity evaluation with hysteroscopy. The incidence of RPOC after MVA and medical management was 13.0% and 29.4%, respectively. After controlling for prior history of miscarriage and prior history of retained products, the adjusted risk ratio for incidence of RPOC after MVA was 0.40 (95% CI 0.16-1.01). On follow-up imaging, there were noted to be 4 cases of adhesions in the MVA group (10.8%) and 1 in the medical management group (3.7%) (RR 2.92, 95% CI 0.3-19.9).

CONCLUSIONS: The incidence of RPOC in both treatments groups was noted to be much higher than the previous reports. This difference may be secondary to close surveillance and post-treatment uterine cavity evaluation with SIS and/or hysteroscopy in a fertility practice. The incidence of RPOC was also higher after medical management. These findings may better inform patient counseling and underscore the importance of close follow up after early pregnancy loss to ensure prompt diagnosis and treatment of RPOC.

P-203 4:30 PM Saturday, October 17, 2020

THE ASSOCIATION BETWEEN ECTOPIC PREGNANCY AND INFLAMMATORY BOWEL DISEASE, IRRITABLE BOWEL SYNDROME, AND CELIAC DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS. Jonah Imee Ramirez Talavera, BSc,[1] Allison Parrill, BSc,[1] Mohamed Ali Bedaiwy, M.D., Ph.D.,[2] Chris Elsayad, MD, FACP,[3] John C. Riggs, MD,[3] Bo Peng, Ph.D.[1] [1]American University of the Caribbean, School of Medicine, Cupecoy, Sint Maarten (Dutch part); [2]University of British Columbia, Vancouver, BC, Canada; [3]Nassau University Medical Center, East Meadow, NY.

OBJECTIVE: Ectopic pregnancy affects about 1% of women of reproductive age. Previous studies that compare risk of ectopic pregnancy (EP) in women with Inflammatory Bowel Disease (IBD), Irritable Bowel Syndrome (IBS) and Celiac Disease (CD) to the general population have yielded inconsistent results. The objective of our study is to provide a systematic

assessment of the risk of EP in women with IBD, IBS as well as CD compared to women without these diseases.

DESIGN: Systematic review and meta-analysis

MATERIALS AND METHODS: Literature search was conducted from MEDLINE and Web of Science using MESH terms: “ectopic pregnancy”, “tubal pregnancy”, “inflammatory bowel disease”, “ulcerative colitis”, “Crohn’s disease”, “irritable bowel syndrome” and “celiac disease”. Peer-reviewed publications and abstracts written in English, published from the database inception date to April 30th, 2020, about the association between EP and IBD, IBS, and CD were included. Included abstracts were cross-checked with publications to avoid duplication. Studies that did not report the outcomes of comparison, were unable to extract data from, or did not contain disease-free controls were excluded. Quality assessment was conducted based on GRADE criteria. Mantel-Haenszel test was used to analyze the association between the binary outcomes (ectopic pregnancy or intrauterine pregnancy) and the binary comparisons (disease or disease-free). Data from cohort studies were presented with Risk Ratio (RR) with 95% Confidence Interval (CI). Heterogeneity between studies was presented with I^2 and P-value.

RESULTS: 471 articles were retrieved from the MEDLINE and Web of Science literature search. A total of five population-based cohort studies that investigated the association between EP and IBD, IBS, and CD were included. Analysis was performed based on a total number of 23,879 patients with IBD (11,221 with ulcerative colitis and 12,658 with Crohn’s disease) and 9,276,714 controls, showing elevated risk of EP in women with IBD (RR=1.25, 95% CI 1.12 to 1.39, P<0.00001; heterogeneity: I^2 =21%, P=0.26) comparing to control women. Interestingly, the risk of EP is significantly increased in women with Crohn’s disease (RR=1.46, 95% CI 1.26 to 1.68, P<0.00001; heterogeneity: I^2 =54%, P=0.14) but not ulcerative colitis (RR=1.03, 95% CI 0.87 to 1.22, P=0.73; heterogeneity: I^2 =0%, P=0.43) compared to controls. In addition, increased risk of EP was observed in a cohort of 26,543 women with IBS (RR=1.45, 95% CI 1.25 to 1.69, P<0.00001) compared to 73,457 women without IBS. However, no significant difference (RR=1.12, 95% CI 0.95 to 1.32, P=0.19; heterogeneity: I^2 =49%, P=0.16) was observed between the risk of EP in 6,319 women with CD and 63,166 women without CD.

CONCLUSIONS: Possible evidence of associations between EP and Crohn’s disease as well as IBS were observed; however, not with ulcerative colitis and CD. These results should be considered with caution, owing to high heterogeneity and relatively small study sizes among included research. Thus, continued research is needed to delineate the pregnancy implications of IBD, IBS and CD.

P-204 4:30 PM Saturday, October 17, 2020

PREGNANCY ULTRASOUND MEASUREMENTS AND EARLY PREGNANCY LOSS: VALIDATION OF A PREDICTIVE MODEL. Irene Peregrin-Alvarez, MD,[1] Jennifer C. Gordon, MD,[1] Patricia Goedecke, MS,[1] Laura Detti, MD[2] [1]University of Tennessee Health Science Center, Memphis, TN; [2]Cleveland Clinic, Cleveland, OH.

OBJECTIVE: We aimed to prospectively validate the use of gestational sac (GS), yolk sac (YS) diameter, crown-rump length (CRL), and embryonal heart rate (HR) dimensions to identify patients at risk for early pregnancy loss.

DESIGN: This was a prospective cohort study of first trimester pregnancies where GS, YS diameter, CRL, and HR measurements were serially obtained via weekly transvaginal ultrasound (TVUS) from 6 through 10 weeks’ gestation.

MATERIALS AND METHODS: We studied patients at our Institution who were evaluated and treated for infertility. The mode of conception included spontaneous, ovulation induction with, or without, intrauterine insemination (IUI), and in vitro fertilization (IVF). TVUS was obtained in singleton, and multiple pregnancies followed from 6 through 11 weeks’ gestation with serial measurements of the GS and YS diameter, CRL, and HR. Non-parametric tests and logistic regression models were used for comparisons of distributions and testing of associations.

RESULTS: We examined a total of 82 patients with 89 pregnancies; 82 of which were singleton pregnancies; 6 were twins (12 fetuses); and 1 was triplets (3 fetuses). There were a total of 97 fetuses. Nineteen patients had 24 pregnancy losses. Nomograms were developed showing the changes of the evaluated parameters in ongoing pregnancies, as well as in pregnancy loss. We previously developed a logistic model for prediction of early pregnancy loss (Detti et al 2020) that showed that in failed pregnancies, all the parameters showed significant changes, with different temporal onsets. This model was used to determine the accuracy of detection of failed pregnancies before the event. This accuracy was different by gestational age (average of 72% detection rate) showing the less accuracy in the earliest ultrasounds at 6 weeks (57%) and at 11 weeks (30%). The highest accuracy was shown at the ultrasounds performed at 8, 9 and 10 weeks.

CONCLUSIONS: Our study confirmed our previous results showing that a small GS and a large YS reliably predicted early pregnancy loss from occurrence, with the YS reliably predicting this outcome in advance. The accuracy for our prediction model was different by gestational age, showing the less accuracy in the earliest ultrasounds at 6 weeks and 11 weeks, with the highest accuracy being found at 8, 9 and 10 weeks. These findings have important implications for patient counseling during early pregnancy care.

P-205 4:30 PM Saturday, October 17, 2020

PREGNANCY LOSS RATES BY DEVELOPMENTAL STAGE AFTER SINGLE EUPLOID FROZEN-THAWED EMBRYO TRANSFER. Devora Aharon, MD,[1] Joseph A. Lee, BA,[2] Jeffrey Klein, MD,[2] Matthew A. Lederman, MD,[2] Beth McAvey, MD,[1] Alan B. Copperman, MD[1] [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Reproductive Medicine Associates of New York, New York, NY.

OBJECTIVE: Patients who conceive naturally experience a predictable decline in pregnancy loss rates as they progress in gestational age, from a 15-25% global loss rate to 3-5% once cardiac activity is observed.[1,2] The objective of this study is to determine the rate of loss at each stage of early pregnancy following single euploid FET.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Patients who underwent a single euploid FET from 2016-2018 were included in the study. Patients with confirmed pregnancy, defined as bHCG $\geq$2.5 mIU/mL, were analyzed. Preimplantation genetic testing for aneuploidy (PGT-A) was performed using Next Generation Sequencing. Primary outcome was pregnancy loss rate at the following stages: 1. Initial HCG positive; 2. second HCG rise; 3. presence of gestational sac; 3. presence of yolk sac; 4. presence of fetal pole; 5. presence of cardiac activity; 6. discharge from the practice with ongoing pregnancy. Results were stratified according to history of prior clinical pregnancy loss. Multinomial logistic regression was used to determine the association of covariates with pregnancy loss at each stage, with generalized estimating equations to account for repeated patients.

RESULTS: A total of 7092 single euploid FET cycles were observed, 2685 of which resulted in pregnancy and were included in the study. Of these, 345 FET were performed in patients with one prior loss and 50 in patients with $\geq$2 prior losses. Rates of pregnancy loss following each developmental stage for patients with and without a history of prior pregnancy loss are shown in Table 1. Multinominal logistic regression showed that among patients with no prior loss, patient age, oocyte age, BMI, AMH, BAFC, and endometrial thickness were not associated with pregnancy loss at any stage. Among patients with any history of loss, endometrial thickness was negatively associated with pregnancy loss (p=0.03).

CONCLUSIONS: High loss rates despite transferring screened embryos indicate a significant contribution of non-genomic factors to reproductive failure. While screening for embryonic competency accounted for maternal age, other factors were found to contribute to likelihood of pregnancy loss including endometrial thickness among patients with a prior loss. Personalized management must take into account a multifactorial approach when counseling patients about the likelihood of early pregnancy loss.

TABLE 1. Rate of pregnancy loss following each developmental stage

Pregnancy stage	No prior loss (N=2290)	1 prior loss (N=345)	≥2 prior losses (N=50)
Positive HCG	20.6%	25.7%	36.0%
HCG rise	20.3%	25.7%	34.7%
Gestational sac	17.5%	21.4%	31.9%
Yolk sac	14.9%	15.5%	27.2%
Fetal pole	12.1%	13.5%	25.6%
Cardiac activity	10.1%	12.0%	21.9%
Discharge	5.7%	7.6%	8.5%

IS EARLY HCG PREDICTIVE OF PREGNANCY AFTER ESET IN BOTH FRESH AND FET CYCLES? Fady I. Sharara, M.D., Anna Lysenko-Brockman, MS, Haneen Taha, MS. Virginia Center for Reproductive Medicine, Reston, VA.

OBJECTIVE: Most ART programs perform β-hCG measurement 9-12 days after embryo transfer(ET) to detect a pregnancy. A prior study using hyperglycosylated hCG in a small sample size showed that a single measurement 6 days after ET had 100% sensitivity and specificity in identifying biochemical and ongoing pregnancies. We sought to determine whether routine serum β-hCG measurement at 5-6 days after ET is predictive of ART outcome. This is important in patient counseling if we can stop P supplementation early in cases of negative tests, especially if taking painful IM P supplementation.

DESIGN: Prospective single center.

MATERIALS AND METHODS: A total of 241 patients undergoing eSET (elective single embryo transfer) had their "early" serum β-hCG measured 5-6 days after ET, and the "official" serum β-hCG was done 9-10 days after ET. There were 91 fresh ET and 150 FET cycles. A test was positive if the β-hCG measurement was ≥ 3 IU/L. All tests were performed at a commercial laboratory with offices around the US (LabCorp).

RESULTS: In the 91 fresh ET cases observed, 65 had positive and 26 had negative "early"β-hCG tests measured 5-6 days post ET. Of the 65 positive β-hCG tests, 10 (15.4%) were biochemical, 9 (13.8%) were pregnancy losses (SAB), and 46 (70.8%) were live births. Of the 26 negative tests, 24 (92.3%) were negative on days 9-10 and 2 (7.6%) were positive on days 9-10. Both positive results on day 9-10 ended with biochemical losses. In the 150 FETs observed, 81 had positive and 69 had negative "early" β-hCG. Of the 81 positive, 19 (23.5%) were biochemical pregnancies, 7 (8.6%) had SAB, and 55 (67.9%) were ongoing/live births. Of the 69 negative β-hCG tests measured 5-6 days post FET, 4 (5.7%) were then positive on day 9-10, 3 resulting in biochemical pregnancies and one live birth. The mean "early" β-hCG levels in the IVF group was 27.03 IU/L which was significantly higher than in the FET 14.09 IU/L ($P<0.001$). There were significant differences in early β-hCG results between ongoing/delivered and biochemical pregnancies in both fresh and FET groups ($P<0.001$), but not between ongoing/LB and SAB. However, by first β-hCG level on days 9-10 there were no differences in the mean β-hCG between the 2 groups ($P=0.04$). ROC for fresh ET showed a cut off value of 7 IU/L. The test can detect with 90% sensitivity a 96% specificity with 3.8% false positive (AUC=0.972). For FET it showed a cut off value of 3.7 IU/L. The test can detect with 89% sensitivity a specificity of 94% with 5.7% false positive (AUC=0.964) (Figure 1).

CONCLUSIONS: Early serum β-hCG measured 5-6 days after ET in eSET cycles is very predictive of successful pregnancies. A negative test 5-6 days after ET is associated with a negative 9-10 day β-hCG test in both fresh and FET cycles. In the fresh group, an early negative β-hCG was 100% predictive of no live births, but in the FET group an early negative in the FET group led to a single live birth (99.33% predictive of no live births). FET cycles were associated with lower early β-hCG levels than fresh transfers but became similar to fresh cycles on the first day of actual pregnancy test. This information is of potential benefit in counseling women undergoing ART.

CHROMOSOMAL ASSOCIATIONS AND GENOMIC INSTABILITY IN IDIOPATHIC RECURRENT PREGNANCY LOSS(RPL), A PILOT SCALE STUDY. Abhik Chakraborty, M.Sc(Masters in Science),[1] Smriti Sanchita, B.S.,[2] Birendranath Banerjee, P.hD[3] [1]INSPIRE Senior research fellow, Bhubaneswar, India; [2]UCLA, Los Angeles, CA, India; [3]Associate Professor, Bhubaneswar, India.

OBJECTIVE: The emotional issues adjoining pregnancy loss become magnified exponentially when miscarriage take place on a repetitive basis. But there are very limited studies correlated with stress in recurrent pregnancy loss (RPL). Telomeres maintain the integrity and stability of our genetic material by protecting our chromosomes. We hypothesized that stress induced background genomic instability and telomere loss plays a pivotal role in unexplained RPL. We aimed to investigate any possible link between background genomic instability, telomere loss and early unexplained recurrent pregnancy loss in a cohort of subjects along with age and sex matched controls.

DESIGN: Participation of a cohort of 50 couples (100 individuals) experiencing with 2 or more earlier pregnancy losses, and struggling for natural conception in a age and sex matched study for elucidating any possible role of chromosomal associations and genomic instability in recurrent pregnancy loss.

MATERIALS AND METHODS: Blood samples were collected from each RPL couple in heparin and EDTA vials along with a consent form for participation in this study. Karyotyping was performed from heparinized blood to screen common/unique chromosomal anomalies associated with unexplained RPL. The lymphocytes were isolated from EDTA blood and subjected for isolation of DNA, RNA and preparation of whole cell protein lysate. The background genomic instability status was examined by using cytokinesis blocked micronucleus (CBMN) assay. We also checked the telomere length of the individuals by quantitative real time PCR (qRT-PCR) and Quantitative-Fluorescent In-Situ Hybridization (Q-FISH). The functional telomeric integrity of telomeric shelterin complex were evaluated through western blot analysis.

RESULTS: Karyotyping analysis demonstrated few novel translocations responsible for RPL, which were not reported previously. In our cohort, we observed that 83 individuals out of 100 were reported karyotypically normal. This prompted us to further examine these karyotpically normal individuals for their background genomic instability. We found that 38.5% (32 out of 83) individuals have high background of genomic instability as compared with the control samples. Next, we investigated the telomere length of the patients with high genomic instability by qRT-PCR and observed that 28.125% (9 out of 32) exhibited loss of telomeres. Q-FISH (PNA-FISH) analysis of these subjects also showed loss in Telomeric signals. Furthermore, western blot analysis of some of the key players of the shelterin components showed reduced level of expression of these proteins in the RPL subjects.

CONCLUSIONS: Apart from numerical or structural chromosomal anomalies background genomic instability leading to loss of telomeres may play a critical role in promoting RPL. This work will further lead to identification of novel biomarkers associated with unexplained recurrent pregnancy loss and it will further help in real time monitoring based on molecular analysis of the couple experiencing recurrent pregnancy failure and aid them with better possibility of conception.

LUTEAL PHASE SUPPORT WITH PROGESTERONE DOES NOT IMPROVE PREGNANCY RATES IN PATIENTS UNDERGOING CONTROLLED OVARIAN STIMULATION WITH LETROZOLE. Elizabeth A. Dilday, M.D., Luis R. Hoyos, M.D.,

Molly M. Quinn, MD, Lindsay Kroener, MD. Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology and Infertility, University of California, Los Angeles, Los Angeles, CA.

OBJECTIVE: Luteal phase support with progesterone is associated with improved pregnancy rates in controlled ovarian stimulation (COS) cycles using gonadotropins, but not in cycles using clomiphene citrate (1). In COS cycles using letrozole, there are limited data to support its use. Our objective was to determine whether luteal phase progesterone in letrozole COS cycles improves clinical pregnancy rate (CPR).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All letrozole COS cycles from 1/2018 to 3/2020 at an academic fertility practice were screened for inclusion. Cycles were excluded if canceled, if severe male factor (<5 million total motile sperm), or if any additional stimulation medications were used. Cycles were classified based on presence or absence of luteal progesterone support. When given, vaginal micronized progesterone 200 mg BID or TID was initiated two days after intrauterine insemination (IUI) or timed intercourse (TIC). Use and dose of luteal support were provider-dependent. Primary outcome was CPR. Secondary outcomes included spontaneous abortion (SAB) and biochemical pregnancy. Univariate logistic regressions were done to evaluate possible predictor variables for CPR. Significant covariates including age, anti-Müllerian hormone (AMH) level, intrauterine insemination (IUI) versus timed intercourse (TIC), diagnosis of ovulatory dysfunction, and multi-follicular development (>1 follicle ≥ 14 mm) were included in a multivariate analysis evaluating the relationship between progesterone use and odds of clinical pregnancy. Statistical analysis included exact chi-square, logistic regression or linear regression with adjustments for clustering, and general estimating equations logistic models, where appropriate.

RESULTS: A total of 276 COH cycles in 156 patients were included. Of these cycles, 221 used vaginal progesterone and 55 did not. The groups were comparable with respect to body mass index (BMI), AMH level, nulliparity, and multi-follicular development. Patients who received progesterone luteal support were 1.8 years older (mean 35.2 versus 33.4 years, p<0.001) and were more likely to undergo IUI than TIC (IUI in 75.6% of cycles with progesterone versus 56.4% of cycles without progesterone, p=0.007). The unadjusted CPR was 11.8% with progesterone and 10.9% without progesterone (p=0.847). There were no differences in SAB (9.4% versus 0%, p=0.999) or biochemical pregnancy (3.1% versus 14.3%, p=0.331). After adjusting for significant covariates including age, AMH level, diagnosis of ovulatory dysfunction and multi-follicular development, the odds for clinical pregnancy were not significantly improved in cycles using luteal progesterone (OR 1.36, 95% CI 0.60-3.12, p=0.464).

CONCLUSIONS: Luteal support with vaginal progesterone, which comes with additional cost and discomfort for patients, does not significantly improve CPR in COS cycles using letrozole. Eliminating progesterone in these cycles could improve the patient experience by simplifying treatment without compromising outcomes. Larger randomized studies are needed to validate these results.

ASSOCIATION OF EARLY BETA HUMAN CHORIONIC GONADOTROPIN WITH ISCHEMIC PLACENTAL DISEASE AFTER IN-VITRO FERTILIZATION.

Jaimin S. Shah, M.D.,[1] Nina Resetkova, M.D., M.B.A.,[2] Michele R. Hacker, Sc.D., M.S.P.H.,[1] Laura E. Dodge, Sc.D., M.P.H.[1] [1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [2]Boston IVF, Waltham, MA.

OBJECTIVE: Determine whether initial or 2-day percent increase in serum beta human chorionic gonadotropin (βhCG) is associated with ischemic placental disease (IPD) in singleton pregnancies after autologous or donor IVF.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Women who had a singleton live birth or an intrauterine fetal demise (IUFD) resulting from IVF from 1999 through 2017 and who delivered at our institution were included. Cycles were included if they had at least one serum βhCG. The primary outcome was IPD (IUFD due to placental insufficiency; pre-eclampsia; placental abruption; and small for gestational age [birthweight <10th percentile]). Two-day percent increase was extrapolated for cycles with βhCG measured 1, 3, or 4 days after the initial measurement. We used generalized estimating equations to estimate mean βhCG with 95% confidence intervals, adjusting for maternal age and cycle type.

RESULTS: Of 2,275 IVF cycles linked to singleton deliveries, 259 (11%) were excluded; 69 (3%) had no initial βhCG measurement, and 190 (8%) had βhCG measured at an inappropriate time. Of the remaining 2,016, 93% were autologous and 7% were donor IVF cycles. Median age (interquartile range) was 36 (33-39) and 42 (39-44) years for autologous and donor IVF, respectively. Initial βhCG was not associated with IPD or any component of IPD for singleton IVF pregnancies (Table 1). Among the 888 pregnancies with two βhCG measurements, the mean 2-day increase in βhCG was significantly higher in those without placental abruption than those with abruption (Table 1).

CONCLUSIONS: Among singleton autologous and donor IVF cycles, initial serum βhCG was not associated with IPD or its components, but a lower 2-day increase in βhCG was associated with placental abruption.

TABLE 1. Mean initial βhCG and mean 2-day increase in βhCG for IPD and components of IPD among singleton IVF pregnancies

P-210 4:30 PM Saturday, October 17, 2020

DOES THE TIMING OF ENDOMETRIAL BIOPSY IMPACT THE DETECTION OF ENDOMETRIAL PLASMA CELLS? Alisha Tara Tolani, MD, Emily Elizabeth Ryan, MD, Ann Katherine Folkins, MD, Ruth Bunker Lathi, MD. Stanford University, Stanford, CA.

OBJECTIVE: Chronic endometritis (CE) has been associated with recurrent pregnancy loss (RPL) and recurrent implantation failure. Incidence rates vary due to significant heterogeneity in biopsy timing and diagnostic criteria. Our group previously demonstrated that plasma cells are found in 59% of endometrial biopsies (EMBs) in the follicular phase compared to 18% in the luteal phase, which led us to question whether menstruation or hormonal changes in the follicular phase impact the diagnosis of CE. The purpose of this study was to assess the incidence and density of endometrial plasma cells in the early versus late follicular phase.

DESIGN: This is a retrospective cohort study of patients undergoing EMB in the follicular phase at a single academic center.

MATERIALS AND METHODS: EMBs performed between 2018 and 2020 were included. The early follicular phase was defined as the end of menses through day 8 of the menstrual cycle. The late follicular phase was defined as 9-14 days after menses. Patients with a prior CE diagnosis or abnormal uterine pathology were excluded. EMBs were assessed by gynecologic pathologists via H&E stain and CD138 immunohistochemistry. Plasma cell density was reported as rare (1-2 per slide), scattered ($\geq$ 3 per slide), or clusters. Continuous variables were compared using t-tests, and categorical variables were compared with chi-square tests.

RESULTS: Plasma cells were found in 74% of EMBs performed in the early follicular phase compared to 45% in the late follicular phase. Although the study was not powered to detect differences in plasma cell density, plasma cells were most commonly noted to be scattered (39%) in the early follicular and rare (18%) in the late follicular phase. See Table 1 for complete results.

CONCLUSIONS: Our data demonstrate that plasma cells are more likely to be detected at higher densities in EMBs performed during the early compared to the late follicular phase. These findings may represent the influence of estrogen levels or menstruation on the endometrium. Further studies with larger cohorts are needed to establish the optimal timing of EMB and determine the clinical significance of low-density endometrial plasma cells.

TABLE 1. The presence of plasma cells in the early versus late follicular phase

	All Follicular	Early Follicular	Late Follicular	p-value
N	75	31	44	–
Cycle Day (median, range)	9 (4-13)	7 (4-8)	10 (9-13)	–
Age (mean)	35.6	36.6	35.0	0.08
BMI (mean)	25.0	24.9	25.1	0.9

P-211 4:30 PM Saturday, October 17, 2020

INTRAUTERINE PATHOLOGY IS ASSOCIATED WITH HIGHER INCIDENCE OF ENDOMETRIAL PLASMA CELL INFILTRATE. Alisha Tara Tolani, MD, Emily Elizabeth Ryan, MD, Ann Katherine Folkins, MD, Ruth Bunker Lathi, MD. Stanford University, Stanford, CA.

OBJECTIVE: Chronic endometritis (CE) is a critical contributor to infertility, recurrent pregnancy loss (RPL), and recurrent implantation failure. The presence of endometrial plasma cells is suggestive of a diagnosis of endometritis; however, the effect of intrauterine pathology such as fibroids, polyps, and retained products of conception on the surrounding endometrial plasma cell infiltrate is unclear. The purpose of this study was to compare plasma cell infiltrate from endometrial biopsies (EMB) in patients with normal and abnormal cavity evaluations.

DESIGN: This is a retrospective cohort study of patients undergoing EMB for evaluation of endometritis at a single academic fertility clinic.

MATERIALS AND METHODS: All patients undergoing EMB between January 2018 and January 2020 were included. Uterine cavity evaluation was performed via hysteroscopy or saline sonogram. Patients with a prior CE diagnosis were excluded. EMBs were evaluated by gynecologic pathologists for plasma cells on H&E stain and via CD138 immunohistochemistry. Plasma cell frequency was reported as rare (1-2 cells per slide), scattered ($\geq$3 cells per slide), or clusters. Continuous variables were compared using t-tests, and categorical variables were compared with chi-square tests.

RESULTS: Of the 201 EMBs that met inclusion criteria, thirty-four (17%) were performed in patients with abnormal uterine cavities - 20 had polyps, 7 had retained POC, and 5 patients had fibroids. Plasma cells were found in 71% of EMBs from abnormal cavities compared to 41% of EMBs from normal cavities (p=0.03). Plasma cell density was significantly higher in the abnormal cavity group compared to the normal cavity group – 54% vs. 26% had scattered or clusters of plasma cells (p= 0.002). See Table 1 for results.

CONCLUSIONS: Intracavitary pathology is associated with a significantly higher frequency and density of endometrial plasma cells. Further studies with larger cohorts are needed to assess the relationship between plasma cells and specific intrauterine pathologies and to determine whether the plasma cell infiltrate is truly infectious in etiology or secondary to the presence of intrauterine pathology.

IMPACT OF ROUTE OF PROGESTERONE ADMINISTRATION ON OUTCOMES OF PREGNANCIES AFFECTED BY SUBCHORIONIC HEMATOMA FOLLOWING FROZEN IVF CYCLES. Daniel Miranian, MD,[1] Erin Inman, MD,[2] Micaela J. Stevenson, BS,[3] Emily K. Kobernik, MPH, MS,[2] Molly B. Moravek, MD, MPH,[2] Samantha B. Schon, MD, MTR[4] [1]Obstetrics and Gynecology, University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]University of Michigan Medical School, Ann Arbor, MI; [4]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI.

OBJECTIVE: Recent data have suggested that intramuscular (IM) progesterone for luteal support during frozen embryo transfer (FET) cycles may lead to higher ongoing pregnancy rates compared to vaginal (PV) progesterone. Since subchorionic hematoma (SCH) has been shown to be associated

with increased risk of early pregnancy loss in a fertile population, it is possible that there is an association between route of progesterone for FET and SCH. The objective of this study was to investigate if route of progesterone during FET impacted the rate of SCH and subsequent pregnancy outcomes. We hypothesized that SCH would be lower in patients on IM progesterone.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: CPT codes were used to identify all obstetric scans performed at a single infertility clinic from 1/2015-3/2018. All viable intrauterine pregnancies visualized on initial obstetric ultrasound following autologous FET (n=324) were included for analysis. Chart review was performed to identify the presence of SCH. Data on patient demographics, comorbidities, baseline laboratory parameters, route of progesterone supplementation, and pregnancy outcomes were collected. Bivariate analysis was used to compare pregnancy outcomes between FET cycles that received IM progesterone versus FET cycles that received PV progesterone supplementation alone.

RESULTS: 88 (27.2%) received IM containing progesterone regimens compared to 236 (72.8%) that received PV progesterone. SCH was significantly more likely to occur in FET cycles that were supplemented with IM progesterone compared to FET cycles supplemented with PV progesterone alone (23.9% vs 13.1%, p=0.02). However, there was no difference in the rate of 1st trimester losses (19.3% vs 20.8%, p=0.77), 2nd trimester losses (1.2% vs 0.4%, p=0.47), or live birth rates (80.2% vs 80.7%, p=0.93) between FET cycles supplemented with IM progesterone versus PV progesterone. Additionally, there was no difference between maternal complications such as hypertensive disorders (18.2% vs 20.9%, p=0.61) or gestational diabetes (9.1% vs 4.7%, p=0.13). The median age of delivery for both groups was 39 weeks (p=0.14) and there were no differences between the rates of preterm premature rupture of membranes, placental abruption, preterm labor, or preterm birth.

CONCLUSIONS: Although SCH was unexpectedly more common in FET cycles with IM progesterone compared to PV, the pregnancy outcomes were not significantly different between these two groups. These results are reassuring that detection of SCH on early ultrasound following FET may be a benign finding with no impact on clinical outcomes. However, further investigation is warranted to determine if these effects are consistent among a larger sample size.

DIFFERENCES IN EARLY ULTRASOUND AND FETAL GROWTH KINETICS BETWEEN NON-HISPANIC WHITE AND BLACK WOMEN. Victoria S. Jiang, MD,[1] Audrey M. Marsidi, MD,[2] Caroline Violette, MD,[1] Audrey J. Gaskins, ScD,[3] Jessica B. Spencer, MD, MSc,[2] Carolyn Drews-Botsch, Ph.D, MPH[3] [1]Emory University School of Medicine, Department of Gynecology and Obstetrics, Atlanta, GA; [2]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA; [3]Emory University, Rollins School of Public Health, Atlanta, GA.

OBJECTIVE: Formulas used to estimate fetal size by ultrasound have been historically based on predominantly white cohorts. The purpose of this study was to assess early ultrasound measurements of crown rump length, growth velocity, and pregnancy outcomes among non-hispanic white and black women given the known racial differences in pregnancy outcomes. Previous studies have been unable to examine whether early measures of embryonic size differ by race due to the relative under-representation of black women undergoing fertility treatments.

DESIGN: Retrospective cohort, academic fertility practice, January-December 2018.

MATERIALS AND METHODS: This cohort included 156 women who conceived via intrauterine insemination (IUI), intercourse with ovulation trigger injection, or in-vitro fertilization (IVF). Only women with a singleton pregnancy and documented fetal cardiac activity between 6 weeks and 6 weeks 6 days gestation were included. Multiple gestation, spontaneous conception, and first trimester miscarriages were excluded. A minimum of two serum hCG measurements were obtained, typically 2 or 4 days apart. Transvaginal ultrasound was used to confirm intrauterine pregnancy and measure crown rump length and fetal heart rate. Average ultrasound age (AUA) was calculated using the Hadlock formula. Differences in the mean and standard deviation of embryo growth parameters were evaluated using student t-tests. Multiple linear regression was used to account for important potential confounders including method of conception (IUI, IVF with fresh embryo transfer, IVF with frozen embryo transfer), maternal age, maternal BMI, and sex of the embryo.

RESULTS: 59 black (37.8%) and 97 non-hispanic white (62.1%) women met inclusion criteria. In our cohort, black women were older (p<0.01) and had a higher BMI (p<0.01) than white women. Tubal factor without hydrosalpinx (33.9% vs 10.3%, p<0.01) and uterine factor (16.9% vs 3.1 %, p<0.01) were more prevalent in black women than white women. Black and white women did not differ in the likelihood of livebirth, miscarriage, development of hypertension or intrauterine growth restriction. There was a trend toward higher rates of preterm delivery (31.9% vs 17.4%, p=0.07) in black women. Unadjusted fetal pole measurements of black women were smaller (0.91 cm ± 1.68) than those of white women (0.61 cm ± 1.72), but this difference was not significant and was attenuated by adjusting for mode of conception, obesity, and maternal age. No significant difference was observed in rates of embryo growth or hCG levels between groups

CONCLUSIONS: Among women who conceived following fertility treatment with IUI, intercourse with ovulation trigger injection, or IVF, no significant differences were noted in early measurements of hCG, embryonic size, growth velocity, or pregnancy outcomes between black and white women. Black women had a non-significant trend towards smaller crown rump lengths at the time of early ultrasound and higher likelihood of preterm birth. Our study was limited by sample size and additional studies involving larger cohorts may be important in validating these findings.

P-214 4:30 PM Saturday, October 17, 2020

ASSOCIATION OF -308G>A, -238G>A, -376G>A SNPS OF TNF GENE IN WOMEN WITH RECURRENT ABORTIONS IN A GREEK POPULATION. Sofoklis Stavrou, MD, Ph.D.,[1] Despoina Mavrogianni, Dr, PhD,[1] Evagelos Basamakis, MSc,[1] Alexandros Psarris, M.D., M.Sc., Ph.D.,[1] Dimitris Loutradis, Professor,[2] Peter Drakakis, Professor[1] [1]Molecular Biology of Reproduction Unit and Recurrent Abortions Unit, Assisted Reproduction Division, Athens, Greece, Greece; [2]Molecular Biology of Reproduction Unit and Recurrent Abortions Unit, Assisted Reproduction Division, Athens, Greece.

OBJECTIVE: To detect a possible association between -308G>A, -238G>A, -376G>A SNPs of TNFa gene in women with recurrent abortions.

DESIGN: This is a prospective, single-centre study carried out at the molecular biology laboratory of gynecological and obstetrics department spanning the period January 2015 to November 2017. We studied the association between the presence of -308G>A, -238G>A, -376G>A polymorphisms and recurrent abortions in 90 women with RSA and 90 controls.

MATERIALS AND METHODS: Genomic DNA was extracted from peripheral blood samples using PureLink Genomic DNA Kit. PCR was performed using specific primers to amplify the studied polymorphisms. The amplified PCR products were sequenced using the ABI Prism 3130 Genetic Analyzer, Applied Biosystems. Variants were validated using the sequencing Analysis v 5.2 software.

RESULTS: A significant association was detected between the presence of -308 G variant and the absence of RSA (p=0.048). No detection of -376A variant was detected and no association was revealed between -238 polymorphism and abortions. Moreover, a possible association between the combination of genotypes and the presence of RSA did not reveal any statistical association. Although It has been suggested that the above TNFα polymorphisms are associated with an increased risk for recurrent spontaneous abortions, published literature worldwide are controversial so far. Ethnic differences or combinations of different SNPs may contribute to the diversity of the results.

CONCLUSIONS: The present study revealed a statistically significant association between -308G>A and the presence of abortions, no detection of A variant in -376G>A SNP and no association between -238 G>A and recurrent abortions. No association was detected between abortions and combination of genotypes. Further research to ascertain a possible combination of TNF polymorphisms in RSA is required. Differences in the genetic backgrounds of various ethnic populations should also be considered. Identification of TNF polymorphisms associated with RSA may lead to new pathophysiology insights, improved diagnostics, and novel treatment approaches.

MINIMALLY INVASIVE FERTILITY SPARING TREATMENT IN NON-TUBAL ECTOPIC PREGNANCIES CAN RESULT IN HIGH SUBSEQUENT LIVE BIRTH RATES. Katherine E. Kostroun, MD,[1] Kathryn M. Goldrick, MD,[1] Jennifer F. Knudtson, MD,[1] Alia M. Yaghi, MD,[1] Cheria C. Brown, RN,[1] Randal D. Robinson, MD[2] [1]University of Texas Health Science Center San Antonio, San Antonio, TX; [2]University of Texas Health Science Center San Antonio, San Antonio, SC.

OBJECTIVE: Ectopic pregnancies represent 2% of all recognized pregnancies, and of these, less than 5% are non-tubal in location (1). Improvements in ultrasound technology and appropriate follow up with serial quantitative HCG levels and the development of specific diagnostic criteria for nontubal ectopic pregnancies have improved earlier diagnostic confirmation and management. Expectant management of non-tubal ectopic pregnancies can result in adverse outcomes including hemorrhage, uterine rupture, and need for hysterectomy (2). Many studies have shown the safety and efficacy of conservative treatment in these pregnancies, but very few have reported outcomes for subsequent pregnancies (3,4). The aim of this study was to evaluate treatment regimens and outcomes of patients with nontubal ectopic pregnancies, and specifically identify outcomes of subsequent pregnancies.

DESIGN: Retrospective chart review.

MATERIALS AND METHODS: This study evaluated women ages 18-50 with the ICD code of 'Ectopic Pregnancy' who, on chart review, were noted to have cervical, cesarean scar, or cornual/interstitial ectopic pregnancies in a university hospital system with a large Hispanic population from January 2010 to May 2020. Information regarding patient demographics, clinical, laboratory, and imaging data used for diagnosis, as well as treatment plans and outcomes were collected from electronic medical records and stored in a REDCap database. Descriptive evaluation of the data was performed.

RESULTS: A total of 445 ectopic pregnancies were identified with 40 non-tubal ectopic pregnancies (9%), including 11 cervical ectopics (28%), 13 cesarean scar ectopics (33%), and 16 cornual/interstitial ectopics (40%). Out of these patients, 34 (85%) had successful fertility sparing treatment including systemic methotrexate (n=25, 74%), intrafetal KCl (n=10, 29%), intragestational methotrexate (n=8, 24%), cornual wedge resection (n=8, 24%), dilation and curettage (n=3, 9%), and uterine artery embolization (n=3, 9%). Six (15%) underwent total hysterectomy. Out of the patients who underwent conservative therapy, 10 (29%) had subsequent pregnancies, with 13 confirmed gestations and a total of 7 confirmed live births (54%). Only one patient was noted to have an adverse pregnancy outcome complicated by a second interstitial pregnancy that was successfully treated with surgical resection. It took an average of 6.3 weeks for the quantitative hCG level to reach a negative hCG value after treatment and ranged from 1 to 15 weeks before resolution.

CONCLUSIONS: Our results support that there is an increase in the prevalence of nontubal ectopic pregnancies and comprised 9% of all ectopics in our case series. This study demonstrates the importance, safety, and high efficacy of minimally invasive, fertility sparing treatment in non-tubal ectopic pregnancies, and the possibility for high live birth rates after conservative treatment. Patients should be counseled that it could take up to 15 weeks after minimally invasive treatment to complete resolution via a negative hCG level.

P-217 4:30 PM Saturday, October 17, 2020

DYSREGULATED EMBRYONIC PLACENTATION IS MORE SIGNIFICANTLY ASSOCIATED WITH RISK OF EARLY SPONTANEOUS PREGNANCY LOSS THAN MATERNAL UTERINE SIGNALING. Sydney L. Lane, PhD, Blair R. McCallie, BS, William B. Schoolcraft, MD, Mandy G. Katz-Jaffe, PhD. Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: Biochemical pregnancy loss (BPL) rates have remained persistent at 12-15% despite significant developments in *in vitro* fertilization including improved embryo culture, aneuploidy screening, and endometrial receptivity testing. In order to elucidate factors important for early pregnancy maintenance that could lead to BPL, we utilized a mouse model to investigate sites of implantation corresponding to viable embryos or spontaneous embryo resorption (miscarriage).

DESIGN: Uterine and placental gene expression of implantation sites corresponding to either viable or spontaneously resorbing embryos from early murine pregnancy.

MATERIALS AND METHODS: Female wild-type, outbred CF-1 pregnant mice were identified on day 10.5 of embryonic development for collection of uterine implantation sites containing either viable embryos (controls) or embryos that were in the early stage of resorption and not yet hemorrhagic. Total RNA was isolated from embryonic placentas (n=6 per group) and maternal uterine tissue (n=5 per group). Quantitative real-time PCR was performed on the QuantStudio 5 (Applied Biosystems) for key implantation and early pregnancy genes including: *Cd81*, *Glrx*, *Bdnf*, *Cox2*, *Ptgs2*, *Vegfa*, and *Icos*. Gene expression data were analyzed by the REST software (Qiagen) and Student's t-test, with significance at $P<0.05$.

RESULTS: Embryonic placental expression of *Cd81* was significantly increased in embryo resorption sites ($P<0.001$). Elevated *Cd81* inhibits cytotrophoblast invasion, indicating that insufficient placentation may have contributed to early pregnancy loss. Expression of embryonic placental *Glrx* was decreased in resorption sites ($P<0.01$), suggesting that heightened oxidative stress hindered placentation and/or maternal-fetal communication resulting in fetal loss. On the maternal side, expression of the paracrine growth factor *Bdnf* was decreased in uterine tissue from embryo resorption sites ($P<0.01$). Previous studies have reported increased *Bdnf* in the pregnant uterus and reduced *Bdnf* in uterine flushings from repeat implantation failure patients. In contrast, genes involved in tissue remodeling, angiogenesis, and decidualization (*Cox2*, *Ptgs2*, *Vegfa*), immune balance (*Icos*), trophoblast invasion (*Cd81*), or pinopode formation (*Glrx*) were not differentially expressed in maternal uterine tissue between viable and resorbing implantation sites.

CONCLUSIONS: The etiology of BPL is likely diverse and complex. Our preliminary data suggest that dysregulated embryonic placentation is more significantly associated with risk of early pregnancy loss than maternal uterine signaling. As lipid composition and amino acid metabolism are important for implantation, ongoing studies will utilize liquid chromatography mass spectrometry to identify metabolite changes that correlate with these observed significant embryonic placentation changes.

LEUKEMIA INHIBITORY FACTOR IN RECURRENT PREGNANCY LOSS: IS THERE ANY ROLE OF LIFESTYLE INTERVENTION?

Vidhu Dhawan, MD,[1] Neena Malhotra, MD FRCOG,[2] Neeta Singh, MD,[2] Vatsla Dadhwal, MD,[2] Rima Dada, MD, Ph.D[1] [1]All India Institute of Medical Sciences, Anatomy, New Delhi, India; [2]All India Institute of Medical Sciences, Obstetrics & Gynaecology, New Delhi, India.

OBJECTIVE: Leukemia inhibitory factor (LIF), has been cited to play important role in embryo development and implantation. This pleiotropic cytokine affects a range of events in implantation, such as, endometrial receptivity, embryo-endometrial interaction, stromal decidualization, trophoblast invasion and blastocyst development. Lower levels of LIF have been found in blood and endometrial tissue of women with recurrent pregnancy loss (RPL). The objective of this study was to assess the levels of LIF in plasma of women with RPL and healthy fertile females. Further evaluation was done to assess the effect of yoga based lifestyle (YBL) on the levels of LIF in RPL patients.

DESIGN: Phase I- Case control study, Phase II- Prospective single arm exploratory study.

MATERIALS AND METHODS: This study was conducted on non-pregnant women with history of recurrent pregnancy loss (RPL, N=30) and healthy fertile females with proven fertility. Blood samples were obtained from the patients as well as controls and EDTA plasma was separated for estimation of LIF by ELISA. The patients were further recruited for structured YBL program and after obtaining samples (pre-yoga, day 0) the samples were obtained after enrolment in the program for 30 days (post-yoga, day 30) and LIF levels were estimated.

RESULTS: The plasma levels of LIF in non-pregnant women with history of RPL were estimated to be significantly lower as comapred to healthy fertile females ($p=0.0107$). An increase in the plasma levels of LIF was seen in women wth RPL after the end of active intervention of 30 days from the base-line values measured at day 0 ($p=0.0291$).

CONCLUSIONS: LIF has been shown to play an indispensible role in initiating embry-endometrial interaction, and facilitating implantation along with uterine decidualization, trophoblast invasion and blastocyst development. The current study supports the hypothesis that lower levels of LIF are found in women with RPL and infertility. To the best of our knowledge the present study is one of the first studies to analyze the effect of yoga based lifesyle on the inflammatory markers affecting embryonic implantation the patients with RPL.

P-220 4:30 PM Saturday, October 17, 2020

DOES ADDING HYDROXYCHLOROQUINE TO EMPIRIC TREATMENT IMPROVE THE LIVE BIRTH RATE IN REFRACTORY OBSTETRICAL ANTIPHOSPHOLIPID SYNDROME?

Allyssa Hooper, MSc, BSc,[1] Arianne Y. K. Albert, PhD,[2] Mohamed Ali Bedaiwy, M.D., Ph.D.[1] [1]University of British Columbia, Vancouver, BC, Canada; [2]Women's Health Research Institute, Vancouver, BC, Canada.

OBJECTIVE: To investigate the live birth rate (LBR) when using hydroxychloroquine (HCQ) in addition to the standard of care therapy, low-dose aspirin and low molecular weight heparin, in women with refractory obstetrical antiphospholipid syndrome (APS).

DESIGN: A systematic literature search using EMBASE, MEDLINE, PubMed, Cochrane Library, and Web of Science was performed from inception to April 2020. Relevant search terms included: Hydroxychloroquine or Plaquenil, and "Antiphospholipid Syndrome" or Antiphospholipid Syndrome/, and abortion or miscarriage* or obstetric* or pregn* adj4 loss or abortion, habitual/.

MATERIALS AND METHODS: We included studies that evaluated the use of HCQ during pregnancy in women with primary APS. The primary outcomes of interest were LBR and pregnancy loss (PL) and the secondary outcomes of interest included maternal complications, neonatal complications, and gestational term of delivery. For studies to be eligible, outcome data with an explicit mean LBR or PL for both the study and control groups were required. We excluded studies that included patients with systemic lupus erythematosus (SLE) and secondary APS.

RESULTS: The search produced a total of 479 results. Following duplicate removal 249 remained and each title and abstract was reviewed. Subsequently, 59 full texts were selected for full review and an additional 44

were excluded, leaving 15 studies for qualitative analysis. Included in the 15 studies were 4 case reports, 3 RCT protocols, 2 prospective studies, and 6 retrospective studies. Due to the limited number of retrospective studies and the high level of heterogeneity a meta-analysis was not possible.

The LBR was significantly improved in 3 retrospective studies. Mekinian et al in 2017 demonstrated an improved LBR from index to subsequent pregnancy (n=49) of 29% to 86% ($p<0.0001$) with the addition of 400mg daily HCQ. Similarly, Sciascia et al in 2016 demonstrated an increase in LBR between control (n=119) and 400mg daily HCQ treated (n=51) pregnancies from 57.1% to 66.7% ($p<0.05$). Interestingly, Ruffatti et al in 2018 demonstrated a dose dependent effect of HCQ, with 400mg daily resulting in a 94% LBR as compared to 200mg daily at 79.5% ($p=0.036$).

Pregnancy loss percentage was significantly improved in 4 retrospective studies. Mekinian et al in 2015 demonstrated a significant reduction from index to subsequent (n=49) pregnancy from 81% to 19% ($p<0.05$) and in 2017 a reduction from 76% to 14% ($p<0.0001$). Sciascia et al in 2016 demonstrated a reduction in fetal loss beyond the 10th week of gestation from 10.9% to 2% ($p<0.05$) and Ye et al in 2017 demonstrated a reduced PL of 22.7% to 11.1% ($p=0.012$) following 200mg BID HCQ treatment.

CONCLUSIONS: There are no RCTs to evaluate the impact of HCQ on LBR in patients with APS. Retrospective studies demonstrated that HCQ may be an effective treatment in patients with refractory obstetrical APS as it has been demonstrated to improve LBRs in patient's non-responsive to empiric anti-thrombotic therapies. However, RCTs that standardize patient selection criteria and explicitly analyze the use of HCQ as a refractory APS treatment are needed.

POSTER SESSION: EDUCATION

P-221 4:30 PM Saturday, October 17, 2020

THE VOICE OF INFERTILITY: A REVIEW OF FERTILITY PODCASTS. Alexandra Peyser, M.D., Baruch Abittan, M.D., Christine Mullin, M.D., Randi H. Goldman, M.D. Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Podcasts are audio recordings distributed across the Internet that users can listen to on a computer or mobile device. There has been rapid growth in the awareness of podcasting with an estimated 70% of the US population now familiar with this term. The objective of this study was to review the availability, content, and authorship of podcasts on the topic of fertility and to compare those hosted by physicians vs. patients.

DESIGN: Content analysis.

MATERIALS AND METHODS: A search for podcasts relating to the search term 'fertility' was performed using 10 podcast hosting platforms, including: Anchor, Apple Podcasts, Spotify, Google Podcasts, Podbean, Overcast, Stitcher, Breaker, Castbox, and RadioPublic. Only English-language series and those in which the overlying theme was fertility-based were included. Information relating to each podcast was recorded, including: title, subject, host type, number of episodes, frequency of episodes, country of origin, number of ratings, and status regarding whether the podcast was active or inactive. The Chi-square test was used for comparison of proportions and the Mann-Whitney U test was used for continuous variables. A p value of <0.5 was considered significant.

RESULTS: One hundred thirty one podcasts met inclusion criteria. The dates of publication ranged from 2009-2020, with a total of 4,760 episodes aired. The most common subject was patient education relating to fertility, which involved the patient experience (62%) followed by fertility awareness (30%), and Third Party Reproduction (13%). Most podcasts were targeted toward patients. Podcasts were hosted by patients (40%), holistic health professionals (28%), physicians (16%), third party agencies (11%), and others, including fertility nurses, social workers, nutritionists, pharmacists, and attorneys (5%). Approximately 11% of podcasts were hosted by private industry, while <2% were organized from academic institutions and <1% from fertility societies. The majority originated from the US (92%) with a smaller percentage from Australia (4%) and the UK (3%). When comparing podcasts hosted by physicians vs. patients, there was no difference in overall content ($p= .07$), frequency of episodes ($p=0.77$), number of episodes ($p=0.63$) and number of ratings ($p=0.47$).

CONCLUSIONS: A large number of fertility podcasts exist with most hosted by patients describing their fertility experiences. Physicians, particularly board certified Reproductive Endocrinologists, should consider having a stronger presence in the podcast industry as a way to best inform patients about evidence-based practices. Further research regarding the profile of the fertility podcast audience, listener motivation, and user experience would be valuable for optimizing usage of this medium.

P-222 4:30 PM Saturday, October 17, 2020

RESIDENT PERCEPTIONS OF FERTILITY CARE IN THE LOW RESOURCE SETTING: PRELIMINARY DATA FROM THE FERTILITY PASSPORT PROGRAM. Rachel Ruderman, MD, MPH, Mary Tate, MD, MPH, Emily Lin, MD, Jacqueline Lee, MD, Stephanie Cai, MD, Luce A. Kassi, MD, Bahar D. Yilmaz, MD, Christina E. Boots, MD, MSCI. Northwestern University Chicago, IL.

OBJECTIVE: To assess resident perceptions of their ability to provide infertility care in a low resource setting.

DESIGN: This study includes data from an ongoing Accreditation Council for Graduate Medical Education funded Back to Bedside project, the "Fertility Passport Program," which addresses fragmentation and resident burnout when providing infertility care in low resource settings using an educational intervention (a video) and a tool (a "passport") to streamline the outpatient evaluation. Obstetrics and gynecology residents who practice at a county hospital and a tertiary academic center were surveyed.

MATERIALS AND METHODS: This cross-sectional study utilized a questionnaire of which seven items were on a five-point Likert scale. Residents were queried on confidence in providing infertility care in the low-resource setting, adequacy of clinic time, and confidence in patient knowledge, understanding and ability to complete their workup. For analysis, scores of "1" and "2" were combined to form the category 'disagree' and scores of "4" and "5" were combined to form the category 'agree'.

RESULTS: Of the 47 residents surveyed, 44 responded (93.6%). Over half felt comfortable in their counseling on infertility (54.5%) though most felt that there was insufficient time to address fertility-related issues (70%). Most residents were not confident that patients understood the concept of infertility and reasons for tests that were ordered (70%) or that they would complete their infertility workup (68%).

	Agree % (n)	Neutral % (n)	Disagree % (n)
I feel comfortable addressing infertility-related issues in this patient population.	36% (16)	34% (14)	34% (14)
I feel confident in my ability to counsel patients on infertility and reproduction.	54.5% (24)	29.5% (13)	16% (7)
I feel there is enough time in clinic to address infertility-related issues.	7% (32)	23% (10)	70% (31)
I know how to complete a work-up for infertility.	72% (32)	20% (9)	7% (3)
I feel confident my patient understands the concept of infertility and reasons for the tests we have ordered.	9% (4)	20% (9)	70% (31)
I feel confident my patient knows how to complete the next steps in her infertility work-up.	2% (1)	23% (10)	75% (33)
I feel confident my patient will complete her infertility work-up.	7% (3)	25% (11)	68% (30)

CONCLUSIONS: Our results suggest a discrepancy between resident knowledge base and the perception of patients' understanding of infertility, as well as their ability to complete the evaluation. This finding suggests a need for better patient education and care coordination in the low-resource environment. More data is needed as this program continues to discern whether the Fertility Passport Program is successful in helping to improve the delivery of fertility care in this setting.

P-223 4:30 PM Saturday, October 17, 2020

A CONTENT AND QUALITY EVALUATION OF ACGME-ACCREDITED REPRODUCTIVE ENDOCRINOLOGY AND INFERTILITY FELLOWSHIP PROGRAM WEBPAGES. Alexandra Peyser, M.D., Baruch Abittan, M.D., Christine Mullin, M.D., Randi H. Goldman, M.D. Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Prospective Reproductive Endocrinology and Infertility (REI) fellows often rely on the Internet to obtain valuable information regarding the unique qualities of different fellowship programs. The aim of this study was to analyze the content of websites of ACGME-accredited REI Fellowship programs in the United States and to determine whether there were differences in content across geographic regions.

DESIGN: Content analysis.

MATERIALS AND METHODS: All ACGME-accredited REI Fellowship websites as of March 2020 were evaluated and reviewed using 20 criteria in the following nine domains: program overview, contact information, application information, curriculum, current fellows, research, alumni, faculty, and fellowship benefits. Website content was compared across geographic regions (Northeast, Midwest, South and West) of the United States. A Chi-square univariate analysis was used with $p < 0.05$ considered statistically significant.

RESULTS: Out of the 48 accredited REI fellowship programs, 45 (94%) had a dedicated website. The most commonly available information included a program description (90%), clinical sites (85%), application requirements (79%) and application deadline (70%). Approximately two-thirds shared information regarding research requirements and didactics (66% for each). More than half (52%) of programs did not disclose their interview dates on their websites. Current fellows were featured in 56% of websites with their pictures in 41%, and ongoing research in 21%. Salary and alumni information were included in only 15% and 13% of sites, respectively. When comparing content by geographic region, programs in the South had less information regarding application requirements ($p<0.001$), interview dates ($p=0.026$), and clinical sites ($p=.04$) compared to all other regions. There was no difference among other criteria.

CONCLUSIONS: REI fellowship websites have significant variability in content available to applicants, and many are lacking information about core fellowship requirements. An informative and well-constructed website has the potential to improve perception of a graduate program. Further studies are needed to ascertain the specific interests of REI applicants, and their satisfaction with the content of currently available webpages.

FERTILITY KNOWLEDGE AND VIEWS ON EGG FREEZING AND FAMILY PLANNING AMONG SURGICAL SPECIALTY TRAINEES. Karine Matevossian, DO,[1] Anne Rivelli, MA, MPH,[1] Meike L. Uhler, M.D.[2] [1]Advocate Lutheran General Hospital, Park Ridge, IL; [2]Fertility Centers of Illinois, Chicago, IL.

OBJECTIVE: Describe fertility knowledge and viewpoints on family planning among United States (U.S.) residents and fellows.

DESIGN: Cross sectional survey.

MATERIALS AND METHODS: The Advocate Aurora Health Institutional Review Board approved this study. A 32-question Qualtrics survey was emailed to trainees across U.S. training programs, including residencies/fellowships in the following fields: obstetrics/gynecology (OB-GYN); ophthalmology; otolaryngology; and neuro, plastic, general, and orthopedic surgery. Pearson Chi-square tests were used to address accuracy of fertility knowledge by training specialty groups (OBGYN vs. others), gender (female vs. male), and program type (community vs. academic). Family plans and viewpoints are also described. All analyses were performed using SAS, version 9.4.

RESULTS: A total of 447 surveys were collected from October 2019 to January 2020. Participants included 309 residents, 94 fellows, and 44 with unknown status. Participants mostly identified as female (73%), ages 26-30 (48%), Caucasian (69%), married (59%) and heterosexual (95%) with no children (72%). Three questions were used to evaluate fertility knowledge: 1) age at initial decrease in women's fertility, 2) age at significant decrease in women's fertility, and 3) average success rate of one IVF cycle. Most notably, regarding knowledge of age at initial decrease in women's fertility, non-OBGYN trainees had 2.49 times greater odds of answering correctly relative to OBGYN trainees ($p=0.0011$) and females had 0.77 times lesser odds of answering correctly relative to males ($p=0.3791$).n general, trainees in academic programs had a higher percentage of correct responses than those in community programs, but the differences were not statistically significant (Q1-17% vs 13%, Q2-68% vs 58%, Q3-49% vs. 44%). Descriptively, more females were single (19% vs. 13% of males) and less were married (55% vs. 74% of males). Relative to males, females had 2.89 times increased odds of having zero children ($p<0.0001$) and 1.33 times increased odds of reporting postponed plans for children ($p=0.2438$). Among female respondents, 48% would consider freezing oocytes, but less than 4% of respondents have frozen oocytes. Respondents cited a variety of reasons for postponing children including career plans, concerns about a lack of time to care for a child and availability of childcare, and concerns for their co-residents/fellows.

CONCLUSIONS: This study indicates differences in knowledge regarding fertility; more specifically, despite gender or focused training in reproductive endocrinology and infertility, females and OBGYN trainees are not necessarily more well-versed in basic female fertility knowledge relative to their counterparts. Also, female trainees are less likely to have children or be married, and more likely to report plans to postpone children, highlighting differences in family planning by gender. Fertility-focused educational interventions for OBGYN trainees are necessary. More research into barriers for family plans, particularly by gender, are also merited.

P-225 4:30 PM Saturday, October 17, 2020

SUITABILITY OF MULTI-DOSE VERSUS SINGLE DOSE GONADOTROPIN INJECTION PENS FOR ART USE: A USABILITY PEN STUDY. Helen Saunders, BSc (HONS),[1] Linda Bjaergestad Lamp, BSN,[2] Hasan Donat, MSc,[3] Monja Messner, MSc,[4] Maren Reder, BSc,[5] Helen Kendrew, RGN[6] [1]Medical Affairs Director, Geneva, Switzerland; [2]STOCKHOLM IVF AB, Stockholm, Sweden; [3]Junior Clinical Project Manager, Geneva, Switzerland; [4]Associate Director Research, Berlin, Germany; [5]Research Executive, Berlin, Germany; [6]Clinic Director, United Kingdom.

OBJECTIVE: The success of ovarian stimulation during ART can be impacted by the correct administration of the gonadotropins. The objective of this usability study was to evaluate the suitability of single dose versus multi-dose pens for fertility treatment by investigation of the Instructions for Use (IFU), the dosing steps and the risk of critical errors which could potentially lead to dose administration or safety issues.

DESIGN: The study was performed in 4 European countries (Germany, United Kingdom, France and Spain) to assess 3 pens (Bemfola (single use), Gonal F and Ovaleap (multi-use)) used by nurses and fertility patients. Based on each IFU the individual steps required to administer medication were identified. Critical steps, defined as those which could potentially lead to administration errors if not adhered to correctly were identified for each pen. Participants also assessed their confidence in selecting/administration of correct doses.

MATERIALS AND METHODS: Each nurse performed a mock injection of 150IU, with each of the 3 pens. To eliminate any bias, the order of assessment of pens followed a rotation plan. Patients were then trained with each pen according to the IFUs by an external moderator using a 150IU injection. The patients then carried out independently a further 150IU followed by a 225IU injection with each pen. During each injection, the total number of handling errors, defined as any steps missed or carried out incorrectly, versus total number of steps was recorded.

RESULTS: Overall, 24 patients and 19 nurses participated in the study. The critical error rates reported among nurses was 9%, 24% and 49% for Bemfola, Ovaleap and Gonal-f respectively, whilst among patients the corresponding rates were 4%, 16% and 38% respectively. The main critical error reported with Bemfola was the attachment of the needle where both groups tried to screw on the needle rather than push/click as per the IFU instructions. With Ovaleap, the main errors reported were the incorrect/lack of priming, to ensure correct functioning of the pen, prior to injection and the incorrect use of the dose adjustment button rather than the administration button to carry out the injection. With Gonal-f, the main errors reported were the complete omission of the priming step, when required, and failure to ensure complete dose was administered, especially when the dose was not available in the pen, resulting in delivery of an incomplete dose. Overall, 63%, 37% and 0% of nurses chose Bemfola, Gonal-f and Ovaleap respectively regarding the pen which they would have most confidence that the patient would inject the

correct dose at home. This compared to 67%, 29% and 4% respectively for the patients.

CONCLUSIONS: This study shows that overall single use pens have less steps and in turn a lower chance of critical handling errors leading to potential dosing errors or safety issues. Following the IFU's, especially when experienced nurses are training both patients and less experienced nurses is essential to a successful treatment cycle. Incorrect instruction, particularly with the multi-dose pens, can lead to patient error and in turn a less favourable outcome.

P-226 4:30 PM Saturday, October 17, 2020

SURVEY ON PERCEPTION OF GERMLINE GENE THERAPY AMONG JAPANESE MEDICAL STUDENT. Tomonari Hayama, M.D., Ph.D.,[1] Akifumi Ijuin, M.D.,[1] Ai Miyakoshi, M.D.,[1] Haru Hamada, M.D.,[1] Mitsuru Komeya, M.D., Ph.D.,[1] Teppei Takeshima, M.D., Ph.D.,[1] Shinnosuke Kuroda, M.D.,[1] Yasushi Yumura, M.D., Ph.D.,[1] Mariko Murase, M.D., Ph.D.,[1] Etsuko Miyagi, M.D., Ph.D.,[2] Hideya Sakakibara, M.D., Ph.D.[1] [1]Yokohama City University Medical Center, Yokohama, Japan; [2]Yokohama City University School of Medicine, Yokohama, Japan.

OBJECTIVE: Germline gene therapy (GGT) has potential to be radical treatment approach for monogenic genetic disorder. Because recent CRISPR technology enables us to edit human genome with high efficacy and lowest off-targeting, technical issues for GGT have been almost solved. Mitochondrial replacement therapy (MRT) is also only radical germline gene therapy for heritable mitochondrial disease. Japanese government has issued a statement prohibiting GGT, including MRT, and emphasizing the need for discussions in a wide range of perspectives. A few surveys of Japanese general adults had already shown they generally accepted the use of GGT for monogenic genetic disorder. However, because they know little about GGT, surveys still had limitation to clarify actual Japanese people attitude.

DESIGN: Medical student attitude survey results are thought to be similar to results of young patient final attitude. Here, we conducted a survey of Japanese medical students who might perfectly understand that GGT would have not only potential to be radical treatment for monogenic genetic disorder but also detailed risk for ethics.

MATERIALS AND METHODS: Under the ethical review of Yokohama City University, we recruited 80 medical students (18-24 y.o.) who learn only clinical medicine lecture (not yet bed-side) and evenly explained GGT as fore- and anti- side in bio ethics lecture. Surveys were performed by description style for Q & A, trying to catch opinions from wide rang of perspectives.

RESULTS: A 74% (59/80) of medical students agreed to clinical trial for monogenic disorder GGT by CRISPR. An 82% (65/80) agreed to clinical trial for MRT. Furthermore, 35% (28/80) and 59% (47/80) agreed to clinical treatment for GGT and MRT.

CONCLUSIONS: Our results indicate that the Japanese people will accept the use of GGT and MRT on the future, if they can completely understand the benefit and risk for ethics. To achieve complete understanding about GGT and MRT, it is still important that scientists and science communicators create more opportunities for the public talk. It is also important to continuously track changes in the acceptance for GGT and MRT by various people groups.

POSTER SESSION: LGBTQ

P-227 4:30 PM Saturday, October 17, 2020

REVERSIBILITY OF HORMONAL AND CYCLIC DISRUPTIONS IN A TRANSGENDER MOUSE MODEL AFTER CESSATION OF TESTOSTERONE THERAPY. Prianka H. Hashim, BS, BA, Hadrian M. Kinnear, BA, Gillian E. Rubenstein, -, Faith L. Chang, -, Likitha Nimmagadda, -, Margaret A. Brunette, MS, Vasantha Padmanabhan, MS, PhD, Ariella Shikanov, PhD, Molly B. Moravek, MD, MPH. University of Michigan Ann Arbor, MI.

OBJECTIVE: Suppression of luteinizing hormone (LH) levels and acyclicity has been widely observed in transgender men with gender-affirming testosterone (T) therapy, but it is unknown if LH levels return to baseline and regular cycles resume after stopping T. Estrous cycles can be an indicator for the regular functioning of the hypothalamic-pituitary-gonadal axis, including LH secretion as a measure of GnRH secretion in the hypothalamus. The aim of this study was to determine the impact of T therapy on the reproductive axis (LH secretion and estrous cyclicity), and investigate reversibility following cessation of T, using a previously established transgender mouse model.

DESIGN: Translational Animal Study.

MATERIALS AND METHODS: Ten 9–10-week-old C57BL/6NHsd female mice were injected with 0.90 mg of T enanthate injections once weekly for 6 weeks and then injections were stopped. Ten age-matched control mice received weekly injections with a sesame oil vehicle. Daily vaginal cytology from all mice and weekly blood collection for analysis of T levels from half the mice were undertaken. From the other half, serial blood samples were collected to profile pulsatile diestrus LH levels before and during T administration, after T cessation and at time of sacrifice (~4 estrous cycles following resumption of cyclicity). Serial sampling for LH analysis began 5 hours after vivarium lights were turned on and involved collection of 6 μl of blood every 10 minutes from the lateral tail vein over a fixed 3-hour period. Blood samples were vortexed immediately in buffer to prevent clotting. Data were analyzed in GraphPad Prism to generate descriptive statistics and used Welch's t-test or Mann-Whitney as appropriate.

RESULTS: After 1–2 weeks of T treatment, all T-treated mice stopped cycling and were in persistent diestrus. T-treated mice resumed cycling 3.5–10 weeks following cessation of T treatment. Control mice cycled regularly throughout. Weekly serum samples showed that, during T treatment, serum T levels rose to concentrations similar to those observed in male mice (8.0 $\pm$ 1.1 ng/mL vs. control mice 0.27 $\pm$ 0.07 ng/mL; mean $\pm$ SD, $P = .008$). Serum T levels dropped back down to female levels after cessation of T treatment and subsequent washout period (0.5 $\pm$ 0.1 ng/mL vs. control mice 0.51 $\pm$ 0.07 ng/mL; mean $\pm$ SD, $P = .71$). After 3 weeks of T treatment, serial diestrus blood collection showed suppression of mean LH levels during T administration (0.61$\pm$ 0.07 ng/mL vs. 0.84 $\pm$ 0.09 ng/mL in age-matched control mice, $P < .001$). This LH suppression occurred during the period of acyclicity in T-treated mice. Preliminary single timepoint data of terminal LH levels during diestrus are indicative of no significant difference between T-treated and control mice following T cessation.

CONCLUSIONS: Cessation of T treatment reverses acyclicity, and preliminary results indicate T-induced suppression of LH can be reversed following T cessation. These data denote that changes of the hypothalamic-pituitary-gonadal axis due to T therapy may be reversible, and therefore may not impact long-term reproductive function.

P-228 4:30 PM Saturday, October 17, 2020

FERTILITY PRESERVATION IN A TRANSGENDER MAN WITHOUT PROLONGED DISCONTINUATION OF TESTOSTERONE: A CASE REPORT AND LITERATURE REVIEW. Kristy Cho, MD, FRCSC,[1] Rahana Harjee, MD,[2] Jeffrey Roberts, MD, FRCSC,[1] Caitlin Dunne, MD, FRCSC[3] [1]Division of Reproductive Endocrinology and Infertility, University of British Columbia, Vancouver, BC, Canada; [2]Department of Obstetrics and Gynaecology, University of British Columbia, Vancouver, BC, Canada; [3]Division of Reproductive Endocrinology and Infertility, University of British Columbia, Burnaby, BC, Canada.

OBJECTIVE: When proceeding with hormone therapy or gender affirming surgery, transgender patients should have the option of undergoing fertility preservation [1]. Prior to assisted reproductive technology, transgender men have traditionally had to discontinue exogenous testosterone for up to 6 months or until resumption of menses [2]. The process and experience associated with stopping testosterone has proven to be distressing for patients [3]. This report explores the feasibility of proceeding with fertility preservation in a transgender man without an extended period of androgen cessation and without the resumption of menstruation.

DESIGN: Case report and literature review. Consent was obtained from the patient for publication.

MATERIALS AND METHODS: We present a seminal case report of oocyte cryopreservation in a transgender man without stopping testosterone therapy beforehand. We also performed a literature review, which identified 5 publications reporting on the outcomes of oocyte cryopreservation in transgender men on testosterone therapy.

RESULTS: A 28-year-old transgender man had been taking testosterone for 3 years. He presented to a university-affiliated fertility clinic requesting oocyte cryopreservation before hysterectomy and bilateral salpingo-oophorectomy. He expressed a desire to proceed without stopping testosterone. Pre-treatment AMH was 1.89 ng/mL. A standard antagonist protocol was used with the addition of letrozole to minimize estrogenic side effects. Testosterone therapy was stopped for only three doses (immediately prior to and during COS). Thirteen oocytes were retrieved, 11 were mature and vitrified. In total, the time off of testosterone was 24 days. In all prior publications, testosterone was stopped for 3-6 months prior to starting ART [2-6].

CONCLUSIONS: This is a seminal case report demonstrating the feasibility of ovarian stimulation without a prolonged period of testosterone cessation in a transgender man. Future studies with a larger sample size should be carried out to confirm these findings. The short duration of time off testosterone may improve the patient's experience, increase treatment acceptability, and decrease gender dysphoria for transgender men considering fertility preservation.

The manuscript has subsequently been accepted for publication by F&S Reports.

TIGIT PROMOTE IMMUNE TOLERANCE AT THE FETO-MATERNAL INTERFACE.

Wenyan Fu, M.D.,[1] Zetong Ma, M.D.,[2] Shi Hu, Ph.D.[2] [1]Shanghai Ninth People's Hospital, Shanghai, China; [2]Second Military Medical University, Shanghai, China.

OBJECTIVE: The perfect synchronization of maternal immune-endocrine mechanisms and those of the fetus is necessary for a successful pregnancy. We sought to determine the function role of T cell immune receptor with Ig and ITIM domains (TIGIT), a co-inhibitory receptor, at the maternal-fetal interface and further expand the translational relevance of TIGIT in reproductive medicine.

DESIGN: Recombinant TIGIT-Fc fusion proteins by linking the extracellular domain of TIGIT and silent Fc fragments were generated and characterized. Human samples were collected and decidual immune cells were isolated for in vitro analysis. A mouse model of stress-induced pregnancy failure were employed to investigate the therapeutic role of TIGIT.

MATERIALS AND METHODS: We utilized cell-based models to study the function of TIGIT and TIGIT-Fc protein in decidual immune cells. Cell assays, flow cytometry, qPCR, cytokine analysis, multiplex bead array and mouse models were employed to investigate the mechanisms of action and pharmacodynamic readouts.

RESULTS: We found the TIGIT-Fc fusion protein with a silent Fc fragment did not trigger cytotoxic effect and has good pharmacokinetic parameters. The treatment with TIGIT-Fc of human decidual antigen presenting cells (APCs), the decidual dendritic cells (dDCs) and decidual macrophages (dMϕs) increased the production of interleukin 10 and induced the decidua APCs to powerfully polarize the decidual $CD4^+$ T cells towards a classic T_H2 phenotype. We further proposed that progesterone and Notch signalling shows a synergistic effect on the transcriptional regulation of TIGIT in decidual immune cell subsets. Moreover, The administration of TIGIT-Fc to CBA/J pregnant mice at preimplantation induced $CD4^+$ forkhead box $P3^+$ ($Foxp3^+$) regulatory T cells and tolerogenic dendritic cells and increased pregnancy rates in a mouse model of abortive stress.

CONCLUSIONS: We obtained new experimental evidence to support an immune-tolerance role of TIGIT at the maternal-fetal interface and demonstrated the therapeutic potential of TIGIT-Fc to restore immune tolerance in failing pregnancies.

CO-EXPRESSION OF ACTIVATING AND INHIBITORY RECEPTORS ON PERITONEAL FLUID NK CELLS IN WOMEN WITH ENDOMETRIOSIS.

Shinichiro Saeki, MD,[1] Atsushi Fukui, MD, PhD,[2] Hiroaki Shibahara, MD, PhD,[2] Toru Kato, MD, PhD,[2] Yu Wakimoto, MD,[2] Mai Chuxian, Ph.D. Student,[2] Mayu Yamamoto, Master's Student,[2] Ryu Takeyama, MD[2] [1]Hyogo College of Medicine, Nishinomiya, Japan; [2]Hyogo College of Medicine, Nishinomiya, Hyogo, IL, Japan.

OBJECTIVE: Abnormal function of peritoneal immune cells may cause to the onset and progress of pelvic endometriosis. We have previously reported that the expression of natural cytotoxicity receptor (NCR) including NKp46 on peritoneal fluid NK (pfNK) cells is decreased in women with pelvic endometriosis. NK cell expresses not only NKp46, but also various kinds of activating or inhibitory receptors on its surface. The aim of this study is to investigate participation of NK cells in women with endometriosis by analyzing the co-expression of activating or inhibitory receptors on NK cells and to investigate the immunological relationship between endometriosis and peritoneal fluid immune cells abnormalities.

DESIGN: Case control study.

MATERIALS AND METHODS: We collected peritoneal fluid NK (pfNK) cells and peripheral blood NK (pNK) cells from women who underwent laparoscopic operation for pelvic endometriosis (Endometriosis group, n=6) and control women who underwent laparoscopic operation for benign gynecological diseases such as uterine myoma or ovarian cyst (Controls: 3 cases of uterine fibroids, 4 cases of ovarian cysts, n=8). The co-expression of activating receptors(CD16, NKp46, NKG2C, NKG2D) and inhibitory receptors(CD158a, NKG2A) on pfNK cells (CD56) was analyzed using 6 color flow cytometry. All patients had given informed consent prior to entering the study, and the study was approved by the institutional review board.

RESULTS: The percentage of $CD16^+/CD56^{dim}$ pfNK cells was significantly lower in endometriosis group compared with controls ($p<0.01$). The percentage of $NKp46^+/CD56^+$ pfNK cells was not different between the two groups.

For the expression of activating NK cell receptor NKG2C, the percentage of $NKp46^{bright}/NKG2C^{bright}$ pfNK cells showed a significant increase in endometriosis group compared with controls ($p<0.01$), while that of $NKp46^{brigh}/NKG2C^{dim}$ pfNK cells showed a significant decrease ($p<0.01$). For the expression of NK cell inhibitory receptors NKG2A, the percentage $NKp46^{bright}/NKG2A^{bright}$ pfNK cells showed a significant increase in endometriosis group compared with controls ($p<0.01$), while that of $NKp46^{bright}/NKG2A^{dim}$ pfNK cells showed a significant decrease ($p<0.05$).

CONCLUSIONS: It is suggested that pfNK cells can be classified according to the difference for the intensity of fluorescence of NKG2C, NKG2A and NKp46. Furthermore, the cytotoxicity of pfNK cells may be different depending on the intensity of those receptor expression. We previously reported that $NKG2C^{bright}$ or $NKG2A^{bright}$ NK cells are cytokines producing cells and $NKG2C^{dim}$ or $NKG2A^{dim}$ NK cells are cytotoxic cells. Therefore, it may be speculated that the increase of cytokine-producing pfNK cells and the decrease of cytotoxic pfNK cells in endometriosis group may allow the attachment of endometrial cells and progress of endometriotic lesion.

WITHDRAWN

RESULTS: ***Identifying potential core outcomes:*** A long list of 55 potential core outcomes was developed by extracting outcomes reported in 54 endometriosis trials.

Determining core outcomes: When considering the Delphi survey, 354 participants, from 29 countries, responded. Eighteen consensus outcomes were identified and discussed during the consensus development meeting. Twenty-four participants, from 7 countries, engaged in the consensus development meeting. A minimum data set for endometriosis research was agreed (Table 1).

TABLE 1. Core outcome set for endometriosis.

1 Viable intrauterine pregnancy confirmed by ultrasound accounting for singleton, twin and higher multiple pregnancy
2 Pregnancy loss accounting for ectopic pregnancy, miscarriage, stillbirth and termination of pregnancy
3 Live birth
4 Gestational age at birth
5 Birth weight
6 Neonatal mortality
7 Major congenital anomaly
8 Adverse events
9 Patient satisfaction with treatment
If applicable: time to pregnancy leading to live birth

Determining how core outcomes should be defined: Forty-four potential definitions were identified. Twenty-seven participants, from 11 countries, took part in the consensus development meeting and agreed consensus definitions for individual core outcomes.

CONCLUSIONS: Embedding the core outcome set within future endometriosis research should ensure the comprehensive collection and reporting of core outcomes. Research funders, the SPIRIT statement, and over 80 speciality journals, including *Fertility and Sterility,* have committed to implementing this core outcome set.

References: Hirsch M, **Duffy JMN**, Barker C, Hummelshoj L, Johnson N, Mol B, Khan K, Farquhar C. A protocol for developing, disseminating, and implementing a core outcome set for endometriosis. *BMJ Open* 2016; 6(12): e013998.

SUPPORT: This research was funded by the Catalyst Fund, Royal Society of New Zealand, Auckland Medical Research Fund, and Maurice and Phyllis Paykel Trust.

DEVELOPING A MINIMUM DATA SET FOR RESEARCH EVALUATING TREATMENTS FOR INFERTILITY ASSOCIATED WITH ENDOMETRIOSIS.

James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Martin Hirsch, MRCOG MD(Res) MBBS,[2] Cindy Farquhar, FRANZCOG FRCOG MD MPH[3] ENDO:outcomes: An international collaboration harmonising outcomes outcomes measures for endometriosis research. [1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]University College London Hospitals NHS Foundation Trust, Greater London, United Kingdom; [3]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop a minimum data set for research evaluating fertility treatments for endometriosis.

DESIGN: Consensus development study engaging professionals, researchers and women with endometriosis.

MATERIALS AND METHODS: ***Identifying potential core outcomes:*** Potential core outcomes were identified by extracting outcomes previously reported in endometriosis trials.

Determining core outcomes: Potential core outcomes were entered into a three-round eDelphi survey. Respondents were asked to score the importance of each outcome. Based on their feedback, potential core outcomes were prioritized, and subsequently discussed during a consensus development meeting. Using the modified Nominal Group Technique, a minimum data set was agreed.

Determining how core outcomes should be defined: A long list of potential definitions was developed by identifying definitions which had been reported by formal definition development initiatives, clinical practice guidelines and Cochrane reviews. Potential definitions were discussed in a consensus development meeting. Using a formal consensus development method, consensus definitions were developed.

P-233 4:30 PM Sunday, October 18, 2020

MURINE AVATARS FOR PRECISION MEDICINE IN ENDOMETRIOSIS.

Valerie A. Flores, MD,[1] Cagdas Sahin, MD,[1] Hugh S. Taylor, M.D.[2] [1]Yale School of Medicine, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT.

OBJECTIVE: Endometriosis is a chronic, gynecologic disease afflicting 1-in-10 reproductive-aged women. Response to medical therapy is highly variable as endometriotic lesions do not consistently respond to first-line, progestin-based therapy. We have previously demonstrated in a retrospective study that progesterone receptor (PR) status in lesions can predict response to progestins. Low PR status was associated with a $<10\%$ chance of response, suggesting that some women may benefit from alternative hormonal therapy as first-line. Here, we utilize murine avatars to test human endometriotic lesion response to two different hormonal regimens. We hypothesize this approach will allow clinicians to individualize effective, timely treatment for this debilitating disease.

DESIGN: Patient-Derived Xenograft Murine Model.

MATERIALS AND METHODS: Eight-week old NOD/SCID mice underwent transplantation of endometrioma lesions (5mm) collected from women undergoing surgery for endometriosis. Immunohistochemistry was performed to determine PR expression in lesions prior to implantation. The Histo- Score was used to quantify PR status as *High* or *Low*. Two weeks following transplantation, mice underwent daily subcutaneous injections with vehicle (DMSO), Medroxyprogesterone acetate (MPA, 50ug), or GnRH antagonist, Cetrotide (100ug); n=6-9 lesions per group. After 1 month of treatment mice were sacrificed, lesions collected, and measured. Student's t-test was used for statistical analysis.

RESULTS: Lesions with high PR demonstrated near-complete response to MPA compared to lesions with low PR ($p<0.05$). Average post-treatment

size in high PR lesions was 1.25mm^3 compared to 24.7mm^3 in low PR lesions. As expected, high PR lesions responded completely to GnRH antagonist (i.e., 0 mm) ($p< 0.05$). While lesions with low PR responded poorly to MPA, they responded well to antagonist with a similar degree of response as seen in high PR lesions responding to MPA (>3-fold decrease in lesion size). Untreated lesions with high PR demonstrated slower growth compared to lesions with low PR.

CONCLUSIONS: Use of murine avatars to test clinical response is a novel approach to endometriosis, which currently remains difficult to treat. Hormonal suppression is a cornerstone of therapy, however response can be unpredictable. We have previously shown that women with low PR lesions respond poorly to progestin-based therapy. Here we validate our prior work in a mouse xenograft model by demonstrating that lesions with low PR expression do not respond to progestin-based therapy. We demonstrate that lesions with low PR respond to antagonist therapy in a manner similar to response of high PR lesions to MPA; we anticipate this response will be clinically meaningful in patients. The use of murine avatars can allow clinicians to predict an individual's response to therapy, avoid trialing futile treatments, and allowing a precision medicine approach to endometriosis.

M^{6}A METHYLATION REGULATORS CONTRIBUTE TO THE EUTOPIC ENDOMETRIUM AND MYOMETRIUM DYSFUNCTION IN ADENOMYOSIS.

Junyu Zhai, M.D. Ph.D.,[1] Shang Li, M.D.,[2] Sushmita Sen, B.S.,[1] Yanzhi Du, M.D. Ph.D.,[2] Linda C. Giudice, MD, PhD[1] [1]University of California, San Francisco, San Francisco, CA; [2]Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China.

OBJECTIVE: The goal of this *in silico* and lab-based experimental study was to explore a possible role for N6-methyladenosine (m^{6}A) in adenomyosis.

DESIGN: Through bioinformatic analysis of the data from Gene Expression Omnibus (GEO) database, we investigated the role of m^{6}A methylation regulators in the pathogenesis of adenomyosis. Then human samples were used to validate the results of *in silico* analysis.

MATERIALS AND METHODS: Gene expression profiles of both the endometrium and myometrium of women with and without adenomyosis were obtained from the publicly available GEO database separately. The expression, co-expression and possible target genes of the 16 m^{6}A methylation regulators were investigated using bioinformatic analysis such as Wilcox test, Spearman correlation and WGCNA. Finally, the total m^{6}A content, expression of m^{6}A methylation regulators and possible target genes of m^{6}A regulators were validated using qRT-PCR in both the endometrium and myometrium of adenomyosis women and controls. The clinical samples were collected from the Endometrial Tissue and DNA Bank at UCSF (IRB # 10-02786).

RESULTS: In the endometrium, STRING database analysis revealed that *METTL3* functions as a "hub" gene of m^{6}A methylation regulators, and the genes involved in m^{6}A regulation, including *METTL3*, *FTO*, *ZC3H13* and *YTHDC1* expression, were significantly decreased in cases versus controls. Functional, co-expression and correlational analyses of endometrium from cases versus controls revealed decreased total m^{6}A levels, induced by *METTL3*, and the downstream elevated *insulin-like growth factor-1(IGF1)* and *D-Dopachrome Tautomerase* (*DDT),* with the latter two having known functions in epithelial proliferation and cell migration, which are important processes in the pathogenesis of adenomyosis in endometrium.

M^{6}A methylation regulators, including *RBM15/15B*, *ALKBH5*, *FTO*, *YTHDF1/2*, *KIAA1429*, *HNRNPC*, *METTL3*, *ZC3H13* and *YTHDC2,* were also differentially expressed in the myometrium from cases versus controls. We validated decreased total m^{6}A levels and differential expression of m^{6}A methylation regulators using qRT-PCR and tissues available from our biorepository. Possible target genes, including *cadherin 3(CDH)*, *sodium channel β-subunit 4* (*SCN4B)* and *placenta-specific protein 8 (PLAC8),* which are involved in cell adhesion, muscle contraction and immune response in the myometrium of adenomyosis patients were also validate.

CONCLUSIONS: Thus, through extensive public database mining and validation of select genes with qRT-PCR, this study, for the first time, implicates m^{6}A and its methylation regulators in the pathogenesis of adenomyosis. Decreased *METTL3* and total m^{6}A levels in endometrium of adenomyosis patients may contribute to cell proliferation and invasion through *IGF1* and *DDT.* Furthermore, in the myometrium, m^{6}A methylation regulators work as a cluster and play roles in cell adhesion, muscle contraction and immune response. In conclusion, m^{6}A methylation regulators may be involved the pathogenesis of adenomyosis through aberrant expression and actions in both the uterine endometrium and myometrium.

VARIATION IN THE PERCENTAGE OF ENDOMETRIAL P16-POSITIVE SENESCENT CELLS IN CONSECUTIVE MENSTRUAL CYCLES.

Dimitar Parvanov, PhD, Rumiana Ganeva, MSc, Nina Vidolova, MSc, Georgi Stamenov, MD/PhD. Nadezhda Women's Health Hospital, Sofia, Bulgaria.

OBJECTIVE: Recently, it was found that p16^{ink4a}-positive senescent cells are involved in endometrial receptivity and participate in the acute cellular remodelling at the time of embryo implantation. Our previous research showed that the percentage of glandular p16-positive cells and luminal epithelial p16-positive cells is strongly associated with successful implantation and live births. The aim of the present study was to compare the percentage of p16-positive cells in the glandular and luminal epithelial compartments of the human endometrium during the mid-luteal phase in two consecutive menstrual cycles.

DESIGN: We measured the percentage of p16^{ink4a}-positive cells by immunohistochemistry in endometrial biopsy samples of 94 women in two consecutive menstrual cycles.

MATERIALS AND METHODS: This is a prospective observational study of 94 fertile women who had two endometrial biopsies during the mid-lutheal phase (7 days after LH surge) in two consecutive natural cycles. Patients older than 40 years, with BMI$<$18 kg/m^2 or BMI$\geq$30 kg/m^2, endometriosis, polycystic ovary syndrome (PCOS), endometrial polyps, abnormal uterine development and hydrosalpinx were excluded from the study.

Endometrial biopsies were obtained by pipelle suction and they were immediately fixed in 10% formalin. The endometrial tissue was submitted to paraffin embedding for histological determination and subsequent analysis. Immunohistochemistry (IHC) was performed on the paraffin-embedded sections by Novolink Polymer Detection System (Leica Biosystems, Wetzlar, Hesse, Germany). We used monoclonal antibody against p16^{ink4a} (Master Diagnostica, Granada, Spain) to identify senescent endometrial epithelial cells. The percentage of p16+ cells in each tissue compartment was calculated after enumeration by two independent investigators in multiple endometrial sections. Values were expressed as mean $\pm$ SD. Paired t-test was used to compare the percentage of p16-positive cells between the two time points. $P<0.05$ was considered statistically significant.

RESULTS: The percentage of p16-positive cells in the endometrial glands during the mid-luteal phase of the cycle ranged between 0.12% and 53.22%, while it varied between 1.39% and 85.29% in the luminal epithelium. The temporal change in the percentage of p16-positive cells varied at both time points between 0.55% and 15.56% in the endometrial glands, and between 1.58% and 30.74% in the endometrial luminal epithelium. In addition, for both endometrial glands and luminal epithelium, the proportion of p16+ senescent cells was not significantly different between the two time measurements ($p=0.56$ and $p=0.93$, respectively). In 80% of the patients the difference in the percentage of p16-positive cells at both time points was lower than 20% in the endometrial luminal epithelium and lower than 9% in the luminal epithelium.

CONCLUSIONS: The percentage of endometrial epithelial p16-positive senescent cells is relatively constant in human endometrium during the mid-luteal phase in consecutive menstrual cycles.

P-236 4:30 PM Sunday, October 18, 2020

SIRT1 AND PROGESTERONE (P4) RESISTANCE AND ENDOMETRIOSIS: IMPLICATIONS FOR INFERTILITY MANAGEMENT.

Bruce A. Lessey, Ph.D., M.D.,[1] Steven L. Young, M.D., Ph.D.,[2] Tae Hoon Kim, Ph.D.,[3] Jae-Wook Jeong, Ph.D.[3] [1]Wake Forst Health, WINSTON SALEM, NC; [2]University of North Carolina, Raleigh, NC; [3]Michigan State University, Grand Rapids, MI.

OBJECTIVE: Progesterone (P4) resistance is now considered a central element in endometriosis pathology, but the mechanism and role of P4 resistance in normal uterine function is not understood. SIRT1, an epigenetic regulator that targets key P4-regulated genes, is up-regulated in inflammatory pathologic conditions such as endometriosis, and over-expressed at all stages of the menstrual cycle. We hypothesize that SIRT1 is a central regulator of P4-resistance may also have a role in both normal uterine physiology.

DESIGN: Basic research using the mouse model and immunohistochemistry of human endometrial samples.

MATERIALS AND METHODS: 1) SIRT1 was histologically examined in normal implantation sites in mice during early pregnancy. To investigate the role of SIRT1 in endometrial function and endometriosis, we generated uterine specific *Sirt1* knock-out ($Pgr^{cre/+}Sirt1^{f/f}$) and overexpression ($Pgr^{cre/+}ROSA26^{LSL\text{-}Sirt1}$) mice. 2) The effect of SIRT1 on female fertility was examined in $Pgr^{cre/+}Sirt1^{f/f}$ mice. 3) To assess the effect of SIRT1 over-expression on endometriosis, we surgically induced endometriosis in mice using endometrium from $Pgr^{cre/+}ROSA26^{LSL\text{-}Sirt1}$ and control mice. 4) Treatment with SIRT1 inhibitor EX-527 was used in $Pgr^{cre/+}ROSA26^{LSL\text{-}Sirt1}$ mice. 5) Human endometrium throughout the cycle including menses was immunostained for SIRT1 in control and endometriosis cases.

RESULTS: 1) SIRT1 was expressed in the decidua of pregnant mice only on the day of implantation, day 5.5 of pregnancy. 2) Uterine specific *Sirt1* knock-out mice were infertile and exhibited implantation failure. 3) In the endometriosis mouse model, SIRT1 over-expressing mice have a significantly increased incidence of endometriotic lesions compared to control mice. 4) Infertile SIRT1 over-expressing mice exhibited normal implantation after treatment with EX-527, a SIRT1 inhibitor. In normal human controls ($n = 30$), SIRT1 immunostaining was undetectable during the proliferative and secretory phase endometrium but dramatically elevated only at menses ($p < 0.001$). In endometriosis cases ($n = 39$), SIRT1 was uniformly elevated in both proliferative and secretory phases.

CONCLUSIONS: Together, these results demonstrate that P4-resistance appears to be a natural phenomenon, mediated by SIRT1, and likely required for normal menstruation in women and successful implantation in the mouse. Over-expression of SIRT1 leads to worsening endometriosis and implantation failure in the mouse model which can be rescued by treatment with EX-527. In normal human controls, SIRT1 appears only at menses and may play a role in expediting the transition from secretory to proliferative state at menses. In endometriosis, SIRT1 is pathologically over-expressed in the endometrium and likely contributes to infertility and the pathogenesis of this disease. Timing of SIRT1 expression appears vital for normal physiologic P4-resistance, with functions at menses and implantation, but aberrant expression leads to implantation failure in both mice and humans.

P-237 4:30 PM Sunday, October 18, 2020

CONCOMITANT ENDOMETRIOSIS IN PATIENTS UNDERGOING HYSTERECTOMY WITH SUSPECTED ADENOMYOSIS.

Adela G. Cope, MD, Zaraq Khan, MD, Wendaline M. VanBuren, MD, Isabel C. Green, MD, Tatnai L. Burnett, MD. Mayo Clinic, Rochester, MN.

OBJECTIVE: The current study aims to evaluate the prevalence of concomitant endometriosis in patients undergoing laparoscopic hysterectomy (LH) with suspected adenomyosis. Prior studies have estimated this rate to be 11-37.5%[1-3] but have been limited by lack of laparoscopic pelvic assessment or clinical diagnosis of endometriosis without histologic confirmation.

DESIGN: Retrospective case series at an academic medical center.

MATERIALS AND METHODS: Premenopausal women who underwent LH and had suspected adenomyosis by imaging or confirmed by pathology between 10/1/2015-8/31/19 were included. Close peritoneal inspection was performed, and any visible lesions were excised to capture all cases of endometriosis. Descriptive statistics were performed.

RESULTS: A total of 105 patients met inclusion criteria with a mean age of 42.8±5.8 years old. The most common indications for surgical intervention were dysmenorrhea or pelvic pain (n=89, 84.8%) and/or abnormal uterine bleeding (n=87, 82.9%). Of the 68 women with suspected adenomyosis on imaging, 39 were confirmed on pathology (57.3%). Peritoneal lesions were excised in 81 patients (77.1%), with positive pathology for endometriosis in 64 of 81 (79.0%). Concomitant endometriosis was identified in 69% of women with suspected adenomyosis based on preoperative imaging (47 of 68) and 56% of women with confirmed adenomyosis on pathology (42 of 75). In patients with dysmenorrhea or pelvic pain, the rate of concomitant endometriosis was 77.0% (47 of 61) in those with suspected adenomyosis on imaging.

CONCLUSIONS: Endometriosis was found in 77.0% of women with suspected adenomyosis and dysmenorrhea or pelvic pain, suggesting a role for careful examination of the pelvis at hysterectomy in this population. Further confirmation with a larger sample size and pain outcome data would assist with clinical decision making and counseling.

HEAT SHOCK PROTEIN 90 INHIBITOR 17-AAG SUPPRESSES THE GROWTH OF ENDOMETRIOSIS IN VITRO AND IN VIVO BY INHIBITING ESTROGEN RECEPTOR TRANSCRIPTIONAL ACTIVITY.

Jingjie Li, M.D,[1] Pan Chen, PhD,[2] Jiayu Lin, Bachelor,[1] Xiaoyan Liang, M.D[1] [1]the Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: To investigate the effect of HSP90 inhibitor 17–AAG on the growth of endometriosis in vitro and in vivo.

DESIGN: Pharmacologic interventions in human endometriotic stromal cells and in an experimental mouse model of endometriosis.

MATERIALS AND METHODS: Patient recruitment was carried out at the Sixth affiliated Hospital of Sun Yat-sen University from January 2018 to May 2020. Ectopic endometrium (endometriotic tissue, n=15) was collected from patients with ovarian endometriosis undergoing laparoscopy.- Primary cultured human endometriotic stromal cells were prepared. Cells were incubated with 10nM, 100nM, 1μM and 10μM 17-AAG for 24 h. The 3-(4,5-dimethylthiaziazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay, colorimetric 5'-bromo-2'-deoxy-uridine (BrdU) incorporation assay and Caspase-Glo luminescent-based assays were used to test the cell viability, proliferation ability and apoptosis. Transcriptional activity of estrogen receptor (ER) was measured by luciferase activity after transient transfection of an ERE-tk-Luc reporter construct that contained the consensus estrogen-responsive elements (EREs) sequences. Furthermore, we modeled endometriosis in 30 female C57BL6 mice by intraperitoneal injection of allogeneic endometrial fragments. We divided the mice to 10ug/g and 30ug/g 17-AAG group, control group and vehicle group.

RESULTS: 17-AAG inhibited the viability and proliferation of human primary endometriotic stromal cells in a dose-dependent manner from the concentration of 10nM and 100nM 17-AAG respectively. The caspase-3 activities were enhanced significantly in endometriotic stromal cells from 100nM to 10μM 17-AAG treatments. Transcriptional activity of ER were also inhibited significantly by 17-AAG in a dose-dependent way. In mouse model, no obvious weight loss was observed in all groups, and there was no significantly difference in daily weight between those four groups after 30 days of administration. Compared with the model control and vehicle group, the size of ectopic lesions in the treatment group was significantly reduced. The serum TNF-α level was significantly decreased in the treatment group, but there was no statistical difference in the level of serum AMH/E2/P of mice in each group.

CONCLUSIONS: HSP90 inhibitor 17-AAG controls the growth of endometriosis by inhibiting transcriptional activity of ER. HSP90 inhibitor could provide a hopeful way for better understanding of estrogen signaling on the pathogenesis of endometriosis, as well as for potential clinical application on endometriosis pharmacotherapy.

TOFACITINIB LEADS TO LESION REGRESSION AND ALTERED STAT3 SIGNALING IN ENDOMETRIOSIS. Alexander Kotlyar, MD,[1] Ramanaiah Mamillapalli, PhD,[2] Valerie A. Flores, MD,[3] Hugh S. Taylor, M.D.[2] [1]Yale School of Medicine, Oange, CT; [2]Yale University School of Medicine, New Haven, CT; [3]Yale School of Medicine, New Haven, CT.

OBJECTIVE: We sought to determine if a Janus kinase-inhibitor, Tofacitinib, could affect JAK/STAT signaling in endometriosis and affect lesion size in-vivo.

DESIGN: In-vitro culture and mouse model.

MATERIALS AND METHODS: Gene expression levels in primary cells were assessed by qPCR using primers for HIF1a, and VEGF. Protein expression from in-vitro experiments was performed via western blotting and densitometry. Endometriosis was induced in C57BL/6 mice using heterologous uterine horn transplantation. Lesions were allowed to form over four weeks and Tofacitinib and vehicle were administered via oral gavage at a concentration of 10mg/kg over four weeks.

RESULTS: We first assessed the in-vitro effect of Tofacitinib. This agent reduced HIF1a and VEGF mRNA levels at 12 and 24hrs of treatment. Following 24 hrs of exposure, Tofacitinib effectively reduced STAT3 phosphorylation in Ishikawa cells ($p<0.05$), and patient-derived stromal ($p<0.01$) and epithelial cells ($p<0.01$) from eutopic endometrium. Expression of HIF1a was significantly reduced with Tofacitinib treatment of endometrial stromal and epithelial cells from control patients, but not in patients with endometriosis. Using a mouse model of surgically-induced endometriosis ($n=20$), daily Tofacitinib treatment led to lesion regression ($p<0.01$) and reduced adhesion burden ($p<0.001$).

CONCLUSIONS: This study suggests that inhibition of JAK/STAT signaling using Tofacitinib may be a viable method for the treatment of endometriosis. By reducing STAT3 phosphorylation, lesion size and adhesive disease are both reduced.

P-240 4:30 PM Sunday, October 18, 2020

SYMPATHOMIMETIC AMINE TREATMENT VERY EFFECTIVE FOR RELIEVING PELVIC PAIN IN WOMEN EVEN WHEN HORMONAL THERAPY AND SURGERY WERE NOT SUFFICIENT. Paul A. Carpentier, MD, CFCMC,[1] Barbara Meier, BSN,[1] Jerome H. Check, M.D., Ph.D.,[2] Donna Summers, M.S.[3] [1]The Long Island Gianna Center for Women's Health and Fertility, Babylon, NY; [2]Cooper Medical School of Rowan University, Camden, NJ; [3]Cooper Institute for Reproductive Hormonal Disorders, P.C., Mt. Laurel, NJ.

OBJECTIVE: There had been several published case reports finding that treatment with dextroamphetamine sulfate (DS) resulted in considerable improvement of various types of pelvic pain from endometriosis or adenomyosis including dysmenorrhea, dyspareunia, mittelschmerz, vulvodynia, vulvovaginitis, chronic pelvic pain, backaches, and chronic pelvic pain of bladder origin. These reports all seem to come from one treatment center. A search of the literature did not find any published series. The purpose of this study was to corroborate or refute claims that DS can effectively relieve pelvic pain even when conventional medical and/or surgical therapy was not effective. Case reports may establish that a given therapy can be effective but do not provide information as to whether only a minority of women will respond. Thus, the goal of this study was to determine, in a short time period, the likelihood of success.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: Patients complaining of significant pelvic pain were recruited. It was ascertained if they had failed previous medical therapy including NSAIDs, progestin therapy (oral contraceptives, norethindrone, etc.), estrogen suppression with gonadotropin releasing hormone agonists, e.g., leuprolide acetate, or had failed surgical therapy. All had moderate to severe pain. They were prescribed 10 - 30mg extended release dexamphetamine salts qAM providing 12.5 – 37.6mg of dextroamphetamine sulfate. They were re-evaluated in 3 months and questioned as to whether they had 1) marked relief of pain, 2) moderate relief of pain, or 3) little or no relief.

RESULTS: Thirty-one were recruited for the study. Six dropped out for various reasons. 27 of the 31 had been previously unsuccessfully treated with oral contraceptives, progestins, or progesterone, or leuprolide acetate. All 31 had previously used NSAIDs, and 18 had prior surgical therapy. After 3 months of treatment 17 of 25 (68%) reported that the pain was markedly improved. An additional 2 found moderate relief, so that 76% after 3 months on a relatively small dosage of DS had moderate to marked relief of pain.

CONCLUSIONS: In a totally independent treatment center from the one initially reporting this novel therapy for pelvic pain, we were able to corroborate their findings. Moreover, by evaluating a series of patients we ascertained that this treatment works very quickly in the majority of patients despite their failure to improve previously with conventional medical and/or surgical therapy. Increasing the dosage of DS may further improve the pain. The advantage of DS is that it allows a woman to conceive while being treated, in contrast to standard medical therapy. Surgery may diminish ovarian reserve. Future studies should determine if relieving pain, and therefore inflammation, may translate into correcting infertility problems. DS may work by releasing dopamine from sympathetic nerve fibers which in turn, diminishes cellular permeability, thus inhibiting permeation of irritants causing excessive inflammation.

CHARACTERIZATION OF VAGINAL SECRETION MICROBIOTA IN INFERTILE WOMEN WITH CHRONIC ENDOMETRITIS. Kotaro Kitaya, M.D.,[1] Yoko Nagai, Ph.D.,[2] Suguru E. Tanaka, Ph.D.,[2] Yoshiyuki Sakuraba, Ph.D.,[2] Tomomoto Ishikawa, M.D.[1] [1]Reproduction Clinic Osaka, Osaka, Japan; [2]Varinos Inc., Tokyo, Japan.

OBJECTIVE: Some interventive procedures including hysteroscopy, endometrial biopsy, and endometrial fluid (EF)/tissue aspiration for local microbiota are required for diagnosis of chronic endometritis (CE). In addition, the results of EF/endometrial tissue microbiota do not always reflect the accurate information in the uterine cavity due to inevitable contamination of vaginal microorganisms in the process of trans-vagino-cervical sample collection. The aim of this study is to investigate the feasibility of the vaginal secretion (VS) microbiota as a screening tool for CE.

DESIGN: We diagnosed CE in infertile patients by three methods (i) hysteroscopy, (ii) endometrial biopsy and histopathology/immunohistochemistry, and (iii) VS/EF microbiota analysis using next generation sequencing. The results were compared to characterize the VS microbiota in CE and non-CE patients.

MATERIALS AND METHODS: A total of 123 infertile women were enrolled in the study under written informed consent. Hysteroscopy was performed in the proliferative phase of the menstrual cycle followed by endometrial biopsy. The paired VS/EF samples were obtained in the secretory phase of the same cycle. VS was collected using a sterile swab followed by thorough cleansing/disinfection of vaginal cavity and EF aspiration using a pipette. Hysteroscopic CE was diagnosed according to the criteria proposed by International Working Group for Standardization of CE Diagnosis. Histopathologic CE was diagnosed with immunohistochemistry for a endometrial stromal plasmacyte marker CD138. The VS/EF microbiota was analyzed by pyrosequencing of variable region 4 of bacterial 16S rRNA. The diversity indices were calculated. Fisher's exact, Wilcoxon rank-sum, adjusted Welch's *t* test were used for statistics.

RESULTS: CE was diagnosed in 16.2% of patients (20/123, hysteroscopic CE in eight patients and histopathologic CE in 20 patients).There were no differences in α-diversity (Shannon index, Chao1 richness, and phylogenetic diversity whole tree) and β-diversity (PERMANOVA test) indices between the CE and non-CE group ($p > 0.21$). The detection rate ($p = 0.030$, OR 8.91, 95% CI 1.39- 57.3) and bacterial abundance ($p = 0.0062$) of *Rhodanobacter* in the EF microbiota of the CE group (15.0%, 3/20) was higher than in that of the non-CE group (1.9%, 2/103). Meanwhile, the detection rate ($p = 0.0033$, OR 0.08, 95% CI 0.004-0.52) and bacterial abundance ($p = 0.0073$) of *Streptococcus* in the VS microbiota was significantly lower in the CE group (5.0%, 1/20) than in the non-CE group (38.8%, 40/103). The detection rate ($p = 0.042$) and bacterial abundance ($p = 0.045$) of *Enterococcus* in the VS microbiota was significantly lower in the CE group (0%, 0/20) than in the non-CE group (17.5%, 18/103). By contrast, the detection rate and bacterial abundance of *Lactobacillus* in the EF/VS microbiota was similar between the two groups ($p > 0.19$).

CONCLUSIONS: Our findings suggest that VS microbiota in infertile CE patients is characterized by reduction in the detection rate and bacterial abundance of two lactic acid-producing bacteria *Streptococcus* and *Enterococcus*, but not of *Lactobacillus*.

BOWEL OCCULT MICROSCOPIC ENDOMETRIOSIS IN RESECTION MARGINS IN DEEP COLORECTAL ENDOMETRIOSIS SPECIMENS HAS NO IMPACT ON THE LONG-TERM RISK OF RECURRENCE. Simone Ferrero, MD, PhD,[1] Umberto Leone Roberti Maggiore, MD, PhD,[2] Ennio Biscaldi, MD,[3] Michele Altieri, MD,[4] Valerio Gaetano Vellone, MD, PhD,[5] Cesare Stabilini, MD, Phd,[6] Fabio Barra, MD[4] [1]DINOGMI, University of Genova, Genova, Italy; [2]Department of Gynecologic Oncology, IRCCS National Cancer Institute, Milan, Italy; [3]Department of Radiology, Galliera Hospital, Genova, Italy; [4]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [5]Anatomic Pathology, Genova, Italy; [6]DISC, University of Genova, Genova, Italy.

OBJECTIVE: The variables influencing the risk of recurrence after segmental resection for rectosigmoid endometriosis are mostly unknown. This study aimed to assess if the risk of recurrence is influenced by the presence of bowel occult microscopic endometriosis (BOME) implants in colorectal resection specimen margins.

DESIGN: Prospective study.

MATERIALS AND METHODS: This study included patients who underwent segmental resection for rectosigmoid endometriosis and had a follow-up of at least 5 years. Every year the patients underwent an assessment of pain (measured on a 10 cm VAS scale), intestinal symptoms (measured on a 10-point Likert scale), gastrointestinal function (measured using the Gastrointestinal Quality of Life Index, GIQLI), and quality of life (assessed using the Endometriosis Health Profile-30, EHP-30). Also, the patients underwent transvaginal ultrasonography to evaluate the presence of deep endometriosis recurrence. Magnetic resonance enema was performed in symptomatic patients with ultrasonographic suspicion of deep endometriosis recurrence. Outcomes were compared between patients with and without BOME implants in colorectal resection specimen margins.

RESULTS: 72 patients were included in the study. 13 patients had BOME implants in colorectal resection specimen margins. Therefore, BOME was found in 18.1% of patients (in one margin in 8 patients and in both margins in 5 patients). Patients with and without BOME implants were similar in demographic and surgical characteristics (length of the rectosigmoid specimen removed, size of the largest intestinal endometriotic nodule, depth of infiltration of endometriosis in the intestinal wall, distance between the lower margin of the lesion and the anal verge, associated deep endometriotic lesions). The median length of follow-up was 9 years (range, 5-14 years); there was no significant difference in the length of follow-up between patients with and without BOME (p=0.282). 67 patients (93.1%) of the patients used some type of hormonal therapies during follow-up. 34 patients (47.2%) conceived during follow-up. No significant difference was observed in pain symptoms, intestinal symptoms, gastrointestinal function, and quality of life between patients with and without BOME. At five-year follow-up, imaging diagnosis of rectosigmoid endometriosis recurrence was observed in 5 patients without BOME implants (8.5%; 95% CI, 2.8%-18.7%) and 2 patients with BOME implants (15.4%; 95% CI, 1.9-45.4%; p=0.580). In 6 out of 7 patients, the diagnosis of rectosigmoid endometriosis recurrence was confirmed by surgery and histology.

CONCLUSIONS: This study suggests that BOME implants do not affect the long-term risk of rectosigmoid endometriosis recurrence. Also, BOME implants do not influence postoperative symptoms. The major limitation of the study is the small sample size. The primary strength of the study is the long-term follow-up.

CHRONIC ENDOMETRITIS IN WOMEN WITH SUSPECTED RETAINED PRODUCTS OF CONCEPTION AND THEIR REPRODUCTIVE OUTCOMES. Simone C. Elder, MD, Pietro Bortoletto, MD, Phillip A. Romanski, MD, Steven Spandorfer, MD. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To determine if women who underwent operative hysteroscopy for suspected retained products of conception (rPOC) have histopathologic evidence of chronic endometritis (CE).

DESIGN: Retrospective cohort conducted at a university-affiliated center.

MATERIALS AND METHODS: We identified women who underwent operative hysteroscopy for suspected rPOC. Histopathologic evidence of CE on final surgical pathology was the primary outcome. Secondary outcomes included subsequent pregnancy outcomes following diagnosis, stratified by treatment status.

RESULTS: A total of 111 women were analyzed, of which 26 (23.4%) were diagnosed with CE. Compared to those without CE, women diagnosed with CE had a lower median gravidity (1 vs. 2, p=0.021) and were twice as likely to have undergone a prior operative hysteroscopy (42.3 vs. 18.8 %, p=0.015), with polypectomy (54.6%) being the most common indication. Of those diagnosed with CE, 84.6% were also diagnosed with retained products of conception compared to 75.3% without CE (p=0.32). Of the 111 patients, subsequent pregnancy data was available for 63 of them. There was no difference in pregnancy rate (61.5 vs 54%, p=0.626) between those with and without CE. Once pregnant, miscarriage (37.5 vs 25.9%, p=0.524) and live birth rates (50 vs. 55.6%, p=0.782) were similar between groups. Women with CE received antibiotic treatment 57.7% of the time, the most common being doxycycline (42.3%). Five women underwent repeat endometrial sampling after antibiotic treatment, only 1 of which had persistent CE. Of the women with CE who were treated with antibiotics (n=10), 8 became pregnant and 4 had a live birth. There were patients with CE who were not treated with antibiotics, none of which became pregnant.

CONCLUSIONS: Nearly 1 in 4 women undergoing hysteroscopy for rPOC were incidentally diagnosed with CE. The role of CE as a causative agent for retained products versus a response to the pregnancy loss is not clear. In this cohort, a diagnosis of CE did not negatively impact subsequent reproductive outcomes.

ALTERED EXPRESSION OF ATP-MEDIATED PURINERGIC SIGNALING PATHWAYS IN MACAQUES WITH ENDOMETRIOSIS. Fangzhou Luo, BS,[1] Ov D. Slayden, PhD[2] [1]Oregon National Primate Research Center, Beaverton, OR; [2]Professor, Beaverton, OR.

OBJECTIVE: To assess the expression of nucleotide-converting and purine-converting enzymes Adenylate Kinase 1 (ADK1), Adenylate Kinase 2 (ADK2), and ectonucleotidase CD73 in the endometrium and endometriotic lesions of rhesus macaques.

DESIGN: Real-time PCR and immunohistochemical analysis of macaques with endometriosis.

MATERIALS AND METHODS: We compared endometrium from endometriosis-free rhesus macaques (*Macaca mulatta*) with "eutopic" endometrium and "ectopic" endometriotic lesions from monkeys with endometriosis. Samples were examined from the proliferative and secretory phases of the menstrual cycle (n=5/group). Transcript expression of ADK1, ADK2, and CD73 was assayed by q-RT-PCR carried out on an ABI7900HT FAST Real-Time PCR System normalized to S10 RNA. Samples were fixed, embedded in paraffin and 5μm sections were subjected to IHC with antibodies targeting ADK1 (Invitrogen 15485), ADK2 (Invitrogen 29365), and CD73 (Abcam 175396).

RESULTS: IHC showed strong cytoplasmic ADK1 staining in the epithelium and the stroma in diseased endometrium, and very strong cytoplasmic staining in both cell types in the lesion. ADK1 transcript was found unregulated in the proliferative phase in both endometrium and endometriosis. ADK2 localized to both the epithelium and the stroma in healthy tissue in both proliferative and secretory phase. In endometriosis, secretory eutopic endometrium showed weak staining. In the lesion, strong ADK2 staining was seen in the epithelial cells in both menstrual stages. A significantly higher level of ADK2 transcript was shown at eutopic site at proliferative stage when compared with the secretory counterpart. A significant decrease was noted in the diseased secretory endometrium compared with healthy secretory endometrium. CD73 localized to epithelial, stromal and endothelial cells in healthy endometrium. Weaker staining was seen in the secretory eutopic and ectopic tissues. In the diseased endometrium, CD73 staining was negligible to none in the epithelium. In the lesion, epithelial staining of CD73 was completely lost. A significant decrease in CD73 transcript was seen in the eutopic secretory endometrium.

CONCLUSIONS: The glycolytic phenotype and insulin resistance (previously found in our studies), combined with altered expression of AK1, ADK2 and CD73 may contribute to inflammation associated with endometriosis.

P-246 4:30 PM Sunday, October 18, 2020

A PROSPECTIVE STUDY TO EVALUATE THE USE OF BOWEL PREPARATION BEFORE THREE-DIMENSIONAL RECTAL WATER CONTRAST TRANSVAGINAL ULTRASONOGRAPHY FOR DIAGNOSING RECTOSIGMOID ENDOMETRIOSIS. Fabio Barra, MD,[1] Matteo Tantari, MD,[1] Giulio Evangelisti, MD,[1] Carolina Scala, MD,[2] Simone Ferrero, MD PhD[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Istituto G. Gaslini, Genova, Italy.

OBJECTIVE: To evaluate the impact of bowel preparation on the diagnostic parameters of three-dimensional rectal water-contrast transvaginal ultrasonography (3D-RWC-TVS) in women with suspicion of rectosigmoid endometriosis.

DESIGN: This was a single-center prospective comparative pilot study.

MATERIALS AND METHODS: Women referred to our institution for the suspicion of rectosigmoid endometriosis between January 2018 to December 2019 were included. Patients underwent 3D-RWC-TVS with and without bowel preparation within an interval of 1-8 weeks. Bowel preparation consisted in a low-residue diet given in the two days before the ultrasonographic exam and a rectal enema administered a few hours before it. During the two RWC-TVS, acquisitions of images by 3D rendering were made in the sagittal and coronal planes. After storing data file, the two exams were separately analyzed offline by two experienced sonographers, blinded to the results of bidimensional RWC-TVS. The findings of 3D-RWC-TVS with and without bowel preparation were compared with surgical and histological results.

RESULTS: Overall, 31 out of 51 patients (60.8%) had rectosigmoid endometriosis at surgery; 13 women underwent segmental bowel resection, 6 discoid resection, and 12 rectal shaving. 3D-RWC-TVS without previous bowel preparation had a significantly lower performance for diagnosing the presence of rectosigmoid endometriosis than 3D-RWC-TVS with bowel preparation (p=0.046). The sensitivity (SE), specificity (SP), positive predictive value (PPV), negative predictive value (NPV), positive likelihood ratio (LR+) and negative likelihood ratio (LR-) of 3D-RWC-TVS with bowel preparation were 87.1% (95% CI, 70.2-96.4%), 90.0% (68.3-98.8%), 93.1% (78.3-98.1%), 81.8% (64.1-91.9%), 8.7 (2.3-32.6) and 0.1 (0.1-0.4). The SE, SP, PPV, NPV, LR+ and LR- of 3D-RWC-TVS without bowel preparation were 71.0% (52.0-85.8%), 70.0% (45.7-88.1%), 78.8% (64.4-88.1%), 60.1% (45.5-74.3%), 2.4 (1.2-4.8) and 0.4 (0.2-0.8); 3D-RWC-TVS with bowel preparation described more accurately largest diameter and volume of rectosigmoid nodules (p<0.001 and p<0.001). There was no significant difference in diagnosing the presence of multifocal disease between the two exams (p=0.69).

CONCLUSIONS: Before performing 3D-RWC-TVS, bowel preparation may be necessary in order to avoid presence of feces, which may negatively impact the visualization of endometriotic rectosigmoid nodules.

A NOVEL LOW-DOSE COMBINATION DRUG THERAPY FOR ENDOMETRIOSIS THAT INCREASES PROGESTERONE RECEPTOR TO ENHANCE PROGESTIN EFFICACY. Elliott G. Richards, MD, Emily L. Esakov, PhD, Ofer Reizes, PhD. Cleveland Clinic Foundation, Cleveland, OH.

	No Endometriosis			Endometriosis					
				Endometrium			Lesion		
	Prol.	Sec.	*P*	Prol.	Sec.	*P*<	Prol.	Sec.	*P*<
ADK1	1.1±0.1 **[++]**	0.6±0.1 **[++]**	ns	1.2±0.2 **[+++]**	0.4±0.1 **[++]**	0.01	2.2±0.2 **[++++]**	0.9±0.29 **[++]**	0.01
ADK2	1.0±0.1 **[++]**	1.1±0.1 **[+++]**	ns	1.2±0.1 **[+++]**	0.6±0.15 **[++]**	0.01	1.4±0.3 **[+++]**	1.2±0.3 **[+++]**	ns
CD73	0.2±0.8 **[++]**	3.0±1.4 **[+++]**	ns	0.12±0.06 **[++]**	0.4±0.1 **[+]**	ns	1.56±1.46 **[++]**	0.98±0.8 **[+]**	ns

OBJECTIVE: Endometriosis is an estrogen-dependent disease that is a leading cause of pelvic pain and infertility worldwide. While ectopic endometrial tissue should theoretically regress with progesterone treatment, resistance to progesterone is common, limiting the effectiveness of hormonal therapies to treat established disease and to prevent post-surgical disease recurrence. We sought to apply a quality-by-design (QbD) approach to develop a novel sensitizing therapy for endometriosis by targeting progesterone receptor (PR) expression.

DESIGN: Our group has previously successfully utilized a QbD approach to develop a novel combination of clinical compounds to induce estrogen receptor alpha (ESR1) in hormone-positive breast cancer cells to sensitize them to tamoxifen therapy; similar to endometriosis, many types of breast cancer are resistant to hormonal therapies. This QbD approach leverages advanced automation technology and predictive mathematical modeling to investigate the additive and synergistic effects of combinatorial drug treatment on gene expression in immortalized cell lines.

MATERIALS AND METHODS: We selected 12 different compounds that are either known to be involved in sex hormone signaling, used in the treatment of endometrioid ovarian cancer (arising from endometriosis), and/or currently used or under investigation for the treatment of endometriosis. Using our custom-design QbD platform, we measured the relative effects of these compounds, each at concentrations well below their efficacious dose, on a variety of genes in 12Z cells (an immortalized endometriotic cell line).

RESULTS: We identified five drugs (belinostat, celecoxib, everolimus, bentamapimod, and paclitaxel) that in combination have a synergistic effect on PR expression. *In vitro* studies confirmed elevated PR expression in both RNA and protein. After three days of drug treatment on 12Z cells compared to controls, combinatorial drug treatment resulted in a 8.8 fold increase in PR expression levels with no change in ESR1 levels.

CONCLUSIONS: This work offers a novel combinatorial drug therapy and proof-of-concept for endometriosis treatment. It also provides new insight into the mechanisms by which known endometriosis drugs reduce disease burden. Efforts are underway to utilize a mouse model of endometriosis to determine whether this drug cocktail can enhance PR expression and thereby efficacy of progestin therapy. Future work will involve determining the precise molecular pathways by which these drugs act to enhance PR expression.

P-248 4:30 PM Sunday, October 18, 2020

INVESTIGATING THE ROLE OF INFERTILITY IN ENDOMETRIOSIS RISK.

Amber C. Kiser, BS,[1] Alex Henrie, MSc,[1] Karen C. Schliep, PhD, MSPH,[1] C Matthew Peterson, MD,[1] Kurt Peterson, DO,[2] Karen Eilbeck, MSc, PhD[1] [1]University of Utah, Salt Lake City, UT; [2]University of Cincinnati, Cincinnati, OH.

OBJECTIVE: The goal of this study was to provide evidence that the risk of endometriosis is elevated in the presence of other symptoms even when infertility is absent or unknown.

DESIGN: We used electronic health record data from the University of Utah Healthcare enterprise data warehouse (EDW) in a retrospective study. A Bayesian network was developed to calculate the risk of having endometriosis, given the presence of specific comorbidities.

MATERIALS AND METHODS: From the EDW data, International Classification of Diseases, (ICD-10) codes, were used to identify patient conditions. Due to the long diagnostic delay of endometriosis, we included all conditions regardless of temporality. ICD codes most associated with endometriosis in the data and supported by the literature were selected as nodes in the Bayesian network.

The structure and probabilities of the network were learned from the data. Each node of the network represented a condition that could be present, absent, or unknown. Based on the learned conditional probabilities in the network, we calculated an absolute risk (AR) and relative risk ratio (RR) for endometriosis. While the AR indicates the probability of a person having endometriosis, the RR reflects how many times more at risk the patient is compared to the population average.

RESULTS: Data from over 1.6 million patients was included in the analysis with 7785 patients diagnosed with endometriosis. The selected conditions were infertility, dysmenorrhea, pelvic pain, dyspareunia, uterine fibroids, endometrial polyps, pelvic inflammatory disease (PID), irregular menstruation, cervical cancer, abdominal pain, and anxiety disorders. Dysmenorrhea resulted in the highest risk when infertility was absent or unknown.

TABLE. Selected results for relative risk ratio of endometriosis.

Condition Present	Infertility Present	Fertility Unknown	Infertility Absent
Dysmenorrhea	59.6 ± 4.34	50.5 ± 4.64	49.6 ± 3.82
Irregular menstruation	35.9 ± 7.92	49.1 ± 4.92	47.7 ± 3.36
Pelvic pain	75.7 ± 2.34	47.2 ± 3.93	44.8 ± 3.16
PID	76.8 ± 7.99	42.0 ± 3.30	37.8 ± 4.65
Uterine fibroids	51.0 ± 10.3	38.1 ± 9.85	36.8 ± 9.95
Dyspareunia	57.9 ± 4.69	32.1 ± 2.64	29.6 ± 2.07

CONCLUSIONS: Previous studies have supported an association between endometriosis and infertility. Indeed, it is a driving factor in the diagnosis of endometriosis. There is a significant diagnostic delay for endometriosis patients; however, those with infertility have less diagnostic delay. We found the risk for having endometriosis is significantly elevated when other comorbidities are present even when infertility is absent. This study provides evidence that symptomatic patients should be evaluated for endometriosis even when the patient is fertile or the fertility status of the patient is unknown.

IMPACT OF ENDOMETRIOSIS ON SEXUAL LIFE OF WOMEN AND PARTNERS: RESULTS FROM THE ENDOVIE SURVEY.

Pietro Santulli, MD - PHD,[1] Géraldine Giraudet, MD - PhD,[2] Jean-Philippe Estrade, MD,[3] Emilie Indersie, PhD,[4] Céline Solignac, PharmD,[5] Horace Roman, MD - PhD[6] [1]Université Paris Descartes, Sorbonne Paris Cité, Faculté de Médecine, Assistance Publique–Hôpitaux de Paris (AP–HP), Hôpital Universitaire Paris Centre, Centre Hospitalier Universitaire (CHU) Cochin, Paris, France; [2]Hôpital Jeanne de Flandre, CHU de Lille, Lille, France; [3]Clinique Bouchard-Elsan, Marseille, France; [4]EndoFrance association, Dagneux, France; [5]Gedeon Richter France, Paris, France; [6]Clinique Tivoli-Ducos, Bordeaux, France.

OBJECTIVE: Endometriosis affects mostly young, sexually active women during different phases of their sexual life. Symptoms include painful periods, pelvic pain, chronic fatigue and dyspareunia that can lead to negative impact on their sexuality. The objective of this study was to evaluate the

impact of endometriosis on couple's sexual life among women with the condition and their partners.

DESIGN: A prospective cross-sectional web-based survey.

MATERIALS AND METHODS: An online survey was conducted in women suffering from endometriosis from January 15th to February 3rd, 2020. The sample population of women with endometriosis was targeted and investigated through the Ipsos Access Panel that gathers data from 235,171 French subjects (n=803) and EndoFrance, a French non-profit organization for endometriosis (=754). Another online survey was conducted among 100 partners of women with endometriosis throughout the Ipsos AccessPanel. The 2 questionnaires were constructed with the directing committee of the study and aimed to assess experience and perceptions with endometriosis, including the impact of the condition on affective and sexual life as evaluated on a scale of 0 to 10 (0 for very low impact to 10 for very high impact).

RESULTS: The main survey included 1,557 women (33% deep endometriosis, 22% endometrioma, 13% superficial endometriosis). Their average age was 42.2±12.8 years and 70% were in a relationship. The disease had started at an average age of 23.8±10.2 years old. Among first symptoms, 78% experienced painful periods, 66% pelvic pain, 54% chronic fatigue and 50% dyspareunia. Sexual life was the main impacted area of women's lives with an impact rated 5.5±3.5 out of 10; in 48% of the cases the impact was severe ($\geq$ 7). Furthermore, 71% were often/very often confronted with decrease in libido and 58% refrained often/very often from having sexual intercourse for several weeks or even months. The average rating of women for the impact of endometriosis on couple's life was 4.9±3.4 out of 10 and 38% rated scores $\geq$ 7. 568 women (37%) faced often/very often reproaches from their partner concerning their complaints related to their endometriosis and 28% of women report that their partners blame them for not being able to have children. Moreover, 25% of the women felt often/very often the desire to separate from their spouse. Among the 100 partners (92 men and 8 women) surveyed, the impact of endometriosis on sexual life was rated 4.2±3.2 out of 10. Being afraid of hurting their partner during sexual intercourse, having refrained from having sexual intercourse, and being faced with decreased libido were situations often/very often reported by 49%, 24% and 18% of partners, respectively. The impact of endometriosis on their couple's life was rated 3.6±2.8 out of 10.

CONCLUSIONS: The study provided evidence that endometriosis has a main impact on sexual and couple's life in women with the condition but also, although lower, among the partners. Health professionals should consider this important aspect of couples' lives to improve the quality of life of women suffering from endometriosis and that of their partners.

P-250 4:30 PM Sunday, October 18, 2020

FREQUENCY OF AND SWITCHING BETWEEN HORMONAL CONTRACEPTIVES IN WOMEN WITH ENDOMETRIOSIS UP TO 8 YEARS BEFORE DIAGNOSIS.

Stephanie E. Chiuve, ScD,[1] Andrew L. Campbell, MD,[1] Stephanie J. Estes, MD,[2] Amanda Kelly, MS,[3] Michael C. Snabes, MD, PhD,[1] Oscar Antunez Flores, MD,[1] Stacey A. Missmer, ScD[4] [1]AbbVie, North Chicago, IL; [2]Penn State Milton S. Hershey Medical Center, Hershey, PA; [3]Aetion Inc, New York, NY; [4]College of Human Medicine, Michigan State University, Grand Rapids, MI.

OBJECTIVE: Combined estrogen-progestin oral contraceptives (COC) is one of the first-line treatment options for endometriosis, despite limited evidence of efficacy in all types of endometriosis-associated pain. In a small online survey of women with diagnosed endometriosis (N=441; mean age 28), 40% of women had been prescribed 3 or more COCs for relief of endometriosis-associated pain. This may be due to clinician's lack of understanding of effectiveness of COCs in the different types of endometriosis-associated pain, inappropriate application of the "OC failure" concept and the lack of implementation of goal oriented, time bound treatment plans. We aimed to characterize the frequency of and switching between types of COCs and other hormonal contraceptives (HC) within a real-world population of women with endometriosis. Given the well documented multi-year delay between symptom onset and surgical diagnosis, we focused on the 8 years prior to endometriosis diagnosis.

DESIGN: Longitudinal descriptive analysis within an electronic medical records (EMR) database (Optum, 2007-2019).

MATERIALS AND METHODS: We identified 20,179 women with incident endometriosis, defined by ICD code in the medical record, and 8+ years of activity in the EMR system prior to diagnosis. We included 44 individual HC types (mono-, bi-, tri-, quadphasic and extended cycle COCs, progestin only pills, IUDs, implants, injections, rings and patches) captured through written prescriptions, which capture the clinician's "intention to treat". Analyses were stratified by the presence of most common endometriosis-associated pain symptoms, defined by ICD diagnosis code for dysmenorrhea, dyspareunia and pelvic pain.

RESULTS: Mean age at diagnosis was 47 years (5% <25, 17% 25-34, 78% 35+ years) and 71% had presence of pain. Overall, 6180 (31%) women were prescribed at least 1 HC during the 8 years before diagnosis, with a mean of 1.8 (SD: 1.1) types. The frequency of any HC use was higher in women with pain (37.2%) than in women without (14.5%) and in women diagnosed at younger ages (71% in women <25, 58% in women 25-34 and 22% in women 35+ years). The most commonly prescribed HC were monophasic COCs [10 mcg ethinyl estradiol & 1 mg norethindrone (20%); 20 mcg ethinyl estradiol & 0.1 mg levonorgestrel (12%); 35 mcg ethinyl estradiol & 1 mg norethindrone (13%); 35 mcg ethinyl estradiol & 0.25 mg norgestimate (26%)], progestin-IUDs (Mirena; 17%), progestin-only pills (15%) and injections (depoprovera; 18%). Among HC users, 19% of women used $\geq$3 types of HCs (21% of women with pain, 11% of women without) and 7% of women used $\geq$4 types (8% of women with pain, 2% of women without).

CONCLUSIONS: Over 8 years prior to diagnosis, 31% of women with endometriosis used at least 1 HC within the 8 years prior to diagnosis, and this was more common in women with pain symptoms and in women diagnosed at younger ages. Switching between HC types was less frequent than in previous studies, which may be explained by the older age at diagnosis in this real-world data source. Better understanding and implementation of the OC failure concept and goal-oriented time bound approaches are needed.

DOES GNRH DOWN REGULATION AMONGST WOMEN WITH ABNORMAL BCL6 AND/OR BETA 3 INTEGRIN EXPRESSION IMPROVE IMPLANTATION RATES? AN INTERIM ANALYSIS.

Garth Kellogg Summers, DO, Stephanie Gustin, MD, Taylar Lynn Swartz, DO, MPH. The University of Nebraska Medical Center, Omaha, NE.

OBJECTIVE: Does GnRH agonist treatment in patients with abnormal expression of BCL6 and/or beta 3 integrin restore implantation rates to a comparative level with those patients without known endometrial receptivity abnormalities?

DESIGN: A single-institutional, retrospective convenience cohort analysis of 44 patients with recurrent implantation failure was performed comparing patients with abnormal expression of BCL6 and/or beta 3 integrin treated to GnRH agonist therapy versus 39 patients with tubal factor infertility in 2019.

MATERIALS AND METHODS: Patients were identified using CPT diagnostic/billing codes. A manual review of electronic medical records was used to screen for patients that met the inclusion criteria. PC SAS version 9.4 was used for analyses. The statistical level of significance was set to 0.05. The nonparametric Mann-Whitney test was used to compare GnRH agonist versus tubal factor for continuous variables. Fisher's exact tests were used to make comparisons on categorical variables.

RESULTS: After accounting for age, BMI, gravity, parity (p-values of 0.72, 0.59, 0.94, and 0.74 respectively) the only significant descriptive characteristic identified was prior ART (0.003) skewed towards prior treatment in those patients with recurrent implantation failure. Of the 44 patients identified to have recurrent implantation failure, 25 underwent GnRH agonist therapy and subsequent embryo transfer. Of these patients, 21 had successful implantation defined as a positive beta-HCG. Thirty-nine patients were identified to have tubal factor infertility. Within this cohort, 15 underwent embryo transfer resulting in 12 successful implantations.

TABLE 1.

Outcome	Recurrent implantation failure N=25	Tubal factor N=15	P-value
Positive beta-hCG	21 (84%)	12 (80%)	0.9569
Live birth	5 (20%)	7 (47%)	
Currently pregnant (>10wk GA)	8 (32%)	2 (13%)	
SAB	1 (4%)	1 (7%)	
Biochemical pregnancy	4 (16%)	2 (13%)	
Negative beta-hCG	4 (16%)	3 (20%)	

CONCLUSIONS: Endometriosis affects 20-40% of women with infertility and is known to decrease fecundity by approximately 50%. There is a high correlation between elevations of BCL6 and inadequate secretion of beta 3 integrin and a concurrent diagnosis of endometriosis. Further, research has shown that patients with abnormal BCL6 and beta 3 integrin expression have approximately an 18% pregnancy rate in their next transfer attempt versus 70% pregnancy rate in those patients with normal expression.

Our preliminary data suggests that GnRH agonist treatment in patients with abnormal expression of BCL6 and/or beta 3 integrin restores implantation rates to a comparative level with those patients without known endometrial receptivity abnormalities.

PERSISTENCE OF RECTAL ENDOMETRIOSIS FOLLOWING LAPAROSCOPIC SHAVING OF RECTOVAGINAL NODULES INFILTRATING THE RECTUM.

Simone Ferrero, MD, PhD,[1] Carolina Scala, MD,[2] Gloria D'Alessandro, MD,[1] Ennio Biscaldi, MD,[3] Valerio Gaetano Vellone, MD, PhD,[4] Cesare Stabilini, MD, Phd,[5] Umberto Leone Roberti Maggiore, MD, PhD,[6] Fabio Barra, MD[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Istituto G. Gaslini, Genova, Italy; [3]Department of Radiology, Galliera Hospital, Genova, Italy; [4]Anatomic Pathology, Genova, Italy; [5]DISC, University of Genova, Genova, Italy; [6]Department of Gynecologic Oncology, IRCCS National Cancer Institute, Milan, Italy.

OBJECTIVE: While recurrence of deep endometriosis after shaving of rectovaginal endometriosis has been extensively studied, no data exists on the postoperative persistence of rectal endometriosis. The objective of this study was to assess the risk of rectal endometriosis persistence following laparoscopic shaving of rectovaginal nodules.

DESIGN: Prospective cohort study.

MATERIALS AND METHODS: This study included patients who underwent shaving for rectovaginal nodules infiltrating the rectum. During surgery, the pararectal spaces were longitudinally opened to avoid injury of the hypogastric and splanchnic nerves. The diseased rectum was mobilized. The endometriotic nodule was excised by shaving using cold scissors, electrosurgery or the Harmonic scalpel device (Ethicon Endo-Surgery). At 3- and 6-month from surgery, the presence of persistent endometriosis was assessed by rectal-water contrast transvaginal ultrasonography (RWC-TVS). At each follow-up, the patients were asked to rate the satisfaction with treatment that was assessed according to a five-category scale (very satisfied, satisfied, neither satisfied nor dissatisfied, dissatisfied, very dissatisfied). Variations in pain symptoms were assessed using a 10 cm visual analogue scale. Changes in intestinal symptoms were measured using a 0-10-point numeric rating scale.

RESULTS: 96 patients were included in the study. At 3-month follow-up, persistence of rectal endometriosis was observed in 4 patients (4.2%; 95% CI, 1.1%-10.3). The nodules were observed in the area where the rectal shaving was performed; hyperechogenicity of the intestinal wall was observed and, in two patients, it was possible to observe the suture performed after shaving. The mean (± SD) diameter of the persistent rectal endometriotic nodule detected at ultrasonography was 8.7 ± 2.1 mm; its mean (± SD) volume assessed by virtual organ computer-aided analysis was 184.8 (± 117.6) mm^3. Pain and intestinal symptoms were significantly improved by surgery. 29 patients (30.2%) were very satisfied, 52 were satisfied (54.2%), 14 were neither satisfied nor dissatisfied (14.6%), and 1 patient was dissatisfied (1.0%). Among the patients with persistence of endometriosis, three were satisfied and one patient was neither satisfied nor dissatisfied. The 6-month follow-up confirmed the persistence of rectal endometriosis in the 4 patients. The mean diameter of the persistent endometriotic nodule detected at ultrasonography was 8.3 ± 1.5 mm. Concerning the satisfaction with the treatment, 34 patients (35.4%) were very satisfied, 56 were satisfied (58.3%), 5 were neither satisfied nor dissatisfied (5.2%), and 1 patient was dissatisfied (1.0%).

CONCLUSIONS: Persistence of small ultrasonographically detectable rectal endometriotic lesions occurs in approximately 4% of patients undergoing laparoscopic shaving of rectovaginal nodules infiltrating the rectum. Although these patients have significant improvement in pain and intestinal symptoms, their long-term follow-up is required to establish the clinical relevance of persisting rectal endometriosis.

P-253 4:30 PM Sunday, October 18, 2020

EVALUATION OF ENDOMETRIOMA PATHOPHYSIOLOGY AND RELATED OVARIAN DAMAGE BY PTEN / AKT APOPTOSIS SIGNALING PATHWAY.

Furkan Sen, M.D.,[1] Kiper Aslan, M.D.,[2] Goktan Kuspinar, PhD. candidate,[2] Cihan Cakir, M.D., PhD.,[3] Isıl Kasapoglu, M.D.,[1] Berrin Avcı, M.D., PhD,[3] Gürkan Uncu, Prof.[2] [1]Uludag University School of Medicine, Gynecology and Obstetric ART Center, Bursa, CT, Turkey; [2]Bursa Uludag University Faculty of Medicine, Bursa, Turkey; [3]Uludag University School of Medicine, Bursa, Turkey.

OBJECTIVE: To investigate the role and significance of PTEN/AKT apoptosis signaling pathway in the occurrence and changes in ovarian reserve for patients with endometriosis in the manner of ovarian reserve markers.

DESIGN: Prospective Cohort Study.

MATERIALS AND METHODS: This prospective study was conducted at a tertiary University Hospital between May 2019 and April 2020. Patients between 18-38 years old, who underwent cystectomy for benign ovarian pathologies were included in the study. Patients were divided into two groups according to their ovarian pathologies, respectively; endometrioma and the other benign cysts (control). Tissue samples were collected from the cyst wall right after the surgery, and gene expression of PTEN/AKT for the tissue samples were interpreted with real-time PCR analyses. Gene expressions of two groups were compared. Additionally, PTEN/AKT expressions were evaluated between patients with diminished and normal ovarian reserve markers (evaluated with serum Anti-mullerian hormone (AMH) levels and antral follicle counts) for all samples.

RESULTS: A total of 40 age matched patients with endometrioma (n=20), and with the other benign ovarian cysts (dermoid, serous, mucinous, hemorrhagic cyst). (n=20) were included for tissue sample evaluation. The mean (SD) age was 31.1 (±5,8) and 31.2 (±6,0) years in endometrioma and other cyst groups respectively (p:0,937). The mean antral follicle count of the endometrioma group was significantly lower than the control group. (p:0,028). In the Endometrioma group, PTEN expression ratio was higher 1,69-fold than the other group with no statistical significance. For AKT gene expression there was a significant 5,99-fold increase in the endometrioma group ($p<0.01$). When patients totally were divided by diminished versus normal ovarian reserve, the PTEN expression ratio of patients with diminished ovarian reserve was 4,92-fold lower than the normal ovarian reserve group ($p<0.01$) PTEN expression showed a positive correlation with serum AMH levels overall. ($r:0.48$, $p<0.01$).

CONCLUSIONS: The alteration of PTEN expression may be a vital part of the pathological and physiological mechanisms in endometriosis and related diminished ovarian reserve. However, the potential mechanisms underlying abnormal expression the pathway and its role have not been thoroughly elucidated. In this study, AKT expression was found higher in the endometrioma group. Meanwhile, PTEN expression was lower for DOR patients overall. Our results suggest that these expression alterations for the PTEN/AKT apoptosis signaling pathway should be considered for further investigation for the prevention of endometriomas and related ovarian damage.

PAIN AND HEALTH RELATED QUALITY OF LIFE IN WOMEN WITH ENDOMETRIOSIS SCHEDULED FOR IN-VITRO-FERTILIZATION (IVF).

Ahmed M. Abdelmagied, MD,[1] Ahmed M. Abbas, MD,[1] Mohamed F. Aboelnasr, MD,[2] Waleed M. AbdElaziz, MD,[3] Eman ALRefai, EFOG-EBCOG,[4] Amal Y. Zaman, MD,[4] Fawzia Ahmed Habib, MD[4] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Departement of Obstetrics and Gynecology, Faculty of Medicine, Menoufiya

University, Shebin Elkom, Egypt; [3]Department of Obstetrics and Gynecology, Faculty of Medicine,Zagazig University, Zagazig, Egypt; [4]Department of Obstetrics and Gynecology, Faculty of Medicine, Taibah University, Saudi Arabia.

OBJECTIVE: This study aimed to compare health related quality of life (HRQOL) and pain scores between women with endometriosis and disease-free women undergoing IVF.

DESIGN: Prospective observational cohort study.

MATERIALS AND METHODS: Infertile women scheduled for IVF who attended a tertiary assisted conception unit from January 2017 to June 2019 were counseled to complete RAND SF-36 (HRQOL) questionnaire and Visual analogue scale (VAS) for painful symptoms related to dysmenorrhea, dyspareunia and non-cyclic chronic pelvic pain. Participants were counseled to complete the questionnaires in their baseline visit, prior to enrollment in IVF work up. HRQOL questionnaire is an instrument that comprised 8 sub-scales and 2 major component scores; physical (PCS) and mental (MCS) component scores. Consented women were categorized into 2 groups based on endometriosis disease status. Group 1 comprised women with endometriosis, while group 2 included women without evidence of endometriosis (reference group). The HRQOL and VAS scores were compared between the 2 groups at baseline. Comparisons between groups were evaluated utilizing the t-test, Wilcoxon rank sum test, chi-square test and regression analysis as appropriate.

RESULTS: Among 640 women indicated for IVF and screened, only 224 subjects consented to complete the questionnaires. Out of the consented IVF women, 65 subjects (29%) have evidence of endometriosis and were allocated to group 1. Groups 1 and 2 were comparable in age, BMI, duration of infertility, and prior IVF trials. Moreover, group 1 women were more likely to have a surgery/laparoscopy than group 2 (97% vs 66.6%, $p<0.003$). There was a significant trend for lower scores among the 8 subscales of HRQOL in group 1 compared to group 2 ($p<0.001$).
Endometriosis women had significant lower MCS and PCS compared to women without endometriosis (median (IQR);53(18.9)vs.61.3(19.2), $p<0.001$; 50.6(24.4)vs.67.5(23.8),$p<0.001$, respectively). The median of VAS scores for painful symptoms was higher in the endometriosis group ($p<0.001$). The highest scores were reported for dysmenorrhea in endometriosis women compared to the reference group (median (IQR) 8(3) vs.5(3),$p<0.001$). In addition, subgroup analysis according to endometriosis stage demonstrated comparable baseline pain and HRQOL scores between women (n=41, 63.1%) with minimal and mild endometriosis, and women (n=24,36.9%) with moderate and severe disease. Utilizing stepwise multivariable regression analysis, dysmenorrhea was the only painful symptom that was associated with low MCS and PCS (aOR = 1.3,95%CI=1.1 -1.5,$P<0.009$; aOR = 1.3,95%CI=1.1 -1.6,$P<0.005$).

CONCLUSIONS: IVF women with endometriosis have higher baseline pain scores and lower quality of life compared to their disease-free counterparts.

P-255 4:30 PM Sunday, October 18, 2020

IMPACT OF ENDOMETRIOSIS ON PARTNER'S DAILY LIFE : RESULTS FROM THE ENDOVIE SURVEY.

Pietro Santulli, MD - PHD,[1] Géraldine Giraudet, MD - PhD,[2] Jean-Philippe Estrade, MD,[3] Emilie Indersie, PhD,[4] Celine Solignac, PharmD,[5] Horace Roman, MD - PhD[6] [1]Université Paris Descartes, Sorbonne Paris Cité, Faculté de Médecine, Assistance Publique–Hôpitaux de Paris (AP–HP), Hôpital Universitaire Paris Centre, Centre Hospitalier Universitaire (CHU) Cochin, Paris, France; [2]Hôpital Jeanne de Flandre, CHU de Lille, Lille, France; [3]Clinique Bouchard-Elsan, Marseille, France; [4]EndoFrance association, Dagneux, France; [5]Gedeon Richter France, Paris, France; [6]Clinique Tivoli-Ducos, Bordeaux, France.

OBJECTIVE: Endometriosis is a chronic condition which has been shown to negatively impact women's quality of life and may strain couple intimacy. There is scarce evidence about the impact of endometriosis on partners. The objective of this study was to collect perceptions and experiences concerning endometriosis in partners of women suffering from endometriosis.

DESIGN: A prospective cross-sectional web-based survey.

MATERIALS AND METHODS: An online survey was conducted in partners of women suffering from endometriosis from January 21st to 28th, 2020. The investigated sample group (n=100) was taken from a targeted population among the Ipsos Access panel that gathers data from 235,171 French subjects. The 21-point questionnaire was constructed by the directing committee of the study and aimed to assess the impact of endometriosis on partner well-being and daily life, evaluated on a scale of 0 to 10 (0 for very low impact to 10 for very high impact).

RESULTS: The survey included 92 men and 8 women, all partners of a woman suffering from endometriosis. Most of them (78%) were at least 45 years old and had been in the relationship for over 13 years (63%). For 75%, the diagnosis of the partner's endometriosis was made after the start of the relationship. Upon diagnosis of endometriosis, the dominant feelings in partners were concern, understanding and compassion but 17% also reported negative feelings such as embarrassment or disgust. Half of them considered that, for their partner, they were the only person that they could count on but 40% reported also having had negative feelings towards their partner.

The average rating for impact of endometriosis on sexual and couple's life were 4.2±3.2 and 3.6±2.8 out of 10, respectively. Furthermore, 49% declared being often/very often afraid of hurting their partner during sexual intercourse, 44% were confronted with a decrease in their partner's libido and 18% with their own decrease in libido. 24% reported having often/very often refrained from having sexual intercourse, and 15% abstained from planning to have a child. The psychological impact, the impact on leisure and on relationships with friends and family were less significant with an average rating of 3.3±2.2, 2.7±2.8 and 2.0±2.5 out of 10 respectively. Endometriosis also had an impact on partner's emotions with 26% reporting that they often/very often did not understand the expectations of their partners during pain associated with endometriosis and 19% feeling guilty about blaming their partner. Within the couple, 21% considered that endometriosis was taboo, the subject was raised less than once a month by 43% of couples, or even never for 8%.

CONCLUSIONS: This study provides new insights concerning impact of endometriosis on partners of women who suffer from this disease and demonstrate that endometriosis has a significant effect on their sexual and couple's life. This study highlights the need of greater awareness on partner impact of endometriosis and the importance of counseling both partners in the management of endometriosis.

SUPPORT: Financial support of the ENDOVIE survey was provided by Gedeon Richter France.

P-256 4:30 PM Sunday, October 18, 2020

ENDOMETRIAL STAINING FOR CD138 AS A MARKER OF CHRONIC ENDOMETRITIS DOES NOT PREDICT FAILED IMPLANTATION.

Nola S. Herlihy, MD,[1] Shiny Titus, PhD,[1] Cynthia S. Scott,[2] Amber M. Klimczak, MD,[1] Brent M. Hanson, MD,[1] Julia G. Kim, MD, MPH,[1] Ashley W. Tiegs, MD,[1] Emily K. Osman, MD,[1] Emre Seli, MD,[1] Richard Thomas Scott, Jr., MD[1] [1]IVI RMA New Jersey, Basking Ridge, NJ; [2]Foundation for Embryonic Competence, Basking Ridge, NJ.

OBJECTIVE: Chronic endometritis, diagnosed by endometrial biopsy and analysis for plasma cells, has been implicated as a cause of implantation failure. Staining for CD138, an antigen specific to plasma cells, is the current standard for diagnosis. Previous studies examining chronic endometritis and pregnancy outcomes included patients treated with antibiotics prior to transfer and those who transferred embryos of unknown ploidy status. The aim of this study was to examine the prevalence of plasma cells in patients who underwent endometrial biopsy with no subsequent intervention prior to euploid single embryo transfer (SET) to determine if the presence of plasma cells predicts failed implantation.

DESIGN: Case-control study.

MATERIALS AND METHODS: Endometrial biopsies were obtained from patients undergoing IVF at the time of retrieval. Paraffin embedded endometrial sections were stained using mouse mono-clonal antibody for CD138 (B-A38, Sigma), with tonsil tissue known to contain plasma cells serving as a positive control. Two independent reviewers examined five randomly selected HPFs in each sample, and the results were averaged. Patients underwent euploid SET in a subsequent cycle. Sustained implantation (SI) was defined as fetal heartbeat at discharge. Logistic regression was used to determine if there were significant differences in implantation rates based on presence or absence of CD138.

RESULTS: Fifty-six patients were included, n=28 with SI and n=28 with failed implantation (Table 1). Patient age, baseline AMH and FSH, BMI, day of blastulation and embryo morphology were not significantly different between groups. There was no difference in mean number of plasma cells/HPF between those who sustained implantation and those who did not. Only a minority of samples demonstrated $\geq$ 1 plasma cell per HPF.

CONCLUSIONS: The majority of patients who underwent CD138 staining for plasma cells exhibited at least one plasma cell in five randomly selected HPFs, indicating that some plasma cells are present in women with normal endometrial receptivity. Further analysis is needed to determine what, if any, threshold of plasma cells is associated with decreased implantation.

TABLE 1. Comparison of age, ovarian reserve, embryo quality, and prevalence of plasma cells between patients with and without SI.

	No implantation (n= 28)	Sustained implantation (n=28)	p value
AGE (mean, SD)	34.1 ± 3.8	33.9 ± 4.2	NS
Day 3 FSH (mean, SD)	7.2 ± 1.6	6.7 ± 1.8	
AMH (mean, SD)	3.7 ± 2.1	4.7 ± 3.5	
BMI (mean, SD)	26.0 ± 4.6	26.5 ± 4.4	
Day 5, 6, 7 Blasts	36%, 53%, 11%	36%, 61%, 3%	
Mean # of plasma cells/HPF	0.5 ± 0.4	0.4 ± 0.3	
No plasma cells	2/28 (7%)	5/28 (18%)	
0.1-0.9 plasma cells/HPF	22/28 (79%)	21/28 (75%)	
≥1 plasma cell/ HPF	4/28 (14%)	2/28 (7%)	

P-257 4:30 PM Sunday, October 18, 2020

CHRONIC ENDOMETRITIS (CE) BY CD138 IN AN INFERTILE POPULATION: A NON-SELECTION STUDY DISCOVERING BASELINE PREVALENCE AND EFFECT ON EARLY EUPLOID EMBRYO IMPLANTATION.

Jennifer K. Blakemore, MD,[1] David L. Keefe, M.D.,[2] David H. McCulloh, Ph.D.,[3] Alexis Masbou, MD,[4] James A. Grifo, MD, PhD[5] [1]NYU Langone School of Medicine, New York, NY; [2]New York University School of Medicine, Department of Obstetrics and Gynecology, New York, NY; [3]NYU Langone Fertility Center, New York, NY; [4]Kofinas Fertility Group, New York, NY; [5]New York University, New York, NY.

OBJECTIVE: The diagnosis and management of CE is debated[1-4]. Since many patients undergoing assisted reproductive technology (ART) are only tested after treatment failure, definitive management remains imprecise. The objectives of this study were to 1) determine the prevalence of CE in infertility patients and 2) the impact of CE on euploid embryo implantation.

DESIGN: Prospective, blinded, non-selection study of patients undergoing IVF/PGT-A.

MATERIALS AND METHODS: All IVF/PGT-A patients cycling between 6/2019 - 3/2020 were eligible. Exclusion criteria were: 1) age 42+, 2) embryo banking/not planning ET, 3) planning untested/fresh/mosaic ET. Consented subjects underwent a standardized endometrial biopsy (EMB) at retrieval. EMB results by a single laboratory were blinded until after single euploid ET resulted in 1) +heartbeat, 2) confirmed SAB or 3) negative hCG. Primary outcome was 1) presence/absence of CE, defined as 1+ plasma cell by CD138/section and 2) ongoing pregnancy rate. Secondary outcomes included number of plasma cells/section and stratified pregnancy outcomes. Power analysis for a prevalence of 20%[5] with a 95% confidence = 246 subjects. Statistical analyses included Student's t-test, Fischer's Exact, logistic regression with $p<0.05$ considered significant.

RESULTS: 104 subjects consented and underwent EMB. Seven withdrew after EMB with 97 eligible for FET. In all biopsied patients, the mean age was 36.1±3.2 years (range 28-41), 66.4% identified as Caucasian, and the most frequent infertility diagnosis was primary/unexplained infertility (42.3%). On 3/17/20, in compliance with ASRM's COVID recommendations, all IVF/FET cycles and recruitment stopped, at which time 54/97 had undergone FET/unblinding. There were no differences in age (p=0.83), distribution of race/ethnicity (p=0.57) or infertility diagnoses (p=0.77) between transferred and untransferred patients. Due to COVID cycle stop, unblinded biopsies were reviewed for result only (not unblinded), showing 25/104 biopsies (24.0%) positive for CE with plasma cells ranging 1-34. Demographics of transferred patients showed 46 (85.2%) had a programmed ET, 50 (92.6%) with a grade 3-5Bb or higher, and a median time to ET of 56 days. Overall, 39 (72.2%) had an ongoing pregnancy. 20.4% (11/54) had CE with plasma cells ranging 1-14. Subjects with CE had an ongoing pregnancy rate of 63.6% (7/11) that was not significantly different than 74.4% (32/43) in those subjects that were CE negative (p=0.48). Logistic regression showed no difference in ongoing pregnancy when stratified by cycle type, time to ET, lining thickness, embryo day or grade, and plasma cell count. To date, the SAB rate after implantation was similar (2/7 CE positive vs. 1/32 in CE negative, p=0.07). Notably, plasma cell count had an AOR 0.822 (0.668-1.01) and the only 2 SABs seen in patients with CE had plasma cell counts >10.

CONCLUSIONS: We found a baseline prevalence of roughly 24.0% in ART patients that, to date, did not affect the ongoing pregnancy rate. Further analysis with a larger cohort to examine 1) the SAB rate, 2) alternative definitions of CE, and 3) the impact of COVID are necessary.

THE ASSOCIATION OF ADENOMYOSIS WITH UTEROPLACENTAL INSUFFICIENCY AND PREECLAMPSIA IN WOMEN UNDERGOING ICSI CYCLE. Can Benlioglu, M.D., Erkan Kalafat, M.D., Yavuz Emre Sukur, M.D., Batuhan Ozmen, Professor, Murat Sonmezer, M.D., professor, Cem Somer Atabekoglu, Professor. Ankara University, Turkey.

OBJECTIVE: To explore the association of adenomyosis with maternal and perinatal outcomes in women undergoing ICSI.

DESIGN: Prospective cohort study over a 2-year period between 2018 and 2020.

MATERIALS AND METHODS: Women with ongoing pregnancy (>20 weeks) after ICSI were included. Exclusion criteria were oocyte donation cycles, high-order pregnancies and women with uterine fibroids, hydrosalpinx, or stage 3-4 endometriosis according to revised AFS criteria. Adenomyosis was diagnosed according to MUSA group consensus statement. The analysis groups were divided into women with and without adenomyosis. The primary outcomes were prevalence of preeclampsia and composite adverse perinatal outcomes (small-for-gestational age at birth, neonatal care unit admission, asphyxia, preeclampsia, preterm delivery). Secondary outcome was the difference of uterine artery Doppler pulsatility index between two groups. Group comparison of primary and secondary outcomes were performed using Bayesian inference methods (Metropolis Hastings MCMC) with vague priors due to limited sample size. The results were reported as mean difference between the groups, 95% credible intervals (CrI) and the probability of significant difference. Additional results were reported via frequentist statistical methods.

RESULTS: There were 486 ongoing ICSI cycles during the study period and 101 (20.8%) ongoing pregnancies were eligible for inclusion. The adenomyosis prevalence was 18.8% (19/101). The prevalence of preeclampsia (21.1 vs. 13.4%) and composite adverse perinatal outcomes (63.1 vs. 42.7%) were higher in women with adenomyosis. Bayesian analysis showed the probability of preeclampsia (probability 84.1%, mean difference: 7.7%, 95% CrI: -11.7%-27.2%) and composite adverse perinatal outcomes (probability 99.5%, mean difference: 29.6% 95% CrI: 7.3%-51.8%) could be higher in women with adenomyosis compared to those without. First trimester mean uterine artery pulsatility index was higher in women with adenomyosis compared to those without (probability: 99.5%, mean difference: 0.32, 95% CrI: 0.07 to 0.57). Results of additional adverse pregnancy and neonatal outcomes are available in Table 1.

CONCLUSIONS: Women with adenomyosis show signs of uteroplacental malperfusion during the first trimester and possibly have an increased risk of preeclampsia and composite adverse perinatal outcomes.

Adverse Outcome	Adenomyosis (number, percentage)	Control (number, percentage)
Preeclampsia	4 (21.1)	4 (13.4)
SGA at birth	7 (36.8)	9 (10.9)
Preterm Delivery	8 (42.3)	15 (18.3)
NICU admission	7 (36.8)	7 (8.5)
Asphyxia	2 (10.5)	2 (2.4)

SUPPORT: None.

IMPACT OF ENDOMETRIOSIS ON ANXIETY, DEPRESSION AND QUALITY OF LIFE AND ITS ASSOCIATION WITH PREGNANCY OUTCOMES IN INFERTILE PATIENTS AT A TERTIARY LEVEL INFERTILITY CENTRE IN INDIA. Kanad Dev Nayar, M.D., DGO., FICOG, Poonam Nayar, Ph.D, Shweta Gupta, MD, MRCOG, Minal Singh, DGO, DNB, Ratnaboli Bhattacharya, MD, DNB, FNB, MRCOG, Gaurav Kant, M.Sc, Rahul Gahlot, M.D., Dip. Clinical Embryology, Kapil Dev Nayar, MBBS. Akanksha IVF Centre, Delhi, India.

OBJECTIVE: Endometriosis is one of the most common gynecological diseases and affects around 30-50 % of women with infertility. Symptoms of endometriosis as well as infertility often affect psychological and social functioning of patients. The current study was undertaken to assess the level of psychological distress in infertile patients with and without endometriosis. Screening and management should be considered during routine assessment since neglect of mental health might have negative impact on couple‘s infertility treatment and outcomes. The aim of the current study was to evaluate if infertile patients with endometriosis have increased levels of anxiety,

depression and poor quality of life parameters when compared to endometriosis free infertile controls and if it affects pregnancy outcomes.

DESIGN: A single centre cross sectional study was carried out at a tertiary care infertility centre in India from 1st January 2019 through 31st December 2019.

MATERIALS AND METHODS: Three hundred patients consented to participate in the study. One hundred and fifty infertile patients with endometriosis (Group A) were matched with 150 endometriosis free infertile controls. (Group B).For assessing levels of anxiety and depression Hamilton's Rating Scales (HAM-A, and HAM-D) were used. Core Fertility and Quality of Life Questionnaire (FertiQoL) was used to index the quality of life. Primary outcomes were the prevalence of anxiety& depression in infertile patients with and without endometriosis and secondary outcome was the quality of life and its association with pregnancy outcomes (clinical pregnancy rates and live birth rates) in the two groups.

RESULTS: The baseline prevalence of anxiety in (Group A) was 42% and in (Group B) was 29.33% ($p>0.05$);baseline prevalence of depression in infertile patients with endometriosis(Group A) was 40% and in endometriosis free infertile controls(Group B) was 28%($p>0.05$), both were statistically significant. The HAM-A scores and HAM-D scores in infertile patients with endometriosis (Group A) and endometriosis free infertile controls (Group B)(14.48±6.34vs. 12.78±7.65 [t=2.095 ; p= <0.05,] 13.84±6.12 vs. 12.34±6.67 [t=;2.029 p <0.05]) the difference was statistically significant.

There was a statistically significant difference in Ferti QoL scores between the two groups (46.06±11.03,72.15±14.65 t = 17.42 $p<0.05$). QoL scores were significantly and positively associated with pregnancy outcomes (i.e., clinical pregnancy rate($p<0.05$), live birth rate ($p<0.05$).

CONCLUSIONS: Endometriosis with Infertility is a complex disorder with psychological distress which is much greater than in Endometriosis free infertile controls. Clinicians should routinely evaluate infertile patients with endometriosis from a mental health perspective. Psychotherapy and pharmacotherapy would help improve quality of life thus helping patients cope up with financial and emotional burden of their treatment and will also help to improve overall pregnancy outcome of the ART treatment.

PELVIC INFLAMMATORY DISEASE IS AN AGGRAVATING FACTOR ON ENDOMETRIOSIS WOMEN DEVELOPING OVARIAN CANCER: A STUDY OF 2-MILLION-SAMPLE LONGITUDINAL HEALTH AND WELFARE DATABASE IN TAIWAN.

Hui-Wen Lo, MD,[1] Cheng-Yang Hsu, MD,[1] Eing-Mei Tsai, MD, PhD[2] [1]Kaohsiung medical university hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University, Taiwan.

OBJECTIVE: Previous studies have mentioned the links between endometriosis or pelvic inflammatory disease and ovarian cancer. Recently evidences have also showed endometriosis associated with ovarian cancer might depend on chronic inflammation and impaired immune surveillance. Besides, few studies have mentioned that inflammation might cause relationship between microbiota and ovarian cancer. However, the role of microbiota is still unclear on ovarian cancer. Due to above reasons, we have analyzed the interaction between endometriosis and pelvic inflammatory disease for identifying the risk of ovarian cancer.

DESIGN: A retrospective study with a 2-million-sample longitudinal health and welfare database, cancer register and death registry in Taiwan.

MATERIALS AND METHODS: Selecting patients who are diagnosed as endometriosis or pelvic inflammatory disease between January 2000 to December 2015 from a 2-million-sample longitudinal health and welfare database. The exclusion criteria are patients with previous cancer history before endometriosis or pelvic inflammatory disease diagnosis.

Five groups are divided on women with endometriosis, pelvic inflammatory disease, endometriosis first then pelvic inflammatory disease, pelvic inflammatory disease first then endometriosis later, and health women. We used to two steps for preventing potential confounding factors and bias. One step was using propensity score matching (PSM) and another step was applying with inverse probability of treatment weighting (IPTW). The logistic regression model was applied for occurrence event of ovarian cancer.

RESULTS: Women with endometriosis or pelvic inflammatory disease in Taiwan have increased risk for development of ovarian cancer compared with health women. The ovarian cancer risk is higher on women with endometriosis and pelvic inflammatory disease compared with other groups (endometriosis, pelvic inflammatory or health women, $P<0.001$). The developing malignancy rate is also higher compared with endometriosis groups.

CONCLUSIONS: Our data show women with endometriosis and pelvic inflammatory disease have increased risk for development of ovarian cancer. This finding might match not only the concept of pre-cancer but also the inflammation on microbiota on pelvic cavity.

IDENTIFICATION OF TRANSCRIPTOMIC CHANGES TO EUTOPIC ENDOMETRIUM BY PRESENCE OF ENDOMETRIOTIC CYSTS – HARNESSING THE POWER OF EXISTING NONHUMAN PRIMATE DATASETS.

Cecily Vauna Bishop, Ph.D.,[1] Fangzhou Luo, BS,[2] Lina Gao, Ph.D.,[1] Suzanne S. Fei, Ph.D.,[1] Ov D. Slayden, PhD[3] [1]Oregon National Primate Research Center, Oregon Health & Sciences University, Beaverton, OR; [2]Oregon National Primate Research Center, Beaverton, OR; [3]Professor, Beaverton, OR.

OBJECTIVE: To identify significant changes to eutopic endometrium by presence of endometriotic cysts, removing confounding effects of hyperandrogenemia (T) and/or western style diet (WSD). Increased susceptibility to endometriosis was previously reported in a cohort of rhesus monkeys following treatment with mild hyperandrogenemia in the presence/absence of WSD [1].

DESIGN: Retrospective analysis of an existing non-human primate RNA-seq dataset.

MATERIALS AND METHODS: Details of treatment of rhesus macaques within this cohort are published [2]. Following 4.5 years of treatment Tru-cut biopsies were obtained in the secretory phase to collect endometrial tissue. RNA was extracted, and paired-end sequencing was performed followed by analyses of contrasts Control (C) vs T, WSD vs T+WSD and T vs T+WSD groups (n=4-6/group [3]), and between endometriosis Stages 0-II (n=16), and females with mild (Stage III) to moderate (Stage IV) endometriosis diagnosed at/within 6 months of biopsy (n=6) to detect significantly altered RNAs (Differentially Expressed RNAs (DEs)). Venn Diagram analyses were used to identify lists of gene products unique to contrast of Stages 0-II vs III&IV, and overlap between these three lists, followed by PANTHER gene ontology enrichment analyses.

RESULTS: 2,171 DE RNAs were altered in the eutopic endometrium of females with advanced stages of endometriosis. A previous analysis found the greatest number of gene products identified by contrasts of T vs T+WSD, WSD vs T+WSD, and C vs T [3]. Venn diagram analyses identified 164 DEs associated with advanced endometriosis found in C vs T contrast DEs, 386 of T vs T+WSD DEs, and 57 of WSD vs T+WSD. Removing these potentially confounding gene products resulted in 2007, 1785, and 2114 RNAs remaining in contrasts of Stages 0-II vs III&IV (Advanced endometriosis DEs), with 77% overlap. Enrichment of gene products in WNT-signaling (21-fold, p=0.02) and CCKR signaling (13-fold, p=0.03) pathways, monoamine transmembrane transporter activity (7-fold, p=0.02), and inosine monophosphate metabolic process (5-fold, p=0.037) were identified. Underrepresented processes included innate immune responses (p=7.8E-4) and cytokine activity (p=0.03).

CONCLUSIONS: This analyses show conversely, if confounding gene processes associated with T and/or WSD are removed from the dataset, a suppression of normal immune function within the eutopic endometrium of

females with more advanced stages of endometriosis. This could aid in disease progression. Funded by P50-HD071835 (ODS), and P51-OD011092 (ONPRC).

ADENOMYOSIS AND PERITONEAL ENDOMETRIOSIS EXHIBIT A CLONAL RELATIONSHIP WITH EUTOPIC ENDOMETRIUM. Maria Facadio Antero, MD,[1] Lihong Li, MD,[2] Tiffany Chu, BS,[2] Leslie Cope, PhD,[2] Tian-Li Wang, MD,[2] Ayse Ayhan, MD, PhD,[2] Tamer A. Seckin, MD,[3] James H. Segars, MD,[4] Ie-Ming Shih, MD, PhD[2] [1]John Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Lenox Hill Hospital/Northwell Health System, New York, NY; [4]Johns Hopkins University School of Medicine, Baltimore, MD.

OBJECTIVE: To determine if their is a clonal relationship between ectopic and eutopic endometrium in patients with adenomyosis and endometriosis.

DESIGN: Whole exome sequencing analysis.

MATERIALS AND METHODS: This was a retrospective study where formalin-fixed parrafin-embedded tissue blocks were obtained from patients undergoing gynecological surgery for endometriosis and adenomyosis from 2014-2018 at Johns Hopkins Hospital. The diagnoses were validated by an independent pathologist upon reviewing H&E slides. Using laser capture microdissection, the stromal and epithelial components for both ectopic and eutopic endometrium were separated. Whole exome sequencing was performed to analyze the somatic mutations in glandular epithelium and stroma separately in paired adenomyosis, peritoneal endometriosis and matched endometrium to infer their clonal relationship. To determine somatic sequence mutations, matched normal-appearing smooth muscle, fallopian tube or colonic epithelium were also analyzed and acted as controls.

RESULTS: We found somatic mutations in epithelium and stroma of all tissue types. Cancer-driving mutations were only found in the epithelium. Based on somatic mutations, we demonstrated clonal development not only in epithelial but stromal components in adenomyosis and peritoneal endometriosis, with a distribution of mutant allele frequency suggestive of mono-clonality. Alongside private mutations, both lesions in either epithelial or stromal parts shared the same selection-neutral mutations as matched endometrium in most of informative cases, indicating a derivation from the same founder progenitor cells in the endometrium.

CONCLUSIONS: Our data demonstrate that adenomyosis, peritoneal endometriosis and ectopic endometrium are progenies from an ancestral endometrial progenitor cell following distinct evolutionary trajectories.

P-266 4:30 PM Sunday, October 18, 2020

A PROSPECTIVE PILOT ULTRASONOGRAPHIC STUDY TO EVALUATE IMPACT OF PREGNANCY ON CHARACTERISTICS OF DEEP INFILTRATING ENDOMETRIOSIS AND ENDOMETRIOMAS. Fabio Barra, MD,[1] Carolina Scala, MD,[2] Gloria D'Alessandro, MD,[1] Simone Ferrero, MD PhD[1] [1]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [2]Istituto G. Gaslini, Genova, Italy.

OBJECTIVE: Hormonal environment may impact the appearance of endometriotic lesions during pregnancy. The objective of this study is to evaluate the change of ultrasonographic features of deep infiltrating endometriosis (DIE) and endometriomas after delivery in pregnant women.

DESIGN: This was a prospective single-center study.

MATERIALS AND METHODS: Spontaneous pregnant women with a previous ultrasonographic diagnosis of endometriosis were included in this prospective study. Women did not have received hormonal drugs for endometriosis for at least three months before the last ultrasound evaluation of endometriosis. The ultrasonographic characteristics of endometriotic nodules were compared between the evaluation performed before conception and that performed at 40-60 days after delivery by a single experienced operator. The following locations of DIE were evaluated: uterosacral ligament, vagina, bladder, rectovaginal septum, and rectosigmoid. Changes in the volume were assessed by using the virtual organ computer-aided analysis (VOCAL).

RESULTS: A total of 34 patients (61 DIE lesions; 22 endometriomas) were included; the mean (±SD) age of the study population was 33.4 (±2.8). The mean overall volume of DIE nodules was not significantly different before pregnancy compared to after pregnancy regardless of their localization (2.67 ± 3.42 cm^3 vs. 2.39 ± 2.63 cm^3; p=0.22). The mean volume of the largest nodule of each woman was not significantly different (3.13 ± 3.62 mm^3 vs. 3.09 ± 4.43 mm^3; p=0.29). The volume of DIE lesions decreased in 21.3% (n=13/61), was stable in 75.4% (n=46/61), and increased in 3.4% (n=2/61) of cases. The volume of endometriomas was significantly higher before pregnancy (3.22 ± 2.83 mm^3 vs. 2.56 ± 2.71 mm^3; p<0.001). The ultrasonographic appearance of DIE and endometriomas did not significantly change. During the pregnancies, patients did not experience complications related to endometriosis.

CONCLUSIONS: Women affected by endometriosis do not have a substantial change in dimension and characteristics of DIE lesions during pregnancy. Differently, they have a significant decrease in size of endometriomas.

P-267 4:30 PM Sunday, October 18, 2020

INSTAGRAM USERS' CONTENT ON ENDOMETRIOSIS- DOES ENDOMETRIOSIS AWARENESS MONTH MAKE A DIFFERENCE? Andrea M. Gochi, MS, Noelle Coen, BS, Shaokui Ge, PhD, Mallory A. Stuparich, MD, Samar Nahas, MD, Sadikah Behbehani, MD. UC Riverside School of Medicine, Riverside, CA.

OBJECTIVE: To quantitatively compare Instagram user content before and during Endometriosis Awareness Month.

DESIGN: cross sectional study.

MATERIALS AND METHODS: The first 7 public Instagram posts using the hashtag #endometriosissurgery that fit inclusion criteria were evaluated daily in March- Endometriosis Awareness Month (EAM) (n=217) and the month prior- February (n= 202). Posts were reviewed for the following content: "endo" in the Instagram account name, emotional content, educational content, outcomes of surgery, complications of surgery, posted questions, medical history, symptoms pre-operation, posted pictures, fertility, medications, comfort in pets, alternative therapies, and number of Instagram followers. The association of each categorical variable and time period (before or during EAM) was evaluated by Chi-square test, and the number of followers of each Instagram account that posted was tested by Poisson Univariate regression.

RESULTS: When compared to the month prior to EAM, there were more posts that had both educational (66 [30.41%] vs 25 [12.38%], OR= 3.09, p <0.0001) and emotional content (114 [52.53%] vs 59 [29.21%], OR= 2.68, p< 0.0001) made during EAM, respectively. In contrast, posts during EAM were less likely to comment on surgical outcomes (20 [9.22%] vs 82 [40.58%], OR= 0.15, p<0.0001) and personal medical history (12 [5.53%] vs 59 [29.21], p<0.0001, respectively) when compared to the month prior. In addition, posts during EAM were made by Instagram accounts with more followers (averaged 1796 with SD of 4621) than posts made during the previous months (averaged 1413 with SD of 2540, p<0.0001). Compared to the number of followers in posts made by Instagram accounts in February, the number in EAM increased 1.27 times (p<0.0001), on average. There were no differences noted in the other variables.

CONCLUSIONS: Instagram content posted during EAM includes more emotional (OR= 2.68) and educational (OR= 3.09) content when compared to the month prior to EAM. Furthermore, Instagram accounts with more followers appear to be more active during EAM, as opposed to the month before. These results illuminate the discrepancy between the content posted before and during EAM and highlights the need for consistent visibility and awareness of endometriosis throughout all months, which may improve the education of and emotional support to women undergoing surgery for endometriosis.

P-268 4:30 PM Sunday, October 18, 2020

IMPACT ON WOMEN WITH ENDOMETRIOSIS AND PELVIC INFLAMMATORY DISEASE ON ENDOMETRIAL CANCER DEVELOPMENT: A RETROSPECTIVE COHORT STUDY IN TAIWAN. Cheng-Yang Hsu, MD,[1] Hui-Wen Lo, MD,[2] Eing-Mei Tsai, MD, PhD[1] [1]Kaohsiung medical university hospital, Kaohsiung, Taiwan; [2]Kohsiung Medical University, Kaohsiung, Taiwan.

OBJECTIVE: Endometrial cancer is thought association with endometriosis or pelvic inflammatory disease by previous studies. The possible explanations on endometriosis and endometrial cancer are genetic mutation and imbalanced hormone receptor expression. Recently, the role of vaginal microbiota modulation on endometrial hyperplasia or cancer is focused on the oestrogen changes. For evaluating the impact of vaginal microbiota modulation on endometriosis women, we design this retrospective study.

DESIGN: A population-based study using a 2-million-sample longitudinal health and welfare database, cancer register and death registry in Taiwan.

MATERIALS AND METHODS: From 2-million-sample longitudinal health and welfare database, the inclusion criteria is patients who match the diagnosis as endometriosis and/or pelvic inflammatory disease between January 2000 to December 2015. The exclusion criteria is patients who have cancer history before endometriosis or pelvic inflammatory disease before. They would divided into 4 groups: endometriosis, pelvic inflammatory disease, endometriosis and pelvic inflammatory disease, and healthy women. For decreasing potential confounding factors and bias, we used propensity score matching (PSM) and inverse probability of treatment weighting (IPTW). The logistic regression model was applied for occurrence event of endometrial cancer.

RESULTS: Increasing risk of endometrial cancer is found on women with endometriosis and pelvic inflammatory disease in Taiwan. The risk is significantly higher compared to endometriosis, pelvic inflammatory disease, or healthy women groups (p<0.001).

CONCLUSIONS: Women with endometriosis and pelvic inflammatory disease have increased risk of developing endometrial cancer. This finding might match the concept of hormone changes and vaginal microbiota modulation on women with endometriosis and pelvic inflammatory disease.

PREDICTED LEVELS OF PREOPERATIVE ANTI-MULLERIAN HORMONE IN WOMEN WITH ENDOMETRIOSIS-ASSOCIATED INFERTILITY. William Butler, MD, Sarah E. Byrd, MD, Kelly JANE. Tipton, MD, Kristina C. Hawkins, MD, Abdelmoneim Younis, DVM, PhD HCLD, Mercer University School of Medicine, MACON, GA.

OBJECTIVE: The aim of the study is to examine correlation of preoperative AMH level with the diagnosis of endometriosis and reproductive outcome achieved in women undergoing laparoscopy for pelvic pain or infertility.

DESIGN: IRB approved retrospective study using univariate analysis to compare age corrected AMH values with stages of endometriosis and pregnancy outcomes of women who presented with a complaint of infertility and were found to have endometriosis at the time of laparoscopic evaluation.

MATERIALS AND METHODS: A chart review was performed in patients who chose to undergo laparoscopic evaluation for tubal/peritoneal factors as a potential cause of their infertility and who attempted to achieve pregnancy after surgery. 338 subjects, who had AMH levels measured with normal or induced ovulation, normal male factor and patent Fallopian tubes were identified. Clinical pregnancy rates were determined after spontaneous and COH/IUI cycles within one year. Stages of endometriosis and age corrected AMH levels were compared using analysis of covariance. Race, gravidity/parity, and presence or absence of polycystic ovarian syndrome (PCOS) were additional variables included in the analysis model. All statistical evaluation was performed using SPSS.

RESULTS: Mean AMH values with SD, pregnancy rates and endometriosis status for selected ages of patients with or without PCOS is shown in Table 1. Regardless of the presence of PCOS or not, AMH levels were significantly (P<0.05) lower in patients with endometriosis than aged matched no endometriosis. Clinical pregnancy rates were significantly better in patients without endometriosis (<0.005). Presence of PCOS had a statistically significant effect on AMH values within age groups.

CONCLUSIONS: Women with endometriosis with or without PCOS have lower aged matched AMH levels, suggesting decreased ovarian response, as indicated by the significantly reduced cumulative pregnancy rates. The study

TABLE 1. Predicted AMH values & Clinical Pregnancy rate for selected ages based upon presence or absence of endometriosis & PCOS

Age	No Endometriosis & No PCOS (N=104)	Endometriosis (N=175)	Endometriosis & PCOS (N=36)	No Endo with PCOS (N=23)
< 25 yrs	3.48 ± 2.2 (6)	2.26 ± 1.5 (9)	5.26 ± 4.22 (6)	8.01 ± 6.84 (7)
25-34 yrs	2.48 ± 1.31 (46)	2.07 ± 1.26 (55)	8.36 ± 7.35 (9)	5.17 ± 4.47 (14)
35-40 yrs	1.50 ±0.25 (42)	0.87 ± 0.28 (16)	6.44 ± 1.11 (3)	3.77 ± 0.88 (2)
>41 yrs	0.67 ± 0.50 (10)	0.42 ± 0.63 (1)	0	0
Clinical Pregnancy (%)	61.5% (64/104)	42.9% (75/175)	50.0% (18/36)	82.6% (19/23)

clearly indicate that endometriosis is linked with decline AMH levels and clinical pregnancy suggesting adverse effects of the disease process in reproductive function and ovarian reserve.

P-270 4:30 PM Sunday, October 18, 2020

THE IMPACT OF ENDOMETRIOSIS ON EMBRYO MORPHOKINETICS. Natalia C. Llarena, MD,[1] Tommaso Falcone, M.D.,[2] Nina Desai, Ph.D., HCLD[3] [1]Cleveland Clinic Foundation, Cleveland, OH; [2]cleveland Clinic, cleveland, OH; [3]Cleveland Clinic, Beachwood, OH.

OBJECTIVE: Data suggest that women with endometriosis have impaired oocyte and embryo quality, and higher rates of abnormal embryo development. Time-lapse microscopy (TLM) provides a uniquely detailed perspective on embryonic development and allows for quantitative evaluation of cell cycle parameters. The objective of this study is to compare kinetic parameters between embryos derived from women with and without endometriosis.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Sixty-three oocyte retrievals were performed for 45 patients aged 18-39 undergoing in vitro fertilization (IVF). Patients with endometriosis had the diagnosis confirmed either by laparoscopy or the presence of endometrioma on imaging. Control patients without endometriosis underwent IVF for the indications of (1) prior salpingectomy/tubal ligation, (2) male factor infertility not requiring surgical sperm retrieval, (3) IVF with donor egg, or (4) uterine factor infertility. Patients with polycystic ovarian syndrome, recurrent pregnancy loss, or unexplained infertility were excluded. Observations were made on 491 fertilized oocytes (336 from controls, and 124 from women with endometriosis) cultured in the EmbryoScope using TLM. Timing of cell divisions t2,43,t5,t8, morula formation tM),start of blastulation (tSB) blastocyst formation (tB) and expanded blastocyst (tEB) were determined. Incidence of multinucleation and specific cleavage dysmorphisms were also monitored. Kinetic data and cycle outcomes were analyzed retrospectively. Optimal kinetic ranges for specific endpoints were based on published literature.

RESULTS: The mean patient age in the endometriosis and control groups was similar (34 $\pm$ 4). A total of 76 embryos were transferred. Mean ET number was 1.1 $\pm$ 0.26 and 1.5 $\pm$ 0.47 for endometriosis and control group, respectively. Fertilization rates were significantly lower in women with endometriosis compared to controls (56% vs 76%, $p < 0.001$); however, there were no significant differences in implantation (64% vs 53%, p=NS), clinical pregnancy (69% vs 55%, p=NS), or live birth rates (69% vs 50%, p=NS). There were no significant differences in multinucleation rates, or the incidence of direct uneven cleavage. Overall, embryos derived from women with endometriosis were less likely than controls to fall within optimal kinetic ranges for the start of blastulation (time $<$ 96.2 hours; 22 vs 35%, $p = 0.02$) and expanded blastocyst (time $\leq$ 116 hours; 42 vs 59%, $p < 0.001$). The cohort of embryos transferred showed more favorable kinetic parameters than the overall cohort. Among the embryos transferred, there were no differences in the proportion of embryos falling within optimal kinetic ranges between the endometriosis and control groups.

CONCLUSIONS: Specific timings for the start of blastulation and expanded blastocyst formation have been associated with both implantation potential and aneuploidy rates. A lower proportion of embryos from endometriosis patients exhibited optimal timings for these late developmental end points. However, high clinical pregnancy and live birth rates were still achieved.

POSTER SESSION: ENVIRONMENT AND REPRODUCTION

P-271 4:30 PM Sunday, October 18, 2020

LAND USE AND SEMEN QUALITY: A SINGLE FERTILITY CENTER COHORT STUDY. Eun-Hye Jo, M.D.,[1] Tae Ki Yoon, M.D, Ph.D.,[1] You Shin Kim, M.D, Ph.D.,[1] Inn Soo Kang, MD, PhD,[1] Mi Kyoung Koong, MD, PhD,[1] Hyeok Kim, MD, PhD,[1] Young Sang Kim, M.D,[2] Myung Joo Kim, M.D.,[1] Seung-Ah Choe, M.D.,[1] Ran Kim, M.D.,[1] Eun Jeong Yu, MD,[1] Yun Jung Hur, M.D.,[1] Ji Hye Kim, M.D.,[1] Hannah Kim, MD[1] [1]CHA Fertility Center Seoul Station, CHA University, Seoul, Korea, Republic of (South); [2]CHA Seoul Fertility Center, OB&GY, Seoul, Korea, Republic of (South).

OBJECTIVE: There are growing interests regarding the potential impact of physical environment of residential area on reproductive potential of human. This study was to explore the association between built environment and semen parameters in men who visited for fertility evaluation.

DESIGN: This study is a retrospective cohort study using the data of 7,762 men who have undertaken semen analysis at a single fertility center between January 2016 and September 2019.

MATERIALS AND METHODS: Excluding those diagnosed with varicocele, azoospermia, cryptorchidism, and known chromosomal abnormality, we obtained initial semen analysis results of a total of 7,762 men. Environmental exposures were distance to fresh water (river, lake, creek), distance to major roadway, and neighborhoodgreenness measured by Normalized Difference Vegetation Index (NDVI)within 500m. Outcome indicators were sperm concentration, % of progressive motility and normal morphology by strict criteria.Linear and logistic regression models including clustered effect by district were used for standardized value of sperm concentration, % of progressive motility and normal morphology.

RESULTS: Median age was 39 years and majority were manager, professional or white-collar workers (96.9%). Mean distance to fresh water and major roadway was 443.7 and 3250.0m, respectively. NDVI within 500m was -0.13 on average. In multivariable analyses using quartile scales of environmental exposures, higher distance to fresh water was associated with generally low sperm count which did not reach statistical significance. Men with 2nd quartile of distance to major roadway was showed lower progressive motility (ß = 0.121, P= 0.024). Highest quartile of neighborhood greenness was associated with lower % of normal morphology compared to lowest quartile exposure (ß = -0.176, P = 0.005).

CONCLUSIONS: We observed an association betweenbuilt environment and semen quality of men with infertility history. To confirm this finding, we suggest further studies exploring potential impact of built environment on male infertility in different settings.

AMBIENT AIR POLLUTION AND OVARIAN RESERVE: A SINGLE CENTER COHORT STUDY. Hannah Kim, MD, Seung-Ah Choe, M.D., You Shin Kim, M.D, Ph.D., Tae Ki Yoon, M.D, Ph.D. CHA Fertility Center Seoul Station, CHA University, Seoul, Korea, Republic of (South).

OBJECTIVE: Mounting evidence show possible association between air pollution and reproductive potential of human. Our study assessed the association between air pollution and markers of ovarian reserve in women who visited a fertility center.

DESIGN: 2,276 women who visited a single fertility center were included for study and their ovarian reserve were assessed. Average concentration of pollutant where enrolled women lived were measured to see the correlation between air pollution and ovarian reserve.

MATERIALS AND METHODS: This study included 2,276 women aged between 20 and 50 who visited a single fertility center from Jan. 2016 to Sep. 2018. Ovarian reserve was assessed by measuring serum FSH and AMH on menstrual day 3. Hourly concentrations of fine particulate matter (PM_{10}), NO_2, CO, SO_2, and O_3 measured at 269 air quality monitoring sites across country was used. Based on daily mean concentrations of each air pollutant, average concentration was computed for within 1, 3, 6 and 12 months. Ovarian reserve indicators were observed to expected AMH ratio, FSH $>$ 20IU/mL and AMH $<$ 0.5ng/mL. We assessed the association between concentration of six air pollutants and ovarian reserve indicators adjusting for individual socio-demographic, lifestyle, and spatiotemporal factors.

RESULTS: Mean age of women was 36.6 $\pm$ 4.2. Majority (n=1431, 62.9%) was working at the time of ovarian reserve test and 51 (2.2%) had past smoking history. Mean FSH and AMH were 9.2 $\pm$ 6.4 IU/mL and 3.3 $\pm$ 3.1 ng/mL, respectively. Prevalence of high FSH was 3.4% (n=69) and decreased AMH was 10.3% (n=235). AMH ratio was 0.8 $\pm$ 0.7 on average. In linear regression models, an IQR-increase of 1 month-average of PM_{10} concentration (adjusted ß coefficient=-0.06, 95%confidenceinterval:-0.11, 0.00) and NO_2 concentration (-0.07, 95%CI:-0.12 -0.01) was associated with lower AMH ratio. Except O_3, there were generally negative association between air pollutants concentration and AMH ratio which did not reach statistical significance. In the models for binary outcomes, OR of high FSH was 2.00 (95% CI: 1.08 3.72) per IQR-increase of 12 month-average concentration of SO_2. On the other hand, OR of high FSH was 0.33 (95% CI: 0.13 0.82) with IQR-increase of O_3 concentration within 1 month.

CONCLUSIONS: Higher exposure to PM_{10} and SO_2 was associated with low ovarian reserve in infertile patients, highlighting the importance of the air pollution to infertility.

P-274 4:30 PM Sunday, October 18, 2020

ENVIRONMENTAL CONTAMINANTS INFLUENCE GAMETE DEVELOPMENT BUT NOT HORMONE PROFILES OF PATIENTS UNDERGOING IVF. Lindsay L. Penrose, PhD,[1] Shiva Khalili, M.D.,[1] Dixie Leung, M.D.,[1] Khaliq Ahmad, PhD,[1] Samuel D. Prien, PhD[2] [1]Texas Tech University Health Sciences Center, Lubbock, TX; [2]Texas Tech University Health Sciences Center AND Texas Tech University, Lubbock, TX.

OBJECTIVE: The influences of environmental contaminants on human health, including fertility, are well documented. Previous research from this laboratory has demonstrated the potential effects of agricultural and other industrial pollutants on ART outcomes. In these earlier studies, differences were demonstrated in the available sperm, the number of oocytes recovered, the number of healthy oocytes, and the number of atretic oocytes in patients living in rural and urban environments ($P < 0.05$). However, fertilization rates and pregnancy outcomes did not appear to be influenced by the maternal home environment. These data would suggest that environmental factors can influence the oocyte quality. As organic pollutants can affect hormone cascades, the objective of the present study was to determine if hormone profiles were different in patients from urban and rural environments undergoing ART procedures.

DESIGN: A chart review evaluating the relationship between patient environments and hormone profiles during assisted reproductive technologies outcomes.

MATERIALS AND METHODS: Hormone profiles were reviewed for ART procedure reports from 2014-2017 (N= 163) and were categorized into urban, mainly urban, mainly rural, and rural populations based on zip-code information. Data included precycle profiles, down-regulation, maximum estrogen levels, and pregnancy outcomes. Data were then recategorized between different types of environmental regions (heavy versus limited agrochemical use). Finally, the data were then grouped to correspond to periods of heavy agrochemical use, such as during the growing season for regional crops, and analyzed for each hormone. Data were compared by ANOVA, independent Student's t-test, or Chi-square.

RESULTS: No differences were found between the hormonal profiles of patients for any of the hormones reviewed regardless of the environment of their home residence ($P = 0.118$). Further, there appeared to be no difference between the hormonal profile of patients from different agricultural regions where agrochemical used varied from intense to minimal ($P = 0.077$). Finally, there were no differences seen in the hormonal profiles of patients undergoing treatment cycles during periods of intense versus minimal agrochemical use ($p = 0.127$).

CONCLUSIONS: Previous research has demonstrated differences in egg quality in patients from rural versus urban areas in an agricultural region heavily dependent or organic agrochemicals in the American Southwest. However, current data suggest the changes in oocyte quality are independent of hormonal profile and may be influenced during the hormone-independent stage of follicular development as follicles progress from the primordial to the primary stage of development. Further research will be needed to determine how these compounds influence oocyte development.

P-275 4:30 PM Sunday, October 18, 2020

DISRUPTION OF MALE FETAL REPRODUCTIVE DEVELOPMENT BY EXPOSURE TO BISPHENOLS. Emily G. Hurley, MD,[1] Tony De Falco, Ph.D.[2] [1]University of Cincinnati, West Chester, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

OBJECTIVE: To evaluate the effects of bisphenol A (BPA) and its analogues, bisphenol S and F (BPS, BPF), on fetal mouse testis development.

DESIGN: Experimental investigation at an academic-affiliated research laboratory utilizing CD-1 (IGS) mice.

MATERIALS AND METHODS: Fetal mouse testes at 12.5 days post coitum were cultured for 48 hours with 1 μM of BPA, BPS or BPF treatment and analyzed with immunofluorescence, quantitative polymerase chain reaction (qPCR) and RNA sequencing. Immunofluorescence was used to evaluate changes in vasculature and number/appearance of germ cells, Leydig cells and Sertoli cells. For qPCR, fold changes in mRNA levels relative to control were analyzed using a $\Delta\Delta$Ct method with results calculated as a mean $\pm$ SD. A two-tailed Student t-test was performed to calculate p values, in which $p<0.05$ was considered statistically significant. For RNA sequencing, RNA was extracted and libraries were created using the Illumina protocol, Nextera XT DNA Sample Preparation Kit and sequenced with the Illumina NextSeq 500 instrument. Differentially expressed genes (DEGs) were determined using the R package DESeq2 v.1.26.0 with a log2 fold change $\geq$0.4 and false discovery rate $\leq$ 0.05 when evaluating the combined bisphenol versus control groups and a log2 fold change $\geq$1 when comparing each bisphenol versus control separately. RNA sequencing was also evaluated using Gene Set Enrichment Analysis.

RESULTS: The morphologic appearance of fetal testes and key gene targets (*Amh*, *Sox9*, *Cyp17a1*, *Kdr*, *Ddx4*) were not found to be significantly affected by bisphenol exposure. However, RNA sequencing provided evidence that bisphenol exposure resulted in significant differential gene expression in the exposed gonad. There were a total 387 DEGs identified when analyzing bisphenol (all 3 compounds collectively) versus control groups. Bisphenol exposure resulted in upregulation of gene sets involved in organ morphogenesis/development and immunity and significant downregulation of gene sets involved in gamete generation and sexual reproduction. Gene sets involved in RNA binding/posttranscriptional regulation of gene expression were also downregulated. When analyzing the data for each bisphenol separately versus each control, a total of 1417, 1193 and 1320 DEGs were identified for BPA, BPS and BPF respectively. BPA, BPS and BPF resulted in upregulation of 8 shared genes and downregulation of 77 shared genes, with multiple of these genes having a role in reproduction. BPA and BPF caused more similar effects compared to BPS. All three bisphenols resulted in downregulation of gene sets involving gamete generation; however, the normalized enrichment scores were much lower for BPS compared to BPA and BPF.

CONCLUSIONS: Bisphenol exposure results in altered gene expression in fetal mouse testes, which may ultimately lead to reproductive dysfunction and possibly transgenerational inheritance through effects on germ cells. BPS and BPF share some similar effects on differential gene expression and overall are likely not safe alternatives to BPA.

STRESS-FORCES EMBRYONIC STEM CELLS TO INCREASE EXPRESSION OF HEPATITIS A AND HERPES SIMPLEX 1 VIRUS RECEPTORS AND TWO GENES NECESSARY FOR COVID-19 UPTAKE.

Elizabeth E. Puscheck, MD, MS, MBA,[1] Sudipta Dutta, Ph.D.,[2] Mohammed Abdulkareem Abdulhasan, Ph.D.,[3] Katherine Gurdziel, Ph.D.,[2] Steven J. Korzeniewski, Ph.D.,[4] Douglas Ruden, Ph.D.,[2] Daniel Rappolee, Ph.D.[2] [1]InVia Fertility, Hoffman Estates, IL; [2]Wayne State University, Detroit, MI; [3]Reproductive Stress 3M, Inc., Grosse Pointe Farms, MI; [4]Wayne State University School of Medicine, Detroit, MI.

OBJECTIVE: Determine whether various stresses change the expression in embryonic stem cells (ESC) and their differentiated lineages, of a large set of viral receptors and susceptibility genes.

DESIGN: Experimental.

MATERIALS AND METHODS: ESC were tested by bulk or single cell (sc) RNAseq after 72 hr exposures to 0-300 mM hyperosmotic sorbitol (with stemness-maintaining Leukemia Inhibitory Factor, LIF) to quantify stress-forced differentiation. Controls for normal stemness were LIF+ and normal differentiation were LIF-. RNA was isolated by RNAeasy lysis or 10XGenomics Dropseq, RNA quality was checked by Agilent TapeStation, cDNA was synthesized using Lexogen's QuantSeq library kit, and barcoded, multiplexed and sequenced by Illumina NovaSeq 6000. Data were demultiplexed by CASAVA software and FC expression was compared between conditions. In triplicate experiments, significant fold change (FC) genes ($FC \geq 2$; $FDR \leq 0.05$, $P < 0.05$) identified affected pathways. Proliferation or death were assayed by Hoechst staining or Trypan blue staining, respectively. Validating studies including qPCR.

RESULTS: Using bulk RNAseq it was shown that VIM and TMPRSS2, two genes necessary for Covid-19 cell uptake are up-regulated significantly as measured by P-value and FDR. VIM is up-regulated 5.6 fold higher at 300 mM sorbitol compared with normal differentiation and TMPRSS2 is also up-regulated 3.1 fold higher by high sorbitol despite LIF presence. Havcr1 the hepatitis A virus receptor was up-regulated 55 fold over normal ESC differentiation with significance by p-Value and FDR. Pvrl1 the Herpes simplex 1 (HSV1) virus receptor was up-regulated 4.5 fold compared with ESC undergoing normal differentiation by LIF removal.

CONCLUSIONS: These are proof-of-principle studies that suggest that some viruses have high susceptibility when ESC and their progeny differentiated lineages undergo hyperosmotic stress. HSV1 is known to cross the placenta, and recent data suggest that Covid-19 may cross the placenta and induce IgM detected in cord blood. We intend to extend these tests using Phthalates and cortisol and to test human embryonic stem cells for similar stress-enhanced susceptibility.

IDENTIFYING GENETIC BIOMARKERS OF OVARIAN RESERVE.

Alison Gruber, MD,[1] Deanna Brasile, DO,[2] Will Dampier, PHD,[1] Joshua Chang Mell, PHD,[1] Karen Berkowitz, MD[1] [1]Drexel University College of Medicine, Philadelphia, PA; [2]Main Line Fertility, West Chester, PA.

OBJECTIVE: Diminished Ovarian Reserve (DOR) is a major cause of infertility in women. However, current tests used to assess ovarian reserve in infertile women are limited and do not predict the probability of pregnancy or live birth. Previously, we demonstrated that CHTF18, a conserved DNA replication protein, plays critical roles in mammalian fertility and meiosis. *Chtf18*-null female mice exhibit age-dependent subfertility and a phenotype that closely resembles women with DOR. Our objective is to evaluate *CHTF18*, the human ortholog, and other functionally related genes as possible novel biomarkers of ovarian reserve.

DESIGN: Prospective Clinical Research Study.

MATERIALS AND METHODS: We enrolled 212 Caucasian or Asian women aged 30-45 and placed them into three groups by serum AMH (ng/mL): 1) Infertile women with serum AMH $\geq$ 1.0; 2) Infertile women with serum AMH $<$ 1.0; and 3) Fertile women with serum AMH $\geq$ 1.0. Utilizing a knowledge-based informatics approach and the Human Meiosis Reactome Database, we identified 33 genes functionally related to *CHTF18*. Genomic DNA was isolated from peripheral blood leukocytes and candidate genes were enriched with Illumina TruSeq amplification. Next Generation Sequencing was conducted and bioinformatics analyses were performed with the Broad Institute's standard genome variant pipeline to identify both known and novel

genomic variants. Potential covariates such as age, BMI, smoking, and surgical history were statistically controlled with Ridge regression.

RESULTS: We used a custom sequencing plate to enrich coverage of the candidate genes by an average of 3750-fold. After converting AMH values to age-adjusted percentile scores, we found that women with serum AMH < 1.0 had the lowest AMH percentile scores, as expected, with most falling below 20^{th} percentile for their age. Infertile controls with serum AMH ≥ 1.0 had a range of percentile scores that clustered mainly above 20^{th} percentile. Fertile controls had the highest values, ranging from 30^{th} percentile to 100^{th} percentile. We projected the adjusted AMH values across the variants to evaluate which ones might be altering AMH values, and found 11 variants within the *IGF2* locus that appear to be significantly associated with DOR (OR= 4; $p<0.05$, t-test). We also analyzed the effect of the variants on AMH and found that variants associated with low AMH were present in *IGF2* and *IGF2R*. We analyzed the variants with both linear and non-linear regression models to assess how much they impacted the AMH values and found that they accounted for at least 20-26% of the observed age-adjusted AMH values. Preliminary analyses also suggest a possible association of *CHTF18*, *PRDM9*, *SMC5*, *DMC1, ESR1* with DOR, and additional algorithms are being used to identify and verify significant variants in these genes.

CONCLUSIONS: Our results thus far suggest that genetic variants in *IGF2*, *CHTF18*, and other related genes may be associated with low AMH and DOR. Since the age at which DOR impacts fertility cannot be precisely predicted, we propose that genetic biomarkers could be used to identify women at risk, allowing them to make earlier reproductive choices.

P-279 4:30 PM Sunday, October 18, 2020

ASSOCIATIONS BETWEEN INFERTILITY AND SEXUAL HEALTH IN U.S. FEMALE AND MALE VETERANS. Ginny L. Ryan, MD, MA,[1] Marie E. Thoma, PhD, MHS,[2] Andrea Holcombe, MS, PhD,[3] Anne Sadler, PhD, MS,[3] Bradley J. Van Voorhis, MD,[4] Alicia Y. Christy, MD,[5] Michelle A. Mengeling, MS, PhD[3] [1]Center for Access and Delivery Research and Evaluation, Iowa City, IA; [2]University of Maryland, College Park, MD; [3]Iowa City VA Health Care System, Iowa City, IA; [4]University of Iowa, Iowa City, IA; [5]Veterans Administration, Kensington, MD.

OBJECTIVE: To identify associations between lifetime infertility measures and sexual health in Veterans.

DESIGN: Cross-sectional survey study of 1407 female and 1601 male U.S. Veterans aged 20-45.

MATERIALS AND METHODS: Data were collected using computer-assisted telephone interviews. Lifetime infertility was defined as: 1) twelve or more consecutive months of unprotected intercourse without pregnancy (UI), 2) twelve or more months of trying before any pregnancy (time to pregnancy (TTP)), and 3) ever diagnosis of infertility in participant and/or partner (DX). All Veterans were asked about any past history of sexually transmitted infection (STI) and satisfaction with sexual function. If dissatisfied, they were asked about 5 specific problems based on the Female Sexual Function Index (FSFI): interest, sensation, lubrication, orgasm and pain. Additionally, female Veterans were asked to self-report pelvic inflammatory disease or chronic pelvic pain. Male Veterans were asked to self-report ejaculatory or erectile dysfunction. Infertility prevalence and sexual health characteristics were analyzed by sex.

RESULTS: 84.9% of participants reported having unprotected intercourse and among those 49.6% reported having twelve or more consecutive months of intercourse without pregnancy. Among those ever pregnant (65.3%; n=919), 45.3% (n=416) reported twelve or months of TTP. Overall, 11.7% (n=165) reported ever being diagnosed with infertility. Depending on the infertility measure used, past sexually transmitted infection was associated with infertility in both female and male Veterans (UI measure: 35.1% with infertility vs. 28.6% without infertility in females, p=0.016; TTP measure: 20.1% with infertility vs. 15.2% without infertility in males, p=0.05). Both female and male Veterans with infertility were also more likely to report dissatisfaction with sexual function (UI: 22% with infertility vs. 15.2% without infertility in females, p=0.003; UI: 18.7% with infertility vs. 14.8% without infertility for males, p=0.049).

Female Veterans dissatisfied with sexual function were more likely to report pain with sex if infertile than sexually dissatisfied female Veterans without infertility (DX measure: 78.4% with infertility vs. 51.2% without infertility, p=0.002). Consistent with this finding, chronic pelvic pain (only queried in females) was associated with infertility (DX measure: 11.4% with infertility vs. 4.9% without infertility, p=0.0003). Erectile dysfunction (only queried in males) was also associated with infertility (DX measure: 12.9% with infertility vs. 7.5% without infertility, p=0.15).

CONCLUSIONS: Besides the expected association between STIs and infertility, our study suggests there may also be a relationship between sexual dysfunction and infertility in female and male Veterans. Further research is needed to better elucidate these associations, including the finding of higher rates of pain and erectile dysfunction in the sub-populations of Veterans who had ever been diagnosed with infertility by a healthcare provider.

SUPPORT: The research reported here was supported by the Department of Veterans Affairs, Veterans Health Administration, Health Services Research and Development (HSR&D) grant IIR 13-294. The content is solely the responsibility of the authors and does not necessarily represent the views of the Department of Veterans Affairs.

P-280 4:30 PM Sunday, October 18, 2020

CHARACTERIZATION OF TELOMERE STATUS DURING OVARIAN AGING IN THE SAMP8 (SENESCENCE ACCELERATED MOUSE PRONE 8) MODEL. Alba M. Polonio, MSc,[1] María T. González-García, MSc,[1] Isabel Córdova-Oriz, MSc,[1] Marta Medrano, Lab Technician,[2] Lucía Chico-Sordo, MSc,[1] Juan A. Garcia-Velasco, MD, PhD,[2] Elisa Varela, PhD[3] [1]IVI Foundation, IIS La Fe, Valencia, Spain; [2]IVI-RMA Madrid, Rey Juan Carlos University, Madrid, Spain; [3]IVI-RMA Madrid, Madrid, Spain.

OBJECTIVE: SAMP8 mouse model recapitulates the signs of reproductive aging observed in women. The SAMP8 females at six months of age, present shorter estrous cycles, ovulate less oocytes, with chromosome misalignments and spindle aberrations, and show a declining of their fertility. This study aims to assess whether alterations in the telomere pathway underlie the accelerated reproductive senescence of the SAMP8 model and to elucidate whether telomere maintenance is altered in the offspring of aged mothers.

DESIGN: Prospective study.

MATERIALS AND METHODS: We used SAMP8 adults (seven months-old; reproductive senescence) and young females (three months-old; fertile). As a control, we used SAMR1 model, which does not show signs of premature reproductive senescence. Three and seven months-old SAMP8 females were mated with young fertile males. The weight, size, survival and number of pups per litter were analysed. Follicle count from three and seven months-old SAMP8 and SAMR1 females was measured. SAMP8 and SAMR1 ovaries were used for quantitative FISH with a telomeric probe to check for telomere length at different ages. Telomere length and aberrations were evaluated in mouse embryonic fibroblasts (MEF) that came from SAMP8 and SAMR1. The survival curve of both models was evaluated.

RESULTS: In litters from the SAMP8 females at 3 and 6-7 months old, there were differences in several parameteres such as the number of pups (6.67 vs 5.17), the size (47.81 *vs* 44.73 at day 15, p=0.0003) and weight (8.4 *vs* 6.47 at day 15, $p<0.0001$). The percentage of litters in which we found dead pups during the first weeks of life was higher in 7 months-old mothers than in 3 months-old mothers (25% vs 33%, repectively) . We found a sharper decay in the number of antral follicles with age in the SAMP8 (12.67 *vs* 2, p=0.0235), compared with SAMR1 model (7.83 *vs* 5.11, p=0,1328). However, there were not statistically significant differences in the number of antral follicles in SAMP8 and SAMR1 old females (2 *vs* 5.11, respectively), suggesting that the process of fertilization or embryo development may be altered. The telomere length of MEF from older mothers is statistically significantly shorter than the telomere length of MEF from younger mothers (31.75 vs 37.89, p=0.0002). The survival curve of both SAMP8 and SAMR1 confirms the aging phenotype published for the model.

CONCLUSIONS: Telomeres of embryos from older mothers are statistically significantly shorter than those from younger mothers. Size and weight of pups from older mothers are altered, as well as size and survival of the litters from older mothers. Our preliminary results suggest that the telomere pathway is altered in the SAMP8 mouse model. Therefore, it is possible that the reproductive senescence phenotype observed in SAMP8 can be due to alterations in the telomere pathway, which may have consequences in the offspring of older mothers.

P-281 4:30 PM Sunday, October 18, 2020

THERAPEUTIC STRATEGY TO IMPROVE THE QUALITY OF AGED OOCYTES. Mandy G. Katz-Jaffe, PhD, Jason C. Parks, BS, Blair R. McCallie, BS, Sydney L. Lane, PhD, Rachel Makloski, RN, William B. Schoolcraft, MD. Colorado Center for Reproductive Medicine, Lone Tree, CO.

OBJECTIVE: A significant amount of the age-related reduction in reproductive efficiency is overcome with a euploid embryo transfer. Nevertheless, for women in their forties there are other factors contributing to reproductive senescence and lower IVF success rates. Aging is associated with an imbalanced redox state in the ovaries, with increased reactive oxygen species (ROS) relative to naturally occurring antioxidant signaling. The aim of our study was to determine whether restoration of redox balance using a polyphenol rich antioxidant would counter aging-related oxidative stress in the ovary, serving as a therapeutic strategy to improve aged oocyte quality.

DESIGN: Prospective intervention cohort study.

MATERIALS AND METHODS: Female infertility patients (n=121; 38.1 ± 3.5 years; median 39) consented to 1800 mg/day of encapsulated, freeze-dried naturally occurring açaí pulp, *Euterpe oleracea* (total polyphenol content 6,618 mg GAE/100 g, oxygen radical absorbance capacity 208, 628 μmol TE/100 g) for 8-16 weeks preceding an IVF cycle (mean 9.9 ± 2.2; variability due to menstrual cycle dates). Patient outcomes were analyzed using two-tailed, paired Student's t-test, with significance at $P < 0.05$. For mechanistic studies, female outbred CF-1 mice were naturally aged (9-12 months old) before administration of 4mg/day of the same antioxidant. Control females (9-12 months old) received the same balanced nutritional feed but without the açaí. Murine ovarian RNA was isolated and transcriptome analysis performed with CodeLink™ Mouse Whole Genome (Applied Microarrays), qPCR validation (REST 2009 software; Qiagen) and Ingenuity Pathway Analysis (Qiagen), significance at $P < 0.05$.

RESULTS: In a paired comparison patient analysis with and without antioxidant administration, cycles with intervention resulted in increased oocytes collected following ovarian stimulation (17.4±0.9 vs 15.5±0.8, P=0.0085) and a greater number of blastocysts developed (5.1±0.3 vs 2.9±0.3, P<0.0001). Additionally, in a subset of patients with pre-implantation genetic testing for aneuploidy, more euploid blastocysts were identified (2.9±0.3 vs 1.0±0.2, P<0.0001). To date, 100 frozen embryo transfers have resulted in 75 healthy live births or ongoing pregnancies with no pre- or post-natal complications. In aged mice, antioxidant intervention lead to an improved ovarian transcriptome including upregulated β-adrenergic signaling, cell growth and antioxidant pathways, and downregulated apoptosis and pro-inflammatory signaling (P<0.05). Additionally, in aged mice, antioxidants increased the expression of several antioxidant genes (*GPX1*, *SOD2*, and *GSR; P*<0.05*)* in the oocyte.

CONCLUSIONS: This study provides preliminary evidence that antioxidant intervention with a potent scavenger of oxygen free radicals and ROS, has therapeutic benefit prior to ovarian stimulation to improve aged oocyte quality. Candidates for the underlying molecular mechanisms include transcriptional changes in β-adrenergic signaling, anti-inflammatory processes as well as improvements in ovarian and oocyte antioxidant signaling.

CURRENT STATE OF CLINICAL TRIALS IN INFERTILITY: A COMPREHENSIVE ANALYSIS OF THE CLINICALTRIALS.GOV DATABASE.

Benjamin J. Peipert, MD,[1] Daniel Spinosa, MD,[1] Elizabeth P. Howell, MD,[1] Jeremy M. Weber, MS,[2] Tracy Truong, MS,[2] Benjamin S. Harris, MD, MPH[3] [1]Duke University Medical Center, Durham, NC; [2]Department of Biostatistics & Bioinformatics, Duke University Medical Center, Durham, NC; [3]Division of Reproductive Endocrinology and Infertility, Duke University Medical Center, Durham, NC.

OBJECTIVE: To characterize the landscape of interventional clinical trials for infertility, and to identify factors associated with trial non-completion. We hypothesized that sponsor type and trial location would be associated with trial non-completion.

DESIGN: Retrospective analysis of domestic and international clinical trials registered with ClinicalTrials.gov from 2010-2020.

MATERIALS AND METHODS: ClinicalTrials.gov was queried for completed, suspended, terminated, and withdrawn interventional clinical trials using the search term "infertility." Logistic regression was used to examine whether sponsor type and trial location were associated with trial non-completion with and without adjusting for intervention type, trial

TABLE 1: Trial non-completion and logistic regression results

		Unadjusted		Adjusted	
	Non-completion rates	OR (95% CI)	P value	OR (95% CI)	P value
Industry vs. non-industry	11% vs. 19%	0.53 (0.23, 1.20)	0.13	0.66 (0.22, 1.96)	0.45
Domestic vs. international	32% vs. 16%	2.49 (1.48, 4.18)	<0.01	0.93 (0.42, 2.06)	0.86

OR = odds ratio; CI = confidence Interval.

primary outcome, gender, number of sites, randomization, enrollment size, and trial phase.

RESULTS: Five-hundred and six trials were included in the analysis. Most trials (82%) were conducted outside the United States. A minority (12%) of trials were sponsored by industry with the remainder sponsored by academic, public, or private organizations. Most trials involved drug (48%) or procedural (22%) interventions. A majority (85%) of trials included only female participants. Few trials (4%) provided information on demographics of study participants, such as race or ethnicity. Overall, 18% of trials were not completed. Rates of non-completion by sponsor type and trial location, as well as the results of the logistic regression models, are reported in Table 1. Domestic trial location was associated with higher non-completion rate; however, this association was no longer significant after adjustment. Industry-sponsored trials had a lower non-completion rate compared to non-industry trials, but this relationship was not statistically significant before or after adjustment.

CONCLUSIONS: Far more interventional clinical trials for infertility are conducted internationally than in the United States. Men are underrepresented in clinical trials for infertility, and trial participant demographics are severely under-reported. US trials had higher rates of non-completion, but this was not statistically significant after adjustment. Sponsor type was not associated with trial non-completion. Future efforts should be directed at greater transparency into the demographics of study participants and the creation of more trials addressing male-factor infertility.

MISDIAGNOSED SEPTATE UTERUS IN WOMEN SCHEDULED FOR IN-VITRO-FERTILIZATION (IVF): A 5-YEAR COHORT STUDY. Ahmed M. Abdelmagied, MD,[1] Ahmed M. Abbas, MD,[1] Dina M. Habib, MD,[1] Mohammed Khairy Ali, MD,[1] Osama S. Abdalmageed, MD,[1] Karim S. Abdallah, MSc,[2] Fawzia Ahmed Habib, MD[3] [1]Department of Obstetrics and Gynecology, Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Department of Obstetrics and Gynecology,School of Medicine, Monash University, Melbourne, VIC, Australia; [3]Department of Obstetrics and Gynecology, Faculty of Medicine, Taibah University, Madinah, Saudi Arabia.

OBJECTIVE: This study aimed to evaluate the diagnostic accuracy of three-dimensional ultrasound (3D-US) and hysterosalpingography (HSG) in the differentiation between arcuate and septate uterus in women scheduled for IVF compared to hysteroscopy and/or laparoscopy examination (HL) , the gold standard.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: Infertile women indicated for IVF who attended a tertiary assisted conception center from 2015 till the end of 2019 were screened. Subjects with suspected diagnosis of arcuate and septate uterus based on HSG were considered. Only reports that included analysis of the outer and inner uterine fundal contours as well as the length of the fundal internal indentation during 3D-US and HL evaluations were studied. Two standard classifications, ASRM-2016 and CUME-2018, were utilized for imaging and endoscopic analysis of the uterine morphology to appropriately define each anomaly. The final diagnosis of the anomalies was based on HL, the gold standard. All cases of septate uterus underwent combined hysteroscopy and laparoscopy examination to confirm the final diagnosis, and to guide the hysteroscopic septal incision. The analysis was according to the STARD guidelines for reporting diagnostic accuracy studies. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy and the level of agreement by kappa statistics were calculated for the diagnostic modalities.

RESULTS: Among 1840 women planned for IVF, a cohort of 196 women (10.7%) included in the final analysis. Utilizing ASRM-2016 criteria, 3 categories of uterine anomalies were diagnosed by HL: arcuate uterus (n=83, 42.3%), septate uterus (n=80, 40.8%), and bicornuate uterus (n=11, 5.6%). Others had 1-1.5 cm internal fundal indentations with angles <90 degrees, so were left unclassified (n=22, 11.2%). Sensitivity, specificity, PPV, NPV, and accuracy of HSG were 70%, 90%, 83%,81%, and 82%, respectively. 3D-US yielded perfect diagnostic accuracy (100%) and perfect agreement with HL in identifying all anomalies. On the other hand, the agreement between HSG and HL was only in 161 cases (82.1%), (κ=0.65,CI: 0.55-0.75). For septate uterus, 24 cases (24/80;30%) were misdiagnosed by HSG as arcuate uterus, while for bicornuate uterus, HSG misdiagnosed all of them as septate uteri. When utilizing CUME-2018 criteria for uterine septum diagnosis, the unclassifiable uteri by ASRM-2016 classification would increase the proportion of septate uteri misdiagnosed as arcuate uteri by HSG (46/102,45.1%) (Relative risk:1.5, CI:1.01 - 2.2, P <0.04).

CONCLUSIONS: Women for IVF with suspected fundal depression on HSG should be examined by 3D-US in order to identify subtle septae that can substantially affect implantation. The rate of identifying these septae is affected by the definition system utilized by clinicians.

INTRA- AND INTER-CYCLE VARIABILITY OF ANTI-MÜLLERIAN HORMONE (AMH) LEVELS IN HEALTHY WOMEN MEASURED WITH ELECSYS AMH PLUS IMMUNOASSAY: THE BICYCLE STUDY. Marieke Biniasch, M Med,[1] Ruediger Paul Laubender, PhD,[2] Martin Hund, PhD,[3] Katharina Buck, PhD,[2] Christian De Geyter, MD[1] [1]Reproductive Medicine and Gynecological Endocrinology, Universitätsspital Basel, University of Basel, Basel, Switzerland; [2]Roche Diagnostics GmbH, Penzberg, Germany; [3]Roche Diagnostics International Ltd., Rotkreuz, Switzerland.

OBJECTIVE: To determine variability of anti-Müllerian hormone (AMH) serum levels during the natural menstrual cycle between different women (inter-subject), between separate menstrual cycles within a woman (inter-cycle), and within a menstrual cycle (intra-cycle). Understanding variation in AMH levels may aid with assessment of ovarian reserve and provide a reliable prediction of response to ovarian stimulation in women undergoing assisted reproduction.

DESIGN: A prospective, single-center study using the Elecsys® AMH Plus immunoassay to quantify AMH levels in healthy women.

MATERIALS AND METHODS: Eligible women were aged 18–40, had regular, natural menstrual cycles (i.e. not using any hormonal drugs) between 28–32 days, and a BMI of 19–26 kg/m^2. Serum samples were collected every two days during two separate menstrual cycles with a menstrual cycle in between. Serum AMH levels were measured using the Elecsys AMH Plus assay on the cobas e 411 analyzer (Roche Diagnostics Ltd). Menstrual cycle lengths were standardized to 28 days. Mixed-effects periodic regression models based on Fourier series were performed to evaluate the inter-subject, inter-cycle, and intra-cycle variability. The mesor (mean value based on distribution of values across the cycle[s]) allowed for evaluation of inter-subject and inter-cycle variability; peak-to-peak (PtP) amplitude allowed for evaluation of inter-cycle and intra-cycle variability. Separation of the biological and analytical variabilities was determined by analysis of two remeasured AMH levels, with the original AMH levels, to provide triplicate results. The relationship between AMH levels and progesterone levels was investigated.

RESULTS: A total of 42 women were assessed over two non-subsequent cycles, with a further five women included for one cycle only. Compared with inter-cycle variability, time series plots of AMH levels indicated substantial variability between women (inter-subject variability). Statistical modelling showed large inter-subject variation in both the mesor and PtP amplitude. In addition, for each participant, intra-cycle variability was higher than inter-cycle variability. The inter-cycle mesors showed a strong correlation between cycles (r=0.95), while the PtP amplitude was weakly correlated (r=0.23). Moderate correlation between the mesor and PtP amplitude was seen across both cycles (cycle 1: r=0.63; cycle 2: r=0.65). Coefficient of variation (CV) of unexplained biological variability and analytical variability was 10.8%. Triplicate results provided a CV of unexplained biological variability of 9.6% and reproducibility (analytical variability) of 3.5%. The analyses also demonstrated that the time interval in which serum AMH decreased within a cycle (within Days 14 and 20) was related to the time interval with the largest increase in progesterone levels (within Days 16 and 22).

CONCLUSIONS: Inter-subject and intra-cycle variability of AMH levels were larger than inter-cycle variability. This study also showed that unexplained biological variability was higher than analytical variability of the Elecsys AMH Plus assay.

SUPPORT: This study was funded by Roche Diagnostics International Ltd. Third-party medical writing assistance was provided by Ashlie Butler (Gardiner-Caldwell Communications, Macclesfield, UK) and was funded by Roche Diagnostics International Ltd.

DOES DELAY IN THE DIAGNOSIS OF RUDIMENTARY HORN PREGNANCY IN PATIENTS WITH UNICORNUATE UTERI IMPACT TREATMENT OUTCOME?

Damla C. Gonullu, MD,[1] Jessica Rausch, DO,[1] Omosalewa Itauma, MD, MPH,[1] Chidinma Abara, MD,[2] Megan Fee, BS,[1] Awoniyi Olumide Awonuga, MD[3] [1]Wayne State University School of Medicine, Detroit, MI; [2]Windsor University School Of Medicine, Cayon, MI; [3]Wayne State University School of Medicine, MI.

OBJECTIVE: Rudimentary horn pregnancy (RHP) is a very rare form of ectopic pregnancy (EP) that tends to rupture in the second trimester. Similar to other EPs, the treatment of RHPs is excision, hence delay in diagnosis (DID) can be detrimental. Our objective is to determine whether DID of RHP in patients with unicornuate uteri (UCU) impacts the treatment outcome.

DESIGN: Retrospective cohort study of published case reports in PubMed database.

MATERIALS AND METHODS: A computerized PubMed search of case reports of RHP from 2007 to 2020 was performed using the key words; unicornuate uterus, rudimentary horn, pregnancy, case. Data was analyzed with SPSS version 26.

RESULTS: Of the 97 published cases, due to limited information available, 95 cases were included, 40 (42.1%) in which the diagnosis of RHP was made at first encounter and 55 (57.9%) in which the diagnosis was delayed. Out of these cases, it was possible to calculate the median [range] length of delay (35 [1-1825] days) in only 32 cases. Of 95 cases, 27 (28.4%), 5 (5.3%), 61 (64.2%), 1 (1.1%), underwent laparoscopy, laparoscopy converted to laparotomy, laparotomy, and methotrexate injection respectively. Diagnosis was made at autopsy in one case.

CONCLUSIONS: Diagnosis of RHP was significantly more likely to be made at first encounter when patients were known to have a uterine anomaly. DID was associated with a significantly higher GA at the time of treatment but there was no significant difference in the proportion of fetuses that were alive upon entrance to the abdomen, rate of ruptured RH and hemoperitoneum. Out of all of the cases, only one maternal death was reported. Therefore, delaying surgery to confirm a diagnosis of RHP does not adversely impact the maternal fetal outcome.

TOP TEN RESEARCH PRIORITIES FOR FEMALE AND UNEXPLAINED INFERTILITY.

James M. N. Duffy, DPhil MRes PG HCL MBChB BSc (Hons),[1] Cindy Farquhar, FRANZCOG FRCOG MD MPH,[2] Priority Setting Partnership for Infertility[1]Institute for Women's Health, University College London, Greater London, United Kingdom; [2]University of Auckland, Auckland, New Zealand.

OBJECTIVE: To develop the top 10 research priorities for female and unexplained infertility.

DESIGN: International consensus development study.

MATERIALS AND METHODS: Potential research questions were collated from an initial international survey, a systematic review of national and international fertility guidelines, and Cochrane systematic reviews. A rationalized list of confirmed research uncertainties were prioritized in an international survey. Prioritized research uncertainties were discussed during a consensus development meeting.

RESULTS: The initial survey was completed by 388 participants, from 40 countries, and 131 potential research questions were submitted. By reviewing nine clinical practice guidelines and 162 Cochrane systematic reviews, a further 136 potential research questions were identified. A rationalized list of 48 confirmed research uncertainties were entered into an interim prioritization survey completed by 317 respondents from 43 countries. The top 10 research priorities for female and unexplained infertility were identified during a consensus development meeting involving 41 participants from 11 countries (Table 1).

TABLE 1: Top 10 research priorities for female and unexplained infertility.

1	Can age-related infertility be prevented?
2	Can a predictive model be developed, tested, and validated to compare the outcomes of different management strategies for couples with unexplained infertility?
3	In couples with unexplained infertility, what is the optimal assisted reproductive technique?
4	Can a predictive model for fertility based upon ovarian reserve tests be developed, tested, and validated?
5	In women at risk of age-related infertility does standardized fertility assessment before attempting expectant management improve live birth rates?
6	What causes unexplained infertility?
7	In women with uterine fibroids what is the optimal management strategy to preserve fertility?
8	In women with otherwise unexplained infertility does hysteroscopic removal of an endometrial polyp increase live birth rates?
9	In women with mild intrauterine adhesions and otherwise unexplained infertility, does removal increase live birth rates?
10	In women with a uterine septum and otherwise unexplained infertility does hysteroscopic resection increase live birth rates?

CONCLUSIONS: We anticipate these research priorities will help research funding organizations and researchers to develop their future research agenda. Healthcare professionals, professional organisations, and patient advocacy groups should champion the research priorities to highlight the many unanswered questions which need to be addressed in order to improve the outcomes of people with fertility problems.

THE USE OF VIRTUAL REALITY TECHNOLOGY IN INFERTILE WOMEN UNDERGOING IN VITRO FERTILIZATION-EMBRYO TRANSFER: A RANDOMIZED CONTROLLED TRIAL.

Michal Dviri, MD,[1] Lilach Marom Haham, MD,[1] Jordana Beth Mashiach Friedler, MD,[1] Anjila Roumia, MD,[1] Samantha Yee, Ph.D,[2] Ari Y. Baratz, MD,[3] Karen B. Glass, MD,[2] Prati Sharma, MD,[2] Clifford Lawrence Librach, MD[2] [1]CReATe fertility centre, Toronto, ON, Canada; [2]CReATe Fertility Centre, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada.

OBJECTIVE: Embryo transfer (ET) is a crucial event in determining in vitro fertilization (IVF) outcome, perceived by many patients as the culmination of treatment. Therefore, it is often a stressful procedure for patients. We hypothesized that the stress accompanying this procedure may be inversely correlated with cycle outcome. The use of complementary therapies to reduce anxiety and improve IVF outcome is increasing. Various interventions

have been studied, but their efficacy remains uncertain. Virtual reality (VR) technology, has been gaining attention over the past two decades, owing to evidence of it's therapeutic potential for anxiety management and stress reduction. This study aimed to examine the possible effect of VR exposure on anxiety level and clinical pregnancy rate (CPR) in women undergoing IVF-ET.

DESIGN: A prospective randomized controlled trial (Clinical Trials.gov Protocol Registration: NCT04394962).

MATERIALS AND METHODS: The study was conducted at the CReATe Fertility Centre (Toronto, Canada) after obtaining REB approval. Recruitment period was May 2019-March 2020 (suspended due to Covid-19). Infertile women aged 21-45-year-old using own ovum or older using donor eggs, starting a frozen ET cycle, were recruited. All participants provided a written informed consent before study entry. Exclusion Criteria were contraindications to use VR technology, anxiety disorder and major uterine anomalies. Participants were withdrawn if ET was cancelled. Patients were randomized (1:1) into 2 groups: A. Study group: 15-30 minutes of passive VR exposure (calming environment of choice) before ET; B. Control group: routine care only. Anxiety was assessed at 3 time points: T1=recruitment; T2=pre ET; T3=Post ET, using the validated "State-Trait Anxiety Inventory" questionnaire, heart rate (HR) and blood pressure (BP) measurements. The primary outcome was the CPR and the secondary outcomes were patients' anxiety parameters. T-test or chi square were used as appropriate. $P<0.05$ was considered statistically significant.

RESULTS: Seventy six patients were included in the analysis, 38 in each study arm. Patient and cycle characteristics were comparable between the groups. The mean VR exposure time was 23.2 $\pm$14.1 minutes, the majority chose a beach environment (78.9%) and stated they would recommend VR (75.3%). No serious adverse events were reported. HR was higher in T2 vs T1 and T3 ($p=0.002$), but the mean BP and HR did not differ between the groups. T1 and T2 'trait' anxiety scores were comparable between the groups. No significant differences were found between the VR group to control in the 'state' anxiety scores during T2 (40.3 vs 39.3) and T3 (38 vs 38), respectively ($P>0.05$). CPR was comparable between the VR and the control group (50% vs 34.2%, respectively; $p=0.42$).

CONCLUSIONS: This is the first study to assess VR use in assisted reproduction. The preliminary findings suggest that VR exposure prior to ET does not reduce patients' anxiety levels. Although non-significant, a higher CPR trend in the VR group suggests that this intervention may have a beneficial effect, but a larger sample size is needed to confirm this.

P-289 4:30 PM Sunday, October 18, 2020

REGULATION OF OVIDUCT HOMEOSTASIS AND FERTILITY BY PAX2 AND PAX8 GENES. Abdul Soofi, PhD University of Michigan, Ann Arbor, MI.

OBJECTIVE: In mouse and humans, the development regulatory genes Pax2 and Pax8 are expressed in ovarian duct surface epithelia, yet the function of these genes and proteins in adult females remains unclear. By Generating double & single KO mouse modules of Pax2 and Pax8 we investigate their roles in maintaining the integrity of the oviductal cells. Our studies directly address aspects of oviduct epithelial homeostasis and the effects on fertility.

DESIGN: To create Pax2, Pax8, and Pax2/8 double mutants specifically in oviduct epithelia and characterize changes in gene expression, epithelial cell integrity, and fertility.

MATERIALS AND METHODS: We will implement detailed analyses of oviducts isolated at various times post tamoxifen administration from mice with conditional Pax2, Pax8, or both alleles, using the Ovigp1-CreER driver. Mice will also carry reporter allele ($Gt(ROSA)26Sor^{tm4(ACTB-tdTomato,-EGFP)Luo}$) to mark all active Cre expressing cells with cell surface EGFP. In addition to defining novel functions for Pax proteins in the oviduct, we will utilize state-of-the-art methods for single cell analyses, transcriptomics, and chromatin remodeling.

RESULTS: Mutation of Pax2 and Pax8 in adult female oviducts results in significant changes in gene expression and morphology. Loss of both Pax2 and Pax8 resulted in infertility (Table 1). To date, most of the preliminary data was obtained from Pax2/8 double mutants since we were concerned with redundancy and expected the most significant phenotypes in the double mutants. Analyses of histology, immunohistochemistry and changes in gene expression of total RNA from whole oviducts isolated after tamoxifen administration. For a rapid first pass screen, we compared controls ($Pax2^{f/f};Pax8^{f/f}$) to single Pax mutants and Pax2/8 double mutants ($Pax2^{f/f};Pax8^{f/f}$; *Ovigp1-CreER*) by Affymetrix microarrays. These data show hundreds of changes in gene expression levels upon Pax2 or Pax8 deletion, with significant overlap between the Pax2 and Pax8 mutants but also expression changes unique to each single mutant.

TABLE 1. Fertility of Oviduct Specific Pax Mutants

Genotype	# females	# plugs	Litters	Litter size
$Pax2^{f/f}$, $Pax8^{f/f}$, Ovi-Cre	5	15	0	0
$Pax2^{f/f}$, $Pax8^{f/f}$,	4	12	12	6-9
$Pax8^{f/f}$, Ovi-Cre	3	6	2	6-7

CONCLUSIONS: Little is known regarding the mechanisms underlying epithelial homoeostasis, the proteins that determine cell fates, and epithelial integrity in the adult oviduct. Pax8 expressing secretory cells are thought to give rise to ciliated cells, which help move the oocyte down the duct and Pax2 is associated with cilia motility and physiology. Using a conditional KO model of Pax2 & Pax8 will allow us to understand those mechanisms and identify future novel therapeutic targets for diagnostics and treatments

P-290 4:30 PM Sunday, October 18, 2020

IUI AFTER LH SURGE: HOW SOON IS TOO SOON? Samantha Simpson, MD, Lubna Pal, MBBS Yale University, Orange, CT.

OBJECTIVE: Intrauterine insemination (IUI) following ovulation induction (OI) or in a natural cycle is a first line treatment for many etiologies of infertility. The timing of IUI in relation to ovulation trigger or spontaneous luteinizing hormone (LH) surge, as well as the number of IUI attempts that should be made remains a subject of debate. Many patients prefer a single IUI, whether due to expense of treatment or feasibility of making it to an office appointment on short notice. Sperm can theoretically survive in the female reproductive tract for up to 72 hours. The timing of oocyte(s) release is approximately 35-36 hours after the LH surge; following ovulation, the window of fertilization is restricted to approximately 24 hours. Therefore, it is logical to conclude that as long as the IUI is undertaken within two days of the LH surge, the actual timing of the procedure should not influence the probability of conception. Existing evidence on whether IUI cycle outcomes, such as ongoing pregnancy or live birth, differ following a single IUI timed at either 12 or 36 hours after LH surge is sparse.

DESIGN: Retrospective cohort study at a single academic fertility center.

MATERIALS AND METHODS: All patients presenting for a planned single IUI between January 2018 and December 2019 were eligible. Evidence of bilateral tubal patency, and yield of $\geq$ 15 million /mL sperm in the IUI sample were inclusion criteria. The IUI timing was specified based on timing of hCG induced ovulation (n=260) or by evidence of a positive urinary LH surge reading occurring 12 hours or less after a previous negative reading (n=16). OI treatments included clomiphene (n= 152), letrozole (n=76), or injectable gonadotropins (n=35). Relationships between timing of IUI with ongoing pregnancy greater than 16 weeks (OP) and live birth (LB) were calculated.

RESULTS: 197 women undergoing 276 cycles with single IUI were included in the analyses. In 75 cycles, IUI was performed 12-16 hours following hCG trigger or LH-surge; IUI was performed 36-40 hours after trigger or LH-surge in 201 cycles. 32 cycles successfully lead to live birth or ongoing pregnancy >16 weeks gestation (11.6% of cycles). OP/LB following IUI differed based on timing of IUI. After adjusting for age, BMI, OI regimen, and endometrial thickness, the likelihood for OP/LB was threefold higher than the IUI was timed at 36-40 hours following trigger or LH surge, compared to 12-16 hours (14% v 5%, OR 3.0, 95% CI 1.00-9.81, $p=0.047$).

CONCLUSIONS: In women undergoing IUI for infertility management, the timing of IUI is an independent predictor of IUI cycle outcome.

P-291 4:30 PM Sunday, October 18, 2020

HIGH EXPRESSION OF PGAM FAMILY MEMBER 5 (PGAM5) IS ASSOCIATED WITH DIMINISHED OVARIAN RESPONDER IN CUMULUS CELLS. Li-Te Lin, PhD,[1] Chia-Jung Li, Ph.D,[2] Kuan-Hao Tsui, M.D; Ph.D[2] [1]Kaohsiung Veterans General Hospital, Kaohsiung City, Taiwan; [2]Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan.

OBJECTIVE: Is high PGAM5 expression associated with diminished ovarian responder (DOR) in cumulus cells as well as assisted reproductive technology (ART) outcome, and what is the underlying mechanism of action of PGAM5?

DESIGN: Experimental laboratory study.

MATERIALS AND METHODS: In a prospective study, fresh granulosa cells were obtained from 48 women aged 20–40 years who underwent IVF with embryo transfer and who were divided into two groups: the diminished ovarian reserve (DOR) group (n = 20) and the control group (n = 28). Patient characteristics including age, infertility duration, body mass index, FSH, anti-Müllerian hormone (AMH) and cumulus cell PGAM5 expression levels, autophagy, mitochondrial mass were analysed.

RESULTS: The Drp1 in the DOR group was activated and the PGAM5 translocated to the outer membrane of the mitochondria, the formation of lysosomes increased, thereby increasing the fission of mitochondria. We further observed a significant reduction in the mass of the mitochondria in the DOR group and a severe imbalance, and the formation of LC3, which in turn caused mitophagy.

CONCLUSIONS: High PGAM5 expression levels in cumulus cells were related to DOR, which may be involved in the clinical outcome of ART by promoting mitophagy and affecting mitochondrial function.

P-292 4:30 PM Sunday, October 18, 2020

DETECTION OF CLOCK rs11932595 POLYMORPHISM IN WOMEN WITH RECURRENT PREGNANCY LOSS (RPL). Despoina Mavrogianni, Dr, PhD,[1] Helen Pandi, Biologist,[1] Sofoklis Stavrou, MD, Ph.D.,[1] Dimitris Loutradis, Professor,[2] Peter Drakakis, Professor[1] [1]Molecular Biology of Reproduction Unit and Recurrent Abortions Unit, Assisted Reproduction Division, Athens, Greece, Greece; [2]Molecular Biology of Reproduction Unit and Recurrent Abortions Unit, Assisted Reproduction Division, Athens, Greece.

OBJECTIVE: To evaluate whether the Clock gene Polymorphism rs11932595 is associated with recurrent pregnancy loss in women within the Greek population.

DESIGN: This is a case-control study consisting of 57 women with a history of two or more recurrent miscarriages before the 24th week of gestation and 61 women with no history of pathological pregnancies and at least one live birth.We studied the expression of Clock gene Polymorphism rs11932595.

MATERIALS AND METHODS: DNA was extracted from blood and in all samples the genomic region of CLOCK containing the rs11932595 polymorphism was amplified by applying the Polymerase Chain Reaction (PCR). Subsequently, the PCR product was sequenced, in order to detect the specific polymorphism.

RESULTS: Results have indicated that 50 out of 57 women of the RPL group (87.7%) and 41 out of 61 women in control group (67.2) carry the polymorphic allele. Evaluation of the results showed that there is a statistically significant positive correlation between the presence of the polymorphism and the medical history of RPL.

CONCLUSIONS: This particular study, carried out for the first time in the Greek population, verifies the results of recent studies which have indicated that the CLOCK gene rs11932595 SNP is related with the presence of recurrent abortions. A possible correlation of polymorphisms present in CLOCK gene and miscarriages may lead to a better understanding of the recurrent pregnancy loss mechanism.

COMPARISON OF HUMAN ANTRAL FOLLICLES OF XENOGRAFT VERSUS OVARIAN ORIGIN REVEALS DISPARATE MOLECULAR SIGNATURES. Limor Man, M.D, M.Med.Sc, Nicole Lustgarten, PhD, Eleni Kallinos, B.S, Kolbe Hancock, MD, Nikica Zaninovic, Ph.D., Glenn Schattman, MD, Zev Rosenwaks, M.D., Daylon James, PhD Weill Cornell Medicine, New York, NY.

OBJECTIVE: The activation, growth and maturation of oocytes to an ovulatory phase, termed folliculogenesis, is governed by the orchestrated activity of multiple specialized cells types within the ovary, yet mechanisms governing diversification and behavior of discrete cellular sub-populations within follicles are poorly understood. We set out to identify and characterize unique subsets among the granulosa (GC), theca (TC) and stromal cell fractions, and to compare the molecular profiles of these sub-populations when isolated from native ovarian versus xenograft-derived antral follicles.

DESIGN: Small antral follicles (< 5mm) were isolated from ovaries of organ donors or patients undergoing whole ovarian resection for fertility preservation. These were compared to antral follicles that developed in long term (> 14 weeks) xenografts of cryopreserved/thawed human ovarian cortex. Immunostaining, flow cytometry, bulk and single-cell RNA sequencing were used to segregate and interrogate discrete follicle-derived cell fractions.

MATERIALS AND METHODS: The GC fraction was first purified from 3 small (2-3 mm) ovary-derived antral follicles and subjected to bulk RNA sequencing to identify candidate surface molecules that may specifically identify follicle cell sub-types. Candidate factors were screened using immune-staining and flow cytometry of xenograft and ovary-derived follicles. 22 unique single-cell library preparations (∼100,000 cells) representing fractions from 13 individual follicles (8 ovary origin, 5 xenograft origin) and 6 women were prepared, sequenced and analyzed.

RESULTS: Analysis of GC, TC and stromal subpopulations deconstructed phenotypic diversification during early antral follicle development, identifying secreted factors that are differentially enriched between mural and oophorus GCs, and segregating stromal/support and steroidogenic activity between theca externa and interna, respectively. Numerous factors were differentially expressed in follicles of xenograft versus ovarian origin, highlighting the potential contribution of humoral factors to follicular development that have not been considered, to date.

CONCLUSIONS: These data shed light on previously undescribed subpopulations of both GC and TC compartments and provide a systems level portrait of cellular diversification in early antral human follicles.

P-296 4:30 PM Sunday, October 18, 2020

THE USE OF DYDROGESTERONE TO PREVENT LH PEAK IN RANDOM-START OVARIAN STIMULATION FOR FERTILITY PRESERVATION. Marouen Braham, Associate Professor,[1] Khadija Kacem, Associate Professor,[1] Zeineb Zemni, Medical Doctor,[1] Sarah Amari, Medical Doctor,[1] Wissal Jaafar, Medical Doctor,[1] Sana Chtourou, Assistant Professor,[2] Manel Hamdoun, Associate Professor,[1] Linda Debbabi, Medical Doctor,[1] Nozha Chakroun, Professor,[1] Olfa Bahri, Professor,[1] Fethi Zhioua, Professor,[3] Anis Fadhlaoui, Associate Professor[3] [1]Aziza Othmana University hospital, Tunis, Tunisia; [2]Reproductive Medecine Laboratory. Aziza Othmana University Hospital., Tunis, Tunisia; [3]Aziza Othmana Hospital , department of gynecology and obstetrics, tunis, Tunisia.

OBJECTIVE: Compare the efficacy of oral dydrogesterone to prevent LH peak during ovarian stimulation versus usual antagonist protocol in fertility preservation cases with oocyte vitrification.

DESIGN: Randomized prospective study from August 2019 to March 2020 at the Gynecology, Obstetric and Reproductive Medicine department of the Aziza Othmana University Hospital.

MATERIALS AND METHODS: Inclusion criteria: All patients underwent controlled ovarian stimulation for fertility preservation via oocyte vitrification.

Exclusion criteria: Patients with hormone-dependent diseases (breast cancer, systemic lupus).

Random-start ovarian stimulation was conducted with 300 IU of recombinant FSH for all patients.

Patients were randomized into 2 groups on the day of the onset of ovarian stimulation: Group 1: prevention of LH peak using Dydrogesterone orally: 10 mg three times a day; beginning the first day of ovarian stimulation. Group 2: Prevention of LH peak by subcutaneous injection of Cetrotelix 0.25 mg per day from the first day of ovarian stimulation.

Ovulation was triggered with 0.2 mg triptoreline. Oocyte pickup took place 37 hours later, either vaginally or per urethral transvesical route (for virgin patients).

$\chi 2$ test was used to compare qualitative variables. Student's t-test was used to compare quantitative variables. P-value < 0.05 was considered as statistically significant.

RESULTS: Forty-seven patients were included in our study: 22 in Group 1 and 25 in Group 2. There was no significant difference regarding the clinical characteristics of the 2 groups (Group 1 vs Group 2) in terms of age (23.14 ± 5.07 vs 23.8 ± 5.7 , p: 0.7), BMI (21.63 ± 3.6 vs 22.48 ± 4.03 , p: 0.5), AMH levels (2.04 ± 1.24 vs 3.3 ± 1.93, p: 0.06), the duration of ovarian stimulation (9.14 ± 1.55 vs 9.33 ± 1.79 , p: 0.5), the number of follicles with a diameter > 15 mm on the day of triggering (7.62 ± 4.1 vs 7.5 ± 3.3, p: 0.6) and plasma oestrogen levels on the day of triggering ovulation (2587 ± 1601 vs 2083 ± 1163, p: 0.1) Moreover, pickup results were similar (goupe 1 vs group 2) for the number of CCOS(12.71 ± 7.7 vs 12.29 ± 7.6 , p: 0.3) and the number of mature oocytes (9.85 ± 5.9 vs 9 ± 6.7 , p: 0.9). It should be noted that LH monitoring was performed in all patients and the difference was not significant either.

CONCLUSIONS: Prevention of premature LH peak during COS is possible using dydrogesterone in Random-start protocols for fertility preservation, excluding cases of hormone-dependant diseases.

P-297 4:30 PM Sunday, October 18, 2020

MODIFIED RNA ENCODING FOR ANTI-MULLERIAN HORMONE CONFERS OVARIAN PROTECTION FROM CYCLOPHOSPHAMIDE IN BOTH MOUSE AND HUMAN XENOGRAFT MODELS. Limor Man, M.D, M.Med.Sc,[1] Eleni Kallinos, B.S,[1] Lior Zangi, PhD,[2] Zev Rosenwaks, M.D.,[1] Daylon James, PhD[1] [1]The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY; [2]Icahn school of Medicine at Mount Sinai, NYC, NY.

OBJECTIVE: Women and young girls are at risk of ovarian failure secondary to chemotherapy treatment. The risk varies according to type, amount of chemotherapy, and patient's age at treatment (1). Several groups are studying different compounds that may protect the ovary using diverse models (2). In mice, AMH was found to protect primordial follicle (PF) pool loss due to cyclophosphamide (Cp) treatment (3,4). We investigated the potential of modified RNA encoding for Anti-Mullerian hormone (ModRNA-AMH) to protect ovarian pool when administered before Cp in both wild-type (WT) mice and on xenografted human ovarian tissue.

DESIGN: Murine model: intraovarian injection (IO) (saline/murine ModRNA-AMH) followed by intraperitoneal (IP) injection 24 hours later (saline/Cp). A total of 4 arms, 6 ovaries in each. Ovaries were harvested 2 weeks after the first chemotherapy injection.

Xenotransplantation model: human ovarian tissue transplanted into immunocompromised mice for two weeks, followed by: intra-graft (IG) injection (buffer) followed by an IP injection 24 hours later (saline/Cp), or IG injection of human ModRNA-AMH followed by IP Cp. A total of 3 arms, 4 grafts in each group in the short term (2 weeks after first Cp injection), and 8 grafts in each arm in the long term (12 weeks after the first Cp injection).

MATERIALS AND METHODS: In the murine model, we used 6-week old C57/B6 females.

In the xenograft model, we co-transplanted human ovarian cortical tissue from 12- and 29-years old organ donors, with endothelial cells, into NOD scid gamma (NSG) mice.

Cp was administered at the dose of 60mg/Kg and the protocol was repeated a week later.

After harvest of the ovaries/xenografts, histologic sections using H&E staining and light microscopy were used for counting of follicles.

RESULTS: In WT mice, we found retention of PF similar to the controls, Saline - IO /saline -IP; 49±12.10, ModRNA-AMH/saline 53.33±7.81 compared to ModRNA-AMH/Cp 47.17±13.61. A 50% decreased was noted with saline/Cp 26.5±9.01. In xenografts, in the short term, retention of PF was markedly improved with ModRNA-AMH pre-treatment. Buffer-IG/Cp-IP 9.41±10.91% PF, vs 56.24±39.44% with IG-ModRNA-AMH/Cp. Notably, the percentage of PF was similar to grafts treated with buffer/saline 51.67± 4.04%. Interestingly, long-term grafts treated with ModRNA-AMH/Cp yielded 3 antral follicles (AF), similar to 2 AF that were found in the buffer/saline, while only 1 AF was present in the buffer/Cp group. Moreover, the density of follicles in the ModRNA-AMH/Cp condition was normalized, while it was reduced in the buffer/Cp treated group.

CONCLUSIONS: In this study we evaluated the potential for ModRNA-AMH to confer a benefit to ovaries/ovarian tissue in the presence of CP and demonstrated retention of the PF pool in the short term and improved output in the long term. Administration of ModRNA-AMH provides an optimal mode of delivery due to its high efficiency and transient protein expression without eliciting a substantial innate immune response. Intra-ovarian administration before chemotherapy may confer a fertoprotective benefit with minimal expense and intervention.

Patent filing- "Using AMH modRNA to protect ovarian follicles against toxic effects from chemotherapy". Docket number 9222

OUTCOMES OF FERTILITY PRESERVATION IN WOMEN WITH ENDOMETRIOMA BEFORE AND/OR AFTER OVARIAN CYSTECTOMY. Hyun Kyoung Lee, M.D., Yeon Hee Hong, MD., Jung Ryeol Lee, MD, PhD Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South).

OBJECTIVE: Endometrioma is a major risk factor of infertility, reducing ovarian reserve and the quality of oocytes. Moreover, when it is surgically removed, ovarian reserve is further reduced. Therefore, women with endometrioma in reproductive age can be suitable candidates for fertility preservation (FP) before surgery. The purpose of this study is to analyze the outcomes of oocyte or embryo cryopreservation in women with endometrioma. We compared the controlled ovarian stimulation (COS) outcomes with infertile women without endometrioma and with other benign cysts. Subgroup analyses were done according to the laterality of endometrioma and COS repeat orders.

DESIGN: A retrospective study

MATERIALS AND METHODS: A total of 52 women with endometrioma were enrolled. Patients took baseline AMH and trans-vaginal ultrasonography before surgery. Patients were counseled about oocyte or embryo cryopreservation if she was expected to have a lower ovarian reserve. Inclusion criteria were typical sonographic features of endometrioma, planned ovarian cystectomy, and oocyte or embryo cryopreservation before surgery. Gonadotropin-releasing hormone antagonist protocols were conducted for COS. Primary outcomes were number of retrieved mature (MII) oocytes and cryopreserved oocytes. We used 1:1 propensity score matching analysis to compare COS outcomes of patients with endometrioma and infertile patients without endometrioma.

RESULTS: A total of 52 COS cycles from 52 patients were included. Patients with endometrioma showed lower AMH (1.20 [0.83, 2.17] vs. 2.96 [2.20, 3.90] ng/ml, $p \leq 0.001$), number of retrived MII oocytes (5.0 [3.0, 8.0] vs. 6.0 [5.0, 11.0], p=0.041),and number of cryopreserved oocytes (3.0 [2.0, 6.0] vs. 6.5 [4.0, 8.3], p=0.014) than matched control infertile patients. Total gonadotropin dose was significantly higher in endometrioma patients (2400 [2100, 2400] vs. 2025 [1743.75, 2400] IU, p=0.003). 21 women underwent repeated COS for 2 to 4 times. The number of cryopreserved oocyte at first to fourth cycles were 3.50 [2.00, 6.00], 5.00 [2.50, 7.50], 3.00 [2.75, 4.75], 3.00 [2.50, 3.50], respectively. Cumulative number of cryopreserved oocytes was 8, 11.5, 14.50 for 2, 3, and 4 times, having a cumulative effect.

CONCLUSIONS: Controlled ovarian stimulation of women with endometrioma for fertility preservation is feasible and effective. Patients with endometrioma who has plan for ovarian cystectomy should be counseled about oocyte or embryo cryopreservation. Furthermore, repeated COS cycles can increase cumulative number of cryopreserved oocytes.

INHIBITING NECROPTOSIS OF SPERMATOGONIAL STEM CELL AS A NOVEL STRATEGY FOR MALE FERTILITY PRESERVATION. Guihua Liu, Ph.D.,[1] Xing Yang, Ph.D.,[1] Tingting Li, Doctor[2] [1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Reproductive Medicine Research Center, Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

OBJECTIVE: Fertility preservation is a common concern for male cancer survivors of reproductive age. However, except for testicular tissue cryopreservation which is not very effective, there is no feasible and precise therapy capable of protecting spermatogenesis for prepubertal boys prior to or during gonadotoxic treatment. This study aims to investigate the effects of inhibiting necroptosis of spermatogonial stem cell (SSC) in fertility preservation.

DESIGN: Animal study was designed.

MATERIALS AND METHODS: Male mice aged 12 weeks were used to establish gonadotoxicity with two intraperitoneal injections of busulfan at a total dose of 40 mg kg^{-1}. The mouse model and the primary cultured mouse SSCs were used to characterize the relationship between necroptosis of SSC and gonadotoxicity. Meanwhile, the effects of an inhibitor of necroptosis pathway, RIPA-56, were observed at day 36 in the mouse model of busulfan induced gonadotoxicity.

RESULTS: The number of SSCs was decreased but the level of necroptosis was up-regulated at day 18 after busulfan treatment in testes from gonadotoxic mice. Further experiments in primary cultured cells showed that the necroptosis caused the cell death in busulfan induced SSCs.

After suppressing RIPK1 throughout the seminiferous epithelium cycle (36 days), when compared to the model group, those in the RIPA-56 group had a decreased loss of spermatogenic cells as shown by histology and an increased Johnsen's score ($P<0.001$), the testis/body weight ratio ($P<0.05$) and the protein expression of SSCs ($P<0.001$) .Moreover, the quantities of SSCs and epididymal spermatozoa were restored after intervention with RIPA-56, indicating a series of beneficial effects by targeting the necroptosis of SSCs in mice undergoing busulfan treatment.

CONCLUSIONS: Our findings reveal that the necroptosis of SSCs plays a critical role in busulfan induced gonadotoxicity and may be a potential target for male fertility preservation.

DUAL-TRIGGERING WITH HUMAN CHORIONIC GONADOTROPIN AND GONADOTROPIN RELEASING HORMONE AGONIST IS BENEFICIAL FOR ACQUISITION OF MATURE OOCYTES IN LETROZOLE-COMBINED OVARIAN STIMULATION CYCLES. Yeon Hee Hong, MD.,[1] Jung Ryeol Lee, MD. PhD.,[2] Chang Suk Suh, MD. PhD.,[3] Seok Hyun Kim, MD. PhD.[2] [1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South); [2]Seoul National University College of Medicine, Seoul, Korea, Republic of (South); [3]Sheikh Khalifa Specialty Hospital Ras Al Khaimah, RAK City, United Arab Emirates.

OBJECTIVE: It is critical to set up an efficient maturation method to increase the yield of mature oocytes, especially for cancer patients with fewer chances of fertility preservation (FP) before gonadotoxic therapy. The purpose of this study is to investigate whether dual triggering with human chorionic gonadotropin (hCG) and gonadotropin-releasing hormone agonist (GnRHa) for final oocyte maturation improve the controlled ovarian stimulation (COS) outcomes for women undergoing FP.

DESIGN: Retrospective study

MATERIALS AND METHODS: A total of 317 patients undergoing COS using GnRH antagonist protocol for FP were enrolled. Patients' basal characteristics and COS outcomes were analyzed according to triggering methods. The control group (n=208) used 250 μg of recombinant hCG (rhCG), and the study group (n=109) used 250 μg of rhCG and 0.2mg of triptorelin for triggering. All information was collected via medical records. Subgroup analyses were done for patients with decreased ovarian reserve (DOR) defined as AMH<1.1ng/mL (n=74), with endometrioma (n=88), or with breast cancer and endometrial cancer using 5mg of letrozole during the COS cycles (n=73). The main outcomes are the number of mature oocytes and the maturation rate. Continuous variables were compared using either the Student t-test or Mann-Whitney test. The chi-square test was used for categorical variables. P-value < 0.05 was considered statistically significant. SPSS version 25.0 was used for statistical analyses.

RESULTS: The mean age, BMI, and AMH in all patients are 31.4±6.3 years, 21.3±3.0 kg/m^2, and 2.6±2.6 ng/mL, respectively. There was no significant difference in basal characteristics and the number of total and mature oocytes between the two groups. Subgroup analyses for women with endometrioma or DOR showed similar results. However, the dual-trigger group had significantly higher number of mature oocytes than the hCG trigger group in breast and endometrial cancer patients using letrozole during COS cycles (7.0±6.4 vs. 4.3±3.6, p=0.041). The maturation rate was higher in the dual-triggering group, though it was not statistically significant

(60.5±28.3 vs. 48.2±28.0, p=0.072). The rate of ovarian hyperstimulation syndrome is comparable between the two groups (6.3% vs. 0%, p=0.189).

CONCLUSIONS: The dual triggering method significantly increases the yield of mature oocytes and could be a useful method for final oocyte maturation in breast and endometrial cancer patients using letrozole-combined COS regimen.

EGG FREEZING CRACKS UP TO BE A VIABLE FERTILITY PRESERVATION (FP) METHOD: FIFTEEN YEARS OF AUTOLOGOUS OOCYTE (AO) THAW OUTCOMES AT A LARGE UNIVERSITY-BASED FERTILITY CENTER. Sarah Druckenmiller Cascante, MD, Shannon Devore, MD, Jennifer K. Blakemore, MD, Tsai-Ling Lee, MS, Caroline McCaffrey, PhD, James A. Grifo, MD, PhD NYU Langone School of Medicine, New York, NY.

OBJECTIVE: AO cryopreservation (cryo) is widely used for FP, but published thaw data is scarce. Our aim was to review our AO thaws.

DESIGN: Retrospective cohort.

MATERIALS AND METHODS: Patients (pts) who thawed AOs at our university-based fertility center from 2004-2019 were reviewed. Pts were excluded if cryo was performed for a medical indication, as research, due to lack of sperm, due to a natural disaster or in combination with embryos. Pts were also excluded if they had cancer or planned to use a gestational carrier. Outcomes included implantation (IR), spontaneous abortion (SABR) and ongoing pregnancy + live birth (LBR) rates. Statistics included Mann-Whitney U and Fisher's exact tests, with $p<0.05$ as significant.

RESULTS: We reviewed 468 pts (median age at first cryo 38y, range 27-46y), who underwent 677 cryos (89% at our center, 8% elsewhere, 2% at both), 523 thaws and 360 embryo transfers (ET). Cryo involved vitrification for 69%, slow freezing for 4% and both for 27% of pts. Median time between first cryo and first thaw was 4y. Overall AO cryo survival was 79%, M2 cryo survival was 80% and 2PN fertilization (fert) was 66%. 441 thaws (84%) led to $\geq$1 embryo for fresh ET, trophectoderm biopsy (TEBX) or cryo while 82 thaws (16%) led to no embryos for ET, TEBX or cryo. Of thaws with TEBX, 65% had $\geq$1 euploid embryo. 142 ETs (39%) were fresh, with 2% using rush biopsied embryos. 218 ETs (61%) were frozen, with 97% using biopsied embryos. In euploid ETs (n = 205), IR was 64%, SABR was 10% and LBR was 55%. In non-biopsied ETs (n = 146), IR was 28%, SABR was 14% and LBR was 32%. There were 8 mosaic and 1 aneuploid ET. See table for outcomes by age. In total, our pts have 155 babies (11 twin, 1 triplet) and 19 ongoing pregnancies (2 twin) from AO cryo. 51 pts (11%) have remaining frozen AOs and 117 (25%) have euploid or untested embryos.

CONCLUSIONS: AO cryo is a viable FP method and led to live birth in 32% of pts, comparable to our center's 34% LBR per intended retrieval[1] and the national 26% LBR per intended retrieval in pts of similar age (38-40y)[2].

P-303 4:30 PM Sunday, October 18, 2020

MEDICALLY-INDICATED OOCYTE (OC) AND EMBRYO CRYOPRESERVATION (EC) IN PATIENTS WITH NON-ONCOLOGIC CONDITIONS: 5 YEARS OF EXPERIENCE AT AN URBAN UNIVERSITY-BASED FERTILITY CENTER. Amani Sampson, B.A.,[1] Emily Michelle Weidenbaum, MD,[1] Jennifer K. Blakemore, MD,[2] Gwendolyn P. Quinn, Ph.D.,[1] James A. Grifo, MD, PhD[2] [1]NYU Langone School of Medicine, New York, NY; [2]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: The use of OC and EC, a standard option of fertility preservation (FP) for patients with cancer, has expanded to include non-oncologic medical conditions that may affect future fertility, such as cardiomyopathy. Our objective was to examine the distribution of non-oncologic medically-indicated FP by indication and FP type at our center.

DESIGN: Retrospective Cohort of all medically-indicated non-oncologic (MINO) FP from 1/2013-12/2018.

MATERIALS AND METHODS: All medically-indicated OC and EC cycles in the study time period were reviewed. All cycles of patients with cancer or planned oocyte/embryo cryopreservation were excluded. Cycles were reviewed for demographics, FP type, indication, cycle number and outcome, return rate, and live births. Descriptive results are reported as median (range). Statistical analyses included Mann-Whitney and Fisher's exact, with $p<0.05$ considered significant.

RESULTS: 421 cycles from 302 patients were reviewed: 284 OC and 137 EC. A total of 115 cycles from 81 patients with a non-oncologic condition were included representing 26% of all medically-indicated OC and 35% of medically-indicated EC respectively. Median cycle number was 1 for both OC and EC, with a range of 1-5 cycles. Median age at time of cycle start was 34 (range 13-44) for the cohort. OC patients were significantly younger than EC patients (33 vs 35, $p<0.003$). Median number of oocytes retrieved was 14 (range 0-76) and there was not a difference between OC and EC patients (13 vs 15, p=0.34). The median number of euploid embryos for EC patients was 1 (range 0-7). Patients were grouped by medical indication and compared, as shown in Table 1. To date, 9 EC patients have pursued pregnancy with gestational carriers and 3 more underwent a total of 6 frozen embryo transfers resulting in 4 livebirths. No OC patients have returned yet for oocyte warming.

TABLE 1: Distribution of MINO FP by Indication and Cycle Type

Indication	OC	EC	p-value
Chronic Medical Condition planning gonadotoxic therapy (eg. Ulcerative colitis)	13%	4%	.43
Sex Chromosome Disorder	21%	0%	.014
Transmen prior to gender affirmation	9%	0%	.32
Hereditary Cancer Susceptibility Syndromes	29%	12%	.16
Hereditary Condition (Non-Cancer)	0%	8%	.09
Benign/Congenital GYN Condition (eg. Endometriosis)	29%	44%	.21
Contraindication to Pregnancy (eg. Cardiomyopathy)	0%	32%	.0001

Age at first cryo (no. pts)	Median M2s thawed per pt / Median AOs thawed per pt	Embryos for fresh ET + TEBX + cryo / 2PN fert (%)	Euploid embryos / TEBX embryos (%)	Pts with $\geq$ 1 ET (%)	Euploid ETs / All ETs	IR (%)	SABR (%)	LBR (%)	Pts with $\geq$ 1 baby or ongoing pregnancy from AO cryo (%)
All ages (468)	12 / 14	1588 / 3781 (42)	383 / 1260 (30)	280 (60)	205 / 360 (57)	208 / 478 (44)	20 / 185 (11)	162 / 360 (45)	150 (32)
<38y (191)	14 / 15	742 / 1697 (44)	228 / 636 (36)	122 (64)	112 / 164 (68)	99 / 191 (52)	9 / 90 (10)	80 / 164 (49)	75 (39)
38 – 40y (216)	10.5* / 12*	701/ 1699 (41)	147 / 531 (28)*	129 (60)	85 / 162 (52)*	87 / 222 (39)*	8 / 77 (10)	67 / 162 (41)	61 (28)*
>41y (61)	9* / 12*	145 / 385 (38)*	8 / 93 (9)**	29 (48)*	8 / 34 (24)**	22 / 65 (34)*	3 / 18 (17)	15 / 34 (44)	14 (23)*

* = lower than the <38y age group
** = lower than the <38y and 38 – 40y age groups

CONCLUSIONS: Non-oncologic indications represent 30% of medically-indicated FP cycles at our center. Many women pursue MINO FP for GYN conditions affecting fertility. Notably, more women with sex chromosome disorders pursued OC compared to pregnancy contraindications in the EC group. These results advocate for further research on the support, counseling, and referral needs of women with MINO conditions.

P-304 4:30 PM Sunday, October 18, 2020

PLANNED OOCYTE CRYOPRESERVATION (PL-OC) IN WOMEN AGE 40-45. Bat-Sheva L. Maslow, MD, MSCTR, Leslie B. Ramirez, PhD, Michael M. Guarnaccia, MD, MPH, Joshua U. Klein, MD Extend Fertility, New York, NY.

OBJECTIVE: Women 40-45, particularly if unpartnered, consider Pl-OC to preserve opportunity for a genetic child in the future. According to SART, IVF live birth rates for women >40 are <12% and cycle cancellation rates are as high as 20%. Limited data exist on Pl-OC process and outcomes in this age group, particularly for women 43+.

This study aimed to identify rates of Pl-OC in women age 40-45 following appropriate evidence-based counseling. We hypothesized that women 43+ and those with lower AMH would be less likely to proceed with Pl-OC.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All women age 40-45 presenting for a complimentary Pl-OC assessment (consisting of AMH/AFC) and physician consultation at Extend Fertility Medical Practice, a large single-center oocyte cryopreservation program from 1/1/18-5/25/20 were included. Counseling included specific evidence-based algorithms for oocyte yield based on age and AMH, as well as estimated live birth outcomes based on published aneuploidy data, and where relevant, discussion of the lack of live birth data for women 43+.

Median AMH levels were calculated overall and by age, for the entire cohort and those who chose Pl-OC. Mean number of MII oocytes cryopreserved per cycle and mean number of cycles per patient were also calculated. Comparisons were made using Kruskal-Wallis, *t*-test, and X^2 where appropriate.

RESULTS: 474 women age 40-45 presented for complementary consultation and were included in the study. Following their consultation, 117/474 (24.6%) proceeded with Pl-OC.

CONCLUSIONS: With effective counseling, even in this low efficacy group, women with the highest chances of success can have the opportunity to attempt Pl-OC with a low cycle cancellation rate.

Age at Retrieval (*n*)	Eggs Retrieved	MII Eggs
14 (3)	14.0	10.0
15 (3)	18.7	12.3
16 (2)	29.0	18.5
17 (3)	25.0	21.7
19 (3)	21.0	14.3
20 (5)	15.8	12.0
21 (4)	16.0	13.5
22 (8)	24.9	20.3
23 (18)	28.6	21.3
24 (24)	23.8	16.9
25 (25)	25.2	15.2

13 (8)	22.6	14.1
14 (4)	19.5	15.5

TABLE 1: Demonstrates data for the entire cohort and those who chose Pl-OC (cycling cohort)

	Total Cohort		*Cycling Cohort*			
Age	N	AMH Median±IQR	N(%)	AMH Median±IQR	Frozen MII/Cycle Mean±SD	# of Cycles/Patient Mean±SD
40	156	1.22±1.78	47 (30.2)	1.80±2.21	7.14±5.28	1.77±1.21
41	122	0.75±1.66	27 (22.1)	1.37±2.13	6.61±5.98	2.08±1.90
42	87	0.58±1.18	27 (31.0)	1.01±1.70	7.57±5.64	1.33±0.61
43	47	0.58±1.04	6 (12.8)	1.81±2.45	5.50±4.64	1.79±0.98
44	37	0.50±0.90	6 (16.2)	0.85±1.20	5.07±5.09	1.80±0.94
45	25	0.35±0.55	4 (16.0)	0.81±0.65	3.33±1.63	2.33±1.21
Total	474	0.77±1.35	117 (24.6)	1.34±1.89	6.68±5.45	1.83±1.38

Women who chose not to cycle had lower Median AMH (0.62±1.20 vs 1.34±1.89, p<0.001) and were more likely to be 43+ (OR 0.45 CI 0.25-0.80; 16/109 vs. 101/365 p=0.005) compared to those who cycled. Of those who cycled, only 8/117 (6.8%) had a cycle cancelled for poor response or 0 oocytes cryopreserved.

P-305 4:30 PM Sunday, October 18, 2020

DOES AGE OR GYNECOLOGIC AGE AFFECT OUTCOMES OF OOCYTE CRYOPRESERVATION IN PERI-PUBERTAL AND ADOLESCENT FEMALES? Nicole D. Yoder, MD,[1] Emily E. Auran, MD,[1] David H. McCulloh, Ph.D.,[2] Mary Elizabeth Fino, MD[3] [1]NYU School of Medicine, New York, NY; [2]NYU Langone Fertility Center, New York, NY; [3]NYU Langone Prelude Fertility Center, New York, NY.

OBJECTIVE: Current data on fertility preservation outcomes in peri-pubertal and adolescent females is limited, with most data originating from oncofertility studies. Few studies explore outcomes in those undergoing fertility preservation for gender dysphoria or other non-oncologic indications. Our objective was to review fertility preservation outcome in patients with gender dysphoria and non-oncologic indications under age 25 at a single academic institution. Specifically, we sought to investigate egg retrieval outcomes as they relate to patient age, gynecologic age (age from menarche to egg retrieval), and AMH.

DESIGN: Retrospective case series

MATERIALS AND METHODS: Patients undergoing oocyte retrieval at an academic institution between age 14 and 25 from 1/2000 to 1/2020 were identified. Included patients were those undergoing egg retrieval for non-medical indication, transgender patients, and egg donors. Patients with ovarian pathology and Sex chromosome disorders including Turners syndrome were excluded. Patients with a cancer diagnosis were excluded given non-traditional stimulation, as well as the potential for cancer to impact ovarian response. Age of menarche and AMH level prior to cycle were identified by chart review. Cycles were evaluated by number of eggs retrieved and number of metaphase II (MII) oocytes. Comparisons were made between cycle outcome and patient age, gynecologic age, and AMH at cycle start.

RESULTS: 73 patients were included. There were 10 patients with gender dysphoria, 44 egg donors, and 19 patients undergoing elective egg retrieval. Neither age nor gynecologic age were correlated with number of eggs retrieved (n=88, r=0.16; n=86, r=0.16 respectively) or number of MII

eggs (n=88, r=0.05; n=86, r=0.10). AMH value was positively correlated to number of eggs retrieved (n=83, r=0.29) and number of MII eggs (n=83, r=0.26).

CONCLUSIONS: Overall, in young female patients undergoing egg retrieval for non-oncologic indication, neither age nor gynecologic age were predictive of egg retrieval outcome. As seen in other populations, AMH value may positively correlate with egg retrieval outcome in young females. Further research with a larger study population may elucidate ideal timing for egg retrieval or donation in these peri-pubertal and adolescent females.

P-306 4:30 PM Sunday, October 18, 2020

FACTORS THAT INCREASE LIKELIHOOD OF USE OF CRYOPRESERVED SPERM IN AYA MALES UNDERGOING FERTILITY PRESERVATION. Kathryn M. Goldrick, MD, Molly Bergen, BS, Randal D. Robinson, MD, T. Arthur Chang, PhD, HCLD, ELD, Mario Octavio de la Pena, Jr., BS, Jennifer F. Knudtson, MD University of Texas Health Science Center, San Antonio, TX.

OBJECTIVE: An estimated 12,400 AYA patients are diagnosed with cancer each year, but due to advances in treatment, almost 80% of those diagnosed will achieve long term survival (1). These treatment advances include multimodal chemotherapeutic regimens, radiation, and surgery which can have reproductive consequences. The most effective and established means of fertility preservation for men prior to chemotherapy is sperm cryopreservation, which is used by 99% of male AYA patients who undergo fertility preservation (2). However, a systematic review of 11,798 male patients who underwent fertility preservation for cancer showed that the usage rate of cryopreserved sperm was only 8% (3). The objective of this study is to determine factors associated with an increased likelihood of usage of cryopreserved sperm for AYA males who undergo fertility preservation.

DESIGN: Retrospective chart review at an academic fertility center.

MATERIALS AND METHODS: A retrospective chart review of AYA males ages 15-39 who underwent fertility preservation by sperm cryopreservation for cancer and/or future gonadotoxic treatment at an academic fertility center between 2009 and 2019 were identified, and demographic, clinical, and laboratory data were collected in REDCap database. Patient attributes were assessed to see what factors, if any, are associated with an increased likelihood of fertility preservation and future use of cryopreserved sperm. Statistical analysis was performed via Chi-square.

RESULTS: In this population of 118 AYA males that cryopreserved sperm, they were primarily Hispanic (30%, n=36) had testicular cancer (36%, n=43) and an average age of 24. The most common planned treatment was chemotherapy (78%, n=92). Four of the 118 patients, a total of 3%, have returned to use their cryopreserved sperm. Three of these four patients had testicular cancer and were 2-3 years from their cancer treatment. There were 14 patients who discarded cryopreserved sperm and 5 who transferred sperm to another institution. Assuming the 5 patient who transferred their sperm did use it, there would be 8% of the samples used. The total motile count of the cryopreservation analysis was lower for patients who used their cryopreserved sample compared to those who discarded, but this was not statistically significant (32.8M vs 105.6M, p=0.2).

CONCLUSIONS: At our center, only a small percentage of cryopreserved sperm banked from the AYA males with cancer and/or planned gonadotoxic treatment is being used. Type of cancer, time from cancer treatment, and TMC on cryopreservation analysis may be predictive of future use of sperm and could be useful in counseling patients undergoing sperm cryopreservation.

CARE GAPS IN FERTILITY PRESERVATION SERVICES FOR RESIDENT PHYSICIANS: *A SURVEY OF FERTILITY PRESERVATION AWARENESS AND INSURANCE COVERAGE*. Ashley S. Kim, M.D., Amy S. Dhesi, M.D., Sami I. Jabara, M.D., Marsha B. Baker, M.D., M.P.H Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA.

OBJECTIVE: To assess awareness and attitudes towards fertility preservation services for resident physicians, as well as availability of covered benefits.

DESIGN: Cross-sectional survey

MATERIALS AND METHODS: Surveys were emailed to program directors of Accreditation Council for Graduate Medical Education (ACGME) residency programs across five medical specialties: Obstetrics and Gynecology, Pediatrics, Internal Medicine, Family Medicine and General Surgery. From March through May 2020, 102 voluntary responses were collected. Fertility preservation was defined as oocyte or sperm cryopreservation for elective purposes, transgender care or cancer. Respondents were queried about demographics, formalized education on fertility preservation for trainees, availability of insurance coverage and attitudes about coverage. Descriptive statistics were used to analyze responses. Qualitative data in the form of open-ended comments were also collected.

RESULTS: Of the 102 total responses, 29 (28%) were obtained from Obstetrics and Gynecology (OBGYN), 25 (25%) from Family Medicine, 19 (19%) from Pediatrics, 18 (18%) from General Surgery, and 11 (10%) from Internal Medicine. While almost half (45%) of program directors revealed that their residents have expressed concern regarding delayed childbearing or future fertility, formal discussion of fertility preservation options appears limited. Only 10% of program directors report formal didactics with residents about elective oocyte cryopreservation, with the majority of those programs being from OBGYN. Less than 5% of programs report having formal didactics about fertility preservation for transgender care or cancer. Most program directors across all specialties personally support fertility preservation as a covered benefit for their residents (78%), but resident access to fertility preservation services is limited with 6% of respondent programs offering coverage for elective oocyte cryopreservation, and 12 % offering coverage for elective oocyte cryopreservation for residents with new cancer diagnoses. Programs reporting fertility preservation coverage for residents are predominantly in the Northeast, consistent with the mandated fertility coverage for many states in that region.

CONCLUSIONS: This study suggests that barriers to fertility preservation services for resident physicians include the lack of formal didactics across specialties and limitations of state mandated coverage. This study provides novel data supporting the need for enhanced discussion and awareness to bridge the gap in access to care for fertility preservation services among resident physicians.

P-308 4:30 PM Sunday, October 18, 2020

RELUGOLIX COMBINATION THERAPY IMPROVES UTERINE FIBROID-ASSOCIATED PAIN DURING MENSTRUAL AND NON-MENSTRUAL DAYS: RESULTS FROM THE LIBERTY PHASE 3 PROGRAM. Ayman Al-Hendy, MD, PhD,[1] Andrea S. Lukes, MD, MHSc,[2] Roberta Venturella, MD, PhD,[3] Yulan Li, PhD,[4] Rachel B. Wagman, MD,[5] Elke Hunsche, PhD,[6] Elizabeth A. Stewart, MD.[7] [1]Department of Surgery, University of Illinois at Chicago, Chicago, IL; [2]Carolina Women's Research and Wellness Center, Durham, NC; [3]Magna Graecia University of Catanzaro, Catanzaro, Italy; [4]Myovant Sciences, Inc., Brisbane, CA; [5]Myovant Sciences Inc., Brisbane, CA; [6]Myovant Sciences GmbH, Basel, Switzerland; [7]Mayo Clinic Department of OB/GYN, Reproductive Endocrinology and Infertility, Rochester, MN.

OBJECTIVE: To evaluate the effect of Relugolix combination therapy (Rel-CT) on pain symptoms associated with uterine fibroids (UF) in the Phase 3 LIBERTY studies.

DESIGN: LIBERTY 1 and LIBERTY 2 were multinational, randomized, double-blind, placebo-controlled studies that evaluated the effect of Rel-CT (once-daily relugolix 40 mg, estradiol 1 mg, norethindrone acetate 0.5 mg) on heavy menstrual bleeding (HMB) in women with UF. UF-associated pain was a secondary endpoint of each study.

MATERIALS AND METHODS: The pain-evaluable population was defined as women with moderate to severe UF-associated pain at baseline (maximum pain $\geq$ 4 on the 0–10 numerical rating scale during the 35 days before randomization and >80% compliance to the e-diary completion). Analyses included the prespecified endpoint of the proportion of women with no/minimal UF-associated pain at Week 24 (maximal pain score $\leq$ 1 during the last 35 days of treatment) in the pain-evaluable population, as well as additional analyses of subgroups of patients with moderate/severe pain during menstrual and non-menstrual days at baseline. Treatment comparisons were performed on the pooled data from the LIBERTY 1 and 2 studies using the Cochran–Mantel–Haenszel test stratified by baseline menstrual blood loss volume (<225 mL vs $\geq$225 mL).

RESULTS: In total, 277 patients in the pooled dataset were pain-evaluable: 126 patients randomized to Rel-CT and 151 randomized to placebo (54% of the combined LIBERTY 1 and 2 cohort). Most of the pain-evaluable patients (117 in the Rel-CT group and 145 in the placebo group) reported moderate/severe pain during menstruation, while 65 patients in the Rel-CT group and 74 in the placebo group had moderate/severe pain on non-menstrual days. After 24 weeks of treatment, a significantly greater proportion of patients in the Rel-CT group (45.2%) had no/minimal UF-associated pain during the last 35 days of treatment, compared with the placebo group (13.9%, $p<0.0001$). The percentages of women reporting no/minimal UF pain during menstrual days (65.0% vs 19.3%; $p<0.001$) and during non-menstrual days (44.6% vs 21.6%; $p=0.004$) were significantly higher in patients on Rel-CT vs placebo, respectively, at Week 24. The mean percentage of menstrual days with pain medication use decreased with Rel-CT from 35.9% at baseline to 7.2% at Week 24; the placebo group had a small reduction from 34.7% at baseline to 25.5% at Week 24. Adjusting for increased analgesic use at Week 24 vs baseline did not impact the results.

CONCLUSIONS: Once-daily Rel-CT treatment for 24 weeks led to a significant reduction of UF-associated pain in patients with moderate to severe pain at baseline. Both pain during menstrual and non-menstrual days improved with Rel-CT. The significant reduction in measures of pain is clinically meaningful and relevant to patients, and is supported by quality-of-life improvements that have been observed in the LIBERTY program.

P-309 4:30 PM Sunday, October 18, 2020

UTERINE FIBROID-CAUSING MUTAGENESIS INDUCED BY DEVELOPMENTAL EXPOSURE TO ENDOCRINE DISRUPTING CHEMICALS IS MEDIATED VIA ABROGATION OF NUCLEOTIDE EXCISION REPAIR PATHWAY IN MYOMETRIAL STEM CELLS THROUGH UPREGULATION OF TGF-β1. Maria Victoria Bariani, Ph.D., Hoda Elkafas, B. Pharm, MSc, Mohamed Ali, BPharm, MSc, Qiwei Yang, PhD, Ayman Al-Hendy, MD, PhD. Department of Surgery, University of Illinois at Chicago, Chicago, IL.

OBJECTIVE: The cause of uterine fibroid (UFs) is largely unknown, but it is well established that one of the major risk factors for the development of these tumors is early environmental exposure to endocrine-disrupting chemicals (EDCs). It has been shown that UFs originate from abnormal stem cells (SCs) in the myometrium (MM) that acquire a driver mutation in pivotal genes such as Tsc-2 (Eker rat) or Med12 (human), and there is evidence that DNA repair capacity could be involved in the emergence of such mutations. Furthermore, the pleiotropic cytokine TGF-β1 has been related to UF development. Recent studies have suggested a link between TGF-β1 and the DNA damage response with implications for tumor initiation and growth. In this context, this work aimed to evaluate the possible role of TGF-β1 and the nucleotide excision repair (NER) on the tumorigenesis process on EDC-exposed MMSCs.

DESIGN: Laboratory research studies using an Eker rat fibroid model MMSCs.

MATERIALS AND METHODS: Female Eker rats were received subcutaneous injections of 10 μg of Diethylstilbestrol (DES, endocrine-disrupting chemical) per rat per day or 50 μl of sesame seed oil (vehicle, VEH) on days 10, 11, and 12 after birth. MMSCs were isolated from 5 months adult MM tissue (N=5 for each group) using Stro-1 and CD44 surface markers. Whole-genome RNA-sequencing was performed in VEH- and DES-MMSCs to determine global gene expression profiles. Latent-TGFβ-binding protein 1 (Ltbp-1), Tgf-β1, Xpc, Ddb1, and Ddb2 (three proteins involved in DNA damage recognition on NER pathway) mRNA levels in VEH- and DES-MMSCs were measured using qRT-PCR. Thrombospondin 1 (TSP-1), LTBP1, TGF-β1, XPC, and DDB1 protein expressions were evaluated by Western Blot (WB). Two-tailed unpaired Student t-test was used to assess any statistically significant differences (P-value<0.05).

RESULTS: The RNA-seq data analysis demonstrated that the expression of 19 genes belonging to TGF-β1 signaling were altered in DES-MMSCs compared to VEH-MMSCs. Moreover, 6 genes involved in the NER pathway showed changes in RNA expression between DES-MMSCs. The mRNA levels of Ltbp-1 and Tgf-β1 in MMSCs showed an increase when animals were exposed neonatally to DES. Regarding NER related genes, Xpc, and Ddb2 were higher in DES-MMSCs than VEH-MMSC, while Dbb1 mRNA levels showed the opposite results ($p<0.05$). The protein levels of TSP-1, LTBP1, and TGF-β1 were increased in DES-MMSCs compared to VEH-MMSCs ($p<0.05$). We did not find differences in XPC protein levels ($p>0.05$). However, DDB1 protein levels were upregulated in DES-MMSCs in comparison to VEH-MMSCs.

CONCLUSIONS: Our results showed that early-life exposure to DES provokes changes in TGF-β1 and NER pathways on MMSCs, therefore it could increase the predisposition to develop UFs later in life. Further studies are needed to determine the relation between TGF-β1 and NER pathways on DES-exposed MMSCs and parallel studies in the human uterus.

THE YAP INHIBITOR VERTEPORFIN REGULATES ACTIVIN-A/SMAD SIGNALING AND MECHANOTRANSDUCTION IN UTERINE FIBROID CELLS. Md Soriful Islam, PhD, Sadia Afrin, PhD, Joshua T. Brennan, MPH, Subbroto Kumar Saha, PhD, Mostafa A. Borahay, MD, PhD, James H. Segars, MD. Johns Hopkins University School of Medicine, Baltimore, MD.

OBJECTIVE: Uterine fibroids are mechanically stiff fibrotic tumors of the uterus. Activin A, a member of the TGF-β superfamily, is overexpressed in fibroids and is known to increase expression of extracellular matrix (ECM) proteins. The increased stiffness of ECM in fibroids leads to activation of mechanotransduction signaling. Hippo is a key pathway that regulates cell growth and fibrosis in response to stiffness of ECM. YAP (yes-associated protein), a transcriptional effector of Hippo signaling, is also overexpressed in fibroids. Here, we investigated whether YAP contributes to mechanical signaling in fibroid cells via activin-A/SMAD.

DESIGN: Translational research study using human myometrial (P51M) and uterine fibroid (P51F) cells.

MATERIALS AND METHODS: To explore the role of YAP in regulating activin-A/SMAD signaling and mechanotransduction, we used the YAP inhibitor, verteporfin. Protein and/or mRNA levels of the key components of activin-A/SMAD and mechanotransduction pathways were measured using real time qPCR and western blot, respectively, following treatment with verteporfin at 1μM for 24 hrs. We included proteins involved in mechanical signaling, such as FAK, and mRNA for integrins. Statistical significance was defined as a $p<0.05$.

RESULTS: We observed increased mRNA levels of activin-A (*INHBA*) (4.1-fold) in fibroid compared to myometrial cells. Treatment of verteporfin reduced mRNA levels of activin-A ($p<0.001$) and its receptors *ACVR2A* ($p<0.001$) and *ACVR1B* ($p<0.05$), but not *ACVR2B* ($p=0.14$) in fibroid cells. Verteporfin also inhibited *SMAD2* mRNA and phosphorylated SMAD2 protein in fibroid cells ($p<0.05$). PAI-1 represents downstream target of activin A and is known to mediate fibrosis, which highly expressed at mRNA (2.5-fold) and protein (2.1-fold) levels in fibroid compared to myometrial cells. Verteporfin treatment significantly reduced both mRNA and protein levels in both cell types ($p<0.05$). The initiators of mechanotransduction signaling, integrin receptors *ITGB1* (1.3-fold), but not *ITGA6* (0.8-fold), were highly expressed in fibroid compared to myometrial cells. Treatment of verteporfin significantly decreased both *ITGB1* and *ITGA6* transcript levels in both cell types ($p<0.001$). The cytoplasmic kinase *FAK* mRNA was also elevated in fibroid (1.3-fold) compared to myometrial cells; and levels were reduced by verteporfin treatment ($p<0.05$). Notably, levels of phosphorylated FAK were also reduced by verteporfin treatment ($p<0.01$). AKAP13, a target of FAK, was increased (mRNA) in fibroid cells (1.4-fold) and was also suppressed by verteporfin treatment ($p<0.01$). Furthermore, we found that the increased levels of phosphorylated ERK1/2 (1.6-fold) in fibroid compared to myometrial cells were also reduced after verteporfin treatment ($p<0.05$).

CONCLUSIONS: Verteporfin reduced key components of activin-A/SMAD signaling and its downstream target PAI-1, as well as key mechanotransduction signaling factors. These results suggest crosstalk between Hippo/YAP signaling and activin-A/SMAD and ERK 1/2 pathways in regulation of critical genes involved in cell growth and fibrosis.

SINGLE CELL TRANSCRIPTOMES FROM UTERINE FIBROIDS AND FIBROID-FREE MYOMETRIUM ELUCIDATE MYOMETRIAL TUMORIGENESIS.

Wanxin Wang, PhD,[1] Aymara Mas, PhD,[2] Patricia Escorcia, BS,[2] Javier Monleón, MD,[3] Stephen R. Quake, DPhil,[1] Carlos Simon, MD, PhD.[4] [1]Stanford University, Stanford, CA; [2]Igenomix Foundation, Valencia, Spain; [3]Hospital Universitario La Fe, Valencia, Spain; [4]Professor University of Valencia, INCLIVA, Founder and Head of the Scientific Advisory Board, Igenomix, Paterna (Valencia), Spain.

OBJECTIVE: Uterine fibroids represent the most common benign tumors in women in reproductive age. It has been reported that they arise from a single dysregulated myometrial smooth muscle cell. However, the underlying tumorigenic mechanism remains unclear and because of that, surgery has been the gold standard for their treatment. Our primary motivation stems from the need to better understand the cellular hierarchy of uterine fibroids and myometrium, leveraging the high resolution of single cell RNAseq. We aim to identify cell types and states that are unique to the fibroids, based on their molecular signatures. This may point towards more targeted and less invasive treatment strategies for the disease, and better elucidate the mechanism of myometrial tumorigenesis.

DESIGN: scRNAseq analysis were performed from uterine fibroids (F), fibroid-free matched myometrium (M) and healthy myometrium (hM) from 7 patients, presenting a high- resolution transcriptomic map decoupled in cell type and state.

MATERIALS AND METHODS: After tissue dissociation, full length cDNA libraries of 5332 individual cells were prepared using an adapted SmartSeq2 protocol. Nextera XT DNA Sample Preparation kit was used for library preparation. Each cell was sequenced on a NovaSeq to ~1e06 reads/cell. Additional quality control and bioinformatic analyses were performed using custom R scripts.

RESULTS: Dimensional reduction revealed that F, M and hM consist of 14 cell types and states. Canonical markers and highly differentially expressed genes identified major lineages of smooth muscle cells (SMC), fibroblasts (FB), vascular smooth muscle cells, lymphatic endothelia (LEC), vascular endothelia, macrophages / dendritic cells and mast cells. We discovered that the tumor (F) and the non-tumor (M/hM) tissues differ most drastically in FB, SMC, LEC. LEC is more abundant in the tumor. For both SMC and FB, we identified states that are enriched in tumor and non-tumor, respectively, and report signatures that differentiate the two states.

CONCLUSIONS: Single-cell transcriptomic analyses revealed cellular hierarchies that are common or different among F, M, and hM. Cell types and states that are unique to F and their expression signatures might provide molecular targets for less invasive treatment of these benign tumors.

P-312 4:30 PM Sunday, October 18, 2020

STAT3 AND AP-1 SIGNALING IN HUMAN UTERINE LEIOMYOMA CELLS IS REGULATED BY GONADAL HORMONES.

Minnie Malik, Ph.D.,[1] Joy L. Britten, MD,[1] Anthony DeAngelis, MD, PhD,[2] William Catherino, M.D., Ph.D.[1] [1]Uniformed Services University of the Health Sciences, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD.

OBJECTIVE: Uterine leiomyomas are benign tumors regulated by gonadal hormones and are composed of an abundance of disorganized extracellular matrix. We have demonstrated that the expression of ECM proteins including collagen and fibronectin are modulated by activated STAT3 and TGFβ3 in leiomyoma cells, indicating an interaction between the two pathways. Our objective in this study was to characterize the changes in STAT3 protein in response to estrogen, progesterone and combination of both. We further examined the interaction between JAK/STAT pathway and downstream regulators of signaling pathways.

DESIGN: Laboratory study.

MATERIALS AND METHODS: Leiomyoma cell lines were exposed to estradiol, progesterone and combination of both. Leiomyoma cells were exposed to AP-1 inhibitor, SR11302 for various time points. STAT3 pathway proteins were analyzed using western blot analysis. Data is presented as fold difference +/- SEM; with fold difference in density units between untreated and treated samples and normalized for internal control. Student t-test and Wilcoxon-Signed Rank test were used for nonparametric statistical evaluation. Values below $p<0.05$ were considered significant.

RESULTS: In leiomyoma cells, both estradiol (E2) and progesterone (P4) increased the expression of pSTAT3 by 1.34+/-0.062-fold and 1.39+/-0.052-fold, respectively. Combination of the two hormones (E2+P4) resulted in a higher fold increase in pSTAT3 (1.74+/-0.006-fold) protein. Increased expression of pSTAT3 by the hormones was confirmed using anti-estrogens and anti-progestin. AP-1 (activating protein-1) transcription factor proteins that include c-jun and c-fos are known to interact with JAK/STAT pathway. In leiomyoma cells, inhibiting the AP-1 pathway resulted in a significant decreased expression (0.72+/-0.09) in activated STAT3 protein after 24hr exposure.

CONCLUSIONS: Human uterine leiomyoma cells demonstrate a crosstalk between gonadal hormones and STAT3 signaling with increased activation of STAT3. Increase in pSTAT3 leads to increased production of fibrosis-related proteins such as collagen. The common pathway for multiple signaling pathways in leiomyomas appears to involve AP-1.

THYROID DYSFUNCTION AND FIBROIDS IN LATINA/LATINX (LLX) FEMALES: INSIGHTS FROM THE ENVIRONMENT, LEIOMYOMAS, LATINAS, AND ADIPOSITY STUDY (ELLAS).

Emma C. Manuel, BS,[1] Torie C. Plowden, MD, MPH,[2] Nicole Contreras-Rodriguez, BS,[1] Richard L. Bryce, DO,[3] Lisa M. Neff, MD,[4] Mercedes Carnethon, PhD,[4] Erica E. Marsh, MD, MSCI, FACOG.[1] [1]Reproductive Endocrinology and Infertility, University of Michigan, Ann Arbor, MI; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]Community Health and Social Services (CHASS) Center, Detroit, MI; [4]Northwestern University, Chicago, IL.

OBJECTIVE: A retrospective analysis published in 2014 showed an association between hypothyroidism and uterine fibroids (UFs) in European populations, however, there are a paucity of studies on the relationship between thyroid pathophysiology and UF prevalence. Here we use the ELLAS cohort to explore the relationship between a prior diagnosis of thyroid dysfunction, and/or TSH levels, and UF prevalence in LLX reproductive aged females.

DESIGN: Cross-sectional analysis of data from a prospective longitudinal cohort study.

MATERIALS AND METHODS: All study members were participants in ELLAS, an NIH funded community engaged longitudinal study, and were between the ages of 21-50 years at the time of enrollment. Participants had completed the first visit of the study which included detailed questionnaires on demographics and medical history including questions regarding prior diagnosis of thyroid disease. Additionally, blood samples were collected to assess TSH levels and vaginal probe pelvic ultrasounds were performed to determine the presence of UFs in each participant. All ultrasounds were performed by a single ultrasonographer and all images were reviewed by a single blinded expert reviewer. The study was IRB approved by University of

Michigan and statistical associations were determined using Chi-squared and Wilcoxon rank-sum tests.

RESULTS: To date, 633 participants have enrolled and 537 participants have completed the baseline visit, including pelvic ultrasound and blood sample. The mean age of participants was 37.4 ± 6.9 years and mean BMI was 29.9 ± 6.5 kg/m2. 7.1% of all participants had been told by a health professional that they had a thyroid condition and 9.7% of all participants had fibroids on ultrasound. 6.8% of participants without UFs on ultrasound had a prior diagnosis of a thyroid condition vs. 9.6% of participants with UFs on ultrasound (p = 0.47). Mean TSH of all participants was 2.35 ± 1.51 mIU/L. Mean TSH of participants with ultrasound-confirmed UFs was 2.33 ± 1.36 mIU/L vs 2.35 ± 1.52 mIU/L in participants without UFs on ultrasound (p= 0.85).

CONCLUSIONS: This cross-sectional analysis did not find a significant association between UF prevalence, TSH levels, and/or self-reported prior diagnosis of a thyroid condition in LLX reproductive-aged females. More research is needed to further characterize the potential association between fibroids and thyroid disease in different racial and ethnic groups and to understand the mechanisms behind the association.

SUPPORT: This work was supported by the NIMHD grant R01MD011570.

P-314 4:30 PM Sunday, October 18, 2020

N^6-METHYLADENOSINE REGULATORS IN PREVALENCE AND BURDEN OF BLACK WOMEN IN UTERINE FIBROIDS.

Qiwei Yang, PhD,[1] Mohamed Ali, BPharm, MSc,[2] Shan He, MS,[1] Maria Victoria Bariani, Ph.D.,[3] Tom Boyer, Ph.D.,[4] Ayman Al-Hendy, MD, PhD.[5] [1]University of Illinois at Chicago, Chicago, IL; [2]Department of Surgery, University of Illinois at Chicago, Chicago, IL; [3]Departmen of Surgery, University of Illinois at Chicago, Chicago, IL; [4]University of Texas Health Science Center at San Antonio, San Antonio, TX; [5]University of Illinois College of Medicine, Chicago, IL.

OBJECTIVE: Uterine fibroids (UFs) are monoclonal tumors arising in the myometrium, and are the most common tumors of reproductive age women. Although UFs impact the quality of life of women of all ethnicities, this disease is more prevalent and more severe among African American (AA) women compared with Caucasian (CC) women. To date, little is known about the mechanism of this ethnic disparity. An increasing body of evidence demonstrates that abnormal genetic and epigenetic alterations contribute to development of UFs. Recently, another layer of gene regulation at the RNA level, i.e., RNA epitranscriptomics has gained increased attention and interest in the research community. To date, over 150 post-transcriptional modifications of RNA have been identified. Among them, N6-methyladenosine (m^{6}A) is the most abundant, dynamic and reversible modification involved in many biological events and diseases. However, the knowledge of epitranscriptomics in UFs is completely lacking.

DESIGN: Laboratory research studies using human myometrium and UFs tissues

MATERIALS AND METHODS: Human UFs (n=14) and adjacent myometrium tissues (MyoF, n=14) were collected at time of hysterectomy. Western blot (WB) was performed to determine the protein levels of m^{6}A writers (METTL3, WTAP, VIRMA, and RBM15) and Readers (YTHDC1, and YTHDF2). Student's t-test was used to determine the significant difference.

RESULTS: Our studies demonstrated that 62.5% (5 of 8) of AA patients exhibited an upregulation of METTL3 in UFs compared to MyoF while only 16.7% (1 of 6) of CC patients showed upregulation of METTL3. On the other hand, 37.5% AA women and 83.3% CC women showed downregulation of METTL3 in UFs compared to MyoF respectively. These data suggest that this key m^{6}A writer may contribute to the ethnic disparities of UFs. In addition, we measured the adaptors of m^{6}A writers (WTAP, VIRMA, RBM15), no trend of differential expression between UFs and MyoF in both AA and CC population was observed. Next, we determined the protein levels of key m^{6}A readers YTHDC1 and YTHDF2, and demonstrated that a significant upregulation of YTHDC1 and YTHDF2 in UFs over MyoF was found ($p<0.05$) in AA women, but not in CC women. Moreover, 87.5% (7/8) of AA exhibited upregulation of YTHDC1 and YTHDF2 respectively, while only 33.3% (2/6) and 50% (3/6) of CC showed upregulation of YTHDC1 and YTHDF2 respectively.

CONCLUSIONS: These results suggest that abnormal epitranscriptomic alteration, e.g. the METTL3-m^{6}A-YTHDC1/YTHDF2 signaling axis could be involved not only in the pathogenesis of UFs, but also contributing to increased UF prevalence and burden in AA women. Further studies are needed to determine the expression patterns of m^{6}A regulators in a large sample size, and characterize the role of m^{6}A regulators in pathogenesis of UFs.

COMPARATIVE ANALYSIS OF FK506-BINDING PROTEINS 51 (FKBP51) AND 52 (FKBP52) IN UTERINE FIBROIDS COMPARED TO NORMAL MYOMETRIUM.

Erika P. New, MD, MPH,[1] Joung Woul Kim, PhD,[1] A. S. L. I. Ozmen, PhD,[2] Xiaofang Guo, MD,[2] Ozlem Guzeloglu-Kayisli, PhD,[2] Anthony N. Imudia, MD,[1] Charles J. Lockwood, MD, MHCM,[1] Umit A. Kayisli, PhD.[2] [1]University of South Florida, Tampa, FL; [2]Department of Obstetrics and Gynecology, Morsani College of Medicine, University of South Florida, Tampa, FL.

OBJECTIVE: FK506-binding protein 51 (FKBP51) and 52 (FKBP52) are immunophilins and common co-regulators of transcription meditated by the glucocorticoid receptor (GR), progesterone receptor (PR) and androgen receptor (AR). While FKBP51-PR or -GR binding inhibits transcriptional activity, FKBP51-AR binding induces AR-mediated transcription. FKBP52 has the opposite effect on PR and GR transcriptional activity, enhancing transcription. Although all three steroid receptors are expressed in both uterine myometrial and fibroid cells, the steroid-induced proliferative response of fibroid cells differ from that in adjacent myometrial cells, indicating aberrant steroid signaling in fibroids. GR signaling represses, whereas AR signaling induces proliferation in fibroids. Our previous research revealed increased FKBP51 expression in uterine fibroids. Since competition for binding to steroid receptors by both immunophilins induce opposite functions, we hypothesize that an increased ratio of FKBP51 to FKBP52 in fibroid vs. myometrial tissues will dysregulate steroid receptor signaling thereby contributing to fibroid proliferation. Thus, this study sought to investigate the relationship between FKBP51 and FKBP52 levels in uterine fibroids compared to normal myometrium.

DESIGN: Basic science laboratory research

MATERIALS AND METHODS: Paired myometrial vs. fibroid tissue from proliferative (n=11) and secretory (n=10) phases were processed for protein extraction for immunoblot analysis. Immunoblotting was performed using a goat polyclonal FKBP51 antibody and a rabbit FKBP52 antibody. Data were compared by a paired t-test. $P< 0.05$ was considered statistically significant.

RESULTS: Immunoblot results in uterine fibroid tissue revealed significantly lower FKBP52 levels compared to FKBP51 (Mean: 1.04 vs. 1.46; P=0.018). However, no difference was detected in myometrial samples, between FKBP52 and FKBP51 levels (Mean: 0.721 vs. 0.681, P=0.685). Comparison of the FKBP51 to FKBP52 ratio in matched myometrial samples to fibroid samples revealed no statistically significant difference. Cycle dependent analysis of uterine fibroid tissue also revealed significantly lower FKBP52 versus FKBP51 levels in the proliferative phase (Mean± SEM: 0.92±0.15 vs. 1.32±0.084; P=0.035), but not in secretory uterine fibroid tissue.

CONCLUSIONS: These results demonstrate that there is reduced expression of FKBP52 compared to FKBP51 in uterine fibroid tissue. The increased FKBP51 level compared to FKBP52 is likely implicated in dysregulation of steroid signaling by blocking GR and/or PR action as well as stimulating AR action to promote proliferation of fibroid cells. Inhibition of FKBP51 in fibroid cultures or increasing expression of FKBP52 may help clarify the exact role of these two immunophilins in uterine fibroid pathogenesis.

SUPPORT: None. Of note, this abstract was originally submitted to the Pacific Coast Reproductive Society 2020 Annual Meeting which was cancelled. After cancellation, PCRS allowed for abstracts to be published or withdrawn. This abstract was withdrawn and was not published so as to allow for this updated abstract to be submitted to ASRM.

ACTIVATION OF SIRTUIN 3 BY NATURAL COMPOUND HONOKIOL INHIBITS HUMAN UTERINE FIBROID PHENOTYPE.

Michal Ciebiera, MD, PhD,[1] Mohamed Ali, BPharm, MSc,[2] Qiwei Yang, PhD,[2] Jack L. Arbiser, MD, PhD,[3] Ayman Al-Hendy, MD, PhD.[2] [1]Center of Postgraduate Medical Education, Warsaw, Poland; [2]University of Illinois at Chicago, Chicago, IL; [3]Emory University, Atlanta, GA.

OBJECTIVE: Uterine Fibroids (UFs) are the most common benign tumors in women of reproductive age with subsequent significant quality of life and

economic negative impact. Current treatment options are primarily surgical and no US Food and Drug Administration approved medical treatment is available so far. Natural compounds may be beneficial for UFs patients as safe non-hormonal therapeutic option. Honokiol (HKL) is a natural compound that showed promising anti-fibrotic effects in several diseases via activation of Sirtuin3 (SIRT3), yet to be explored in UF.

DESIGN: Cell culture study of immortalized human leiomyoma and patient-matched myometrium cells treated with honokiol and hexafluoro honokiol.

MATERIALS AND METHODS: Human uterine leiomyoma (HuLM) and normal uterine smooth muscle (UTSM) cells were treated with (5μM-100μM) of HKL or its synthetic agonist hexafluoro honokiol (HEX), and cell proliferation was assessed by MTT assay after 24, 48 and 72 hr. Protein expression of several UF phenotype related markers were measured in both HKL or HEX treated HuLM (24 hr) and compared or untreated cells using western blot (WB) analysis, including fibrosis related markers {collagen type1 (COLL1A) and fibronectin (FN)}, proliferation markers {Cyclin D1 (CCND1) and (PCNA)}, tumor related marker (P21). Protein expression of Sirt3 was measured in matched UF and myometrium patients' tissues (n=6) from African American (AA) and Caucasian (CC) patients. Student-t test was used for statistical analysis and $p<0.05$ was considered significant.

RESULTS: HKL and HEX showed a potent anti-proliferative effect on HuLM cells in a concentration and time dependent manner ($p<0.05$), HKL inhibit HuLM cell growth significantly starting at 5 μM, while HEX showed inhibitory effect at higher dose (50 μM). Interestingly, normal UTSM cells showed resistant effects to both treatment as compared to HuLM at all used doses suggesting selective growth-inhibitory effect on HuLM not UTSM. HKL treatment at 20-50 μM for 24 hr. significantly decreased protein levels of COLL1A, CCND1 and PCNA while increased protein levels of FN1 in HuLM cells compared to untreated control in dose dependent manner ($p<0.05$). p21, Bax, and cleaved caspase-3 protein expression did not change in response to HKL treatment. Moreover, WB analysis showed that normal myometrial tissues from both AA and CC patients expressed higher Sirt3 protein expression as compared to its matched UF tissue ($p<0.05$), suggesting that Sirt3 activation using HKL might exert anti-UF effects.

CONCLUSIONS: Our studies provide a novel link between Sirt3 and UF phenotype. HKL exhibited a promising anti-fibrotic effect via activation of this link. HKL might offer a promising therapeutic option as safer non-hormonal long term and cost-effective treatment against UFs with potential clinical utility, yet pending further research.

SURGICAL AND OBSTETRICAL OUTCOMES OF SINGLE PORT LAPAROSCOPIC MYOMECTOMY: RESULTS OF 502 CASES. Jung Ryeol Lee, MD., PhD., Yeon Hee Hong, MD., Eunjin Song, MD. Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South).

OBJECTIVE: Single-port laparoscopic myomectomy (SPLM) has been introduced as an effort to minimize the invasiveness of the surgical method. Previous studies reported comparable surgical and better cosmetic outcomes of SPLM than conventional multi-port laparoscopic myomectomy. However, there have been few studies reported obstetric outcomes of SPLM. This study aims to analyze the surgical and obstetric outcomes of 502 SPLM cases performed for 10 years.

DESIGN: A retrospective single-center study.

MATERIALS AND METHODS: A total of 502 patients undergoing SPLM for symptom relief or due to myomas that continue to grow from October 2009 to December 2019 were enrolled. The patients who had combined surgery with other surgical departments were excluded. Patients' demographics, operative variables, and obstetrical outcomes were analyzed. All information was collected according to the electronic medical record and/or patients' answers. Continuous parameters were compared using either Student t-test or Mann-Whitney's test as appropriate. The proportions were compared using the chi-square test. P-value <0.05 was considered statistically significant.

RESULTS: The mean age and BMI of the patients were 40.5±6.7 years and 22.9±3.4 kg/m^2. The mean diameter of the largest myoma and the total number of myomas removed were 6.7±2.5 cm and 2.2±2.1, respectively. The intramural type was the most common (57.4%), and subserosal (28.1%) and submucosal (6.0%) types follow. The mean operation time and hemoglobin drops were 112.1±45.0 min and 1.6±1.1 g/dL. The rate of postoperative complications was 8.4% (42/502), and the major complications were transfusion (3.0%, 15/502) and wound problem (3.0%, 15/502). Of the women of childbearing age (n=397), 55 women who tried to become pregnant. The pregnancy, miscarriage, and live birth rates were 72.7% (40/55), 3.6% (2/55), and 63.6% (35/55), respectively. Of the remaining 3 women, 2 patients are currently pregnant state. Pregnancy was confirmed in the remaining 1 woman, but we could not obtain the obstetrical outcomes because she could not be contacted afterward. Among confirmed 35 live birth cases, 85.7% (30/35) of them delivered at full term, and 91.4% (32/35) had cesarean section delivery. No intrapartum or postpartum complication was reported. The three most common obstetrical complications were preterm labor (5.7%, 2/35), gestational diabetes (5.7%, 2/35), and placenta previa (2.9%, 1/35).

CONCLUSIONS: Our results show that operative and subsequent obstetric outcomes of SPLM are feasible and satisfactory. SPLM is a safe and effective treatment option for women with myomas who require surgery and wish to get pregnant after surgery.

P-318 4:30 PM Sunday, October 18, 2020

IN VITRO COLLAGEN CLEARANCE OF OVARIAN FIBROSIS TISSUE WITH PURIFIED COLLAGENASE I. Rumiana Ganeva, MSc, Dimitar Parvanov, PhD, Nina Vidolova, MSc, Ivaylo Stoykov, MSc, Georgi Stamenov, MD/PhD. Nadezhda Women's Health Hospital, Sofia, Bulgaria.

OBJECTIVE: Ovarian dysfunction is often caused by ovarian fibrosis. This condition is associated with excessive proliferation of ovarian fibroblasts and deposition of extracellular matrix. The fibroid tissue contains substantial amounts of altered and disordered collagens. Available treatment options are limited and not sufficiently efficient. One approach is the direct targeting these collagens with collagenase.

The aim of this study was to evaluate the efficacy of *Clostridium histolyticum* collagenase type I on in vitro collagen clearance in ovarian fibrous tissue.

DESIGN: Research study. Comparison of collagen distribution in ovarian fibroid tissue samples after in vitro treatment with *Clostridium histolyticum* collagenase type I at different concentrations and time exposure.

MATERIALS AND METHODS: Ovarian tissue was obtained from 10 patients undergoing scheduled ovariectomy. Twelve tissue cubes (0.5cm^3) from each biopsy were injected with 1 ml collagenase I (EC 3.4.24.3, Genaxxon) (0.1, 1, or 5 mg/ml) diluted in PBS or with 1 ml PBS (control). Samples were then incubated in DMEM F12 at 37°C for 30 min, 60 min and 12 h. Tissue samples from each collagenase concentration and time point were paraffin embedded and sectioned for Masson's trichrome staining.

Mean outcomes: percentage of fibrosis and the structural preservation of the tissue.

Statistics: ANOVA, using SPSS v21.

RESULTS: Mean fibrosis in the untreated ovarian samples was 75±7% and remained the same in the PBS injected tissues through all time points. Treatment of the ovarian fibroid tissues with collagenase I have led to time and dose dependant decrease of collagen-stained area at all concentrations tested.

After 30 minutes of incubation the collagen staining remained high in all samples: 69±6% (0.1 mg/ml), 50±4% (1 mg/ml) and 46±5% (5 mg/ml) and the tissue structure were preserved.

One hour treatment with collagenase I have led to significant decrease in the fibrosis in all concentrations tested when compared to the untreated tissues ($p<0.05$). Also the collagen reduction differed between the three concentrations significantly: 52±5% (0.1 mg/ml), 10±8% (1 mg/ml) and 5±3% (5 mg/ml) ($p<0.05$). The 5 mg/ml collagenase treated samples showed tissue structural deformation.

Treatment with collagenase I for 12 hours reduced significantly the fibrosis up to 5±2% (0.1 mg/ml), 3±1% (1 mg/ml) and 2±1% (5 mg/ml) when compared to the control ($p<0.05$). Longer incubation times ($\geq$60 minutes) with collagenase (>1 mg/ml) reduced stiffness and treated tissue lost their initial shape and structure. Only 0.1 mg/ml treated tissue cube preserved its initial structure.

CONCLUSIONS: *Clostridium histolyticum* collagenase I was shown to be efficient for in vitro collagen clearance of ovarian fibrosis tissue while preserving the tissue structure. The most appropriate concentration of the collagenase for treatment of 0.5 cm^3 ovarian tissue cubes was 0.1 mg/ml

for 12 hours. Additional clinical trials are needed for the evaluation of the efficacy and safety of this treatment approach in humans.

P-319 4:30 PM Sunday, October 18, 2020

A SYSTEMATIC REVIEW OF UTERINE-SPARING MINIMALLY INVASIVE TREATMENTS FOR FIBROID BLEEDING. Jiahui Zhang, BA,[1] Bhuchitra Singh, MD, MPH, MS,[2] Virginia-Arlene Acosta Go, MD,[3] James Segars, MD.[2] [1]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Saint Joseph Hospital, Denver, CO.

OBJECTIVE: To evaluate and compare the efficacy of available uterine-sparing, minimally invasive, surgical treatment modalities for the management of bleeding symptoms associated with uterine fibroids.

DESIGN: A systematic literature review using PRISMA methods and standards.

MATERIALS AND METHODS: We conducted a systematic review on April 20, 2020 of full-text English-language studies published on PubMed from inception. Observational studies and randomized controlled trials were included. Only studies including pre-menopausal women with a confirmed diagnosis of uterine fibroids were included. Participants must have reported heavy menstrual or abnormal uterine bleeding at baseline and undergone a uterine-sparing, minimally invasive fibroid treatment. The severity of bleeding was assessed through validated questionnaires such as The Uterine Fibroid Symptom and Quality of Life (UFS-QOL) questionnaire before and after treatment. Patients were excluded if another etiology for their bleeding was more likely.

RESULTS: The initial search yielded 2,327 articles. After review of titles, abstracts, and full text, 49 studies met eligibility criteria and comprised the dataset. For all treatment modalities, patients reported lower quality of life score and worse bleeding symptoms at baseline than after treatment. Six studies assessing laparoscopic and hysteroscopic myomectomy reported short-term resolution of abnormal uterine bleeding in up to 85% of patients and maintenance of symptom resolution at up to 8 years postoperative. Comparison between different routes of myomectomy demonstrated no difference on long-term follow up ($p>0.05$). Results of seven studies demonstrated significant shortening and decrease in the amount of bleeding in at least 80% of patients following uterine artery embolization. Three studies suggested that the combination of laparoscopic uterine artery occlusion with myomectomy resulted in preferential improvement in bleeding symptoms over myomectomy alone. Two studies suggested that laparoscopic uterine artery occlusion may be inferior to uterine artery embolization in the reduction of heavy menstrual bleeding. Promising results were reported for newer techniques including cryomyolysis, radiofrequency ablation, and magnetic resonance-guided focused ultrasound surgery, though available literature did not demonstrate superiority of one technique over another for long-term reduction of uterine bleeding.

CONCLUSIONS: Evidence indicates a high clinical efficacy for all minimally invasive treatment modalities in the reduction of bleeding symptoms associated with fibroids. These techniques allow for uterus preservation and increase treatment options for patients seeking relief from symptomatic uterine fibroids.

SUPPORT: Supported, in part, by the Howard and Georgeanna Jones Research Endowment.

THE ROLE OF UTERINE FIBROIDS IN HUMAN ENDOMETRIAL ANGIOGENESIS. Antonia Navarro, PhD,[1] Ayman Al-Hendy, MD, PhD.[2] [1]University of Illinois at Chicago, Chicago, IL; [2]■■■.

OBJECTIVE: Uterine fibroids (UF) are benign tumors in women of reproductive age, they cause heavy menstrual bleeding (HMB), leading to severe anemia and subsequent major negative effects on quality of life. The aim of this study is to investigate the effects of human uterine leiomyoma smooth muscle cells (HuLM) and HuLM-derived exosomes on growth and angiogenesis of the human endometrium-related endothelial cells.

DESIGN: We designed an in vitro study using HuLM secretome and HuLM-derived exosome and human endometrial microvascular endothelial cells (HEMEC) to understand the molecular mechanisms by which uterine fibroids mediates their proliferative and angiogenic properties that ultimately cause heavy menstrual bleeding.

MATERIALS AND METHODS: Human endometrial microvascular endothelial cells were treated with HuLM secretome and HuLM-derived exosome at several time points and different concentrations. Then, we measured cell proliferation via BrdU incorporation assay, and will also examine by RT-PCR, FACS and immunoblotting for the expression of proliferation and angiogenesis markets such as PCNA, Cyclin D1, VEGF, VEGFR2 and endoglin.

RESULTS: We observed that both HuLM secretome and HuLM-derived exosomes cocultured with HEMEC increased cell proliferation, and this increase is more significant 60% ($P<0.01$) in HEMEC cocultured with HuLM secretome for 48 hours. We propose that this effect is associated with the up-regulation of specific markers for proliferation (PCNA and cyclin D1), and work is in progress in our lab. HuLM secretome and HuLM-derived exosomes treatments also increased considerably the expression of several angiogenesis markers such as VEGF, VEGFR2 and endoglin compared to untreated cells.

CONCLUSIONS: Our study suggests that both human leiomyoma cells (HuLM) secretome and HuLM-derived exosomes have strong paracrine effect on human endometrial microvascular endothelial cells, likely containing bioactive factors that enhance endometrial angiogenesis, which eventually cause heavy menstrual bleeding. Further characterization of these factors can lead to novel druggable therapeutic targets to improve health care for women with uterine fibroids associated heavy menstrual bleeding.

POSTER SESSION: GENETIC COUNSELING

P-321 4:30 PM Sunday, October 18, 2020

LIKELIHOOD FOR REACHING EMBRYO TRANSFER FOLLOWING EXCLUSION-BASED NON-DISCLOSURE PREIMPLANTATION GENETIC TESTING FOR MONOGENIC CONDITIONS (PGT-M). Katrina Merrion, MS, Nina Wemmer, MS. Natera, Inc., San Carlos, CA.

OBJECTIVE: Non-disclosure (ND) preimplantation genetic testing (PGT) for monogenic disorders (PGT-M) via in vitro fertilization (IVF) is an option for individuals at risk for having a late-onset dominant condition. One method involves testing the patient for a familial mutation without disclosing the results, and blinding them to whether their embryos are tested via PGT-M with concurrent PGT for aneuploidy (PGT-A) if they have the mutation, or via PGT-A only if they do not. Exclusion-based testing is an alternate method which does not require the patient's mutation status to be known. Rather, by determining which of the patient's chromosome homologs with the gene of interest was inherited from their affected parent, embryos that inherit that copy of the chromosome are excluded from transfer due to the potential risk for inheriting the mutation. Exclusion-based testing eliminates the risk for accidental disclosure of the patient's mutation status but may exclude unaffected embryos from transfer if the patient does not have the familial mutation. Patients may consider cryopreservation of potentially at-risk embryos in case they pursue testing for themselves at a later time. In this study, we review the likelihood of unaffected and euploid embryo results using exclusion-based ND testing.

DESIGN: Retrospective analysis of trophectoderm (TE) biopsy results from IVF patients referred for exclusion-based ND PGT-M with concurrent PGT-A.

MATERIALS AND METHODS: For each case, a mutation/clinical diagnosis report for the affected relative and samples from the couple and the at-risk patient's parent(s) were required. TE biopsies were shipped to a lab for genotyping using Illumina Cyto12 SNP-based microarrays with informatics.

RESULTS: Twenty-five patients underwent exclusion-based ND PGT-M for 7 disorders (Huntington's Disease (HD), n=19; Spinocerebellar ataxia (SCA) type 3, n=1; SCA type 6, n=1; Polycystic kidney disease, n=1; Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL), n=1; Familial TTR amyloidosis, n=1; Creutzfeldt-Jakob disease, n=1). A total of 273 TE samples from 46 IVF cycles were tested (average of 5.9 embryos/cycle, range 1-21). Average maternal age was 33.1 years (range 26.2–41.9 years). 73.9% (34/46) of cycles had at least one euploid and unaffected embryo. Analysis by maternal age groups indicated that the chance of having at least one euploid and unaffected embryo was 83.3% (5/6) for <30 years, 76.7% (23/30) for 30-34 years, and 60% (6/10) for women ≥35 years.

CONCLUSIONS: Exclusion-based ND testing avoids the risk of accidental disclosure of a patient's mutation status, while allowing a relatively

high rate of having an embryo for transfer after a single IVF cycle. This information may be useful for counseling patients considering ND exclusion-based PGT-M and discussing the potential need for additional IVF cycles in order to reach transfer, especially for women of advanced maternal age. Although ND exclusion-based testing is most commonly performed for HD, here we demonstrate that this method can be utilized for other dominant late-onset conditions.

SUPPORT: Natera, Inc.

P-322 4:30 PM Sunday, October 18, 2020

INCREASING SCALE AND THROUGHPUT OF TELEHEALTH GENETIC COUNSELING ACROSS THE SPECTRUM OF REPRODUCTIVE CARE, WHILE MAINTAINING HIGH PATIENT SATISFACTION. Kiley Johnson, MS, Jill Davies, MS, Colleen Caleshu, MS. GeneMatters, Minneapolis, MN.

OBJECTIVE: Multiple professional societies recommend genetic counseling alongside reproductive genetic testing, including the American Society for Reproductive Medicine and the American College of Obstetrics and Gynecology. However, access to genetic counselors (GCs) continues to be an issue. Efforts are being made to remedy this with increased GC throughput and novel approaches to service delivery. We sought to describe one such approach by examining the volume, scope, and capacity of a high throughput telehealth genetic counseling service that provides care to reproductive patients across the country.

DESIGN: Retrospective review of consult data from a telehealth genetic counseling service.

MATERIALS AND METHODS: We examined data for reproductive genetic counseling consults that occurred between 1/1/2018 and 12/31/2019. Extracted data included indication, time required to complete consult, and patient satisfaction. To assess throughput, the number of reproductive consults a GC could complete per week was estimated.

RESULTS: In 2018, 541 reproductive genetic counseling consults were performed, and 1922 were performed in 2019. Care was provided to patients from reproductive endocrinology clinics, genetic testing laboratories, and maternal fetal medicine clinics. Indications included carrier screening, preimplantation genetic testing (PGT), egg donor screening, abnormal aneuploidy screen, advanced maternal age, ultrasound findings, and family history of a genetic condition. The mean time to complete all aspects of a consult (preparation, counseling, and writing genetic counseling summary report) was 40.6 minutes (standard deviation 6.7 minutes). At 40.6 minutes per consult, a full-time GC working in this efficient and high-throughput model can perform 53 consults per week, assuming the same mix of routine and complex cases. This is more than double the weekly caseloads for reproductive GCs reported by the National Society of Genetic Counselors (15.6-20.5 consults per week), which primarily represents traditional lower throughput models. Despite the high throughput nature of the service, patient satisfaction remained high during the study period (95.6%). Consistent with their complexity, PGT consults took longer than other consults in preparation and counseling (preparation: 13.0 minutes vs. 4.0 minutes, $p<0.001$; counseling: 29.2 minutes vs. 16.0 minutes, $p<0.001$; documentation: 10.4 minutes vs. 9.0 minutes, $p=0.18$). In contrast, carrier screening consults took less time than other consults (preparation: 5.5 minutes vs. 9.6 minutes, $p<0.001$; counseling: 18.3 minutes vs. 21.2 minutes, $p<0.001$; documentation: 7.5 minutes vs. 11.4 minutes, $p<0.001$).

CONCLUSIONS: Genetic counseling provided by a national telehealth organization covers the full range of reproductive indications, from routine to complex. The approach is scalable, with a 3.5 fold increase in consult volumes from 2018 to 2019. Given the high patient satisfaction, increased throughput, and nation-wide nature of this approach, it is a promising option for increasing access to reproductive genetic counseling.

P-323 4:30 PM Sunday, October 18, 2020

PATHOGENIC VARIANTS WITHIN ACMG SECONDARY FINDINGS GENES IN 24,591 HEALTHY INDIVIDUALS USING CLINICAL EXOME SEQUENCING FOR CARRIER SCREENING. Pere Mir Pardo, PhD,[1] Joaquin Panadero, MSc,[1] Gema Escribano, MSc,[1] Jorge Jimenez-Almazán, PhD,[1] Roberto Alonso, MSc,[1] Claudia Abellan, MSc,[2] Carlos Simon, MD, PhD,[3] Julio Martin, MSc.[1] [1]Igenomix, Valencia, Spain; [2]INCLIVA/University of Valencia, Valencia, Spain; [3]Professor University of Valencia, INCLIVA, Founder and Head of the Scientific Advisory Board, Igenomix, Paterna (Valencia), Spain.

OBJECTIVE: Expanded carrier screening (ECS) aims to reduce the burden of recessive single-gene disorders by identifying the genetic risk for the offspring of individuals in reproductive age. ECS using exome sequencing could also reveal information that may influence on individual's health. A significant group of clinically actionable genes are the secondary findings (SF) list defined by the ACMG. Our objective was to assess the frequency of SF pathogenic variants in individuals undergoing ECS.

DESIGN: Retrospective analysis of clinical exome data from an ECS program to assess the frequency of pathogenic variants for the 59 SF gene list defined by the ACMG.

MATERIALS AND METHODS: A database was built using anonymized sequencing data of 24,591 clinical exomes (TruSight One sequencing panel; Illumina) intended for ECS before Assisted Reproductive Techniques, from September 2015 to June 2019. Females represented the 50.9% (12,525) of tested individuals and males the remainder 49.1% (12,066). Distribution between patients and gamete donors was 59.3% (14,588) *vs* 40.7% (10,003), respectively. All patients self-reported European ancestry except a subset of 475 Emirati individuals. Sequencing data were processed using a proprietary bioinformatic pipeline for the 59 genes included in the ACMG recommendations for reporting of secondary findings (ACMG SFv2.0) (Kalia et al., 2016). Variant pathogenicity was performed in compliance with ACMG-AMP guidelines (Richards et al., 2015) using an in-house algorithm, private and public databases, and updated literature, only (likely) pathogenic variants were considered as a SF.

RESULTS: The overall frequency of individuals with pathogenic variants was 2.6% (n=636). No differences in the frequency of SF was found between genders neither between patients and donors. At least one (likely) pathogenic variant was identified in 39 of 59 ACMG genes. In total, 344 unique variants were detected in 652 alleles. The most frequent pathogenic variant was the X-linked NM_000169.2:c.427G>A in *GLA* gene (n=19). *BRCA1* and *BRCA2* were the most frequently positive called genes, with 95 unique pathogenic variants detected in 131 individuals (20.6%).

When dividing by ancestry, same frequency of SF was found in Emiratis (2.5%) and European (2.6%). In contrast, differences were found for the most frequently positive genes. Top-three positive genes among Emiratis were *SCN5A*, *KCNQ1* and *RYR1*; while for Europeans were *BRCA2*, *MYBPC3* and *LDLR*. Remarkably, the variant most frequently detected in European-ancestry individuals (NM_000169.2:c.427G>A in GLA) was not detected in Arabs. Conversely, 6 out of 10 unique variants found in Arabs were not detected in the large European database.

CONCLUSIONS: The analysis of the ACMG SF genes provided evidence of pathogenicity in 2.6% of the tested individuals. Same frequency was found among genders and patient-donor status, as well as for European and Emirati populations. However, genetic heterogeneity was found among the two populations both at the gene and at the variant level.

P-324 4:30 PM Sunday, October 18, 2020

WHAT TO ADVISE TO PATIENTS WITH ONE GOOD QUALITY BLASTOCYST? PGT-A OR NOT? OUTCOMES OF 1737 CYCLES. Murat Cetinkaya, M.D., PhD, Cigdem Cinar Yapan, MsC, Mehmet Ali Tufekci, PhD, Hakan Kadir Yelke, MsC, Yesim Kumtepe Colakoglu, MsC, Semra Kahraman, MD. Prof. Istanbul Memorial Hospital, Istanbul, Turkey.

OBJECTIVE: Preimplantation Genetic Testing for Aneuploidy (PGT-A) has been extensively studied and shown to improve pregnancy rates per transfer particularly in advanced maternal age patients ($\geq$35 years old), decrease risk of miscarriage, as well as shorten time to have a healthy birth. These benefits are more apparent if PGT-A is performed on multiple blastocysts. However, application of PGT-A for couples who have only one blastocyst to be biopsied is still in debate. The aim of this study is to compare different age groups with a single good quality blastocyst and evaluate the clinical outcomes of transferring with or without a PGT-A cycle.

DESIGN: This retrospective study was based on 1737 cycles initiated between 2017 and 2020 in Istanbul Memorial Hospital and resulted with a single good quality blastocyst. Preimplantation genetic testing for aneuploidy (PGT-A) represent 886 cycles and a total of 851 cycles were transferred without PGT-A.

MATERIALS AND METHODS: The single blastocyst was tested as euploid in only 108 out of 886 PGT-A cycles (19.5%). The overall ongoing pregnancy rate was 53.7% in PGT-A cycles and 28.2% in untested cycles. For the PGT-A group, 90 patients were <35, 93 between 35-37, 185 between 38-

39, 326 between 40-42 and 192 were ≥43. For the untested group, 434 patients were <35, 182 between 35-37, 79 between 38-39, 92 between 40-42 and 64 were ≥43. Chi-square test was applied for categorical group comparisons. PGT-A was done by NGS ReproSeq on Ion Torrent S5 (ThermoFisher) following trophectoderm biopsy.

RESULTS: In the <35 age group, ongoing pregnancy rates (OPRs) per transfer were 58.8% and 36.8% in the tested and untested group, respectively (p= 0.0672). In the 35-37 age group, OPRs were 64% and 32.9% (p= 0.0026); in the 38-39 age group 36.3% and 13.9% (p= 0.0076); in the 40-42 age group 57.1% and 6.5% (p<0.0001), in the ≥43 age group 80% and 5% (p <0.0001), with and without PGT-A, respectively.

In the group without PGT-A, under 35 years of age, OPRs per initiated cycle were found to be higher than the group with PGT-A (20.6% vs. 11%; p<0.0001), showing that the underlying cause for infertility may not be directly related with aneuploidy but other clinical factors may be in play. For the 35-37 age group, OPRs per initiated cycle were 15.6% and 17.2% (p=0.0058), for the 38-39 age group 4.3% and 6.5% (p=0.0502), for the 40-42 age group 1.6% and 5% (p=0.5409) and for the ≥43 age group 1.1% and 2% (p=0.2695), in the untested and tested groups, respectively.

CONCLUSIONS: Above 35 years of age, OPRs per embryo transfer and per initiated cycle are higher in the PGT-A group when compared to the untested group. Therefore, PGT-A is a good option for women who are above 35 years of age and have low number of blastocysts.

SUPPORT: No financial support needed for the study.

PGT-A INCIDENTAL FINDING: RECURRENT MOSAIC SEGMENTAL ANEUPLOIDY INDICATIVE OF BENIGN FAMILIAL VARIANT.

Rachel A. Donnell, MMSc, CGC,[1] Lauren Thomas Garrett, MS, CGC.[2] [1]Seattle Reproductive Medicine, Seattle, WA; [2]Pacific Northwest Fertility, Seattle, WA.

OBJECTIVE: To describe the first known cases of recurring mosaic segmental aneuploidy (RMSA) identified through PGT-A and present the results of subsequent genetic testing.

DESIGN: Case report.

MATERIALS AND METHODS: At a single clinic, results of 396 PGT-A cases were reviewed from February 2019 to December 2019 for RMSA. RMSA was defined as 3 or more embryos with the same mosaic deletion or duplication with the same breakpoints.

RESULTS: Two cases were identified.

Case 1: A G0, 37-year-old female with a history of primary infertility and male factor (oligospermia) underwent IVF with PGT-A. PGT-A results identified 3 out of 14 embryos with a mosaic dup(22)(pter-q12.1).

Case 2: A G0, 34-year-old female with a history of primary infertility and male factor (oligospermia). The family history was suggestive of a chromosomal translocation and parental karyotype results were consistent with 45,XX,der(13;14)(q10;q10) and 46,XY. IVF with PGT-SR was recommended. PGT-A results from the first cycle were abnormal and identified 2 out of 4 embryos with a mosaic dup(12)(q24.32-qter). PGT-A results from the second cycle identified 2 out of 2 embryos with the same mosaic duplication.

These results can suggest an underlying parental translocation, so all parents underwent karyotype analysis. Results of all karyotypes were normal except for the patient previously identified with a robertsonian translocation.

In our second case, parental fluorescence in situ hybridization (FISH) for the distal 12q arm and SNP microarray were performed. Results of both tests were normal. However, the lab commented that the female patient had a 1.7Mb interstitial triplication of 12q24.32 in all cells. The triplication did not contain any genes of clinical significance.

CONCLUSIONS: To our knowledge, these are the first descriptions of RMSA identified through PGT-A. By definition, mosaic abnormalities occur at random, yet we identified two cases of recurring mosaic duplications that were suggestive of dominant inheritance.

In our first case we did not identify an inheritable cause. In the second, a parent was found to carry a benign 12q24.32 triplication in all cells that explained the recurring finding in her embryos. A 1.7Mb interstitial triplication is below the resolution of NGS which may explain why the embryos were classified as mosaic and highlights the limitations of NGS.

RMSA may be indicative of a uniform copy number variation (CNV) in a parent and follow up testing should be considered to determine the clinical significance and true breakpoints. Embryos reported with benign CNV can be suitable for transfer and may help couples undergoing IVF pursue less treatment.

Although we did not identify an inheritable cause in our first case, it is unlikely that the recurrent mosaic duplication occurred by chance alone. One hypothesis is that these findings may be suggestive of an inherited benign autosomal fragile site. 22q12.2 is a known common fragile site (FRA22B).

As clinics continue to consider mosaic embryo transfer, it will be important to investigate the clinical significance of RMSA and this may warrant additional parental follow up testing.

P-326 4:30 PM Sunday, October 18, 2020

GENOMICS ANALYSIS OF MATERNAL EXOMES REVEALS NEW CANDIDATE GENES AND PATHWAYS FOR THE DIAGNOSIS AND PREDICTION OF RECURRENT PREIMPLANTATION EMBRYO ARREST IN IVF CYCLES.

Semra Kahraman, MD, Prof.,[1] Fulya Gokdagli Sagir, MD,[1] Beril Yuksel, MD, Assoc. Prof.,[1] Murat Cetinkaya, M.D., PhD,[1] Meral Gavaz, MSc,[1] Burcu Kara, BSc,[1] Mesut Yesil, MSc,[1] Gunkut Akar, MSc,[1] Silvia Buonaiuto, BSc,[2] Gianluca Damaggio, MS,[2] Marco Fabiani, PhD,[3] Adriano De Marino, PhD,[3] Vincenza Colonna, PhD,[2] Carlos Simon Prof, MD,[4] Antonio Capalbo, PhD.[3] [1]Istanbul Memorial Sisli Hospital, Istanbul, Turkey; [2]Institute of Genetics and Biophysics, National Research Council (CNR), Naples, Italy; [3]Igenomix, Marostica, Italy; [4]Igenomix Foundation, Valencia, Spain.

OBJECTIVE: The aim of our study was to discover whether genomic analysis of maternal exomes is capable of identifying new target genes to improve infertility diagnosis in cases with recurrent preimplantation developmental embryo arrest.

DESIGN: Genetic analysis.

MATERIALS AND METHODS: The study was conducted at Istanbul Memorial Hospital ART and Reproductive Genetics Unit between December 2018-November 2019 in cooperation with Igenomix, Italy. Ten women, five with consanguinity history, four being the offspring of first-cousin marriage with a history of recurrent embryo developmental failure in multiple IVF cycles were recruited. WES was performed *(Agilent SureSelect whole-exome capture and Illumina sequencing technology).* Variant calling against the reference genome GRCh38 was done using Freebayes and identified on average 436k high quality variants per samples. According to Ensembl classification 2.8% are expected to have high (0.25%) or moderate (2.56%) disruptive impact in the gene product. Variants were filtered on a per-individual base using a number of criteria (frequency <0.05% in the 1000 Genomes and gnomeAD; severity as estimated by Ensembl; the functional effect using the CADD score above the 90 percentile and variants location in genes highly intolerant to loss of function, pLI>0.9. Finally variants retained had to be in genes relevant to the early embryonic development (3600 gene list). To control for false positives, we run the same filtering on 100 replicates of 10 random samples from the publicly available Human Genome Diversity Project data set, and we filtered out variants falling in genes showing up in 50% of the hundred replicates, controlling for random occurrence of hits.

RESULTS: Overall, 1700 unique variants in 1281 unique genes were retained after filtering, most involved in lethal embryonic pathways. Thirty-one unique retained variants have high impact and among them sixteen are splice variants and nine are stop-gains. Each sample carries on average 185.9 (10.0 s.d.) potentially detrimental variants. Of particular relevance two individuals had pathogenic variants in SPAG5, an essential component of the mitotic spindle required for normal chromosome segregation and progression into anaphase. Furthermore, two individual showed pathogenetic variants in the zinc finger protein 91 (ZFP91). The knockdown of ZFP91 reduces FOXA1 polyubiquitination and cellular progression in embryonic and cancer cells. Finally, three samples share the G allele of the rs1217009744 variants in homozygosis in the *SHANK3* gene.

CONCLUSIONS: Exome analysis of women with recurrent embryo arrest successfully identifies genomic variants lethal at the embryonic stage, thus providing a diagnostic tool. However, functional genomics studies and validation in an independent cohort of patients with preimplantation embryo arrest phenotype and of different ethnicity is required to corroborate these findings. The generation of polygenic models will also further contribute to increasing discovery rate and to the development of more general and powerful predictive models for this phenotype.

P-327 4:30 PM Sunday, October 18, 2020

NOT ALL PREIMPLANTATION GENETIC TESTING IS CREATED EQUAL: EVALUATING PATIENT OPINIONS BASED ON TEST TYPE. Jennifer L. Garbarini, MS, CGC, Dina Nusblat, MS, CGC, Marie Discenza, MS, CGC. CooperSurgical, Trumbull, CT.

OBJECTIVE: Evaluate patient motivations for pursuing preimplantation genetic testing (PGT), insurance coverage implications and utility of PGT to their In-vitro fertilization (IVF) cycle.

DESIGN: IVF can be combined with PGT. Patients seeking to reduce hereditary disease risk for monogenic disorders can pursue PGT-M. Those with a chromosome rearrangement can have embryos tested for unbalanced outcomes (PGT-SR). Additionally, patients can screen embryos for aneuploidy (PGT-A). Increased availability of testing requires providers to understand patient motivations, potential barriers and how to integrate PGT into an IVF cycle.

MATERIALS AND METHODS: All patients undergoing pre-test genetic counseling through CooperGenomics were eligible to take a survey.

RESULTS: Between April 2019- May 2020, there were 169 respondents; 100 PGT-A, 16 PGT-SR, and 53 PGT-M (with and without PGT-A).

Patients were asked whether PGT contributed to their deciding to pursue IVF. 38/51 (75%) PGT-M patients and 10/16 (63%) PGT-SR patients stated that PGT was a "very important" factor in deciding to pursue IVF. PGT-A patients were less likely to pursue IVF for the purpose of PGT; 16% cited PGT as a reason for pursuing IVF.

PGT-M and PGT-SR patients were similarly motivated to pursue IVF, even if insurance coverage was not available. More than two-thirds of PGT-M and PGT-SR patients would continue IVF in the absence of insurance coverage. PGT-A patients were mixed, with 44/96 (46%) stating that they would continue IVF in the absence of insurance coverage; 39/96 (41%) patients were uncertain

9% (32/165) of all respondents previously had genetic counseling for PGT. Specifically, 9/98 (9%) PGT-A patients, 6/16 (38%) PGT-SR patients and 17/51 (33%) PGT-M patients previously had genetic counseling for PGT. CooperGenomics genetic counseling was rated "useful" or "very useful" by 93% (90/97) of PGT-A patients, 88% (14/16) of PGT-SR patients and 88% (45/51) of PGT-M patients.

For PGT-A patients, the most common reasons for pursuing PGT were "infertility" and "doctor recommended". For PGT-M patients, "carriers of the same genetic disease" and "personal/family history of a genetic disease" and PGT-SR patients reported "previous miscarriage(s)" and "personal/family history of a chromosomal condition".

CONCLUSIONS: Overall, patients pursuing PGT-M and PGT-SR had similar goals for PGT. They report that PGT is a very important factor in deciding to pursue IVF and are more likely to pursue IVF without insurance coverage as compared to PGT-A patients. Importantly, insurance coverage is a main reason why patients without an underlying genetic condition or aberration may pursue PGT. Patients pursuing PGT-M or PGT-SR rate PGT as very important to their IVF cycle as it may be the only reason for pursuing IVF. Although PGT is an important reason for these patients to pursue IVF, the majority have not spoken with a genetic counselor regarding PGT yet found genetic counseling for PGT useful. It is important to understand the motivations of patients seeking IVF and utility of PGT for each patient.

POSTER SESSION: HEALTH DISPARITIES

P-328 4:30 PM Sunday, October 18, 2020

INFLUENCE OF MALE PARTNER RACE ON USE AND OUTCOMES OF ASSISTED REPRODUCTIVE TECHNOLOGIES. Adriana Nicholson Vest, PhD,[1] Lauren M. Kipling, MPH,[2] Heather S. Hipp, MD,[1] Jennifer F. Kawwass, MD,[3] Akanksha Mehta, M.D., M.S.[4] [1]Emory University School of Medicine, Atlanta, GA; [2]Emory University Rollins School of Public Health, Atlanta, GA; [3]Emory University School of Medicine, Division of Reproductive Endocrinology and Infertility, Atlanta, GA; [4]1365 Clifton Road NE, Building B, Atlanta, GA.

OBJECTIVE: There are persistent racial disparities in outcomes from assisted reproductive technologies (ART), though the majority of studies have focused on the female partner. This work aims to investigate the association of race with reproductive choices and outcomes, especially in regards to paternal race and male factor infertility.

DESIGN: A retrospective cohort study using an existing institutional dataset, representing a racially and ethnically diverse patient population.

MATERIALS AND METHODS: We included all non-sperm donor in-vitro fertilization (IVF) cycles performed at our institution from 2014-2019. Cycle-level data that is collected and submitted to the Society for Assisted Reproductive Technology Clinical Outcomes Reporting System (SART CORS) was included. We compared demographic and clinical characteristics of age, BMI, infertility diagnoses, number of previous IVF cycles, use of preimplantation genetic testing (PGT), use of donor oocytes, freeze-all cycles, and the outcomes of pregnancy, miscarriage, and live birth, stratified by male and female partner race.

T-test and Fisher's exact test were used to compare continuous and categorical data, respectively. Significance was set as $p<0.05$.

RESULTS: A total of 2,030 IVF cycles involving 1,084 couples were examined. Fifty percent of male partners were White, 28% Black, 13% Asian, 2% Hispanic, 2% Other, and 4% non-reported. The majority of couples (88%) shared a common race category.

Non-White men were significantly older in age (39.3 vs 37.4 yr), had a higher BMI (29.1 vs 28.0 kg/m^2), and were more likely to have an older female partner (36.7 vs 35.5 yr) compared to White men. Black men were more likely to have a diagnosis of male factor infertility (39%) than non-Black men (White – 34%, Asian – 28%). Black men and their partners were less likely to proceed with PGT (14%) than White (19%) or Asian men (19%). Use of freeze-all cycles and donor oocytes did not vary significantly among the races. Asian males had the highest average number of prior cycles at 1.24, followed by Hispanics (0.96), Whites (0.93), and Blacks (0.88). Black males had the highest average number of prior pregnancies at 1.38, followed by Asians (1.22), Whites (1.1), and Hispanics (1.08).

White men were more likely to have higher clinical pregnancy rate (44% vs 38%) and live birth rate (37% vs 30%) than non-White men. Miscarriage rates were not significantly different among the races.

CONCLUSIONS: In this uncontrolled analysis of a diverse patient population, paternal race was found to be associated with IVF cycle characteristics and reproductive outcomes. These findings highlight the importance of including paternal demographic data in the assessment of reproductive care and outcomes. Future analysis controlling for confounding variables such as female partner age and etiology of female infertility will help to determine whether male factors contribute independently to outcomes.

P-329 4:30 PM Sunday, October 18, 2020

AFRICAN AMERICAN WOMEN HAVE LOWER ODDS OF LIVE BIRTH FROM DONOR EGG IVF. Jasmine Aly, MD,[1] Kate Devine, MD,[2] Samad Jahandideh, PhD,[2] Alicia Y. Christy, MD,[3] Alan H. DeCherney, MD,[1] Micah J. Hill, DO.[1] [1]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; [2]Shady Grove Fertility Center, Rockville, MD; [3]Veterans Administration, Kensington, MD.

OBJECTIVE: African American women have poorer ART outcomes compared to Caucasian women and the etiology is unknown. Studies have found African American women to have fewer mature oocytes, fertilized oocytes, and lower blastocyst development rates compared to Caucasian women, suggesting that competence of the oocyte may play a role. Our objective is to assess ART clinical outcomes in African American women, while controlling for oocyte quality by using the oocyte donor–recipient model.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A total of 1,101 African American and 5,373 Caucasian recipients of fresh and frozen donor oocytes were included. Donor characteristics included age 21-32, BMI between 18 to 29.9, non-smoking status, high school graduate status, AMH $>$ 2 and AFC$>$ 15. All recipients underwent single embryo transfer. Statistical analyses of clinical outcomes was performed using chi-square analysis, t-test, or Mann-Whitney U. $P<$ 0.05 was considered statistically significant.

RESULTS: African American recipients were older (42.8 years old vs 41.5 years old; $p<0.001$), and more likely to have tubal disease (6.9 % vs 1.8 %; $p<0.001$). Mean BMI was higher in the African American recipient group (28.1 kg/m^2 vs 25.4 kg/m^2; $p<0.001$). Presence of ovulation disorders, DOR, endometriosis, and uterine factor infertility were the same in both groups. African Americans had a lower odds of pregnancy in fresh and frozen cycles (fresh- 59.8% vs 70%; $p<0.001$, frozen- 41.5% vs 50%; $p<0.001$).

Pregnancy Outcome (%): Fresh Donor Oocyte Cycle	African American (n=492)	White (n=2641)	*p*-value	**p*-value (adjusted)
Positive ß-Hcg	59.8	70.0	<0.001	<0.001
Clinical Intrauterine Gestation	53.0	62.1	<0.001	0.004
Spontaneous Abortion	10.2	10.6	0.800	0.243
Livebirth	40.2	49.9	<0.001	0.005
Pregnancy Outcome (%): Frozen Donor Oocyte Cycle	**African American (n=609)**	**White (n=2732)**	***p*-value**	***p*-value (adjusted)**
Positive ß-Hcg	41.5	50.0	<0.001	<0.001
Clinical Intrauterine Gestation	33.5	48	<0.001	<0.001
Spontaneous Abortion	8.4	11.9	0.020	<0.001
Livebirth	22.3	33.7	<0.001	<0.001

*Adjusted for age, BMI, diagnosis (tubal disease, uterine factor, endometriosis, DOR).

Live birth was decreased in African Americans in fresh and frozen cycles (fresh- 40.2% vs 49.9%; $p=<0.001$, frozen-22.3% vs 33.7%; $p<0.001$). Differences remained statistically significant after adjustment for age, BMI, and diagnosis) (Table 1).

CONCLUSIONS: When using a donor oocyte model, ART outcomes including odds of pregnancy, clinical intrauterine gestation, and live birth rate remain lower in African American women, even after controlling for BMI, uterine factor and tubal factor. These data suggest that poorer ART outcomes in African American patients may be due to factors other than oocyte quality.

P-330 4:30 PM Sunday, October 18, 2020

THERE IS A DISPARITY IN ART OUTCOMES BETWEEN ASIAN AND CAUCASION WOMEN IN OOCYTE DONATION CYCLES. Jasmine Aly, MD,[1] Micah J. Hill, DO,[1] Samad Jahandideh, PhD,[2] Alicia Y. Christy, MD,[3] Alan H. DeCherney, MD,[1] Kate Devine, MD,[2] Frank E. Chang, MD.[2] [1]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; [2]Shady Grove Fertility Center, Rockville, MD; [3]Veterans Administration, Kensington, MD.

OBJECTIVE: To assess ART clinical outcomes in Asian patients while controlling for oocyte quality by using the oocyte donor–recipient model, given that several studies have shown that Asian women have poorer ART outcomes compared to Caucasian women and the etiology of this disparity is unknown.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: A total of 459 Asian recipients and 2,641 Caucasian recipients of fresh donor oocytes were included. Donor characteristics included age 21-32, BMI between 18 to 29.9, non-smoking status, high school graduate status, AMH > 2 and AFC> 15. All recipients underwent single embryo transfer. Statistical analyses of clinical outcomes between groups were performed using chi-square analysis and t-test or Mann-Whitney U. $P< 0.05$ was considered statistically significant. GEE models were used to adjust for age, BMI, and primary diagnosis.

RESULTS: Recipient baseline characteristics including age, number of previous FET, and primary infertility diagnosis were largely similar amongst Asian and Caucasian recipients. Asian recipients were more likely to have ovulation disorders and PCOS (3.5% vs 1.6%; $p<0.009$). Mean BMI was lower in the Asian recipient group (23.5kg/m^2 vs 25.4 kg/m^2; $p<0.001$). There was no difference in clinical pregnancy, or spontaneous abortion between the groups. Live birth was decreased in Asians compared to Caucasian recipients (43.6% vs 49.9%; $p=0.014$). This difference remained statistically significant after adjustment for age, BMI, and diagnosis (Table 1).

Pregnancy Outcome (%)	Asian (n= 459)	Caucasian (n=2641)	*p*-value	**p*-value (adjusted)
Clinical Intrauterine Gestation	58.2	62.1	0.12	0.08
Spontaneous Abortion	12.2	10.6	0.35	0.11
Livebirth	43.6	49.9	0.01	0.003

* Adjusted for age, BMI, diagnosis (tubal disease, uterine factor, endometriosis, DOR).

CONCLUSIONS: The decrease in ART live birth in Asian patients persisted even in a fresh donor oocyte model. While this decrease was small, it highlights the need for continued research into the etiologies of ethnic disparities seen in ART.

P-331 4:30 PM Sunday, October 18, 2020

RACIAL DISPARITIES IN FROZEN EMBRYO TRANSFER SUCCESS. Quetrell D. Heyward, MD, MBA,[1] Jessica R. Walter, MD,[1] Snigdha Alur-Gupta, MD MSCE,[1] Arnav Lal,[2] Dara S. Berger, PhD,[1] Samantha Butts, MD, MSCE,[1] Clarisa Gracia, MD, MSCE.[1] [1]University of Pennsylvania, Division of Reproductive Endocrinology and Infertility, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA.

OBJECTIVE: Racial and ethnic disparities in pregnancy outcomes have been reported after fresh in vitro fertilization (IVF) cycles, but there are limited data on disparities after frozen embryo transfers (FETs). The objective of this study was to compare pregnancy and live birth rates after FETs among women of different self-reported race/ethnicity groups and explore the effect of patient, protocol, and cycle characteristics on success.

DESIGN: Retrospective cohort study

MATERIALS AND METHODS: Women undergoing an autologous FET between January 2013 and March 2020 were included. Co-maternity, surrogacy, donor oocyte/embryo cycles, or those not surviving the thaw were excluded. Demographics and clinical characteristics including self-reported race and ethnicity were abstracted from the medical record. Continuous variables were compared using the Student's t-test or Mann–Whitney U test while the $\chi 2$ or Fisher's exact tests were used to compare categorical variables. Multivariable logistic regression was used to examine the relationships between pregnancy, live birth, and race while adjusting for potential confounders.

RESULTS: White, Black, and Asian women underwent a total of 1664 (73.7%), 257 (11.4%), and 336 (14.9%) frozen embryo cycles, respectively. Only 3.4% of the population self-identified as Hispanic/Latino. Programmed FETs were performed in 83.4% of all cycles (n=1975). Black women were significantly older at the time of egg retrieval, had a higher prevalence of fibroids, higher BMIs, were less likely to transfer PGT-tested blastocysts, and less likely to undergo a single embryo transfer when compared to non-Black women ($p < 0.05$).

Overall, Black women were significantly less likely to achieve pregnancy after FET when adjusting for age, BMI, parity, and number of embryos transferred compared to non-Black women (AOR 0.68, 95% CI 0.51-0.92, p=0.01). Though there was no significant overall difference in live birth rates, endometrial preparation protocol modified the effect of race on live birth. Black women were significantly less likely to achieve a live birth after a natural cycle FET compared to non-Black women (37.1% vs 13.0%, p=0.02), a difference not observed with programmed FETs (42.2% vs 40.0%, p=0.5). A sub-analysis investigating lower implantation rates showed no racial differences in mean estradiol or progesterone within 24 hours of transfer or endometrial morphology in programmed FETs (n=1680). Results were unchanged when restricting the analysis to women without fibroids and non-PGT cycles.

CONCLUSIONS: In this study using a diverse cohort of more than 2000 women, Black race was associated with a significantly lower rate of embryo implantation following FET independent of the effects of endometrial preparation protocol, PGT, and established predictors of treatment success. Our finding that racial differences in live birth after FET may depend on the endometrial preparation protocol is novel and requires further study. Disparities in success are not only important for patient counseling, but also warrant further investigation to develop strategies to improve success rates in Black women.

P-332 4:30 PM Sunday, October 18, 2020

COMPARISON OF PREGNANCY AND LIVE BIRTH OUTCOMES FOLLOWING FRESH EMBRYO TRANSFER BETWEEN BLACK AND WHITE PATIENTS WITH CONCORDANT BMI CLASSIFICATION. Phillip A. Romanski, MD, Pietro Bortoletto, MD, Steven Spandorfer, MD. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To compare the pregnancy and live birth outcomes between black and white women with concordant body mass index (BMI, kg/m^2) classifications following controlled ovarian hyperstimulation with a planned fresh embryo transfer.

DESIGN: Retrospective cohort study was performed in an academic hospital setting. Each patient's first oocyte retrieval with planned autologous fresh embryo transfer in our IVF clinic between 01/01/2012 and 12/31/2018 was included. Patients with uterine factor infertility were excluded (black: n=29, white: n=147). Patients were stratified by race (black vs. white) and BMI classification: normal weight (18.5-24.9; black: n=69, white: n=2,113) and overweight (25.0-29.9; black: n=60, white: n=569).

MATERIALS AND METHODS: The primary outcomes were pregnancy and live birth rates. Logistic regression adjusted *a priori* for patient age and the number of embryos transferred was used to estimate the OR with a 95% CI among the BMI study groups for pregnancy outcomes. A secondary analysis of singleton pregnancies was performed to assess delivery outcomes.

RESULTS: A total of 2,811 oocyte retrievals resulting in 2,601 embryo transfers met inclusion criteria. In the normal-weight cohort, the rate of no transfer was significantly lower in the white patients (7.2%) compared to the black patients (14.2%; OR 2.19 (1.10-4.38)). The difference in no-transfer rate was due to a higher rate of unplanned cryopreservation in the black patients (60.0%) compared to the white patients (36.4%). In overweight patients, the no-transfer rate was similar between the white (8.1%) and black (5.0%) patients. After embryo transfer in normal-weight patients, there were no statistically significant differences between the white compared to black patients for pregnancy (60.0 vs 49.1%; OR 0.71 (0.42-1.21)), miscarriage (7.4 vs 10.2%; OR 1.33 (0.56-3.16)) or live birth rates (42.3 vs 32.2%; OR 0.74 (0.41-1.31)). Similarly in overweight patients, there were no statistically significant differences between the white compared to black patients for pregnancy (57.6 vs 61.4%; OR 1.22 (0.69-2.15)), miscarriage (8.2 vs 14.0%; OR 1.80 (0.80-4.06)) or live birth rates (38.1 vs 36.8%; OR 1.00 (0.56-1.78)). Among singleton deliveries, the preterm delivery (<37 weeks gestation) and C-section rates were similar between the white and black patients in both BMI classifications: Normal-weight preterm birth (7.7% vs 6.7%; OR 0.86 (0.11-6.64)) and overweight preterm birth (8.4 vs 21.1%; OR 2.78 (0.79-9.80)).

CONCLUSIONS: Previous studies have reported worse IVF outcomes in black compared to white patients. This has been theorized to be due to increased obesity and uterine factor infertility in black patients. In this study, we compared pregnancy outcomes after removing these potential confounders and we indeed observed similar pregnancy and live birth rates after embryo transfer between black and white patients. Normal-weight black patients had a higher no-transfer rate in our cohort; however, this was explained by a higher proportion of unplanned cryopreservation and not due to an increased rate of no embryos available for transfer.

SUPPORT: None

P-333 4:30 PM Sunday, October 18, 2020

COMPARISON OF LIVE BIRTH OUTCOMES IN FRESH EMBRYO TRANSFER IVF CYCLES BETWEEN ASIAN AND WHITE WOMEN WITH CONCORDANT BMI CLASSIFICATION. Phillip A. Romanski, MD, Pietro Bortoletto, MD, Steven Spandorfer, MD. The Ronald O. Perelman and Claudia Cohen Center for Reproductive Medicine, Weill Cornell Medicine, New York, NY.

OBJECTIVE: To compare the pregnancy and live birth outcomes between Asian and white women with concordant body mass index (BMI, kg/m^2) classifications following controlled ovarian hyperstimulation with a planned fresh embryo transfer.

DESIGN: We conducted a retrospective cohort study in an academic hospital setting of patients who underwent their first oocyte retrieval with planned autologous fresh embryo transfer in our IVF clinic between 01/01/2012 and 12/31/2018. Patients were stratified by race (Asian vs. white) and BMI classification: underweight (<18.5; Asian: n=70, white: n=127) and normal weight (18.5-24.9; Asian: n=797, white: n=2,221).

MATERIALS AND METHODS: The primary outcomes were pregnancy and live birth rates. Logistic regression adjusted *a priori* for patient age and the number of embryos transferred was used to estimate the odds ratio with a 95% confidence interval (CI) among the BMI study groups for pregnancy outcomes. A secondary analysis of singleton pregnancies was performed to assess delivery outcomes.

RESULTS: A total of 3,215 oocyte retrievals resulting in 2,985 embryo transfers met inclusion criteria. After embryo transfer in the underweight cohort, the pregnancy rate was significantly higher in the white patients (66.7%) compared to the Asian patients (43.5%; OR 0.44; 0.23-0.82). A similar association was observed in the normal-weight cohort (59.8% vs. 49.9%, respectively; OR 0.70; 0.59-0.83). In the underweight cohort, the live birth rate trended higher in the white patients (48.3%) compared to the Asian patients (33.3%; OR 0.62; 0.22-1.17), but was not statistically significant. In the normal-weight cohort, the live birth rate was significantly higher in the white patients (42.2%) compared to the Asian patients (32.8%; OR 0.72; 0.60-0.86). Among singleton deliveries, the preterm delivery rate (<37 weeks gestation) was similar among underweight (white: 13.0% versus Asian: 5.6%; OR 0.68 (0.07-6.92)) and normal-weight patients (white: 7.7% versus Asian: 8.4%; OR 1.12 (0.63-1.99)). Further, c-section rates were similar among underweight (white: 32.6% versus Asian: 22.2%; OR 0.49 (0.13-1.89)) and normal-weight patients (white: 34.2% versus Asian: 37.1%; OR 1.06 (0.76-1.48)).

CONCLUSIONS: Worse IVF outcomes in Asian compared to white patients have been reported previously and attributed to an increased proportion of underweight patients in the Asian population. However, even when stratifying by BMI, we observed that Asian women have worse pregnancy outcomes compared to white women. Further, live birth rates were worse among normal-weight patients. In the underweight cohort, despite a non-significant difference in live birth rates, the 15% absolute decrease in live births in Asian patients is clinically significant. Since worse IVF outcomes in Asian compared to white patients are not entirely due to weight, further studies should focus on alternative explanations to develop improved treatment strategies for these patients.

DO SOCIOECONOMIC DEMOGRAPHIC PROFILES BY ETHNICITY AND REGION MAKE A DIFFERENCE IN THE OBJECTIVE ASSESSMENT OF THE ONCOFERTILITY EDUCATIONAL INFORMATION ON NCI-DESIGNATED CANCER CENTER WEBSITES IN THE US - A FIVE YEAR COMPARISON. Janelle M. Jackman, MBBS,[1] Christopher de Haydu, MD,[2] Melody A. Rasouli, MD, MBA,[3] Angela H. Liu, MD,[3] Kajal Verma, MD,[3] Sriram Eleswarapu, MD, PhD,[4] Cindy M. Duke, MD, PhD.[5] [1]The Camran Nezhat Institute, Palo Alto, CA; [2]University of Miami, Miami, FL; [3]University of Nevada, Las Vegas, Las Vegas, NV; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Nevada, Las Vegas and Nevada Fertility Institute, Las Vegas, Las Vegas, NV.

OBJECTIVE: Fertility preservation (FP) is an important aspect to consider in patients diagnosed with cancer. Though guidelines recommend discussing FP with patients in the reproductive age group prior to cancer treatment, this is not always followed. Hospital websites should also serve as a source for information related to FP but were previously shown to be devoid of this information, especially in areas with a prevalent minority ethnic background. This study aims to assess if there are any improvements in socio-demographic health disparities & the availability and quality of information on FP on major cancer center websites based on the ethnicities in the location.

DESIGN: Prospective observational study.

MATERIALS AND METHODS: National Cancer Institute Designated Cancer Centers (NCICC) & Cleveland Clinic Foundation (CCF) were evaluated. Centers were analyzed based on the US Census Bureau data for their

location and the FP information given on the center's website. A previously developed validation rubric for FP/oncofertility content quality standards using a scoring system, developed by this group, for commonly accepted definitions & terminology was utilized. Specific queries included: 1) Discuss the risk of cancer treatment on fertility? 2) Discuss the FP options 3) Is there a designated page for FP? 4) Is there a link to other resources for FP counseling? 5) Counseling on cancer survivorship or parenting after cancer? 6) Female fertility discussion? 7) Male fertility discussion? 8) Affiliation with an Academic institution. Chi-square tests were performed to assess for differences between FP website scores (individually & within Regional groups); analysis was also performed to assess for any correlation between socioeconomic/racial differences within States/Regions where NCICC are located. Multivariate logistic regression analyses are ongoing.

RESULTS: 65 oncology clinics identified. 37% of websites had information on FP under all 8 questions asked, a distinct increase over the past 5 years from 3%. Previously 50% lacked information in 4 or more questions, whereas now only 15%. Remarkably, the information on the websites were generally consistent regardless of the prevalent ethnic background of the people living in the area of the center. Thus, there were no differences observed in the quality of information regardless of ethnic predominance. Two statistically significant disparities were found. In centers where the city contained the highest ratios of Caucasians, there was a higher level of counseling on cancer survivorship on the websites ($p=0.041$). Also, in counties with higher prevalence of Asian ethnicity, the websites had more information on male FP ($p<0.019$).

CONCLUSIONS: NCICC websites are now more consistent in the quality of onco-fertility preservation information that they provide; an improvement over the past 5 years. Ethnic makeup of the state, county or city is no longer significantly associated with the quality of patient centered oncofertility web-based resources. These findings show a big improvement and demonstrate a bridging of the health disparity gap in one major aspect of health care.

SINGLE MOTHERS BY CHOICE: DEFINING AND UNDERSTANDING SINGLE WOMEN UNDERGOING IN VITRO FERTILIZATION. Samantha L. Estevez, M.D., Baruch Abittan, M.D., Mary Rausch, MD. Northwell Health Fertility, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

OBJECTIVE: Single women undergoing in vitro fertilization (IVF) with the goal of achieving a pregnancy during the cycle are a unique and little-studied patient population. The objectives of our study were to define and compare this population to the general IVF population and to assess trends within this group over time.

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: From 2008-2019, our institution completed a total of 14,171 cycles, of which 352 cycles involved a single woman. A single woman (SW) was defined as a patient who did not have either a male or female partner and was not undergoing fertility preservation. Between 2008 and 2019, 6060 unique IVF patients and 148 unique SW were identified. We compared patient age, hormone levels, use of preimplantation genetic testing (PGT), and per-transfer pregnancy outcomes (pregnancy, spontaneous abortion, and livebirth rate) between the IVF patients and SW. We then assessed trends in the patient demographics, IVF indications, and outcomes within the SW cohort over the study period. Statistical analysis was performed using chi-square, Fisher-exact test, and t test.

RESULTS: In SW cycles, patients had an average age of 40.4 years, FSH value of 11.34 IU/L, and AMH value of 2.75ng/mL. In evaluating reasons for infertility, we found the most common in the SW cohort included advanced maternal age/diminished ovarian reserve (50.7%), unexplained (26.3%), tubal factor (6.8%), and PCOS (4.7%). Comparing cycles involving SW to the general IVF population, SW were significantly older (40.4 years vs. 36.3 years, $p<0.01$). All other baseline characteristics, as well as pregnancy outcomes examined, were not significantly different. Evaluating trends within the SW cohort, we subdivided the time frame into 3 time periods: 2008-2001 (T1), 2012-2015 (T2), and 2016-2019 (T3). There was a significant increase in IVF utilization by SW during the study period, from 0.8% (13/1645) of the IVF population in T1, to 2.5% (50/1991) in T2, and 4.6% (111/2424) in T3 ($p<0.01$). Use of PGT within the SW cohort increased with time (0% in T1 to 37.7% in T3, $p=0.002$). However, overall PGT utilization is significantly higher among all patients as compared to the SW cohort in T3 (56% vs 38%, $p=0.003$).

CONCLUSIONS: No study has been previously performed to assess whether there has been a corollary rise in rates of IVF for single women as "non-traditional" parents and "single mothers by choice" have gained visibility. Excluding fertility preservation, we found a significant increase in SW undergoing IVF over the past twelve years. The majority of SW were undergoing IVF for advanced maternal age and diminished ovarian reserve. Many SW approach fertility treatment without an infertility diagnosis and usually attempt IUIs first. Interestingly, SW were significantly older than the general IVF population, and age may be playing a larger role in why IUI fails and IVF is necessary within this group. A closer look at this group is warranted to determine which women may benefit from altered protocols, such as earlier IVF treatment, to achieve pregnancy.

INVESTIGATION OF THE RACIAL DISPARITIES AMONGST SEMEN ANALYSES IN WHITE, BLACK, HISPANIC, AND ASIAN MEN. Zachary Walker, MD, Lindsay Rucker, MD, John Owen, MD, MSPH, Ashley Wiltshire, MD, Lacey M. Kendall, BS, Johnathan W. Edmonds, PhD, HCLD/ELD/TS, Deidre Gunn, MD. University of Alabama at Birmingham, Birmingham, AL.

OBJECTIVE: To assess the relationship between different racial-ethnic groups and rates of abnormal semen analysis (SA).

DESIGN: Retrospective cohort study.

MATERIALS AND METHODS: All men who underwent a SA between January 1, 2017 and December 31, 2019 at a single tertiary care center were considered for the study sample. Those with an unknown race-ethnicity, varicocele, history of testicular surgery (e.g., varicocelectomy, vasectomy, or vasectomy reversal), genetic anomalies, congenital absence of bilateral vas deferens, prior testosterone use, or prior exposure to chemotherapy/radiation were excluded. Samples obtained via testicular sperm extraction, postejaculatory urine, or analyzed $\geq$1 hour from being received were also excluded. The World Health Organization (WHO) 2010 criteria was used to determine normal semen parameters. If a second SA was interpreted as normal following an initial abnormal result, the result was considered normal for the analysis. Racial-ethnic groups comprised White, Black, Hispanic, and Asian. Chi-square and Fisher's exact test were used to compare categorical variables. ANOVA was used to compare continuous variables among groups

Table 1. Differences in Semen Analysis based on Race-Ethnicities using ANOVA

	White (reference) N = 508	Black N = 188	Hispanic N = 24	Asian N = 30	P value
Semen volume (mL)	3.0	2.6*	2.8	2.7	0.008^{+}
Semen pH	8.3	8.2	8.2	8.2	0.99^{+}
Sperm concentration (million/mL)	75	47*	108	98	<.0001^{+}
Total sperm count (million)	226	122*	279	239	<.0001^{+}
Percentage of motile spermatozoa (%)	55	48	60	56	0.01^{+}
Percentage of morphologically normal spermatozoa (%)	4.1	3.2	4.6	3.9	0.04^{+}
Total motile sperm count (millions)	149	82*	196	150	<.0001^{+}

*Multiple range t-test ($p<0.05$). $^{+}$Controlled for age.

and logistic regression modeled the relationship between SA result and selected predictors.

RESULTS: In total, 872 SAs were initially performed. Only 750 met inclusion criteria, yielding 456 Normal and 294 Abnormal results. Only Race-ethnicity ($p<0.0001$) and Age ($p=0.003$) were statistically significant in the baseline demographics. 54% of Black men had an abnormal semen analysis. Black men were more likely to have hypospermia, oligozoospermia, and lower total motile sperm counts (Table 1). In a logistic regression model, controlling for age and using White as the referent group, only Blacks had lower odds for a normal SA (OR=0.49, 95% CI 0.35, 0.70).
